User Guide

Amazon Elastic Compute Cloud

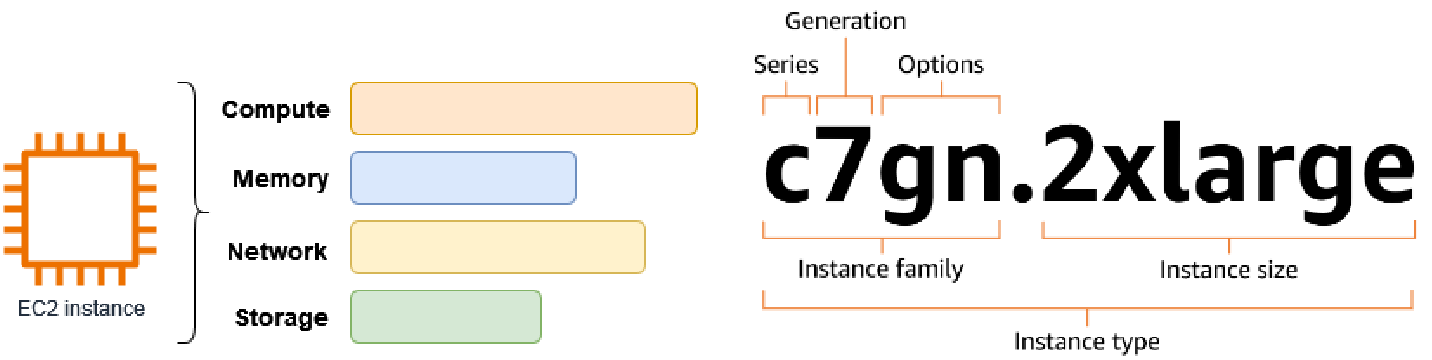
Amazon Elastic Compute Cloud: User Guide

Table of Contents

What is Amazon EC2?

Amazon Elastic Compute Cloud (Amazon EC2) provides on-demand, scalable computing capacity in the Amazon Web Services (AWS) Cloud. Using Amazon EC2 reduces hardware costs so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage. You can add capacity (scale up) to handle compute-heavy tasks, such as monthly or yearly processes, or spikes in website traffic. When usage decreases, you can reduce capacity (scale down) again.

An EC2 instance is a virtual server in the AWS Cloud. When you launch an EC2 instance, the instance type that you specify determines the hardware available to your instance. Each instance type offers a different balance of compute, memory, network, and storage resources. For more information, see the Amazon EC2 Instance Types Guide.



Features of Amazon EC2

Amazon EC2 provides the following high-level features:

Instances

Virtual servers.

Amazon Machine Images (AMIs)

Preconfigured templates for your instances that package the components you need for your server (including the operating system and additional software).

Instance types

Various configurations of CPU, memory, storage, networking capacity, and graphics hardware for your instances.

Amazon EBS volumes

Persistent storage volumes for your data using Amazon Elastic Block Store (Amazon EBS).

Instance store volumes

Storage volumes for temporary data that is deleted when you stop, hibernate, or terminate your instance.

Key pairs

Secure login information for your instances. AWS stores the public key and you store the private key in a secure place.

Security groups

A virtual firewall that allows you to specify the protocols, ports, and source IP ranges that can reach your instances, and the destination IP ranges to which your instances can connect.

Amazon EC2 supports the processing, storage, and transmission of credit card data by a merchant or service provider, and has been validated as being compliant with Payment Card Industry (PCI) Data Security Standard (DSS). For more information about PCI DSS, including how to request a copy of the AWS PCI Compliance Package, see PCI DSS Level 1.

Related services

Services to use with Amazon EC2

You can use other AWS services with the instances that you deploy using Amazon EC2.

Amazon EC2 Auto Scaling

Helps ensure you have the correct number of Amazon EC2 instances available to handle the load for your application.

AWS Backup

Automate backing up your Amazon EC2 instances and the Amazon EBS volumes attached to them.

Amazon CloudWatch

Monitor your instances and Amazon EBS volumes.

[Elastic Load Balancing]

Automatically distribute incoming application traffic across multiple instances.

[Amazon GuardDuty]

Detect potentially unauthorized or malicious use of your EC2 instances.

[EC2 Image Builder]

Automate the creation, management, and deployment of customized, secure, and up-to-date server images.

[AWS Launch Wizard]

Size, configure, and deploy AWS resources for third-party applications without having to manually identify and provision individual AWS resources.

[AWS Systems Manager]

Perform operations at scale on EC2 instances with this secure end-to-end management solution.

Additional compute services

You can launch instances using another AWS compute service instead of using Amazon EC2.

[Amazon Lightsail]

Build websites or web applications using Amazon Lightsail, a cloud platform that provides the resources that you need to deploy your project quickly, for a low, predictable monthly price. To compare Amazon EC2 and Lightsail, see [Amazon Lightsail or Amazon EC2].

[Amazon Elastic Container Service (Amazon ECS)]

Deploy, manage, and scale containerized applications on a cluster of EC2 instances. For more information, see [Choosing an AWS container service].

[Amazon Elastic Kubernetes Service (Amazon EKS)]

Run your Kubernetes applications on AWS. For more information, see [Choosing an AWS container service].

Access Amazon EC2

You can create and manage your Amazon EC2 instances using the following interfaces:

Amazon EC2 console

A simple web interface to create and manage Amazon EC2 instances and resources. If you've signed up for an AWS account, you can access the Amazon EC2 console by signing into the AWS Management Console and selecting **EC2** from the console home page.

AWS Command Line Interface

Enables you to interact with AWS services using commands in your command-line shell. It is supported on Windows, Mac, and Linux. For more information about the AWS CLI , see AWS Command Line Interface User Guide. You can find the Amazon EC2 commands in the AWS CLI Command Reference.

AWS CloudFormation

Amazon EC2 supports creating resources using AWS CloudFormation. You create a template, in JSON or YAML format, that describes your AWS resources, and AWS CloudFormation provisions and configures those resources for you. You can reuse your CloudFormation templates to provision the same resources multiple times, whether in the same Region and account or in multiple Regions and accounts. For more information about supported resource types and properties for Amazon EC2, see EC2 resource type reference in the *AWS CloudFormation User Guide*.

AWS SDKs

If you prefer to build applications using language-specific APIs instead of submitting a request over HTTP or HTTPS, AWS provides libraries, sample code, tutorials, and other resources for software developers. These libraries provide basic functions that automate tasks such as cryptographically signing your requests, retrying requests, and handling error responses, making it easier for you to get started. For more information, see Tools to Build on AWS.

AWS Tools for PowerShell

A set of PowerShell modules that are built on the functionality exposed by the SDK for .NET. The Tools for PowerShell enable you to script operations on your AWS resources from the PowerShell command line. To get started, see the AWS Tools for PowerShell User Guide. You can find the cmdlets for Amazon EC2, in the AWS Tools for PowerShell Cmdlet Reference.

Query API

Amazon EC2 provides a Query API. These requests are HTTP or HTTPS requests that use the HTTP verbs GET or POST and a Query parameter named `Action`. For more information about the API actions for Amazon EC2, see Actions in the *Amazon EC2 API Reference*.

Pricing for Amazon EC2

Amazon EC2 provides the following pricing options:

Free Tier

You can get started with Amazon EC2 for free. To explore the Free Tier options, see AWS Free Tier.

On-Demand Instances

Pay for the instances that you use by the second, with a minimum of 60 seconds, with no long-term commitments or upfront payments.

Savings Plans

You can reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.

Reserved Instances

You can reduce your Amazon EC2 costs by making a commitment to a specific instance configuration, including instance type and Region, for a term of 1 or 3 years.

Spot Instances

Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.

Dedicated Hosts

Reduce costs by using a physical EC2 server that is fully dedicated for your use, either On-Demand or as part of a Savings Plan. You can use your existing server-bound software licenses and get help meeting compliance requirements.

On-Demand Capacity Reservations

Reserve compute capacity for your EC2 instances in a specific Availability Zone for any duration of time.

Per-second billing

Removes the cost of unused minutes and seconds from your bill.

For a complete list of charges and prices for Amazon EC2 and more information about the purchase models, see Amazon EC2 pricing.

Estimates, billing, and cost optimization

To create estimates for your AWS use cases, use the AWS Pricing Calculator.

To estimate the cost of transforming **Microsoft workloads** to a modern architecture that uses open source and cloud-native services deployed on AWS, use the AWS Modernization Calculator for Microsoft Workloads.

To see your bill, go to the **Billing and Cost Management Dashboard** in the AWS Billing and Cost Management console. Your bill contains links to usage reports that provide details about your bill. To learn more about AWS account billing, see AWS Billing and Cost Management User Guide.

If you have questions concerning AWS billing, accounts, and events, contact AWS Support.

To calculate the cost of a sample provisioned environment, see Cloud Economics Center. When calculating the cost of a provisioned environment, remember to include incidental costs such as snapshot storage for EBS volumes.

You can optimize the cost, security, and performance of your AWS environment using AWS Trusted Advisor.

You can use AWS Cost Explorer to analyze the cost and usage of your EC2 instances. You can view data up to the last 13 months, and forecast how much you are likely to spend for the next 12 months. For more information, see Analyzing your costs and usage with AWS Cost Explorer in the *AWS Cost Management User Guide*.

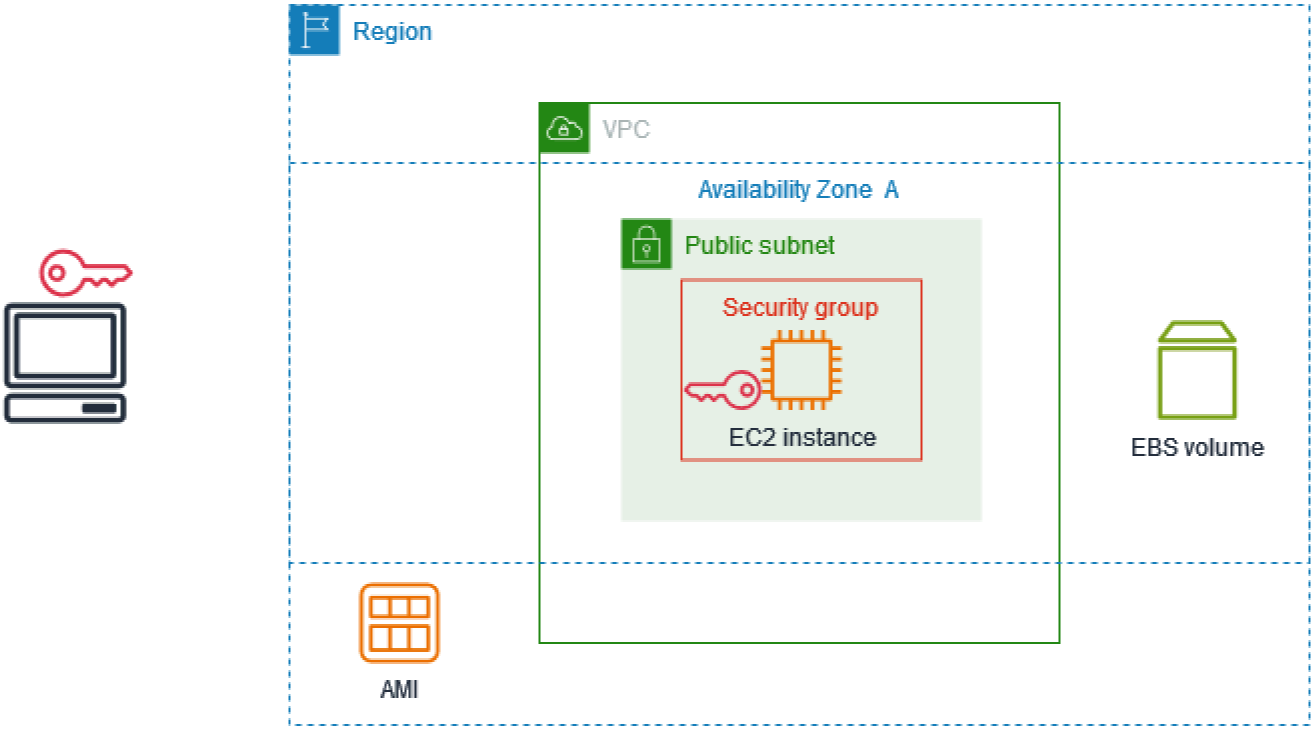
Get started with Amazon EC2

Use this tutorial to get started with Amazon Elastic Compute Cloud (Amazon EC2). You'll learn how to launch and connect to an EC2 instance. An *instance* is a virtual server in the AWS Cloud. With Amazon EC2, you can set up and configure the operating system and applications that run on your instance.

Overview

The following diagram shows the key components that you'll use in this tutorial:

- **An image –** A template that contains the software to run on your instance, such as the operating system.
- **A key pair –** A set of security credentials that you use to prove your identity when connecting to your instance. The public key is on your instance and the private key is on your computer.
- **A network –** A virtual private cloud (VPC) is a virtual network dedicated to your AWS account. To help you get started quickly, your account comes with a default VPC in each AWS Region, and each default VPC has a default subnet in each Availability Zone.
- **A security group –** Acts as a virtual firewall to control inbound and outbound traffic.
- **An EBS volume –** We require a root volume for the image. You can optionally add data volumes.



Cost for this tutorial

When you create your AWS account, you can get started with Amazon EC2 for free using the AWS Free Tier.

If you created your AWS account before July 15, 2025, it's less than 12 months old, and you haven't already exceeded the Free Tier benefits for Amazon EC2, it won't cost you anything to complete this tutorial, because we help you select options that are within the Free Tier benefits. Otherwise, you'll incur the standard Amazon EC2 usage fees from the time that you launch the instance (even if it remains idle) until you terminate it.

If you created your AWS account on or after July 15, 2025, it's less than 6 months old, and you haven't used up all your credits, it won't cost you anything to complete this tutorial, because we help you select options that are within the Free Tier benefits.

For information on how to determine whether you are eligible for the Free Tier, see the section called “Track your Free Tier usage”.

Tasks

- Step 1: Launch an instance
- Step 2: Connect to your instance
- Step 3: Clean up your instance

- [Next steps](#)

Step 1: Launch an instance

You can launch an EC2 instance using the AWS Management Console as described in the following procedure. This tutorial is intended to help you quickly launch your first instance, so it doesn't cover all possible options.

To launch an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, we display the current AWS Region — for example, **Ohio**. You can use the selected Region, or optionally select a Region that is closer to you.
3. From the EC2 console dashboard, in the **Launch instance** pane, choose **Launch instance**.
4. Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
5. Under **Application and OS Images (Amazon Machine Image)**, do the following:

    a. Choose **Quick Start**, and then choose the operating system (OS) for your instance. For your first Linux instance, we recommend that you choose Amazon Linux.

    b. From **Amazon Machine Image (AMI)**, select an AMI that is marked **Free Tier eligible**.
6. Under **Instance type**, for **Instance type**, select an instance type that is marked **Free Tier eligible**.
7. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or choose **Create new key pair** to create your first key pair.

    > **Warning**
    >
    > If you choose **Proceed without a key pair (Not recommended)**, you won't be able to connect to your instance using the methods described in this tutorial.
8. Under **Network settings**, notice that we selected your default VPC, selected the option to use the default subnet in an Availability Zone that we choose for you, and configured a security group with a rule that allows connections to your instance from anywhere (`0.0.0.0/0`).

> **Warning**
>
> If you specify `0.0.0.0/0`, you are enabling traffic from any IP addresses in the world. For the SSH and RDP protocols, you might consider this acceptable for a short time in a test environment, but it's unsafe for production environments. In production, be sure to authorize access only from the appropriate individual IP address or range of addresses.

For your first instance, we recommend that you use the default settings. Otherwise, you can update your network settings as follows:

- (Optional) To use a specific default subnet, choose **Edit** and then choose a subnet.
- (Optional) To use a different VPC, choose **Edit** and then choose an existing VPC. If the VPC isn't configured for public internet access, you won't be able to connect to your instance.
- (Optional) To restrict inbound connection traffic to a specific network, choose **Custom** instead of **Anywhere**, and enter the CIDR block for your network.
- (Optional) To use a different security group, choose **Select existing security group** and choose an existing security group. If the security group does not have a rule that allows connection traffic from your network, you won't be able to connect to your instance. For a Linux instance, you must allow SSH traffic. For a Windows instance, you must allow RDP traffic.

9. Under **Configure storage**, notice that we configured a root volume but no data volumes. This is sufficient for test purposes.
10. Review a summary of your instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.
11. If the launch is successful, choose the ID of the instance from the **Success** notification to open the **Instances** page and monitor the status of the launch.
12. Select the checkbox for the instance. The initial instance state is `pending`. After the instance starts, its state changes to `running`. Choose the **Status and alarms** tab. After your instance passes its status checks, it is ready to receive connection requests.

Step 2: Connect to your instance

The procedure that you use depends on the operating system of the instance. If you can't connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance for assistance.

Linux instances

You can connect to your Linux instance using any SSH client. If you are running Windows on your computer, open a terminal and run the `ssh` command to verify that you have an SSH client installed. If the command is not found, install OpenSSH for Windows.

To connect to your instance using SSH

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and then choose **Connect**.
4. On the **Connect to instance** page, choose the **SSH client** tab.
5. (Optional) If you created a key pair when you launched the instance and downloaded the private key (.pem file) to a computer running Linux or macOS, run the example **chmod** command to set the permissions for your private key.
6. Copy the example SSH command. The following is an example, where *`key-pair-name`*.pem is the name of your private key file, *`ec2-user`* is the username associated with the image, and the string after the @ symbol is the public DNS name of the instance.

    ```
    ssh -i key-pair-name.pem ec2-user@ec2-198-51-100-1.us-east-2.compute.amazonaws.com
    ```

7. In a terminal window on your computer, run the **ssh** command that you saved in the previous step. If the private key file is not in the current directory, you must specify the fully-qualified path to the key file in this command.

    The following is an example response:

    ```
    The authenticity of host 'ec2-198-51-100-1.us-east-2.compute.amazonaws.com
     (198-51-100-1)' can't be established.
    ECDSA key fingerprint is l4UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY.
    Are you sure you want to continue connecting (yes/no)?
    ```

8. (Optional) Verify that the fingerprint in the security alert matches the instance fingerprint contained in the console output when you first start an instance. To get the console output, choose **Actions**, **Monitor and troubleshoot**, **Get system log**. If the fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, continue to the next step.

9. Enter **yes**.

   The following is an example response:

```
Warning: Permanently added 'ec2-198-51-100-1.us-
east-2.compute.amazonaws.com' (ECDSA) to the list of known hosts.
```

Windows instances

To connect to a Windows instance using RDP, you must retrieve the initial administrator password and then enter this password when you connect to your instance. It takes a few minutes after instance launch before this password is available. Your account must have permission to call the GetPasswordData action. For more information, see Example policies to control access the Amazon EC2 API.

The default username for the Administrator account depends on the language of the operating system (OS) contained in the AMI. To determine the correct username, identify the language of the OS, and then choose the corresponding username. For example, for an English OS, the username is `Administrator`, for a French OS it's `Administrateur`, and for a Portuguese OS it's `Administrador`. If a language version of the OS does not have a username in the same language, choose the username `Administrator (Other)`. For more information, see Localized Names for Administrator Account in Windows in the Microsoft website.

To retrieve the initial administrator password

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and then choose **Connect**.
4. On the **Connect to instance** page, choose the **RDP client** tab.
5. For **Username**, choose the default username for the Administrator account. The username you choose must match the language of the operating system (OS) contained in the AMI that you

used to launch your instance. If there is no username in the same language as your OS, choose **Administrator (Other)**.

6. Choose **Get password**.
7. On the **Get Windows password** page, do the following:

    a. Choose **Upload private key file** and navigate to the private key (`.pem`) file that you specified when you launched the instance. Select the file and choose **Open** to copy the entire contents of the file to this window.

    b. Choose **Decrypt password**. The **Get Windows password** page closes, and the default administrator password for the instance appears under **Password**, replacing the **Get password** link shown previously.

    c. Copy the password and save it in a safe place. This password is required to connect to the instance.

The following procedure uses the Remote Desktop Connection client for Windows (MSTSC). If you're using a different RDP client, download the RDP file and then see the documentation for the RDP client for the steps to establish the RDP connection.

To connect to a Windows instance using an RDP client

1. On the **Connect to instance** page, choose **Download remote desktop file**. When the file download is finished, choose **Cancel** to return to the **Instances** page. The RDP file is downloaded to your `Downloads` folder.
2. Run `mstsc.exe` to open the RDP client.
3. Expand **Show options**, choose **Open**, and select the .rdp file from your `Downloads` folder.
4. By default, **Computer** is the public IPv4 DNS name of the instance and **User name** is the administrator account. To connect to the instance using IPv6 instead, replace the public IPv4 DNS name of the instance with its IPv6 address. Review the default settings and change them as needed.
5. Choose **Connect**. If you receive a warning that the publisher of the remote connection is unknown, choose **Connect** to continue.
6. Enter the password that you saved previously, and then choose **OK**.
7. Due to the nature of self-signed certificates, you might get a warning that the security certificate could not be authenticated. Do one of the following:
    - If you trust the certificate, choose **Yes** to connect to your instance.

- [Windows] Before you proceed, compare the thumbprint of the certificate with the value in the system log to confirm the identity of the remote computer. Choose **View certificate** and then choose **Thumbprint** from the **Details** tab. Compare this value to the value of `RDPCERTIFICATE-THUMBPRINT` in **Actions**, **Monitor and troubleshoot**, **Get system log**.
- [Mac OS X] Before you proceed, compare the fingerprint of the certificate with the value in the system log to confirm the identity of the remote computer. Choose **Show Certificate**, expand **Details**, and choose **SHA1 Fingerprints**. Compare this value to the value of `RDPCERTIFICATE-THUMBPRINT` in **Actions**, **Monitor and troubleshoot**, **Get system log**.

8. If the RDP connection is successful, the RDP client displays the Windows login screen and then the Windows desktop. If you receive an error message instead, see the section called "Remote Desktop can't connect to the remote computer". When you are finished with the RDP connection, you can close the RDP client.

Step 3: Clean up your instance

After you've finished with the instance that you created for this tutorial, you should clean up by terminating the instance. If you want to do more with this instance before you clean up, see Next steps.

> **Important**
>
> Terminating an instance effectively deletes it; you can't reconnect to an instance after you've terminated it.

You'll stop incurring charges for that instance or usage that counts against your Free Tier limits as soon as the instance status changes to `shutting down` or `terminated`. To keep your instance for later, but not incur charges or usage that counts against your Free Tier limits, you can stop the instance now and then start it again later. For more information, see Stop and start Amazon EC2 instances.

To terminate your instance

1. In the navigation pane, choose **Instances**. In the list of instances, select the instance.
2. Choose **Instance state**, **Terminate (delete) instance**.

3. Choose **Terminate (delete)** when prompted for confirmation.

   Amazon EC2 shuts down and terminates your instance. After your instance is terminated, it remains visible on the console for a short while, and then the entry is automatically deleted. You cannot remove the terminated instance from the console display yourself.

Next steps

After you start your instance, you might want to explore the following next steps:

- Explore the Amazon EC2 core concepts with the introductory tutorials. For more information, see Tutorials for launching EC2 instances.
- Learn how to track your Amazon EC2 Free Tier usage using the console. For more information, see the section called "Track your Free Tier usage".
- Configure a CloudWatch alarm to notify you if your usage exceeds the Free Tier (for accounts created before July 15, 2025). For more information, see Tracking your AWS Free Tier usage in the *AWS Billing User Guide*.
- Add an EBS volume. For more information, see Create an Amazon EBS volume in the *Amazon EBS User Guide*.
- Learn how to remotely manage your EC2 instance using the Run command. For more information, see AWS Systems Manager Run Command in the *AWS Systems Manager User Guide*.
- Learn about instance purchasing options. For more information, see Amazon EC2 billing and purchasing options.
- Get advice about instance types. For more information, see Get recommendations from EC2 instance type finder.

Best practices for Amazon EC2

To ensure the maximum benefit from Amazon EC2, we recommend that you perform the following best practices.

Security

- Manage access to AWS resources and APIs using identity federation with an identity provider and IAM roles whenever possible. For more information, see Creating IAM policies in the *IAM User Guide*.
- Implement the least permissive rules for your security group.
- Regularly patch, update, and secure the operating system and applications on your instance. For more information, see Update management. For guidelines specific to Windows operating systems, see Security best practices for Windows instances.
- Use Amazon Inspector to automatically discover and scan Amazon EC2 instances for software vulnerabilities and unintended network exposure. For more information, see the Amazon Inspector User Guide.
- Use AWS Security Hub controls to monitor your Amazon EC2 resources against security best practices and security standards. For more information about using Security Hub, see Amazon Elastic Compute Cloud controls in the *AWS Security Hub User Guide*.

Storage

- Understand the implications of the root device type for data persistence, backup, and recovery. For more information, see Root device type.
- Use separate Amazon EBS volumes for the operating system versus your data. Ensure that the volume with your data persists after instance termination. For more information, see Preserve data when an instance is terminated.
- Use the instance store available for your instance to store temporary data. Remember that the data stored in instance store is deleted when you stop, hibernate, or terminate your instance. If you use instance store for database storage, ensure that you have a cluster with a replication factor that ensures fault tolerance.
- Encrypt EBS volumes and snapshots. For more information, see Amazon EBS encryption in the *Amazon EBS User Guide*.

Resource management

- Use instance metadata and custom resource tags to track and identify your AWS resources. For more information, see Use instance metadata to manage your EC2 instance and Tag your Amazon EC2 resources.
- View your current limits for Amazon EC2. Plan to request any limit increases in advance of the time that you'll need them. For more information, see Amazon EC2 service quotas.
- Use AWS Trusted Advisor to inspect your AWS environment, and then make recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. For more information, see AWS Trusted Advisor in the *AWS Support User Guide*.

Backup and recovery

- Regularly back up your EBS volumes using Amazon EBS snapshots, and create an Amazon Machine Image (AMI) from your instance to save the configuration as a template for launching future instances. For more information about AWS services that help achieve this use case, see AWS Backup and Amazon Data Lifecycle Manager.
- Deploy critical components of your application across multiple Availability Zones, and replicate your data appropriately.
- Design your applications to handle dynamic IP addressing when your instance restarts. For more information, see Amazon EC2 instance IP addressing.
- Monitor and respond to events. For more information, see Monitor Amazon EC2 resources.
- Ensure that you are prepared to handle failover. For a basic solution, you can manually attach a network interface or Elastic IP address to a replacement instance. For more information, see Elastic network interfaces. For an automated solution, you can use Amazon EC2 Auto Scaling. For more information, see the Amazon EC2 Auto Scaling User Guide.
- Regularly test the process of recovering your instances and Amazon EBS volumes to ensure data and services are restored successfully.

Networking

- Set the time-to-live (TTL) value for your applications to 255, for IPv4 and IPv6. If you use a smaller value, there is a risk that the TTL will expire while application traffic is in transit, causing reachability issues for your instances.

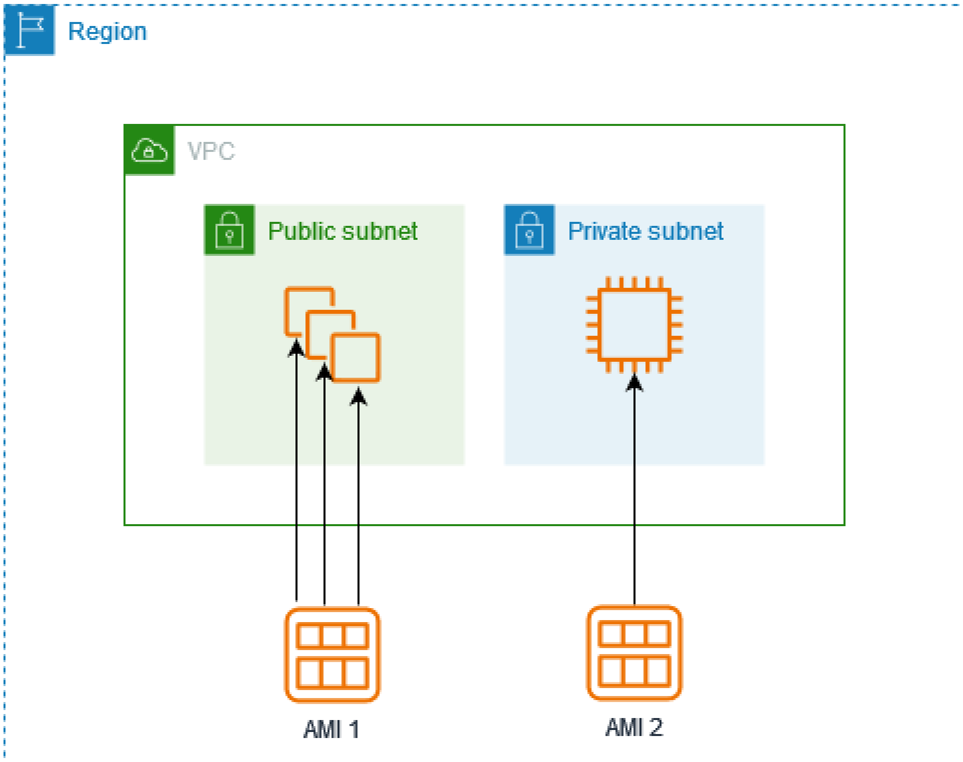
Amazon Machine Images in Amazon EC2

An Amazon Machine Image (AMI) is an image that provides the software that is required to set up and boot an Amazon EC2 instance. Each AMI also contains a block device mapping that specifies the block devices to attach to the instances that you launch. You must specify an AMI when you launch an instance. The AMI must be compatible with the instance type that you chose for your instance. You can use an AMI provided by AWS, a public AMI, an AMI that someone else shared with you, or an AMI that you purchased from the AWS Marketplace.

An AMI is specific to the following:

- Region
- Operating system
- Processor architecture
- Root device type
- Virtualization type

You can launch multiple instances from a single AMI when you require multiple instances with the same configuration. You can use different AMIs to launch instances when you require instances with different configurations, as shown in the following diagram.



You can create an AMI from your Amazon EC2 instances and then use it to launch instances with the same configuration. You can copy an AMI to another AWS Region, and then use it to launch instances in that Region. You can also share an AMI that you created with other accounts so that they can launch instances with the same configuration. You can sell your AMI using the AWS Marketplace.

Contents

AMI types and characteristics in Amazon EC2

When you launch an instance, the AMI that you choose must be compatible with the instance type that you choose. You can select an AMI to use based on the following characteristics:

- Region
- Operating system
- Processor architecture
- Launch permissions
- Root device type
- Virtualization types

Launch permissions

Launch permissions determine who can use an AMI to launch instances. You can think of launch permissions as sharing an AMI—when you grant launch permissions, you're sharing the AMI with other users. Only the owner of an AMI can determine its availability by specifying launch permissions. Launch permissions fall into the following categories.

Launch permission	Description
public	The owner grants launch permissions to all AWS accounts.
explicit	The owner grants launch permissions to specific AWS accounts, organizat ions, or organizational units (OUs).
implicit	The owner has implicit launch permissions for an AMI.

Amazon and the Amazon EC2 community provide a large selection of public AMIs. For more information, see Understand shared AMI usage in Amazon EC2. Developers can charge for their AMIs. For more information, see Paid AMIs in the AWS Marketplace for Amazon EC2 instances.

Root device type

All AMIs are categorized as either *backed by Amazon EBS* or *backed by instance store*.

- Amazon EBS-backed AMI – The root device for an instance launched from the AMI is an Amazon Elastic Block Store (Amazon EBS) volume created from an Amazon EBS snapshot. Supported for both Linux and Windows AMIs.
- Amazon instance store-backed AMI – The root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3. Supported for Linux AMIs only. Windows AMIs do not support instance store for the root device.

For more information, see Root volumes for your Amazon EC2 instances.

Note

Instance store-backed AMIs are considered end of life and are not recommended for new usage. They are only supported on the following older instance types: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

The following table summarizes the important differences when using the two types of AMIs.

Characteristic	Amazon EBS-backed AMI	Amazon instance store-backed AMI
Root device volume	EBS volume	Instance store volume
Boot time for an instance	Usually less than 1 minute	Usually less than 5 minutes
Data persistence	By default, the root volume is deleted when the instance terminates.* Data on any other EBS volumes persists after instance termination by default.	Data on any instance store volumes persists only during the life of the instance.
Stopped state	Can be in a stopped state. Even when the instance is stopped and not running, the root volume is persisted in Amazon EBS.	Cannot be in a stopped state; instances are running or terminated.

Characteristic	Amazon EBS-backed AMI	Amazon instance store-backed AMI
Modifications	The instance type, kernel, RAM disk, and user data can be changed while the instance is stopped.	Instance attributes are fixed for the life of an instance.
Charges	You're charged for instance usage, EBS volume usage, and storing your AMI as an EBS snapshot.	You're charged for instance usage and storing your AMI in Amazon S3.
AMI creation/bundling	Uses a single command/call	Requires installation and use of AMI tools

* By default, EBS root volumes have the `DeleteOnTermination` flag set to `true`. For information about how to change this flag so that the volume persists after termination, see Keep an Amazon EBS root volume after an Amazon EC2 instance terminates.

** Supported with `io2` EBS Block Express only. For more information, see Provisioned IOPS SSD Block Express volumes in the *Amazon EBS User Guide*.

Determine the root device type of your AMI

The AMI that you use to launch an EC2 instance determines the type of the root volume. The root volume of an EC2 instance is either an EBS volume or an instance store volume.

Nitro-based instances support only EBS root volumes. The following previous generation instance types are the only instance types that support instance store root volumes: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

Console

To determine the root device type of an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **AMIs**, and select the AMI.
3. On the **Details** tab, check the value of **Root device type** as follows:
   - `ebs` – This is an EBS-backed AMI.
   - `instance store` – This is an instance store-backed AMI.

AWS CLI

To determine the root device type of an AMI

Use the describe-images command.

```
aws ec2 describe-images \
    --image-ids ami-0abcdef1234567890 \
    --query Images[].RootDeviceType
```

The following is example output.

```
ebs
```

PowerShell

To determine the root device type of an AMI

Use the Get-EC2Image cmdlet.

```
(Get-EC2Image `
    -ImageId ami-0abcdef1234567890).RootDeviceType.Value
```

The following is example output.

```
ebs
```

Virtualization types

Amazon Machine Images use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). The main differences between PV and HVM AMIs are the way in which they boot and whether they can take advantage of special hardware extensions (CPU, network, and storage) for better performance. Windows AMIs are HVM AMIs.

The following table compares HVM and PV AMIs.

Characteristic	HVM	PV
Description	HVM AMIs are presented with a fully virtualized set of hardware and boot by executing the master boot record of the root block device of your image. This virtualization type provides the ability to run an operating system directly on top of a virtual machine without any modification, as if it were run on the bare-metal hardware. The Amazon EC2 host system emulates some or all of the underlying hardware that is presented to the guest.	PV AMIs boot with a special boot loader called PV-GRUB, which starts the boot cycle and then chain loads the kernel specified in the `menu.lst` file on your image. Paravirtual guests can run on host hardware that does not have explicit support for virtualization. For more information about PV-GRUB and its use in Amazon EC2, see User provided kernels.
Supported instance types	All current generation instance types support HVM AMIs.	The following previous generation instance types support PV AMIs: C1, C3, M1, M3, M2, and T1. Current generation instance types do not support PV AMIs.
Support for hardware extensions	HVM guests can take advantage of hardware extensions that provide fast access to the underlyin g hardware on the host system. They are required to use enhanced networkin	No, they can't take advantage of special hardware extension s such as enhanced networkin g or GPU processing.

Characteristic	HVM	PV
	g and GPU processing. To pass through instructions to specialized network and GPU devices, the OS must have access to the native hardware platform, and HVM virtualiz ation provides this access. For more information, see Enhanced networking on Amazon EC2 instances.	
How to find	Verify that the virtualization type of the AMI is set to `hvm`, using the console or the describe-images command.	Verify that the virtualization type of the AMI is set to `paravirtual` , using the console or the describe-images command.

PV on HVM

Paravirtual guests traditionally performed better with storage and network operations than HVM guests because they could leverage special drivers for I/O that avoided the overhead of emulating network and disk hardware, whereas HVM guests had to translate these instructions to emulated hardware. Now PV drivers are available for HVM guests, so operating systems that cannot be ported to run in a paravirtualized environment can still see performance advantages in storage and network I/O by using them. With these PV on HVM drivers, HVM guests can get the same, or better, performance than paravirtual guests.

Find an AMI that meets the requirements for your EC2 instance

An AMI includes the components and applications, such as the operating system and type of root volume, required to launch an instance. To launch an instance, you must find an AMI that meets your needs.

When selecting an AMI, consider the following requirements you might have for the instances that you want to launch:

- The AWS Region of the AMI as AMI IDs are unique to each Region.
- The operating system (for example, Linux or Windows).
- The architecture (for example, 32-bit, 64-bit, or 64-bit ARM).
- The root device type (for example, Amazon EBS or instance store).
- The provider (for example, Amazon Web Services).
- Additional software (for example, SQL Server).

Console

You can select from the list of AMIs when you use the launch instance wizard, or you can search all available AMIs using the **Images** page.

To find a Quick Start AMI using the launch instance wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location. AMI IDs are unique to each AWS Region.
3. From the console dashboard, choose **Launch instance**.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Quick Start**, choose the operating system (OS) for your instance, and then, from **Amazon Machine Image (AMI)**, select from one of the commonly used AMIs in the list. If you don't see the AMI that you want to use, choose **Browse more AMIs** to browse the full AMI catalog. For more information, see Application and OS Images (Amazon Machine Image).

To find an AMI using the AMIs page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location. AMI IDs are unique to each AWS Region.
3. In the navigation pane, choose **AMIs**.
4. (Optional) Use the filter and search options to scope the list of displayed AMIs to see only the AMIs that match your criteria.

For example, to list all AMIs provided by AWS, choose **Public images**. Then use the search options to further scope the list of displayed AMIs. Choose the **Search** bar and, from the menu, choose **Owner alias**, then the **=** operator, and then the value **amazon**. To find AMIs that match a specific platform, for example Linux or Windows, choose the **Search** bar again to choose **Platform**, then the **=** operator, and then the operating system from the list provided.

5. (Optional) Choose the **Preferences** icon to select which image attributes to display, such as the root device type. Alternatively, you can select an AMI from the list and view its properties on the **Details** tab.
6. Before you select an AMI, it's important that you check whether it's backed by instance store or by Amazon EBS and that you are aware of the effects of this difference. For more information, see Root device type.
7. To launch an instance from this AMI, select it and then choose **Launch instance from image**. For more information about launching an instance using the console, see Launch an EC2 instance using the launch instance wizard in the console. If you're not ready to launch the instance now, make note of the AMI ID for later.

AWS CLI

Use the describe-images command to find an AMI that meets your requirements. By default, this command returns all AMIs that are public, that you own, and that are shared with you.

To find an AMI owned by Amazon

Use the describe-images command with the `--owners` option.

```
aws ec2 describe-images --owners amazon
```

To find a Windows AMI

Add the following filter to display only Windows AMIs.

```
--filters "Name=platform,Values=windows"
```

To find an EBS-backed AMI

Add the following filter to display only AMIs backed by Amazon EBS.

```
--filters "Name=root-device-type,Values=ebs"
```

PowerShell

Use the Get-EC2Image cmdlet to find an AMI that meets your requirements. By default, this cmdlet returns all AMIs that are public, that you own, or that are shared with you.

To find an AMI owned by Amazon

Use the Get-EC2Image command with the `-Owner` parameter.

```
Get-EC2Image -Owner amazon
```

To find a Windows AMI

Add the following filter to display only Windows AMIs.

```
-Filter @{Name="platform"; Values="windows"}
```

For additional examples, see Find an Amazon Machine Image Using Windows PowerShell in the *AWS Tools for PowerShell User Guide*.

Related resources

For more information about AMIs for a specific operating system, see the following:

- Amazon Linux 2023 – AL2023 on Amazon EC2 in the *Amazon Linux 2023 User Guide*
- Ubuntu – Amazon EC2 AMI Locator on the *Canonical Ubuntu website*
- RHEL – Red Hat Enterprise Linux Images (AMI) Available on Amazon Web Services (AWS) on the Red Hat website
- Windows Server – AWS Windows AMI reference

For information about AMIs that you can subscribe to on the AWS Marketplace see Paid AMIs in the AWS Marketplace for Amazon EC2 instances.

For information about using Systems Manager to help your users find the latest AMI that they should use when launching an instance, see the following:

Reference AMIs using Systems Manager parameters

When you launch an instance using the EC2 launch instance wizard in the Amazon EC2 console, you can either select an AMI from the list, or you can select an AWS Systems Manager parameter that points to an AMI ID (described in this section). If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID.

A Systems Manager parameter is a customer-defined key-value pair that you can create in Systems Manager Parameter Store. The Parameter Store provides a central store to externalize your application configuration values. For more information, see AWS Systems Manager Parameter Store in the *AWS Systems Manager User Guide*.

When you create a parameter that points to an AMI ID, make sure that you specify the data type as `aws:ec2:image`. Specifying this data type ensures that when the parameter is created or modified, the parameter value is validated as an AMI ID. For more information, see Native parameter support for Amazon Machine Image IDs in the *AWS Systems Manager User Guide*.

Contents

Use cases

When you use Systems Manager parameters to point to AMI IDs, it is easier for your users to select the correct AMI when launching instances. Systems Manager parameters can also simplify the maintenance of automation code.

Easier for users

If you require instances to be launched using a specific AMI, and the AMI is regularly updated, we recommend that you require your users to select a Systems Manager parameter to find the AMI.

Requiring your users to select a Systems Manager parameter ensures that the latest AMI is used to launch instances.

For example, every month in your organization you might create a new version of your AMI that has the latest operating system and application patches. You also require your users to launch instances using the latest version of your AMI. To ensure that your users use the latest version, you can create a Systems Manager parameter (for example, `golden-ami`) that points to the correct AMI ID. Each time a new version of the AMI is created, you update the AMI ID value in the parameter so that it always points to the latest AMI. Your users don't have to know about the periodic updates to the AMI because they continue to select the same Systems Manager parameter each time. Using a Systems Manager parameter for your AMI makes it easier for them to select the correct AMI for an instance launch.

Simplify automation code maintenance

If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID. If a new version of the AMI is created, you can change the AMI ID value in the parameter so that it points to the latest AMI. The automation code that references the parameter doesn’t have to be modified each time a new version of the AMI is created. This simplifies the maintenance of the automation and helps to drive down deployment costs.

> **Note**
>
> Running instances are not affected when you change the AMI ID pointed to by the Systems Manager parameter.

Permissions

If you use Systems Manager parameters that point to AMI IDs in the launch instance wizard, you must add the following permissions to your IAM policy:

- `ssm:DescribeParameters` – Grants permission to view and select Systems Manager parameters.
- `ssm:GetParameters` – Grants permission to retrieve the values of the Systems Manager parameters.

You can also restrict access to specific Systems Manager parameters. For more information and example IAM policies, see Example: Use the EC2 launch instance wizard.

Limitations

AMIs and Systems Manager parameters are Region specific. To use the same Systems Manager parameter name across Regions, create a Systems Manager parameter in each Region with the same name (for example, `golden-ami`). In each Region, point the Systems Manager parameter to an AMI in that Region.

Parameter names are case-sensitive. Backslashes for the parameter name are only necessary when the parameter is part of a hierarchy, for example, `/amis/production/golden-ami`. You can omit the backslash if the parameter is not part of a hierarchy.

Launch an instance using a Systems Manager parameter

When you launch an instance, instead of specifying an AMI ID, you can specify a Systems Manager parameter that points to an AMI ID.

To specify the parameter programmatically, use the following syntax, where `resolve:ssm` is the standard prefix and `parameter-name` is the unique parameter name.

```
resolve:ssm:parameter-name
```

Systems Manager parameters have version support. Each iteration of a parameter is assigned a unique version number. You can reference the version of the parameter as follows, where `version` is the unique version number. By default, the latest version of the parameter is used when no version is specified.

```
resolve:ssm:parameter-name:version
```

To launch an instance using a public parameter provided by AWS, see Reference the latest AMIs using Systems Manager public parameters.

Console

To find an AMI using a Systems Manager parameter

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.

3. From the console dashboard, choose **Launch instance**.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**.
5. Choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**.
6. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears below **Currently resolves to**.
7. Choose **Search**. The AMIs that match the AMI ID appear in the list.
8. Select the AMI from the list, and choose **Select**.

For more information about launching an instance using the launch instance wizard, see Launch an EC2 instance using the launch instance wizard in the console.

AWS CLI

To launch an instance using a Systems Manager parameter

Use the run-instances command with the `--image-id` option. This example uses a Systems Manager parameter named **`golden-ami`**, which specifies an AMI ID.

```
--image-id resolve:ssm:/golden-ami
```

You can create versions of a Systems Manager parameter. The following example specifies version 2 of the **`golden-ami`** parameter.

```
--image-id resolve:ssm:/golden-ami:2
```

PowerShell

To launch an instance using a Systems Manager parameter

Use the New-EC2Instance cmdlet with the `-ImageId` parameter. This example uses a Systems Manager parameter named **`golden-ami`**, which specifies an AMI ID.

```
-ImageId "resolve:ssm:/golden-ami"
```

You can create versions of a Systems Manager parameter. The following example specifies version 2 of the **`golden-ami`** parameter.

```
-ImageId "resolve:ssm:/golden-ami:2"
```

Reference the latest AMIs using Systems Manager public parameters

AWS Systems Manager provides public parameters for public AMIs maintained by AWS. You can use the public parameters when launching instances to ensure that you're using the latest AMIs. For example, the public parameter `/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-default-arm64` is available in all Regions and always points to the latest version of the Amazon Linux 2023 AMI for arm64 architecture in a given Region.

The public parameters are available from the following paths:

- **Linux** – `/aws/service/ami-amazon-linux-latest`
- **Windows** – `/aws/service/ami-windows-latest`

For more information, see Working with public parameters in the *AWS Systems Manager User Guide*.

List the Amazon Linux AMIs

AWS CLI

To list the Linux AMIs in the current AWS Region

Use the following get-parameters-by-path command. The value for the `--path` parameter is specific to Linux AMIs.

```
aws ssm get-parameters-by-path \
    --path /aws/service/ami-amazon-linux-latest \
    --query "Parameters[].Name"
```

PowerShell

To list the Linux AMIs in the current AWS Region

Use the Get-SSMParametersByPath cmdlet.

```
Get-SSMParametersByPath `
```

```
    -Path "/aws/service/ami-amazon-linux-latest" | `
    Sort-Object Name | Format-Table Name
```

List the Windows AMIs

AWS CLI

To list the Windows AMIs in the current AWS Region

Use the following get-parameters-by-path command. The value for the `--path` parameter is specific to Windows AMIs.

```
aws ssm get-parameters-by-path \
    --path /aws/service/ami-windows-latest \
    --query "Parameters[].Name"
```

PowerShell

To list the Windows AMIs in the current AWS Region

Use the Get-SSMParametersByPath cmdlet.

```
Get-SSMParametersByPath `
    -Path "/aws/service/ami-windows-latest" | `
    Sort-Object Name | Format-Table Name
```

Launch an instance using a public parameter

To specify the public parameter when launching an instance, use the following syntax: `resolve:ssm:`*`public-parameter`*, where `resolve:ssm` is the standard prefix and *`public-parameter`* is the path and name of the public parameter.

AWS CLI

To launch an instance using a public parameter

Use the run-instances command with the `--image-id` option. This example specifies a Systems Manager public parameter for the image ID to launch an instance using the latest Amazon Linux 2023 AMI

```
--image-id resolve:ssm:/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-default-x86_64
```

PowerShell

To launch an instance using a public parameter

Use the New-EC2Instance cmdlet with the `-ImageId` parameter. This example specifies a Systems Manager public parameter for the image ID to launch an instance using the latest AMI for Windows Server 2022.

```
-ImageId "resolve:ssm:/aws/service/ami-windows-latest/Windows_Server-2022-English-Full-Base"
```

For more examples that use Systems Manager parameters, see Query for the latest Amazon Linux AMI IDs Using AWS Systems Manager Parameter Store and Query for the Latest Windows AMI Using AWS Systems Manager Parameter Store.

Paid AMIs in the AWS Marketplace for Amazon EC2 instances

A *paid AMI* is an AMI that is listed for sale in the AWS Marketplace. The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs that you can use to launch your EC2 instance. The AWS Marketplace AMIs are organized into categories, such as Developer Tools, to enable you to find products to suit your requirements. For more information about AWS Marketplace, see the AWS Marketplace website.

You can purchase AMIs in the AWS Marketplace from a third party, including AMIs that come with service contracts from organizations such as Red Hat. You can also create an AMI and sell it in the AWS Marketplace to other Amazon EC2 users. Building a safe, secure, usable AMI for public consumption is a fairly straightforward process, if you follow a few simple guidelines. For information about how to create and use shared AMIs, see Understand shared AMI usage in Amazon EC2.

Launching an instance from a paid AMI is the same as launching an instance from any other AMI. No additional parameters are required. The instance is charged according to the rates set by the owner of the AMI, as well as the standard usage fees for the related web services, for example, the hourly rate for running an m5.small instance type in Amazon EC2. Additional taxes might also apply. The owner of the paid AMI can confirm whether a specific instance was launched using that paid AMI.

> **Important**
>
> Amazon DevPay is no longer accepting new sellers or products. AWS Marketplace is now the single, unified e-commerce platform for selling software and services through AWS. For information about how to deploy and sell software from AWS Marketplace, see Selling in AWS Marketplace. AWS Marketplace supports AMIs backed by Amazon EBS.

Contents

Sell your AMI in the AWS Marketplace

You can sell your AMI using AWS Marketplace. AWS Marketplace offers an organized shopping experience. Additionally, AWS Marketplace also supports AWS features such as Amazon EBS-backed AMIs, Reserved Instances, and Spot Instances.

For information about how to sell your AMI on the AWS Marketplace, see Selling in AWS Marketplace.

Find a paid AMI

A paid AMI is an Amazon Machine Image (AMI) that is available for purchase. A paid AMI also has a product code. You can find AMIs that are available for purchase in the AWS Marketplace.

Console

To find a paid AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Choose **Public images** for the first filter.
4. Do one of the following:
   - If you know the product code, choose **Product code**, then **=**, and then enter the product code.
   - If you do not know the product code, in the Search bar, specify the following filter: **Owner alias=aws-marketplace**. Specify additional filters as needed.
5. Save the ID of the AMI.

AWS CLI

To find a paid AMI

Use the following describe-images command.

```
aws ec2 describe-images --owners aws-marketplace
```

The output includes a large number of images. You can specify filters to help you determine which AMI you need. After you find an AMI, specify its ID in the following command to get its product code.

```
aws ec2 describe-images \
    --image-ids ami-0abcdef1234567890 \
    --query Images[*].ProductCodes[].ProductCodeId
```

The following is example output.

```
[
    "cdef1234abc567def8EXAMPLE"
]
```

If you know the product code, you can filter the results by product code. This example returns the most recent AMI with the specified product code.

```
aws ec2 describe-images \
    --filters "Name=product-code,Values=cdef1234abc567def8EXAMPLE" \
    --query "sort_by(Images, &CreationDate)[-1].[ImageId]"
```

PowerShell

To find a paid AMI

Use the Get-EC2Image cmdlet.

```
Get-EC2Image -Owner aws-marketplace
```

The output includes a large number of images. You can specify filters to help you determine which AMI you need. After you find an AMI, specify its ID in the following command to get its product code.

```
(Get-EC2Image -ImageId ami-0abcdef1234567890).ProductCodes
```

The following is example output.

```
ProductCodeId             ProductCodeType
-------------             ---------------
cdef1234abc567def8EXAMPLE marketplace
```

If you know the product code, you can filter the results by product code. This example returns the most recent AMI with the specified product code.

```
(Get-EC2Image -Owner aws-marketplace -Filter @{"Name"="product-
code";"Value"="cdef1234abc567def8EXAMPLE"} | sort CreationDate -Descending | Select-
Object -First 1).ImageId
```

Purchase a paid AMI in the AWS Marketplace

You must sign up for (purchase) a paid AMI before you can launch an Amazon EC2 instance using the AMI.

Typically a seller of a paid AMI presents you with information about the AMI, including its price and a link where you can buy it. When you click the link, you're first asked to log into AWS, and then you can purchase the AMI.

Purchase a paid AMI using the console

You can purchase a paid AMI by using the Amazon EC2 launch wizard. For more information, see Launch an Amazon EC2 instance from an AWS Marketplace AMI.

Subscribe to a product using AWS Marketplace

To use the AWS Marketplace, you must have an AWS account. To launch instances from AWS Marketplace products, you must be signed up to use the Amazon EC2 service, and you must be subscribed to the product from which to launch the instance. You can use one of the following methods to subscribe to products in the AWS Marketplace:

- **AWS Marketplace website**: You can launch preconfigured software quickly with the 1-Click deployment feature. For more information, see AMI-based products in AWS Marketplace.
- **Amazon EC2 launch wizard**: You can search for an AMI and launch an instance directly from the wizard. For more information, see Launch an Amazon EC2 instance from an AWS Marketplace AMI.

Retrieve the AWS Marketplace product code from your instance

You can retrieve the AWS Marketplace product code for your instance using its instance metadata. If the instance has a product code, Amazon EC2 returns it. For more information about retrieving metadata, see Access instance metadata for an EC2 instance.

IMDSv2

Linux

Run the following command from your Linux instance.

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/product-codes
```

Windows

Run the following cmdlets from your Windows instance.

```
[string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds"
 = "21600"} `
    -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/product-codes
```

IMDSv1

Linux

Run the following command from your Linux instance.

```
curl http://169.254.169.254/latest/meta-data/product-codes
```

Windows

Run the following command from your Windows instance.

```
Invoke-RestMethod -Uri http://169.254.169.254/latest/meta-data/product-codes
```

Use paid support for supported AWS Marketplace offerings

Amazon EC2 also enables developers to offer support for software (or derived AMIs). Developers can create support products that you can sign up to use. During sign-up for the support product, the developer gives you a product code, which you must then associate with your own AMI. This enables the developer to confirm that your instance is eligible for support. It also ensures that when you run instances of the product, you are charged according to the terms for the product specified by the developer.

Limitations

- After you set the product code attribute, it can't be changed or removed.
- You can't use a support product with Reserved Instances. You always pay the price that's specified by the seller of the support product.

AWS CLI

To associate a product code with your AMI

Use the [modify-image-attribute] command.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --product-codes "cdef1234abc567def8EXAMPLE"
```

PowerShell

To associate a product code with your AMI

Use the Edit-EC2ImageAttribute cmdlet.

```
Edit-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -ProductCode "cdef1234abc567def8EXAMPLE"
```

Bills for paid and supported AMIs

At the end of each month, you receive an email with the amount your credit card has been charged for using any paid or supported AMIs during the month. This bill is separate from your regular Amazon EC2 bill. For more information, see Paying for products in the *AWS Marketplace Buyer Guide*.

Manage your AWS Marketplace subscriptions

On the AWS Marketplace website, you can check your subscription details, view the vendor's usage instructions, manage your subscriptions, and more.

To check your subscription details

1. Log in to the AWS Marketplace.
2. Choose **Your Marketplace Account**.
3. Choose **Manage your software subscriptions**.
4. All your current subscriptions are listed. Choose **Usage Instructions** to view specific instructions for using the product, for example, a username for connecting to your running instance.

To cancel an AWS Marketplace subscription

1. Ensure that you have terminated any instances running from the subscription.
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the navigation pane, choose **Instances**.
   c. Select the instance, and then choose **Instance state**, **Terminate (delete) instance**.
   d. Choose **Terminate (delete)** when prompted for confirmation.
2. Log in to the AWS Marketplace, and choose **Your Marketplace Account**, then **Manage your software subscriptions**.
3. Choose **Cancel subscription**. You are prompted to confirm your cancellation.

> **Note**
>
> After you've canceled your subscription, you are no longer able to launch any instances from that AMI. To use that AMI again, you need to resubscribe to it, either on the AWS Marketplace website, or through the launch wizard in the Amazon EC2 console.

Amazon EC2 AMI lifecycle

An Amazon Machine Image (AMI) is an image that contains the software configuration required to set up and boot an instance. You must specify an AMI when you launch an instance. You can use AMIs provided by Amazon, or you can create your own AMIs. The AMI must be located in the AWS Region in which you want to launch your instance.

The lifecycle of an AMI includes creating, copying, deprecating, disabling, and deleting (deregistering) the AMI.

Create AMIs. While Amazon provides AMIs that you can use to launch your instances, you can create custom AMIs tailored to your needs. To create a custom AMI, launch an instance from an existing AMI, customize the instance (for example, install software and configure operating system settings), and then create an AMI from the instance. Any instance customizations are saved to the new AMI, so that instances launched from your new AMI include these customizations.

Copy AMIs. You can use an AMI to launch an instance only in the AWS Region in which the AMI is located. If you need to launch instances with the same configuration in multiple Regions, copy the AMI to the other Regions.

Deprecate AMIs. To mark an AMI as superseded or out of date, you can set an immediate or future deprecation date. Deprecated AMIs are hidden from AMI listings, but users and services can continue to use deprecated AMIs if they know the AMI ID.

Disable AMIs. To temporarily prevent an AMI from being used, you can disable it. When an AMI is disabled, it can't be used to launch new instances. However, if you re-enable the AMI, it can be used to launch instances again. Note that disabling an AMI doesn't affect existing instances that have already been launched from it.

Deregister (delete) AMIs. When you no longer need an AMI, you can deregister it, preventing it from being used to launch new instances. If the AMI matches a retention rule, it moves to the Recycle Bin, where it can be restored before its retention period expires, after which it is permanently deleted. If it doesn't match a retention rule, it is permanently deleted immediately. Note that deregistering an AMI does not affect existing instances that were launched from the AMI.

Automate the AMI lifecycle. You can use Amazon Data Lifecycle Manager to automate the creation, retention, copy, deprecation, and deregistration of Amazon EBS-backed AMIs and their backing snapshots. You can also use EC2 Image Builder to automate the creation, management, an deployment of customized AMIs. For more information, see Automate backups with Amazon Data Lifecycle Manager in the *Amazon EBS User Guide* and the EC2 Image Builder User Guide.

Contents

Create an Amazon EBS-backed AMI

You can create your own Amazon EBS-backed AMI from an Amazon EC2 instance or from a snapshot of the root device of an Amazon EC2 instance.

To create an Amazon EBS-backed AMI from an instance, start by launching an instance using an existing Amazon EBS-backed AMI. This AMI can be one you obtained from the AWS Marketplace, created using VM Import/Export, or any other AMI that you can access. After customizing the instance to meet your specific requirements, create and register a new AMI. You can then use the new AMI to launch new instances with your customizations.

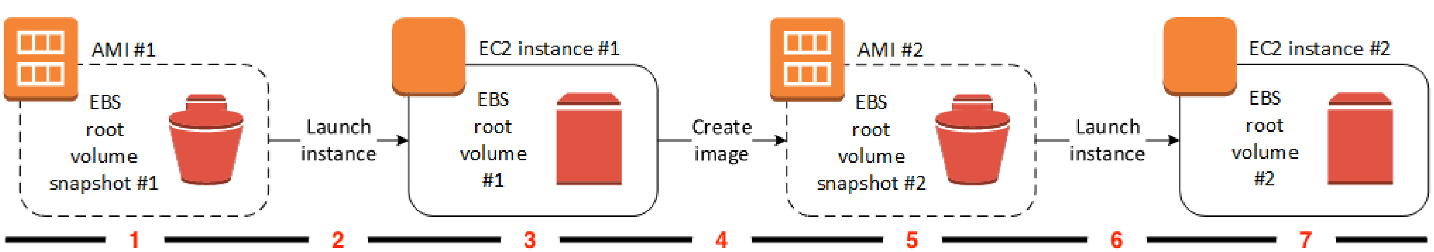
The procedures described below work for Amazon EC2 instances backed by encrypted Amazon Elastic Block Store (Amazon EBS) volumes (including the root volume) as well as for unencrypted volumes.

The AMI creation process is different for instance store-backed AMIs. For more information, see Create an instance store-backed AMI.

Contents

Overview of AMI creation from an instance

The following diagram summarizes the process for creating an Amazon EBS-backed AMI from a running EC2 instance: Start with an existing AMI, launch an instance, customize it, create a new AMI from it, and finally launch an instance of your new AMI. The numbers in the diagram match the numbers in the description that follows.



1 – AMI #1: Start with an existing AMI

Find an existing AMI that is similar to the AMI that you'd like to create. This can be an AMI you have obtained from the AWS Marketplace, an AMI that you have created using VM Import/Export, or any other AMI that you can access. You'll customize this AMI for your needs.

In the diagram, **EBS root volume snapshot #1** indicates that the AMI is an Amazon EBS-backed AMI and that information about the root volume is stored in this snapshot.

2 – Launch instance from existing AMI

The way to configure an AMI is to launch an instance from the AMI on which you'd like to base your new AMI, and then customize the instance (indicated at **3** in the diagram). Then, you'll create a new AMI that includes the customizations (indicated at **4** in the diagram).

3 – EC2 instance #1: Customize the instance

Connect to your instance and customize it for your needs. Your new AMI will include these customizations.

You can perform any of the following actions on your instance to customize it:

- Install software and applications
- Copy data
- Reduce start time by deleting temporary files and defragmenting your hard drive
- Attach additional EBS volumes

4 – Create image

When you create an AMI from an instance, Amazon EC2 powers down the instance before creating the AMI to ensure that everything on the instance is stopped and in a consistent state during the creation process. If you're confident that your instance is in a consistent state appropriate for AMI creation, you can tell Amazon EC2 not to power down and reboot the instance. Some file systems, such as XFS, can freeze and unfreeze activity, making it safe to create the image without rebooting the instance.

During the AMI-creation process, Amazon EC2 creates snapshots of your instance's root volume and any other EBS volumes attached to your instance. You're charged for the snapshots until you deregister the AMI and delete the snapshots. If any volumes attached to the instance are encrypted, the new AMI only launches successfully on instances that support Amazon EBS encryption.

Depending on the size of the volumes, it can take several minutes for the AMI-creation process to complete (sometimes up to 24 hours). You might find it more efficient to create snapshots of your volumes before creating your AMI. This way, only small, incremental snapshots need to be created when the AMI is created, and the process completes more quickly (the total time for snapshot creation remains the same).

5 – AMI #2: New AMI

After the process completes, you have a new AMI and snapshot (**snapshot #2**) created from the root volume of the instance. If you added instance-store volumes or EBS volumes to the instance, in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes.

Amazon EC2 automatically registers the AMI for you.

6 – Launch instance from new AMI

You can use the new AMI to launch an instance.

7 – EC2 instance #2: New instance

When you launch an instance using the new AMI, Amazon EC2 creates a new EBS volume for the instance's root volume using the snapshot. If you added instance-store volumes or EBS volumes when you customized the instance, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. The instance-store volumes specified in the block device mapping for the new instance are new and don't contain any data from the instance store volumes of the instance you used to create the AMI. The data on EBS volumes persists. For more information, see Block device mappings for volumes on Amazon EC2 instances.

When you create a new instance from an EBS-backed AMI, you should initialize both its root volume and any additional EBS storage before putting it into production. For more information, see Initialize Amazon EBS volumes in the *Amazon EBS User Guide*.

Create an AMI from an instance

If you have an existing instance, you can create an AMI from this instance.

Console

To create an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance from which to create the AMI, and then choose **Actions**, **Image and templates**, **Create image**.

   > **Tip**
   >
   > If this option is disabled, your instance isn't an Amazon EBS-backed instance.

4. On the **Create image** page, specify the following information:

   a. For **Image name**, enter a unique name for the image, up to 127 characters.

   b. For **Image description**, enter an optional description of the image, up to 255 characters.

   c. For **Reboot instance**, either keep the checkbox selected (the default), or clear it.

      - If **Reboot instance** is selected, when Amazon EC2 creates the new AMI, it reboots the instance so that it can take snapshots of the attached volumes while data is at rest, in order to ensure a consistent state.
      - If **Reboot instance** is cleared, when Amazon EC2 creates the new AMI, it does not shut down and reboot the instance.

      > **Warning**
      >
      > If you clear **Reboot instance**, we can't guarantee the file system integrity of the created image.

   d. **Instance volumes** – You can modify the root volume, and add additional Amazon EBS and instance store volumes, as follows:

      i. The root volume is defined in the first row.

         - To change the size of the root volume, for **Size**, enter the required value.

- If you select **Delete on termination**, when you terminate the instance created from this AMI, the EBS volume is deleted. If you clear **Delete on termination**, when you terminate the instance, the EBS volume is not deleted. For more information, see Preserve data when an instance is terminated.

ii. To add an EBS volume, choose **Add volume** (which adds a new row). For **Storage type**, choose **EBS**, and fill in the fields in the row. When you launch an instance from your new AMI, additional volumes are automatically attached to the instance. Empty volumes must be formatted and mounted. Volumes based on a snapshot must be mounted.

iii. To add an instance store volume, see Add instance store volumes to an Amazon EC2 AMI. When you launch an instance from your new AMI, additional volumes are automatically initialized and mounted. These volumes do not contain data from the instance store volumes of the running instance on which you based your AMI.

e. **Snapshot destination** – If your instance volumes are in a Local Zone that supports EBS local snapshots, choose where to create the AMI's snapshots:

- **AWS Region**: Create snapshots in the parent Region of the Local Zone of your volumes.
- **AWS Local Zone**: Create snapshots in the same Local Zone as your volumes.

> **Note**
>
> This option appears only in Local Zones that support EBS local snapshots, and only if your instance was created in a Local Zone. If the volume is in a Region, this option does not appear, and the snapshot is automatically created in the same Region as the volume. For more information, see Local snapshots in Local Zones in the *Amazon EBS User Guide*.

> **Important**
>
> All snapshots of the instance's volumes must be in the same location. Verify the location of existing snapshots. If any existing snapshots are in a different location than your selected destination, the AMI creation will fail.

f. **Tags** – You can tag the AMI and the snapshots with the same tags, or you can tag them with different tags.

   - To tag the AMI and the snapshots with the *same* tags, choose **Tag image and snapshots together**. The same tags are applied to the AMI and every snapshot that is created.
   - To tag the AMI and the snapshots with *different* tags, choose **Tag image and snapshots separately**. Different tags are applied to the AMI and the snapshots that are created. However, all the snapshots get the same tags; you can't tag each snapshot with a different tag.

   To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

g. When you're ready to create your AMI, choose **Create image**.

5. To view the status of your AMI while it is being created:

   a. In the navigation pane, choose **AMIs**.
   b. Set the filter to **Owned by me**, and find your AMI in the list.

      Initially, the status is `pending` but should change to `available` after a few minutes.

6. (Optional) To view the snapshot that was created for the new AMI:

   a. Note the ID of your AMI that you located in the previous step.
   b. In the navigation pane, choose **Snapshots**.
   c. Set the filter to **Owned by me**, and then find the snapshot with the new AMI ID in the **Description** column.

      When you launch an instance from this AMI, Amazon EC2 uses this snapshot to create its root device volume.

AWS CLI

To create an AMI

Use the [create-image](https://docs.aws.amazon.com/cli/latest/reference/ec2/create-image.html) command.

```
aws ec2 create-image \
```

```
    --instance-id i-1234567890abcdef0 \
    --name "my-web-server" \
    --description "My web server image" \
    --no-reboot
```

PowerShell

To create an AMI

Use the New-EC2Image cmdlet.

```
New-EC2Image `
    -InstanceId i-1234567890abcdef0 `
    -Name "my-web-server" `
    -Description "My web server image" `
    -NoReboot $true
```

Create an AMI from a snapshot

If you have a snapshot of the root device volume of an instance, you can create an AMI from this snapshot.

> **Note**
>
> In most cases, AMIs for Windows, Red Hat, SUSE, and SQL Server require correct licensing information to be present on the AMI. For more information, see Understand AMI billing information. When creating an AMI from a snapshot, the `RegisterImage` operation derives the correct billing information from the snapshot's metadata, but this requires the appropriate metadata to be present. To verify if the correct billing information was applied, check the **Platform details** field on the new AMI. If the field is empty or doesn't match the expected operating system code (for example, Windows, Red Hat, SUSE, or SQL), the AMI creation was unsuccessful, and you should discard the AMI and follow the instructions in Create an AMI from an instance.

Console

To create an AMI from a snapshot

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot from which to create the AMI, and then choose **Actions**, **Create image from snapshot**.
4. On the **Create image from snapshot** page, specify the following information:

   a. For **Image name**, enter a descriptive name for the image.

   b. For **Description**, enter a brief description for the image.

   c. For **Architecture**, choose the image architecture. Choose **i386** for 32-bit, **x86_64** for 64-bit, **arm64** for 64-bit ARM, or **x86_64** for 64-bit macOS.

   d. For **Root device name**, enter the device name to use for the root device volume. For more information, see Device names for volumes on Amazon EC2 instances.

   e. For **Virtualization type**, choose the virtualization type to be used by instances launched from this AMI. For more information, see Virtualization types.

   f. (For paravirtual virtualization only) For **Kernel ID**, select the operating system kernel for the image. If you're using a snapshot of the root device volume of an instance, select the same kernel ID as the original instance. If you're unsure, use the default kernel.

   g. (For paravirtual virtualization only) For **RAM disk ID**, select the RAM disk for the image. If you select a specific kernel, you may need to select a specific RAM disk with the drivers to support it.

   h. For **Boot mode**, choose the boot mode for the image, or choose **Use default** so that when an instance is launched with this AMI, it boots with the boot mode supported by the instance type. For more information, see Set the boot mode of an Amazon EC2 AMI.

   i. (Optional) Under **Block device mappings**, customize the root volume and add additional data volumes.

      For each volume, you can specify the size, type, performance characteristics, the behavior of delete on termination, and encryption status. For the root volume, the size can't be smaller than the size of the snapshot. For volume type, General Purpose SSD gp3 is the default selection.

   j. (Optional) Under **Tags**, you can add one or more tags to the new AMI. To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

   k. When you're ready to create your AMI, choose **Create image**.

5. (Windows, Red Hat, SUSE, and SQL Server only) To verify if the correct billing information was applied, check the **Platform details** field on the new AMI. If the field is empty or doesn't match the expected operating system code (for example, **Windows** or **Red Hat**), the AMI creation was unsuccessful, and you should discard the AMI and follow the instructions in Create an AMI from an instance.

AWS CLI

To create an AMI from a snapshot using the AWS CLI

Use the register-image command.

```
aws ec2 register-image \
    --name my-image \
    --root-device-name /dev/xvda \
    --block-device-mappings DeviceName=/dev/
xvda,Ebs={SnapshotId=snap-0db2cf683925d191f}
```

PowerShell

To create an AMI from a snapshot using PowerShell

Use the Register-EC2Image cmdlet.

```
$block = @{SnapshotId=snap-0db2cf683925d191f}
Register-EC2Image `
    -Name my-image `
    -RootDeviceName /dev/xvda `
    -BlockDeviceMapping @{DeviceName="/dev/xvda";Ebs=$block}
```

Create an instance store-backed AMI

The AMI that you specify when you launch your instance determines the type of root device volume.

To create an instance store-backed Linux AMI, start from an instance that you've launched from an existing instance store-backed Linux AMI. After you've customized the instance to suit your needs, bundle the volume and register a new AMI, which you can use to launch new instances with these customizations.

You can't create an instance-store backed Windows AMI because Windows AMIs don't support instance store for the root device.

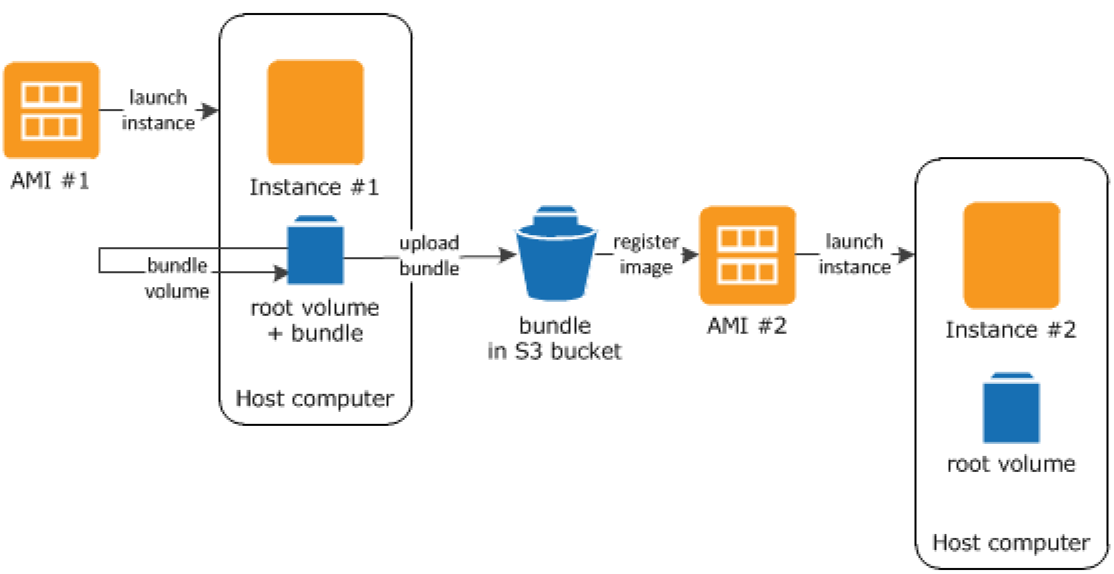
> **Important**
>
> Only the following instance types support an instance store volume as the root device and require an instance store-backed AMI: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

The AMI creation process is different for Amazon EBS-backed AMIs. For more information, see [Create an Amazon EBS-backed AMI](#).

Contents

Overview of AMI creation

The following diagram summarizes the process of creating an AMI from an instance store-backed instance.



First, launch an instance from an AMI that's similar to the AMI that you'd like to create. You can connect to your instance and customize it. When the instance is set up the way you want it, you can bundle it. It takes several minutes for the bundling process to complete. After the process completes, you have a bundle, which consists of an image manifest (`image.manifest.xml`) and files (`image.part.`*xx*) that contain a template for the root volume. Next you upload the bundle to your Amazon S3 bucket and then register your AMI.

> **Note**
>
> To upload objects to an S3 bucket for your instance store-backed Linux AMI, ACLs must be enabled for the bucket. Otherwise, Amazon EC2 will not be able to set ACLs on the objects to upload. If your destination bucket uses the bucket owner enforced setting for S3 Object Ownership, this won't work because ACLs are disabled. For more information, see Controlling ownership of objects and disabling ACLs for your bucket.

When you launch an instance using the new AMI, we create the root volume for the instance using the bundle that you uploaded to Amazon S3. The storage space used by the bundle in Amazon S3 incurs charges to your account until you delete it. For more information, see Deregister an Amazon EC2 AMI.

If you add instance store volumes to your instance in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. For more information, see Block device mappings for volumes on Amazon EC2 instances.

Prerequisites

Before you can create an AMI, you must complete the following tasks:

- Install the AMI tools. For more information, see Set up the Amazon EC2 AMI tools.
- Install the AWS CLI. For more information, see Getting started with the AWS CLI.
- Ensure that you have an S3 bucket for the bundle, and that your bucket has ACLs enabled. For more information on configuring ACLs, see Configuring ACLs.
  - To create an S3 bucket using the AWS Management Console, open the Amazon S3 console at https://console.aws.amazon.com/s3/ and choose **Create Bucket**.

  - To create an S3 bucket with the AWS CLI, you can use the mb command. If your installed version of the AMI tools is 1.5.18 or later, you can also use the `ec2-upload-bundle` command to create the S3 bucket. For more information, see ec2-upload-bundle.
- Ensure that the files in your bundle aren't encrypted in the S3 bucket. If you require encryption for your AMI, you can use an EBS-backed AMI instead. For more information, see Use encryption with EBS-backed AMIs.
- Ensure that you have your AWS account ID. For more information, see View AWS account identifiers in the *AWS Account Management Reference Guide*.
- Ensure that you have credentials to use the AWS CLI. For more information, see Authentication and access credentials for the AWS CLI in the *AWS Command Line Interface User Guide*.
- Ensure that you have an X.509 certificate and corresponding private key.
  - If you need to create an X.509 certificate, see Manage signing certificates. The X.509 certificate and private key are used to encrypt and decrypt your AMI.
  - [China (Beijing)] Use the `$EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-cn-north-1.pem` certificate.
  - [AWS GovCloud (US-West)] Use the `$EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-gov.pem` certificate.
- Connect to your instance and customize it. For example, you can install software and applications, copy data, delete temporary files, and modify the Linux configuration.

Create an AMI from an Amazon Linux instance

The following procedures describe how to create an AMI from an instance store-backed instance running Amazon Linux 1. They might not work for instances running other Linux distributions.

To prepare to use the AMI tools (HVM instances only)

1. The AMI tools require GRUB Legacy to boot properly. Use the following command to install GRUB:

```
[ec2-user ~]$ sudo yum install -y grub
```

2. Install the partition management packages with the following command:

```
[ec2-user ~]$ sudo yum install -y gdisk kpartx parted
```

To create an AMI from an instance store-backed Amazon Linux instance

This procedure assumes that you have satisfied the prerequisites in Prerequisites.

In the following commands, replace each *user input placeholder* with your own information.

1. Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.

   a. Create a temporary directory on your instance for your credentials as follows:

   ```
   [ec2-user ~]$ mkdir /tmp/cert
   ```

   This enables you to exclude your credentials from the created image.

   b. Copy your X.509 certificate and corresponding private key from your computer to the `/tmp/cert` directory on your instance using a secure copy tool such as scp. The `-i my-private-key.pem` option in the following **scp** command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:

   ```
   you@your_computer:~ $ scp -i my-private-key.pem /
   path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem /
   path/to/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-
   user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/
   pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem  100%  717     0.7KB/s   00:00
   cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem  100%  685     0.7KB/s   00:00
   ```

   Alternatively, because these are plain text files, you can open the certificate and key in a text editor and copy their contents into new files in `/tmp/cert`.

2. Prepare the bundle to upload to Amazon S3 by running the ec2-bundle-vol command from inside your instance. Be sure to specify the `-e` option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include `*.sw`, `*.swo`, `*.swp`, `*.pem`, `*.priv`, `*id_rsa*`, `*id_dsa*` `*.gpg`, `*.jks`, `*/.ssh/authorized_keys`, and `*/.bash_history`. To include all of these files, use the `--no-filter` option. To include some of these files, use the `--include` option.

Important

By default, the AMI bundling process creates a compressed, encrypted collection of files in the `/tmp` directory that represents your root volume. If you do not have enough free disk space in `/tmp` to store the bundle, you need to specify a different location for the bundle to be stored with the `-d /path/to/bundle/storage` option. Some instances have ephemeral storage mounted at `/mnt` or `/media/ephemeral0` that you can use, or you can also create, attach, and mount a new Amazon EBS) volume to store the bundle. For more information, see Create an Amazon EBS volume in the *Amazon EBS User Guide*.

a. You must run the **ec2-bundle-vol** command as root. For most commands, you can use **sudo** to gain elevated permissions, but in this case, you should run **sudo -E su** to keep your environment variables.

```
[ec2-user ~]$ sudo -E su
```

Note that bash prompt now identifies you as the root user, and that the dollar sign has been replaced by a hash tag, signalling that you are in a root shell:

```
[root ec2-user]#
```

b. To create the AMI bundle, run the ec2-bundle-vol command as follows:

```
[root ec2-user]# ec2-bundle-vol -k /tmp/cert/pk-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c /tmp/cert/cert-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 123456789012 -r x86_64 -e /tmp/cert --
partition gpt
```

Note

For the China (Beijing) and AWS GovCloud (US-West) Regions, use the `--ec2cert` parameter and specify the certificates as per the prerequisites.

It can take a few minutes to create the image. When this command completes, your `/tmp` (or non-default) directory contains the bundle (`image.manifest.xml`, plus multiple `image.part.xx` files).

c. Exit from the root shell.

```
[root ec2-user]# exit
```

3. (Optional) To add more instance store volumes, edit the block device mappings in the `image.manifest.xml` file for your AMI. For more information, see Block device mappings for volumes on Amazon EC2 instances.

   a. Create a backup of your `image.manifest.xml` file.

```
[ec2-user ~]$ sudo cp /tmp/image.manifest.xml /tmp/image.manifest.xml.bak
```

   b. Reformat the `image.manifest.xml` file so that it is easier to read and edit.

```
[ec2-user ~]$ sudo xmllint --format /tmp/image.manifest.xml.bak > /tmp/
image.manifest.xml
```

   c. Edit the block device mappings in `image.manifest.xml` with a text editor. The example below shows a new entry for the `ephemeral1` instance store volume.

> **Note**
>
> For a list of excluded files, see ec2-bundle-vol.

```
    <block_device_mapping>
      <mapping>
        <virtual>ami</virtual>
        <device>sda</device>
      </mapping>
      <mapping>
        <virtual>ephemeral0</virtual>
        <device>sdb</device>
      </mapping>
      <mapping>
        <virtual>ephemeral1</virtual>
```

```
      <device>sdc</device>
    </mapping>
    <mapping>
      <virtual>root</virtual>
      <device>/dev/sda1</device>
    </mapping>
  </block_device_mapping>
```

d. Save the `image.manifest.xml` file and exit your text editor.

4. To upload your bundle to Amazon S3, run the ec2-upload-bundle command as follows.

```
[ec2-user ~]$ ec2-upload-bundle -b amzn-s3-demo-bucket/bundle_folder/bundle_name -
m /tmp/image.manifest.xml -a your_access_key_id -s your_secret_access_key
```

> **Important**
>
> To register your AMI in a Region other than US East (N. Virginia), you must specify both the target Region with the `--region` option and a bucket path that already exists in the target Region or a unique bucket path that can be created in the target Region.

5. (Optional) After the bundle is uploaded to Amazon S3, you can remove the bundle from the `/tmp` directory on the instance using the following **rm** command:

```
[ec2-user ~]$ sudo rm /tmp/image.manifest.xml /tmp/image.part.* /tmp/image
```

> **Important**
>
> If you specified a path with the `-d` *`/path/to/bundle/storage`* option in Step 2, use that path instead of `/tmp`.

6. To register your AMI, run the register-image command as follows.

```
[ec2-user ~]$ aws ec2 register-image --image-location amzn-s3-demo-
bucket/bundle_folder/bundle_name/image.manifest.xml --name AMI_name --
virtualization-type hvm
```

> **Important**
>
> If you previously specified a Region for the ec2-upload-bundle command, specify that Region again for this command.

Set up the Amazon EC2 AMI tools

You can use the AMI tools to create and manage instance store-backed Linux AMIs. To use the tools, you must install them on your Linux instance. The AMI tools are available as both an RPM and as a .zip file for Linux distributions that don't support RPM.

To set up the AMI tools using the RPM

1. Install Ruby using the package manager for your Linux distribution, such as yum. For example:

   ```
   [ec2-user ~]$ sudo yum install -y ruby
   ```

2. Download the RPM file using a tool such as wget or curl. For example:

   ```
   [ec2-user ~]$ wget https://s3.amazonaws.com/ec2-downloads/ec2-ami-tools.noarch.rpm
   ```

3. Verify the RPM file's signature using the following command:

   ```
   [ec2-user ~]$ rpm -K ec2-ami-tools.noarch.rpm
   ```

   The command above should indicate that the file's SHA1 and MD5 hashes are `OK`. If the command indicates that the hashes are `NOT OK`, use the following command to view the file's Header SHA1 and MD5 hashes:

   ```
   [ec2-user ~]$ rpm -Kv ec2-ami-tools.noarch.rpm
   ```

   Then, compare your file's Header SHA1 and MD5 hashes with the following verified AMI tools hashes to confirm the file's authenticity:

   - Header SHA1: a1f662d6f25f69871104e6a62187fa4df508f880
   - MD5: 9faff05258064e2f7909b66142de6782

If your file's Header SHA1 and MD5 hashes match the verified AMI tools hashes, continue to the next step.

4. Install the RPM using the following command:

```
[ec2-user ~]$ sudo yum install ec2-ami-tools.noarch.rpm
```

5. Verify your AMI tools installation using the ec2-ami-tools-version command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

> **Note**
>
> If you receive a load error such as "cannot load such file -- ec2/amitools/version (LoadError)", complete the next step to add the location of your AMI tools installation to your `RUBYLIB` path.

6. (Optional) If you received an error in the previous step, add the location of your AMI tools installation to your `RUBYLIB` path.

   a. Run the following command to determine the paths to add.

   ```
   [ec2-user ~]$ rpm -qil ec2-ami-tools | grep ec2/amitools/version
   /usr/lib/ruby/site_ruby/ec2/amitools/version.rb
   /usr/lib64/ruby/site_ruby/ec2/amitools/version.rb
   ```

   In the above example, the missing file from the previous load error is located at `/usr/lib/ruby/site_ruby` and `/usr/lib64/ruby/site_ruby`.

   b. Add the locations from the previous step to your `RUBYLIB` path.

   ```
   [ec2-user ~]$ export RUBYLIB=$RUBYLIB:/usr/lib/ruby/site_ruby:/usr/lib64/ruby/site_ruby
   ```

   c. Verify your AMI tools installation using the ec2-ami-tools-version command.

   ```
   [ec2-user ~]$ ec2-ami-tools-version
   ```

To set up the AMI tools using the .zip file

1. Install Ruby and unzip using the package manager for your Linux distribution, such as **apt-get**. For example:

```
[ec2-user ~]$ sudo apt-get update -y && sudo apt-get install -y ruby unzip
```

2. Download the .zip file using a tool such as wget or curl. For example:

```
[ec2-user ~]$ wget https://s3.amazonaws.com/ec2-downloads/ec2-ami-tools.zip
```

3. Unzip the files into a suitable installation directory, such as `/usr/local/ec2`.

```
[ec2-user ~]$ sudo mkdir -p /usr/local/ec2
$ sudo unzip ec2-ami-tools.zip -d /usr/local/ec2
```

   Notice that the .zip file contains a folder ec2-ami-tools-*x.x.x*, where *x.x.x* is the version number of the tools (for example, `ec2-ami-tools-1.5.7`).

4. Set the `EC2_AMITOOL_HOME` environment variable to the installation directory for the tools. For example:

```
[ec2-user ~]$ export EC2_AMITOOL_HOME=/usr/local/ec2/ec2-ami-tools-x.x.x
```

5. Add the tools to your `PATH` environment variable. For example:

```
[ec2-user ~]$ export PATH=$EC2_AMITOOL_HOME/bin:$PATH
```

6. You can verify your AMI tools installation using the ec2-ami-tools-version command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

Manage signing certificates

Certain commands in the AMI tools require a signing certificate (also known as X.509 certificate). You must create the certificate and then upload it to AWS. For example, you can use a third-party tool such as OpenSSL to create the certificate.

To create a signing certificate

1. Install and configure OpenSSL.
2. Create a private key using the `openssl genrsa` command and save the output to a `.pem` file. We recommend that you create a 2048- or 4096-bit RSA key.

```
openssl genrsa 2048 > private-key.pem
```

3. Generate a certificate using the `openssl req` command.

```
openssl req -new -x509 -nodes -sha256 -days 365 -key private-key.pem -outform PEM -
out certificate.pem
```

To upload the certificate to AWS, use the upload-signing-certificate command.

```
aws iam upload-signing-certificate --user-name user-name --certificate-body
 file://path/to/certificate.pem
```

To list the certificates for a user, use the list-signing-certificates command:

```
aws iam list-signing-certificates --user-name user-name
```

To disable or re-enable a signing certificate for a user, use the update-signing-certificate command. The following command disables the certificate:

```
aws iam update-signing-certificate --certificate-id OFHPLP4ZULTHYPMSYEX7O4BEXAMPLE --
status Inactive --user-name user-name
```

To delete a certificate, use the delete-signing-certificate command:

```
aws iam delete-signing-certificate --user-name user-name --certificate-
id OFHPLP4ZULTHYPMSYEX7O4BEXAMPLE
```

Amazon EC2 AMI tools reference

You can use the AMI tools commands to create and manage instance store-backed Linux AMIs. To set up the tools, see Set up the Amazon EC2 AMI tools.

For information about your access keys, see Managing access keys for IAM users in the *IAM User Guide*.

Commands

- ec2-ami-tools-version
- ec2-bundle-image
- ec2-bundle-vol
- ec2-delete-bundle
- ec2-download-bundle
- ec2-migrate-manifest
- ec2-unbundle
- ec2-upload-bundle
- Common options for AMI tools

ec2-ami-tools-version

Description

Describes the version of the AMI tools.

Syntax

`ec2-ami-tools-version`

Output

The version information.

Example

This example command displays the version information for the AMI tools that you're using.

```
[ec2-user ~]$ ec2-ami-tools-version
1.5.2 20071010
```

ec2-bundle-image

Description

Creates an instance store-backed Linux AMI from an operating system image created in a loopback file.

Syntax

ec2-bundle-image -c *path* -k *path* -u *account* -i *path* [-d *path*] [--ec2cert *path*] [-r *architecture*] [--productcodes *code1*,*code2*,...] [-B *mapping*] [-p *prefix*]

Options

`-c, --cert` *path*

The user's PEM encoded RSA public key certificate file.

Required: Yes

`-k, --privatekey` *path*

The path to a PEM-encoded RSA key file. You'll need to specify this key to unbundle this bundle, so keep it in a safe place. Note that the key doesn't have to be registered to your AWS account.

Required: Yes

`-u, --user` *account*

The user's AWS account ID, without dashes.

Required: Yes

`-i, --image` *path*

The path to the image to bundle.

Required: Yes

`-d, --destination` *path*

The directory in which to create the bundle.

Default: `/tmp`

Required: No

`--ec2cert` *path*

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The `us-gov-west-1` and `cn-north-1` Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at `/opt/aws/amitools/ec2/etc/ec2/amitools/`. If you installed the AMI tools from the RPM or ZIP file in Set up the Amazon EC2 AMI tools, the certificates are located at `$EC2_AMITOOL_HOME/etc/ec2/amitools/`.

Required: Only for the `us-gov-west-1` and `cn-north-1` Regions.

`-r, --arch` *architecture*

Image architecture. If you don't provide the architecture on the command line, you'll be prompted for it when bundling starts.

Valid values: `i386` | `x86_64`

Required: No

`--productcodes` *code1,code2,...*

Product codes to attach to the image at registration time, separated by commas.

Required: No

`-B, --block-device-mapping` *mapping*

Defines how block devices are exposed to an instance of this AMI if its instance type supports the specified device.

Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is the corresponding device name. Virtual names include the following:

- `ami`—The root file system device, as seen by the instance
- `root`—The root file system device, as seen by the kernel
- `swap`—The swap device, as seen by the instance
- `ephemeralN`—The Nth instance store volume

Required: No

`-p, --prefix` *prefix*

The filename prefix for bundled AMI files.

Default: The name of the image file. For example, if the image path is `/var/spool/my-image/version-2/debian.img`, then the default prefix is `debian.img`.

Required: No

`--kernel` *kernel_id*

Deprecated. Use register-image to set the kernel.

Required: No

`--ramdisk` *ramdisk_id*

Deprecated. Use register-image to set the RAM disk if required.

Required: No

Output

Status messages describing the stages and status of the bundling process.

Example

This example creates a bundled AMI from an operating system image that was created in a loopback file.

```
[ec2-user ~]$ ec2-bundle-image -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -i image.img -d bundled/ -r x86_64
Please specify a value for arch [i386]:
Bundling image file...

Creating bundle manifest...
ec2-bundle-image complete.
```

ec2-bundle-vol

Description

Creates an instance store-backed Linux AMI by compressing, encrypting, and signing a copy of the root device volume for the instance.

Amazon EC2 attempts to inherit product codes, kernel settings, RAM disk settings, and block device mappings from the instance.

By default, the bundle process excludes files that might contain sensitive information. These files include `*.sw`, `*.swo`, `*.swp`, `*.pem`, `*.priv`, `*id_rsa*`, `*id_dsa*` `*.gpg`, `*.jks`, `*/.ssh/authorized_keys`, and `*/.bash_history`. To include all of these files, use the `--no-filter` option. To include some of these files, use the `--include` option.

For more information, see Create an instance store-backed AMI.

Syntax

ec2-bundle-vol -c *path* -k *path* -u *account* [-d *path*] [--ec2cert *path*] [-r *architecture*] [--productcodes *code1*,*code2*,...] [-B *mapping*] [--all] [-e *directory1*,*directory2*,...] [-i *file1*,*file2*,...] [--no-filter] [-p *prefix*] [-s *size*] [--[no-]inherit] [-v *volume*] [-P *type*] [-S *script*] [--fstab *path*] [--generate-fstab] [--grub-config *path*]

Options

`-c, --cert` *path*

The user's PEM encoded RSA public key certificate file.

Required: Yes

`-k, --privatekey` *path*

The path to the user's PEM-encoded RSA key file.

Required: Yes

`-u, --user` *account*

The user's AWS account ID, without dashes.

Required: Yes

`-d, --destination` *destination*

The directory in which to create the bundle.

Default: `/tmp`

Required: No

`--ec2cert` *path*

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The `us-gov-west-1` and `cn-north-1` Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at `/opt/aws/amitools/ec2/etc/ec2/amitools/`. If you installed the AMI tools from the RPM or ZIP file in Set up the Amazon EC2 AMI tools, the certificates are located at `$EC2_AMITOOL_HOME/etc/ec2/amitools/`.

Required: Only for the `us-gov-west-1` and `cn-north-1` Regions.

`-r, --arch` *architecture*

The image architecture. If you don't provide this on the command line, you'll be prompted to provide it when the bundling starts.

Valid values: `i386` | `x86_64`

Required: No

`--productcodes` *code1,code2,...*

Product codes to attach to the image at registration time, separated by commas.

Required: No

`-B, --block-device-mapping` *mapping*

Defines how block devices are exposed to an instance of this AMI if its instance type supports the specified device.

Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is the corresponding device name. Virtual names include the following:

- `ami`—The root file system device, as seen by the instance
- `root`—The root file system device, as seen by the kernel
- `swap`—The swap device, as seen by the instance
- `ephemeralN`—The Nth instance store volume

Required: No

`-a, --all`

Bundle all directories, including those on remotely mounted file systems.

Required: No

`-e, --exclude` *directory1,directory2,...*

A list of absolute directory paths and files to exclude from the bundle operation. This parameter overrides the `--all` option. When exclude is specified, the directories and subdirectories listed with the parameter will not be bundled with the volume.

Required: No

`-i, --include` *file1,file2,...*

A list of files to include in the bundle operation. The specified files would otherwise be excluded from the AMI because they might contain sensitive information.

Required: No

`--no-filter`

If specified, we won't exclude files from the AMI because they might contain sensitive information.

Required: No

`-p, --prefix` *prefix*

The file name prefix for bundled AMI files.

Default: `image`

Required: No

`-s, --size` *size*

The size, in MB (1024 * 1024 bytes), of the image file to create. The maximum size is 10240 MB.

Default: 10240

Required: No

`--[no-]inherit`

Indicates whether the image should inherit the instance's metadata (the default is to inherit). Bundling fails if you enable `--inherit` but the instance metadata is not accessible.

Required: No

`-v, --volume` *volume*

The absolute path to the mounted volume from which to create the bundle.

Default: The root directory (/)

Required: No

`-P, --partition` *type*

Indicates whether the disk image should use a partition table. If you don't specify a partition table type, the default is the type used on the parent block device of the volume, if applicable, otherwise the default is `gpt`.

Valid values: `mbr` | `gpt` | `none`

Required: No

`-S, --script` *script*

A customization script to be run right before bundling. The script must expect a single argument, the mount point of the volume.

Required: No

`--fstab` *path*

The path to the fstab to bundle into the image. If this is not specified, Amazon EC2 bundles /etc/fstab.

Required: No

`--generate-fstab`

Bundles the volume using an Amazon EC2-provided fstab.

Required: No

`--grub-config`

The path to an alternate grub configuration file to bundle into the image. By default, `ec2-bundle-vol` expects either `/boot/grub/menu.lst` or `/boot/grub/grub.conf` to exist on the cloned image. This option allows you to specify a path to an alternative grub configuration file, which will then be copied over the defaults (if present).

Required: No

`--kernel` *kernel_id*

Deprecated. Use register-image to set the kernel.

Required: No

`--ramdisk`*ramdisk_id*

Deprecated. Use register-image to set the RAM disk if required.

Required: No

Output

Status messages describing the stages and status of the bundling.

Example

This example creates a bundled AMI by compressing, encrypting and signing a snapshot of the local machine's root file system.

```
[ec2-user ~]$ ec2-bundle-vol -d /mnt -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c
 cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -r x86_64
  Copying / into the image file /mnt/image...

```

ec2-delete-bundle

Description

Deletes the specified bundle from Amazon S3 storage. After you delete a bundle, you can't launch instances from the corresponding AMI.

Syntax

ec2-delete-bundle -b *bucket* -a *access_key_id* -s *secret_access_key* [-t *token*] [--url *url*] [--region *region*] [--sigv *version*] [-m *path*] [-p *prefix*] [--clear] [--retry] [-y]

Options

`-b, --bucket` *bucket*

The name of the Amazon S3 bucket containing the bundled AMI, followed by an optional '/'-delimited path prefix

Required: Yes

`-a, --access-key` *access_key_id*

The AWS access key ID.

Required: Yes

`-s, --secret-key` *secret_access_key*

The AWS secret access key.

Required: Yes

`-t, --delegation-token` *token*

The delegation token to pass along to the AWS request. For more information, see [Temporary security credentials](#) in the *IAM User Guide*.

Required: Only when you are using temporary security credentials.

Default: The value of the `AWS_DELEGATION_TOKEN` environment variable (if set).

`--region`*region*

The Region to use in the request signature.

Default: `us-east-1`

Required: Required if using signature version 4

`--sigv`*version*

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

`-m, --manifest`*path*

The path to the manifest file.

Required: You must specify `--prefix` or `--manifest`.

`-p, --prefix` *prefix*

The bundled AMI filename prefix. Provide the entire prefix. For example, if the prefix is image.img, use `-p image.img` and not `-p image`.

Required: You must specify `--prefix` or `--manifest`.

`--clear`

Deletes the Amazon S3 bucket if it's empty after deleting the specified bundle.

Required: No

`--retry`

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

`-y, --yes`

Automatically assumes the answer to all prompts is yes.

Required: No

Output

Amazon EC2 displays status messages indicating the stages and status of the delete process.

Example

This example deletes a bundle from Amazon S3.

```
[ec2-user ~]$ ec2-delete-bundle -b amzn-s3-demo-bucket -a your_access_key_id -
s your_secret_access_key
Deleting files:
amzn-s3-demo-bucket/image.manifest.xml
amzn-s3-demo-bucket/image.part.00
```

```
amzn-s3-demo-bucket/image.part.01
amzn-s3-demo-bucket/image.part.02
amzn-s3-demo-bucket/image.part.03
amzn-s3-demo-bucket/image.part.04
amzn-s3-demo-bucket/image.part.05
amzn-s3-demo-bucket/image.part.06
Continue? [y/n]
y
Deleted amzn-s3-demo-bucket/image.manifest.xml
Deleted amzn-s3-demo-bucket/image.part.00
Deleted amzn-s3-demo-bucket/image.part.01
Deleted amzn-s3-demo-bucket/image.part.02
Deleted amzn-s3-demo-bucket/image.part.03
Deleted amzn-s3-demo-bucket/image.part.04
Deleted amzn-s3-demo-bucket/image.part.05
Deleted amzn-s3-demo-bucket/image.part.06
ec2-delete-bundle complete.
```

ec2-download-bundle

Description

Downloads the specified instance store-backed Linux AMIs from Amazon S3 storage.

Syntax

`ec2-download-bundle -b` ***`bucket`*** **`-a`** ***`access_key_id`*** **`-s`** ***`secret_access_key`*** **`-k`** ***`path`*** **`[--url`** ***`url`*** **`] [--region`** ***`region`*** **`] [--sigv`** ***`version`*** **`] [-m`** ***`file`*** **`] [-p`** ***`prefix`*** **`] [-d`** ***`directory`*** **`] [--retry]`**

Options

`-b, --bucket` *bucket*

The name of the Amazon S3 bucket where the bundle is located, followed by an optional '/'-delimited path prefix.

Required: Yes

`-a, --access-key` *access_key_id*

The AWS access key ID.

Required: Yes

`-s, --secret-key` *secret_access_key*

The AWS secret access key.

Required: Yes

`-k, --privatekey` *path*

The private key used to decrypt the manifest.

Required: Yes

`--url` *url*

The Amazon S3 service URL.

Default: `https://s3.amazonaws.com/`

Required: No

`--region` *region*

The Region to use in the request signature.

Default: `us-east-1`

Required: Required if using signature version 4

`--sigv` *version*

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

`-m, --manifest` *file*

The name of the manifest file (without the path). We recommend that you specify either the manifest (`-m`) or a prefix (`-p`).

Required: No

`-p, --prefix` *prefix*

The filename prefix for the bundled AMI files.

Default: `image`

Required: No

`-d, --directory` *directory*

The directory where the downloaded bundle is saved. The directory must exist.

Default: The current working directory.

Required: No

`--retry`

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

Output

Status messages indicating the various stages of the download process are displayed.

Example

This example creates the `bundled` directory (using the Linux **mkdir** command) and downloads the bundle from the `amzn-s3-demo-bucket` Amazon S3 bucket.

```
[ec2-user ~]$ mkdir bundled
[ec2-user ~]$ ec2-download-bundle -b amzn-s3-demo-bucket/bundles/bundle_name
 -m image.manifest.xml -a your_access_key_id -s your_secret_access_key -k pk-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -d mybundle
Downloading manifest image.manifest.xml from amzn-s3-demo-bucket to mybundle/
image.manifest.xml ...
Downloading part image.part.00 from amzn-s3-demo-bucket/bundles/bundle_name to
 mybundle/image.part.00 ...
Downloaded image.part.00 from amzn-s3-demo-bucket
Downloading part image.part.01 from amzn-s3-demo-bucket/bundles/bundle_name to
 mybundle/image.part.01 ...
Downloaded image.part.01 from amzn-s3-demo-bucket
Downloading part image.part.02 from amzn-s3-demo-bucket/bundles/bundle_name to
 mybundle/image.part.02 ...
Downloaded image.part.02 from amzn-s3-demo-bucket
Downloading part image.part.03 from amzn-s3-demo-bucket/bundles/bundle_name to
 mybundle/image.part.03 ...
```

```
Downloaded image.part.03 from amzn-s3-demo-bucket
Downloading part image.part.04 from amzn-s3-demo-bucket/bundles/bundle_name to
 mybundle/image.part.04 ...
Downloaded image.part.04 from amzn-s3-demo-bucket
Downloading part image.part.05 from amzn-s3-demo-bucket/bundles/bundle_name to
 mybundle/image.part.05 ...
Downloaded image.part.05 from amzn-s3-demo-bucket
Downloading part image.part.06 from amzn-s3-demo-bucket/bundles/bundle_name to
 mybundle/image.part.06 ...
Downloaded image.part.06 from amzn-s3-demo-bucket
```

ec2-migrate-manifest

Description

Modifies an instance store-backed Linux AMI (for example, its certificate, kernel, and RAM disk) so that it supports a different Region.

Syntax

ec2-migrate-manifest -c *path* -k *path* -m *path* {(-a *access_key_id* -s *secret_access_key* --region *region*) | (--no-mapping)} [--ec2cert *ec2_cert_path*] [--kernel *kernel-id*] [--ramdisk *ramdisk_id*]

Options

`-c, --cert` *path*

The user's PEM encoded RSA public key certificate file.

Required: Yes

`-k, --privatekey` *path*

The path to the user's PEM-encoded RSA key file.

Required: Yes

`--manifest` *path*

The path to the manifest file.

Required: Yes

`-a, --access-key` *access_key_id*

The AWS access key ID.

Required: Required if using automatic mapping.

`-s, --secret-key` *secret_access_key*

The AWS secret access key.

Required: Required if using automatic mapping.

`--region` *region*

The Region to look up in the mapping file.

Required: Required if using automatic mapping.

`--no-mapping`

Disables automatic mapping of kernels and RAM disks.

During migration, Amazon EC2 replaces the kernel and RAM disk in the manifest file with a kernel and RAM disk designed for the destination region. Unless the `--no-mapping` parameter is given, `ec2-migrate-bundle` might use the `DescribeRegions` and `DescribeImages` operations to perform automated mappings.

Required: Required if you're not providing the `-a`, `-s`, and `--region` options used for automatic mapping.

`--ec2cert` *path*

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The `us-gov-west-1` and `cn-north-1` Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at `/opt/aws/amitools/ec2/etc/ec2/amitools/`. If you installed the AMI tools from the ZIP file in Set up the Amazon EC2 AMI tools, the certificates are located at `$EC2_AMITOOL_HOME/etc/ec2/amitools/`.

Required: Only for the `us-gov-west-1` and `cn-north-1` Regions.

`--kernel` *kernel_id*

The ID of the kernel to select.

> **Important**
>
> We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see User provided kernels in the *Amazon Linux 2 User Guide*.

Required: No

`--ramdisk` *ramdisk_id*

The ID of the RAM disk to select.

> **Important**
>
> We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see User provided kernels in the *Amazon Linux 2 User Guide*.

Required: No

Output

Status messages describing the stages and status of the bundling process.

Example

This example copies the AMI specified in the `my-ami.manifest.xml` manifest from the US to the EU.

```
[ec2-user ~]$ ec2-migrate-manifest --manifest my-ami.manifest.xml
 --cert cert-HKZYKTAIG2ECMXYIBH3HXV4ZBZQ55CLO.pem --privatekey pk-
HKZYKTAIG2ECMXYIBH3HXV4ZBZQ55CLO.pem --region eu-west-1

Backing up manifest...
Successfully migrated my-ami.manifest.xml It is now suitable for use in eu-west-1.
```

ec2-unbundle

Description

Re-creates the bundle from an instance store-backed Linux AMI.

Syntax

ec2-unbundle -k *path* -m *path* [-s *source_directory*] [-d *destination_directory*]

Options

`-k, --privatekey` *path*

The path to your PEM-encoded RSA key file.

Required: Yes

`-m, --manifest` *path*

The path to the manifest file.

Required: Yes

`-s, --source` *source_directory*

The directory containing the bundle.

Default: The current directory.

Required: No

`-d, --destination` *destination_directory*

The directory in which to unbundle the AMI. The destination directory must exist.

Default: The current directory.

Required: No

Example

This Linux and UNIX example unbundles the AMI specified in the `image.manifest.xml` file.

```
[ec2-user ~]$ mkdir unbundled
$ ec2-unbundle -m mybundle/image.manifest.xml -k pk-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -s mybundle -d unbundled
$ ls -l unbundled
total 1025008
-rw-r--r-- 1 root root 1048578048 Aug 25 23:46 image.img
```

Output

Status messages indicating the various stages of the unbundling process are displayed.

ec2-upload-bundle

Description

Uploads the bundle for an instance store-backed Linux AMI to Amazon S3 and sets the appropriate access control lists (ACLs) on the uploaded objects. For more information, see [Create an instance store-backed AMI](#).

> **Note**
>
> To upload objects to an S3 bucket for your instance store-backed Linux AMI, ACLs must be enabled for the bucket. Otherwise, Amazon EC2 will not be able to set ACLs on the objects to upload. If your destination bucket uses the bucket owner enforced setting for S3 Object Ownership, this won't work because ACLs are disabled. For more information, see [Controlling ownership of objects and disabling ACLs for your bucket](#).

Syntax

ec2-upload-bundle -b *bucket* -a *access_key_id* -s *secret_access_key* [-t *token*] -m *path* [--url *url*] [--region *region*] [--sigv *version*] [--acl *acl*] [-d *directory*] [--part *part*] [--retry] [--skipmanifest]

Options

`-b, --bucket` *bucket*

The name of the Amazon S3 bucket in which to store the bundle, followed by an optional '/'-delimited path prefix. If the bucket doesn't exist, it's created if the bucket name is available. Additionally, if the bucket doesn't exist and the AMI tools version is 1.5.18 or later, this command sets the ACLs for the bucket.

Required: Yes

`-a, --access-key` *access_key_id*

Your AWS access key ID.

Required: Yes

`-s, --secret-key` *secret_access_key*

Your AWS secret access key.

Required: Yes

`-t, --delegation-token` *token*

The delegation token to pass along to the AWS request. For more information, see [Temporary security credentials](#) in the *IAM User Guide*.

Required: Only when you are using temporary security credentials.

Default: The value of the `AWS_DELEGATION_TOKEN` environment variable (if set).

`-m, --manifest` *path*

The path to the manifest file. The manifest file is created during the bundling process and can be found in the directory containing the bundle.

Required: Yes

`--url` *url*

Deprecated. Use the `--region` option instead unless your bucket is constrained to the `EU` location (and not `eu-west-1`). The `--location` flag is the only way to target that specific location restraint.

The Amazon S3 endpoint service URL.

Default: `https://s3.amazonaws.com/`

Required: No

`--region` *region*

The Region to use in the request signature for the destination S3 bucket.

- If the bucket doesn't exist and you don't specify a Region, the tool creates the bucket without a location constraint (in `us-east-1`).
- If the bucket doesn't exist and you specify a Region, the tool creates the bucket in the specified Region.
- If the bucket exists and you don't specify a Region, the tool uses the bucket's location.
- If the bucket exists and you specify `us-east-1` as the Region, the tool uses the bucket's actual location without any error message, any existing matching files are over-written.

- If the bucket exists and you specify a Region (other than `us-east-1`) that doesn't match the bucket's actual location, the tool exits with an error.

If your bucket is constrained to the EU location (and not `eu-west-1`), use the `--location` flag instead. The `--location` flag is the only way to target that specific location restraint.

Default: `us-east-1`

Required: Required if using signature version 4

`--sigv` *version*

The signature version to use when signing the request.

Valid values: `2` **|** `4`

Default: `4`

Required: No

`--acl` *acl*

The access control list policy of the bundled image.

Valid values: `public-read` **|** `aws-exec-read`

Default: `aws-exec-read`

Required: No

`-d, --directory` *directory*

The directory containing the bundled AMI parts.

Default: The directory containing the manifest file (see the `-m` option).

Required: No

`--part` *part*

Starts uploading the specified part and all subsequent parts. For example, `--part 04`.

Required: No

`--retry`

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

`--skipmanifest`

Does not upload the manifest.

Required: No

`--location` *location*

Deprecated. Use the `--region` option instead, unless your bucket is constrained to the EU location (and not `eu-west-1`). The `--location` flag is the only way to target that specific location restraint.

The location constraint of the destination Amazon S3 bucket. If the bucket exists and you specify a location that doesn't match the bucket's actual location, the tool exits with an error. If the bucket exists and you don't specify a location, the tool uses the bucket's location. If the bucket doesn't exist and you specify a location, the tool creates the bucket in the specified location. If the bucket doesn't exist and you don't specify a location, the tool creates the bucket without a location constraint (in `us-east-1`).

Default: If `--region` is specified, the location is set to that specified Region. If `--region` is not specified, the location defaults to `us-east-1`.

Required: No

Output

Amazon EC2 displays status messages that indicate the stages and status of the upload process.

Example

This example uploads the bundle specified by the `image.manifest.xml` manifest.

```
[ec2-user ~]$ ec2-upload-bundle -b amzn-s3-demo-bucket/bundles/bundle_name -m
 image.manifest.xml -a your_access_key_id -s your_secret_access_key
Creating bucket...
Uploading bundled image parts to the S3 bucket amzn-s3-demo-bucket ...
Uploaded image.part.00
Uploaded image.part.01
Uploaded image.part.02
Uploaded image.part.03
Uploaded image.part.04
Uploaded image.part.05
Uploaded image.part.06
```

```
Uploaded image.part.07
Uploaded image.part.08
Uploaded image.part.09
Uploaded image.part.10
Uploaded image.part.11
Uploaded image.part.12
Uploaded image.part.13
Uploaded image.part.14
Uploading manifest ...
Uploaded manifest.
Bundle upload completed.
```

Common options for AMI tools

Most of the AMI tools accept the following optional parameters.

`--help, -h`

Displays the help message.

`--version`

Displays the version and copyright notice.

`--manual`

Displays the manual entry.

`--batch`

Runs in batch mode, suppressing interactive prompts.

`--debug`

Displays information that can be useful when troubleshooting problems.

Convert your instance store-backed AMI to an EBS-backed AMI

You can convert an instance store-backed Linux AMI that you own to an Amazon EBS-backed Linux AMI.

> **Important**
>
> You can't convert an AMI that you don't own.

To convert an instance store-backed AMI to an Amazon EBS-backed AMI

1. Launch an Amazon Linux instance from an Amazon EBS-backed AMI. For more information, see Launch an EC2 instance using the launch instance wizard in the console. Amazon Linux instances have the AWS CLI and AMI tools pre-installed.
2. Upload the X.509 private key that you used to bundle your instance store-backed AMI to your instance. We use this key to ensure that only you and Amazon EC2 can access your AMI.

   a. Create a temporary directory on your instance for your X.509 private key as follows:

   ```
   [ec2-user ~]$ mkdir /tmp/cert
   ```

   b. Copy your X.509 private key from your computer to the `/tmp/cert` directory on your instance, using a secure copy tool such as scp. The *`my-private-key`* parameter in the following command is the private key you use to connect to your instance with SSH. For example:

   ```
   you@your_computer:~ $ scp -i my-private-key.pem /
   path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-
   user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/
   pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem  100%  717     0.7KB/s   00:00
   ```

3. Configure your environment variables to use the AWS CLI. For more information, see Environment variables.

   a. (Recommended) Set environment variables for your AWS access key, secret key, and session token.

   ```
   [ec2-user ~]$ export AWS_ACCESS_KEY_ID=your_access_key_id
   [ec2-user ~]$ export AWS_SECRET_ACCESS_KEY=your_secret_access_key
   [ec2-user ~]$ export AWS_SESSION_TOKEN=your_session_token
   ```

   b. Set environment variables for your AWS access key, and secret key.

   ```
   [ec2-user ~]$ export AWS_ACCESS_KEY_ID=your_access_key_id
   [ec2-user ~]$ export AWS_SECRET_ACCESS_KEY=your_secret_access_key
   ```

4. Prepare an Amazon Elastic Block Store (Amazon EBS) volume for your new AMI.

   a. Create an empty EBS volume in the same Availability Zone as your instance using the create-volume command. Note the volume ID in the command output.

> **Important**
>
> This EBS volume must be the same size or larger than the original instance store root volume.

```
aws ec2 create-volume \
    --size 10 \
    --region us-west-2 \
    --availability-zone us-west-2b
```

b. Attach the volume to your Amazon EBS-backed instance using the attach-volume command.

```
aws ec2 attach-volume \
    --volume-id vol-01234567890abcdef \
    --instance-id i-1234567890abcdef0 \
    --region us-west-2
```

5. Create a folder for your bundle.

```
[ec2-user ~]$ mkdir /tmp/bundle
```

6. Download the bundle for your instance store-based AMI to `/tmp/bundle` using the ec2-download-bundle command.

```
[ec2-user ~]$ ec2-download-bundle -b amzn-s3-demo-bucket/bundle_folder/bundle_name
 -m image.manifest.xml -a $AWS_ACCESS_KEY_ID -s $AWS_SECRET_ACCESS_KEY --
privatekey /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -d /tmp/bundle
```

7. Reconstitute the image file from the bundle using the ec2-unbundle command.

   a. Change directories to the bundle folder.

```
[ec2-user ~]$ cd /tmp/bundle/
```

   b. Run the ec2-unbundle command.

```
[ec2-user bundle]$ ec2-unbundle -m image.manifest.xml --privatekey /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem
```

8. Copy the files from the unbundled image to the new EBS volume.

```
[ec2-user bundle]$ sudo dd if=/tmp/bundle/image of=/dev/sdb bs=1M
```

9. Probe the volume for any new partitions that were unbundled.

```
[ec2-user bundle]$ sudo partprobe /dev/sdb1
```

10. List the block devices to find the device name to mount.

```
[ec2-user bundle]$ lsblk
NAME          MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
/dev/sda     202:0    0   8G  0 disk
##/dev/sda1 202:1    0   8G  0 part /
/dev/sdb     202:80   0  10G  0 disk
##/dev/sdb1 202:81   0  10G  0 part
```

In this example, the partition to mount is `/dev/sdb1`, but your device name will likely be different. If your volume is not partitioned, then the device to mount will be similar to `/dev/sdb` (without a device partition trailing digit).

11. Create a mount point for the new EBS volume and mount the volume.

```
[ec2-user bundle]$ sudo mkdir /mnt/ebs
[ec2-user bundle]$ sudo mount /dev/sdb1 /mnt/ebs
```

12. Open the `/etc/fstab` file on the EBS volume with your favorite text editor (such as **vim** or **nano**) and remove any entries for instance store (ephemeral) volumes. Because the EBS volume is mounted on `/mnt/ebs`, the `fstab` file is located at `/mnt/ebs/etc/fstab`.

```
[ec2-user bundle]$ sudo nano /mnt/ebs/etc/fstab
#
LABEL=/     /           ext4    defaults,noatime  1   1
tmpfs       /dev/shm    tmpfs   defaults        0   0
devpts      /dev/pts    devpts  gid=5,mode=620  0   0
sysfs       /sys        sysfs   defaults        0   0
proc        /proc       proc    defaults        0   0
```

```
/dev/sdb         /media/ephemeral0       auto     defaults,comment=cloudconfig    0
     2
```

In this example, the last line should be removed.

13. Unmount the volume and detach it from the instance.

```
[ec2-user bundle]$ sudo umount /mnt/ebs
[ec2-user bundle]$ aws ec2 detach-volume --volume-id vol-01234567890abcdef --
region us-west-2
```

14. Create an AMI from the new EBS volume as follows.

    a. Create a snapshot of the new EBS volume.

    ```
    [ec2-user bundle]$ aws ec2 create-snapshot --region us-west-2 --description
     "your_snapshot_description" --volume-id vol-01234567890abcdef
    ```

    b. Check to see that your snapshot is complete.

    ```
    [ec2-user bundle]$ aws ec2 describe-snapshots --region us-west-2 --snapshot-
    id snap-0abcdef1234567890
    ```

    c. Identify the processor architecture, virtualization type, and the kernel image (`aki`) used on the original AMI with the **describe-images** command. You need the AMI ID of the original instance store-backed AMI for this step.

    ```
    [ec2-user bundle]$ aws ec2 describe-images --region us-west-2 --image-
    id ami-0abcdef1234567890 --output text
    IMAGES x86_64 amazon/amzn-ami-pv-2013.09.2.x86_64-s3 ami-8ef297be amazon
     available public machine aki-fc8f11cc instance-store paravirtual xen
    ```

    In this example, the architecture is `x86_64` and the kernel image ID is `aki-fc8f11cc`. Use these values in the following step. If the output of the above command also lists an `ari` ID, take note of that as well.

    d. Register your new AMI with the snapshot ID of your new EBS volume and the values from the previous step. If the previous command output listed an `ari` ID, include that in the following command with `--ramdisk-id` *`ari_id`*.

    ```
    [ec2-user bundle]$ aws ec2 register-image --region us-west-2 --
    name your_new_ami_name --block-device-mappings DeviceName=device-
    ```

```
name,Ebs={SnapshotId=snap-0abcdef1234567890} --virtualization-type paravirtual
 --architecture x86_64 --kernel-id aki-fc8f11cc --root-device-name device-name
```

15. (Optional) After you have tested that you can launch an instance from your new AMI, you can delete the EBS volume that you created for this procedure.

```
aws ec2 delete-volume --volume-id vol-01234567890abcdef
```

Create an Amazon EC2 AMI using Windows Sysprep

The Microsoft System Preparation (Windows Sysprep) tool creates a generalized version of the operating system, with instance-specific system configuration removed before it captures a new image.

We recommend that you use EC2 Image Builder to automate the creation, management, and deployment of customized, secure, and up-to-date "golden" server images that are pre-installed and preconfigured with software and settings.

You can also use Windows Sysprep to create a standardized AMI using the Windows launch agents. For more information, see the section called “Use Windows Sysprep with a launch agent”.

> **Important**
>
> Do not use Windows Sysprep to create an instance backup. Windows Sysprep removes system-specific information; removing this information might have unintended consequences for an instance backup.

To troubleshoot Windows Sysprep, see Troubleshoot Sysprep issues with Amazon EC2 Windows instances.

Contents

Windows Sysprep phases

Windows Sysprep runs through the following phases:

- **Generalize**: The Sysprep tool removes image-specific information and configurations. For example, Windows Sysprep removes the security identifier (SID), the computer name, the event logs, and specific drivers, to name a few. After this phase is completed, the operating system (OS) is ready to create an AMI.

> **Note**
>
> When you run Windows Sysprep with the Windows launch agents, the system prevents drivers from being removed because `PersistAllDeviceInstalls` is set to true by default.

- **Specialize**: Plug and Play scans the computer and installs drivers for any detected devices. The Sysprep tool generates OS requirements, like the computer name and SID. Optionally, you can run commands in this phase.
- **Out-of-Box Experience (OOBE)**: The system runs an abbreviated version of Windows Setup and asks you to enter information such as system language, time zone, and registered organization. When you run Windows Sysprep with Windows launch agents, the answer file automates this phase.

Before you begin

- Before performing Windows Sysprep, we recommend that you remove all local user accounts and all account profiles other than a single administrator account under which Windows Sysprep will be run. If you perform Windows Sysprep with additional accounts and profiles, unexpected behavior could result, including loss of profile data or failure to complete Windows Sysprep.
- Learn more about Sysprep Overview.
- Learn which Sysprep Support for Server Roles.

Use Windows Sysprep with a launch agent

You can use Windows Sysprep to create a standardized Amazon Machine Image (AMI) when you start with an AMI that has one of the Windows launch agents installed.

Use Windows Sysprep with EC2Launch v2

This section contains details about the tasks performed by the EC2Launch v2 service as the image is prepared. It also includes the steps to create a standardized AMI using Windows Sysprep with the EC2Launch v2 service.

Windows Sysprep with EC2Launch v2 topics

- Windows Sysprep actions
- Post Sysprep
- Run Windows Sysprep with EC2Launch v2

Windows Sysprep actions

Windows Sysprep and EC2Launch v2 perform the following actions when preparing an image.

1. When you choose **Shutdown with Sysprep** in the **EC2Launch settings** dialog box, the system runs the `ec2launch sysprep` command.
2. EC2Launch v2 edits the content of the `unattend.xml` file by reading the registry value at `HKEY_USERS\.DEFAULT\Control Panel\International\LocaleName`. This file is located in the following directory: `C:\ProgramData\Amazon\EC2Launch\sysprep`.
3. The system run the `BeforeSysprep.cmd`. This command creates a registry key as follows:

   reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v fDenyTSConnections /t REG_DWORD /d 1 /f

   The registry key disables RDP connections until they are re-enabled. Disabling RDP connections is a necessary security measure because, during the first boot session after Windows Sysprep has run, there is a short period of time where RDP allows connections and the Administrator password is blank.
4. The EC2Launch v2 service calls Windows Sysprep by running the following command:

   sysprep.exe /oobe /generalize /shutdown /unattend: "C:\ProgramData\Amazon\EC2Launch\sysprep\unattend.xml"

Generalize phase

- EC2Launch v2 removes image-specific information and configurations, such as the computer name and the SID. If the instance is a member of a domain, it is removed from the domain. The `unattend.xml` answer file includes the following settings that affect this phase:
  - **PersistAllDeviceInstalls**: This setting prevents Windows Setup from removing and reconfiguring devices, which speeds up the image preparation process because Amazon AMIs require certain drivers to run and re-detection of those drivers would take time.
  - **DoNotCleanUpNonPresentDevices**: This setting retains Plug and Play information for devices that are not currently present.
- Windows Sysprep shuts down the OS as it prepares to create the AMI. The system either launches a new instance or starts the original instance.

Specialize phase

The system generates OS-specific requirements, such as a computer name and an SID. The system also performs the following actions based on configurations that you specify in the `unattend.xml` answer file.

- **CopyProfile**: Windows Sysprep can be configured to delete all user profiles, including the built-in Administrator profile. This setting retains the built-in Administrator account so that any customizations you make to that account are carried over to the new image. The default value is `True`.

  CopyProfile replaces the default profile with the existing local administrator profile. All accounts that you log in to after running Windows Sysprep receive a copy of that profile and its contents at first login.

  If you don't have specific user-profile customizations that you want to carry over to the new image, then change this setting to `False`. Windows Sysprep will remove all user profiles (this saves time and disk space).
- **TimeZone**: The time zone is set to Coordinate Universal Time (UTC) by default.
- **Synchronous command with order 1**: The system runs the following command, which enables the administrator account and specifies the password requirement:

  ```
  net user Administrator /ACTIVE:YES /LOGONPASSWORDCHG:NO /EXPIRES:NEVER /
  PASSWORDREQ:YES
  ```

- **Synchronous command with order 2**: The system scrambles the administrator password. This security measure is designed to prevent the instance from being accessible after Windows Sysprep completes if you did not configure the `setAdminAccount` task.

  The system runs the following command from your local launch agent directory (`C:\Program Files\Amazon\EC2Launch\`).

  ```
  EC2Launch.exe internal randomize-password --username Administrator
  ```

- To enable remote desktop connections, the system sets the Terminal Server `fDenyTSConnections` registry key to false.

OOBE phase

1. The system specifies the following configurations using the EC2Launch v2 answer file:
   - `<InputLocale>en-US</InputLocale>`
   - `<SystemLocale>en-US</SystemLocale>`
   - `<UILanguage>en-US</UILanguage>`
   - `<UserLocale>en-US</UserLocale>`
   - `<HideEULAPage>true</HideEULAPage>`
   - `<HideWirelessSetupInOOBE>true</HideWirelessSetupInOOBE>`
   - `<ProtectYourPC>3</ProtectYourPC>`
   - `<BluetoothTaskbarIconEnabled>false</BluetoothTaskbarIconEnabled>`
   - `<TimeZone>UTC</TimeZone>`
   - `<RegisteredOrganization>Amazon.com</RegisteredOrganization>`
   - `<RegisteredOwner>EC2</RegisteredOwner>`

   > **Note**
   >
   > During the generalize and specialize phases, EC2Launch v2 monitors the status of the OS. If EC2Launch v2 detects that the OS is in a Sysprep phase, then it publishes the following message to the system log:
   > Windows is being configured. SysprepState=IMAGE_STATE_UNDEPLOYABLE

2. The system runs EC2Launch v2.

Post Sysprep

After Windows Sysprep completes, EC2Launch v2 sends the following message to the console output:

```
Windows sysprep configuration complete.
```

EC2Launch v2 then performs the following actions:

1. Reads the content of the `agent-config.yml` file and runs configured tasks.
2. Executes all tasks in the `preReady` stage.
3. After it is finished, sends a `Windows is ready` message to the instance system logs.
4. Executes all tasks in the `PostReady` stage.

For more information about EC2Launch v2 , see Use the EC2Launch v2 agent to perform tasks during EC2 Windows instance launch.

Run Windows Sysprep with EC2Launch v2

Use the following procedure to create a standardized AMI using Windows Sysprep with EC2Launch v2.

1. In the Amazon EC2 console, locate an AMI that you want to duplicate.
2. Launch and connect to your Windows instance.
3. Customize settings
   a. From the Windows **Start** menu, search for and choose **Amazon EC2Launch settings**. For more information about the options and settings in the Amazon **EC2Launch settings** dialog box, see Configure EC2Launch v2 settings for Windows instances.
   b. If you've made changes, choose **Save** before you shut down.
4. Choose **Shutdown with Sysprep** or **Shutdown without Sysprep**.

When you are asked to confirm that you want to run Windows Sysprep and shut down the instance, click **Yes**. EC2Launch v2 runs Windows Sysprep. Next, you are logged off the instance, and the instance shuts down. If you check the **Instances** page in the Amazon EC2 console, the instance state changes from `Running` to `Stopping` to `Stopped`. At this point, it's safe to create an AMI from this instance.

You can manually invoke the Windows Sysprep tool from the command line using the following command:

```
"%programfiles%\amazon\ec2launch\ec2launch.exe" sysprep --shutdown=true
```

Use Windows Sysprep with EC2Launch

EC2Launch offers a default answer file and batch files for Windows Sysprep that automate and secure the image-preparation process on your AMI. Modifying these files is optional. These files are located in the following directory by default: `C:\ProgramData\Amazon\EC2-Windows\Launch\Sysprep`.

> **Important**
>
> Do not use Windows Sysprep to create an instance backup. Windows Sysprep removes system-specific information. If you remove this information there might be unintended consequences for an instance backup.

Windows Sysprep with EC2Launch topics

- EC2Launch answer and batch files for Windows Sysprep
- Run Windows Sysprep with EC2Launch
- Update metadata/KMS routes for Server 2016 and later when launching a custom AMI

EC2Launch answer and batch files for Windows Sysprep

The EC2Launch answer file and batch files for Windows Sysprep include the following:

`Unattend.xml`

This is the default answer file. If you run `SysprepInstance.ps1` or choose **ShutdownWithSysprep** in the user interface, the system reads the setting from this file.

`BeforeSysprep.cmd`

Customize this batch file to run commands before EC2Launch runs Windows Sysprep.

`SysprepSpecialize.cmd`

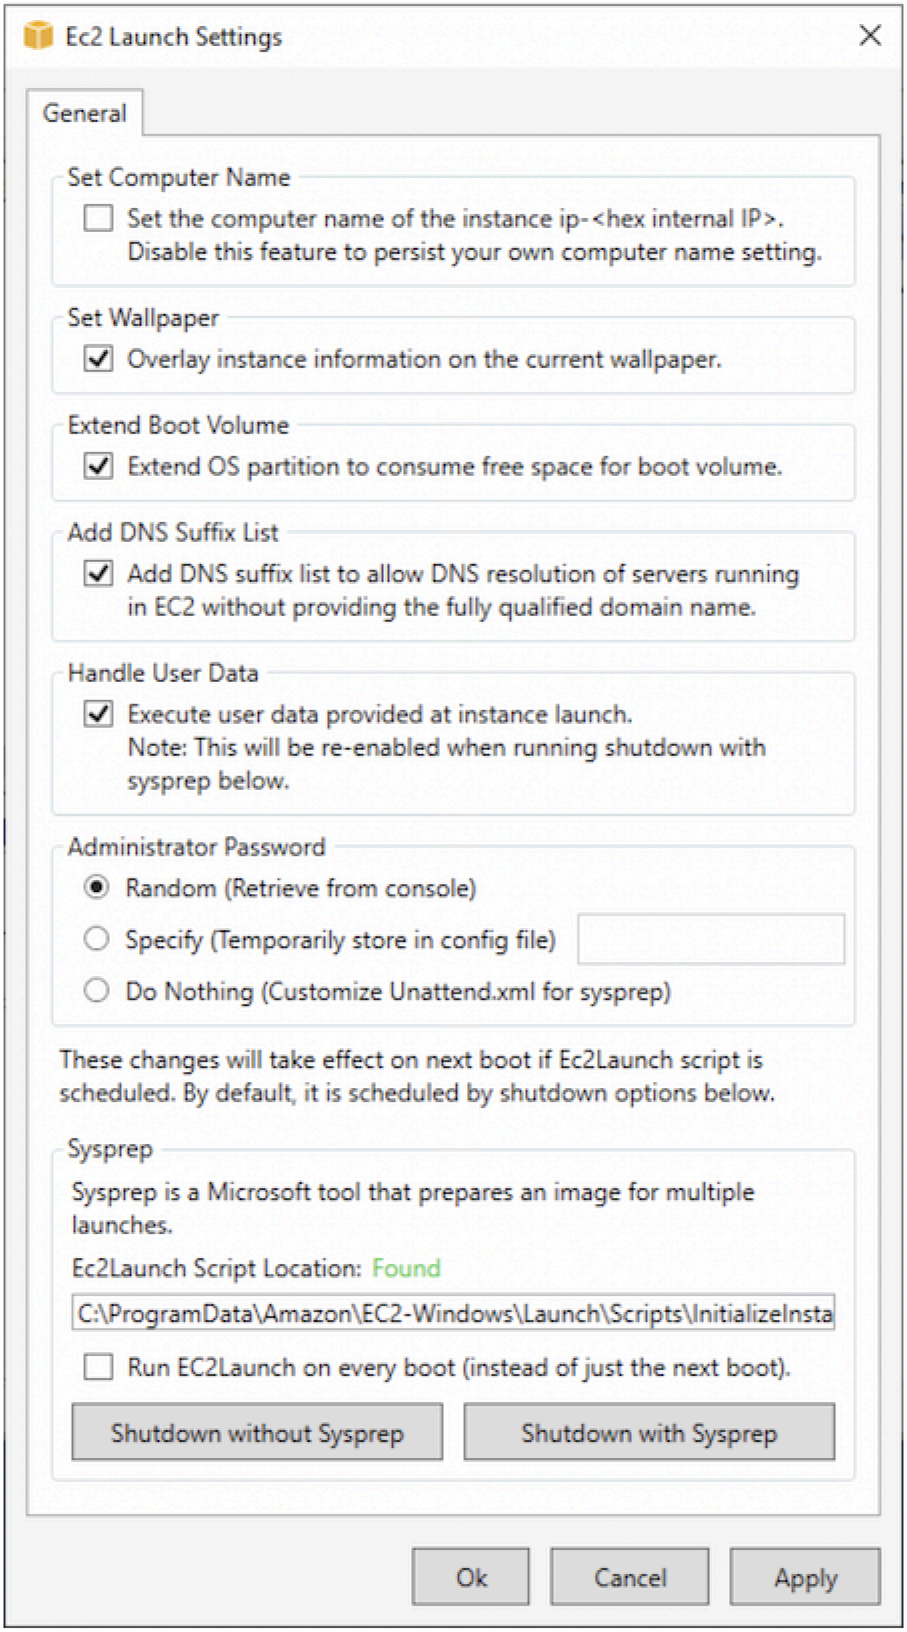
Customize this batch file to run commands during the Windows Sysprep specialize phase.

Run Windows Sysprep with EC2Launch

On the full installation of Windows Server 2016 and later (with a desktop experience), you can run Windows Sysprep with EC2Launch manually or by using the **EC2 Launch Settings** application.

To run Windows Sysprep using the EC2Launch Settings application

1. In the Amazon EC2 console, locate or create a Windows Server 2016 or later AMI.
2. Launch a Windows instance from the AMI.
3. Connect to your Windows instance and customize it.
4. Search for and run the **EC2LaunchSettings** application. It is located in the following directory by default: `C:\ProgramData\Amazon\EC2-Windows\Launch\Settings`.



5. Select or clear options as needed. These settings are stored in the `LaunchConfig.json` file.
6. For **Administrator Password**, do one of the following:

- Choose **Random**. EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.
- Choose **Specify** and type a password that meets the system requirements. The password is stored in `LaunchConfig.json` as clear text and is deleted after Windows Sysprep sets the administrator password. If you shut down now, the password is set immediately. EC2Launch encrypts the password using the user's key.
- Choose **DoNothing** and specify a password in the `unattend.xml` file. If you don't specify a password in `unattend.xml`, the administrator account is disabled.

7. Choose **Shutdown with Sysprep**.

To manually run Windows Sysprep using EC2Launch

1. In the Amazon EC2 console locate or create a Windows Server 2016 or later Datacenter edition AMI that you want to duplicate.
2. Launch and connect to your Windows instance.
3. Customize the instance.
4. Specify settings in the `LaunchConfig.json` file. This file is located in the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory by default.

   For `adminPasswordType`, specify one of the following values:

   `Random`

   EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.

   `Specify`

   EC2Launch uses the password you specify in `adminPassword`. If the password does not meet the system requirements, EC2Lauch generates a random password instead. The password is stored in `LaunchConfig.json` as clear text and is deleted after Windows Sysprep sets the administrator password. EC2Launch encrypts the password using the user's key.

`DoNothing`

EC2Launch uses the password you specify in the `unattend.xml` file. If you don't specify a password in `unattend.xml`, the administrator account is disabled.

5. (Optional) Specify settings in `unattend.xml` and other configuration files. If plan to attend to the installation, then you don't need to make changes in these files. The files are located in the following directory by default: `C:\ProgramData\Amazon\EC2-Windows\Launch\Sysprep`.
6. In Windows PowerShell, run `./InitializeInstance.ps1 -Schedule`. The script is located in the following directory, by default: `C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts`. This script schedules the instance to initialize during the next boot. You must run this script before you run the `SysprepInstance.ps1` script in the next step.
7. In Windows PowerShell, run `./SysprepInstance.ps1`. The script is located in the following directory by default: `C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts`.

You are logged off the instance and the instance shuts down. If you check the **Instances** page in the Amazon EC2 console, the instance state changes from `Running` to `Stopping`, and then to `Stopped`. At this point, it is safe to create an AMI from this instance.

Update metadata/KMS routes for Server 2016 and later when launching a custom AMI

To update metadata/KMS routes for Server 2016 and later when launching a custom AMI, do one of the following:

- Run the EC2LaunchSettings GUI (C:\ProgramData\Amazon\EC2-Windows\Launch\Settings\Ec2LaunchSettings.exe) and select the option to shut down with Windows Sysprep.
- Run EC2LaunchSettings and shut down without Windows Sysprep before creating the AMI. This sets the EC2 Launch Initialize tasks to run at the next boot, which will set routes based on the subnet for the instance.
- Manually reschedule EC2 Launch initialize tasks before creating an AMI from PowerShell.

> **Important**
>
> Take note of the default password reset behavior before rescheduling tasks.

- To update the routes on a running instance that is experiencing Windows activation or communication with instance metadata failures, see "Unable to activate Windows".

Use Windows Sysprep with EC2Config

This section contains details about the tasks performed by the EC2Config service as the image is prepared. It also includes the steps to create a standardized AMI using Windows Sysprep with the EC2Config service.

Windows Sysprep with EC2Config topics

Windows Sysprep actions

Windows Sysprep and the EC2Config service perform the following actions when preparing an image.

1. When you choose **Shutdown with Sysprep** in the **EC2 Service Properties** dialog box, the system runs the **ec2config.exe -sysprep** command.
2. The EC2Config service reads the content of the `BundleConfig.xml` file. This file is located in the following directory, by default: `C:\Program Files\Amazon\Ec2ConfigService\Settings`.

   The `BundleConfig.xml` file includes the following settings. You can change these settings:

   - **AutoSysprep**: Indicates whether to use Windows Sysprep automatically. You do not need to change this value if you are running Windows Sysprep from the EC2 Service Properties dialog box. The default value is `No`.
   - **SetRDPCertificate**: Sets a self-signed certificate for the Remote Desktop server. This enables you to securely use the Remote Desktop Protocol (RDP) to connect to the instance. Change the value to `Yes` if new instances should use a certificate. This setting is not used with Windows Server 2012 instances because these operating systems can generate their own certificates. The default value is `No`.
   - **SetPasswordAfterSysprep**: Sets a random password on a newly launched instance, encrypts it with the user launch key, and outputs the encrypted password to the console. Change the value to `No` if new instances should not be set to a random encrypted password. The default value is `Yes`.

- **PreSysprepRunCmd**: The location of the command to run. The command is located in the following directory, by default: `C:\Program Files\Amazon\Ec2ConfigService\Scripts\BeforeSysprep.cmd`

3. The system runs `BeforeSysprep.cmd`. This command creates a registry key as follows:

```
reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v
 fDenyTSConnections /t REG_DWORD /d 1 /f
```

   The registry key disables RDP connections until they are re-enabled. Disabling RDP connections is a necessary security measure because, during the first boot session after Windows Sysprep has run, there is a short period of time where RDP allows connections and the Administrator password is blank.

4. The EC2Config service calls Windows Sysprep by running the following command:

```
sysprep.exe /unattend: "C:\Program Files\Amazon\Ec2ConfigService\sysprep2008.xml" /
oobe /generalize /shutdown
```

Generalize phase

- The tool removes image-specific information and configurations such as the computer name and the SID. If the instance is a member of a domain, it is removed from the domain. The `sysprep2008.xml` answer file includes the following settings that affect this phase:
  - **PersistAllDeviceInstalls**: This setting prevents Windows Setup from removing and reconfiguring devices, which speeds up the image preparation process because Amazon AMIs require certain drivers to run and re-detection of those drivers would take time.
  - **DoNotCleanUpNonPresentDevices**: This setting retains Plug and Play information for devices that are not currently present.
- Windows Sysprep shuts down the OS as it prepares to create the AMI. The system either launches a new instance or starts the original instance.

Specialize phase

The system generates OS specific requirements such as a computer name and a SID. The system also performs the following actions based on configurations that you specify in the sysprep2008.xml answer file.

- **CopyProfile**: Windows Sysprep can be configured to delete all user profiles, including the built-in Administrator profile. This setting retains the built-in Administrator account so that any customizations you made to that account are carried over to the new image. The default value is True.

  CopyProfile replaces the default profile with the existing local administrator profile. All accounts logged into after running Windows Sysprep will receive a copy of that profile and its contents at first login.

  If you don’t have specific user-profile customizations that you want to carry over to the new image then change this setting to False. Windows Sysprep will remove all user profiles; this saves time and disk space.
- **TimeZone**: The time zone is set to Coordinate Universal Time (UTC) by default.
- **Synchronous command with order 1**: The system runs the following command that enables the administrator account and specifies the password requirement.

  net user Administrator /ACTIVE:YES /LOGONPASSWORDCHG:NO /EXPIRES:NEVER /PASSWORDREQ:YES
- **Synchronous command with order 2**: The system scrambles the administrator password. This security measure is designed to prevent the instance from being accessible after Windows Sysprep completes if you did not enable the ec2setpassword setting.

  C:\Program Files\Amazon\Ec2ConfigService\ScramblePassword.exe" -u Administrator
- **Synchronous command with order 3**: The system runs the following command:

  C:\Program Files\Amazon\Ec2ConfigService\Scripts\SysprepSpecializePhase.cmd

  This command adds the following registry key, which re-enables RDP:

  reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v fDenyTSConnections /t REG_DWORD /d 0 /f

OOBE phase

1. Using the EC2Config service answer file, the system specifies the following configurations:
   - <InputLocale>en-US</InputLocale>
   - <SystemLocale>en-US</SystemLocale>

- <UILanguage>en-US</UILanguage>
- <UserLocale>en-US</UserLocale>
- <HideEULAPage>true</HideEULAPage>
- <HideWirelessSetupInOOBE>true</HideWirelessSetupInOOBE>
- <NetworkLocation>Other</NetworkLocation>
- <ProtectYourPC>3</ProtectYourPC>
- <BluetoothTaskbarIconEnabled>false</BluetoothTaskbarIconEnabled>
- <TimeZone>UTC</TimeZone>
- <RegisteredOrganization>Amazon.com</RegisteredOrganization>
- <RegisteredOwner>Amazon</RegisteredOwner>

> **Note**
>
> During the generalize and specialize phases the EC2Config service monitors the status of the OS. If EC2Config detects that the OS is in a Sysprep phase, then it publishes the following message to the system log:
> EC2ConfigMonitorState: 0 Windows is being configured.
> SysprepState=IMAGE_STATE_UNDEPLOYABLE

2. After the OOBE phase completes, the system runs `SetupComplete.cmd` from the following location: `C:\Windows\Setup\Scripts\SetupComplete.cmd`. In Amazon public AMIs before April 2015 this file was empty and ran nothing on the image. In public AMIs dated after April 2015, the file includes the following value: **call "C:\Program Files\Amazon\Ec2ConfigService \Scripts\PostSysprep.cmd"**.
3. The system runs `PostSysprep.cmd`, which performs the following operations:
   - Sets the local Administrator password to not expire. If the password expired, Administrators might not be able to log on.
   - Sets the MSSQLServer machine name (if installed) so that the name will be in sync with the AMI.

Post Sysprep

After Windows Sysprep completes, the EC2Config services sends the following message to the console output:

```
Windows sysprep configuration complete.
   Message: Sysprep Start
   Message: Sysprep End
```

EC2Config then performs the following actions:

1. Reads the content of the config.xml file and lists all enabled plug-ins.
2. Executes all “Before Windows is ready” plug-ins at the same time.
   - Ec2SetPassword
   - Ec2SetComputerName
   - Ec2InitializeDrives
   - Ec2EventLog
   - Ec2ConfigureRDP
   - Ec2OutputRDPCert
   - Ec2SetDriveLetter
   - Ec2WindowsActivate
   - Ec2DynamicBootVolumeSize
3. After it is finished, sends a “Windows is ready” message to the instance system logs.
4. Runs all “After Windows is ready” plug-ins at the same time.
   - Amazon CloudWatch Logs
   - UserData
   - AWS Systems Manager (Systems Manager)

For more information about Windows plug-ins, see Use the EC2Config service to perform tasks during EC2 legacy Windows operating system instance launch.

Run Windows Sysprep with the EC2Config service

Use the following procedure to create a standardized AMI using Windows Sysprep and the EC2Config service.

1. In the Amazon EC2 console, locate or create an AMI that you want to duplicate.
2. Launch and connect to your Windows instance.
3. Customize it.

4. Specify configuration settings in the EC2Config service answer file:

   ```
   C:\Program Files\Amazon\Ec2ConfigService\sysprep2008.xml
   ```

5. From the Windows **Start** menu, choose **All Programs**, and then choose **EC2ConfigService Settings**.
6. Choose the **Image** tab in the **Ec2 Service Properties** dialog box. For more information about the options and settings in the Ec2 Service Properties dialog box, see Ec2 Service Properties.
7. Select an option for the Administrator password, and then select **Shutdown with Sysprep** or **Shutdown without Sysprep**. EC2Config edits the settings files based on the password option that you selected.
   - **Random**: EC2Config generates a password, encrypts it with user's key, and displays the encrypted password to the console. We disable this setting after the first launch so that this password persists if the instance is rebooted or stopped and started.
   - **Specify**: The password is stored in the Windows Sysprep answer file in unencrypted form (clear text). When Windows Sysprep runs next, it sets the Administrator password. If you shut down now, the password is set immediately. When the service starts again, the Administrator password is removed. It's important to remember this password, as you can't retrieve it later.
   - **Keep Existing**: The existing password for the Administrator account doesn't change when Windows Sysprep is run or EC2Config is restarted. It's important to remember this password, as you can't retrieve it later.
8. Choose **OK**.

When you are asked to confirm that you want to run Windows Sysprep and shut down the instance, click **Yes**. You'll notice that EC2Config runs Windows Sysprep. Next, you are logged off the instance, and the instance is shut down. If you check the **Instances** page in the Amazon EC2 console, the instance state changes from `Running` to `Stopping`, and then finally to `Stopped`. At this point, it's safe to create an AMI from this instance.

You can manually invoke the Windows Sysprep tool from the command line using the following command:

```
"%programfiles%\amazon\ec2configservice\"ec2config.exe -sysprep""
```

> **Note**
>
> The double quotation marks in the command are not required if your CMD shell is already in the C:\Program Files\Amazon\EC2ConfigService\ directory.

However, you must be very careful that the XML file options specified in the `Ec2ConfigService\Settings` folder are correct; otherwise, you might not be able to connect to the instance. For more information about the settings files, see EC2Config settings files. For an example of configuring and then running Windows Sysprep from the command line, see `Ec2ConfigService\Scripts\InstallUpdates.ps1`.

Copy an Amazon EC2 AMI

When you need a consistent Amazon EC2 instance configuration across multiple Regions, you can use a single Amazon Machine Image (AMI) as your template to launch all the instances. However, AMIs are Region-specific resources—to launch an instance in a specific AWS Region, the AMI must be located in that Region. Therefore, to use the same AMI in multiple Regions, you must copy it from the source Region to each target Region.

The method you use to copy an AMI depends on whether you're copying across Regions *within the same partition* or *across different partitions*:

- **Cross-Region copying** – Copy AMIs across Regions *within the same partition*, for example, across the Regions within the commercial partition. This copy method is described in this topic.
- **Cross-partition copying** – Copy AMIs *from one partition to another partition*, for example, from the commercial partition to the AWS GovCloud (US) partition. For information about this copy method, see Store and restore an AMI.
- **Cross-account copying** – Create a copy of an AMI that another AWS account has shared with your AWS account. This copy method is described in this topic.

The time taken to complete the copy operation for cross-Region and cross-account AMI copying is on a best-effort basis. If you need control over the completion time, you can specify a completion window ranging from 15 minutes to 48 hours, ensuring your AMI is copied within your required timeframe. Additional charges apply for time-based AMI copy operations. For more information, see Time-based copies in the *Amazon EBS User Guide*.

Contents

Considerations

- **Permission to copy AMIs –** You can use IAM policies to grant or deny users permission to copy AMIs. Starting October 28, 2024, you can specify resource-level permissions for the `CopyImage` action on the source AMI. Resource-level permissions for the new AMI are available as before.
- **Launch permissions and Amazon S3 bucket permissions –** AWS does not copy launch permissions or Amazon S3 bucket permissions from the source AMI to the new AMI. After the copy operation is complete, you can apply launch permissions and Amazon S3 bucket permissions to the new AMI.
- **Tags –** You can only copy user-defined AMI tags that you attached to the source AMI. System tags (prefixed with `aws:`) and user-defined tags that are attached by other AWS accounts will not be copied. When copying an AMI, you can attach new tags to the new AMI and its backing snapshots.
- **Quotas for time-based AMI copies –** After you reach your *cumulative snapshot copy throughput quota*, subsequent time-based AMI copy requests fail. For more information, see Quotas for time-based copies in the *Amazon EBS User Guide*.
- **Supported source-destination copies –** The location of the source AMI determines whether you can copy it and the allowed destinations for the new AMI:
  - If the source AMI is in a Region, you can copy it within that Region, to another Region, to an Outpost associated with that Region, or to a Local Zone in that Region.
  - If the source AMI is in a Local Zone, you can copy it within that Local Zone, to the parent Region of that Local Zone, or to certain other Local Zones with the same parent Region.
  - If the source AMI is on an Outpost, you can't copy it.
- **CLI parameters for source and destination –** When using the CLI, the following parameters are supported for specifying the source location of the AMI to copy and the destination of the new AMI. Note that the copy operation must be initiated in the destination Region; if you omit the

`--region` parameter, the destination assumes the default Region configured in your AWS CLI settings.

Source to destination	Source parameter	Destination parameter
Region to Region	`--source-region`	`--region`
Region to Outpost	`--source-region`	`--destination-outpost-arn` (the ARN of the Outpost)
Region to Local Zone	`--source-region` Must be the parent Region of the Local Zone.	`--destination-availability-zone` (the name of the Local Zone) or `--destination-availability-zone-id` (the ID of the Local Zone)
Local Zone to Region	`--source-region` Must be the parent Region of the Local Zone. The source Local Zone is assumed from the location of the specified source AMI ID.	`--region` Must be the parent Region of the Local Zone.
Local Zone to Local Zone	`--source-region` Must be the parent Region of the Local Zone. The source Local Zone is assumed from the location of the specified source AMI ID.	`--destination-availability-zone` (the name of the Local Zone) or `--destination-availability-zone-id` (the ID of the Local Zone)

Costs

There is no charge for copying an AMI when no completion time is specified. However, additional charges apply for time-based AMI copy operations. For more information, see Time-based copies in the *Amazon EBS User Guide*.

Standard storage and data transfer rates apply. If you copy an EBS-backed AMI, you will incur charges for the storage of any additional EBS snapshots.

Grant permissions to copy Amazon EC2 AMIs

To copy an EBS-backed or instance store-backed AMI, you need the following IAM permissions:

- `ec2:CopyImage` – To copy the AMI. For EBS-backed AMIs, it also grants permission to copy the AMI's backing snapshots.
- `ec2:CreateTags` – To tag the target AMI. For EBS-backed AMIs, it also grants permission to tag the target AMI’s backing snapshots.

If you're copying an instance stored-backed AMI, you need the following *additional* IAM permissions:

- `s3:CreateBucket` – To create the S3 bucket in the target Region for the new AMI
- `s3:GetBucketAcl` – To read the ACL permissions for the source bucket
- `s3:ListAllMyBuckets` – To find an existing S3 bucket for AMIs in the target Region
- `s3:GetObject` – To read the objects in the source bucket
- `s3:PutObject` – To write the objects in the target bucket
- `s3:PutObjectAcl` – To write the permissions for the new objects in the target bucket

> **Note**
>
> Starting October 28, 2024, you can specify resource-level permissions for the `CopyImage` action on the source AMI. Resource-level permissions for the target AMI are available as before. For more information, see **CopyImage** in the table under Actions defined by Amazon EC2 in the *Service Authorization Reference*.

Example IAM policy for copying an EBS-backed AMI and tagging the target AMI and snapshots

The following example policy grants you permission to copy any EBS-backed AMI and tag the target AMI and its backing snapshots.

> **Note**
>
> Starting October 28, 2024, you can specify snapshots in the `Resource` element. For more information, see **CopyImage** in the table under [Actions defined by Amazon EC2](#) in the *Service Authorization Reference*.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Sid": "PermissionToCopyAllImages",
        "Effect": "Allow",
        "Action": [
            "ec2:CopyImage",
            "ec2:CreateTags"
        ],
        "Resource": [
            "arn:aws:ec2:*::image/*",
            "arn:aws:ec2:*::snapshot/*"
        ]
    }]
}
```

Example IAM policy for copying an EBS-backed AMI but denying tagging the new snapshots

The `ec2:CopySnapshot` permission is automatically granted when you get the `ec2:CopyImage` permission. Permission to tag the new backing snapshots can be explicitly denied, overriding the `Allow` effect for the `ec2:CreateTags` action.

The following example policy grants you permission to copy any EBS-backed AMI, but denies you from tagging the new backing snapshots of the target AMI.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
            "Effect": "Allow",
            "Action": [
                "ec2:CopyImage",
                "ec2:CreateTags"
            ],
            "Resource": [
                "arn:aws:ec2:*::image/*",
                "arn:aws:ec2:*::snapshot/*"
            ]
        },
        {
            "Effect": "Deny",
            "Action": "ec2:CreateTags",
            "Resource": "arn:aws:ec2:::snapshot/*"
        }
    ]
}
```

Example IAM policy for copying an instance store-backed AMI and tagging the target AMI

The following example policy grants you permission to copy any instance store-backed AMI in the specified source bucket to the specified Region, and tag the target AMI.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
            "Sid": "PermissionToCopyAllImages",
            "Effect": "Allow",
            "Action": [
                "ec2:CopyImage",
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws:ec2:*::image/*"
        },
```

```
        {
            "Effect": "Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource": [
                "arn:aws:s3:::*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "s3:GetObject",
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-source-bucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:GetBucketAcl",
                "s3:PutObjectAcl",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::amis-for-111122223333-in-us-east-2-hash"
            ]
        }
    ]
}
```

To find the Amazon Resource Name (ARN) of the AMI source bucket, open the Amazon EC2 console at https://console.aws.amazon.com/ec2/, in the navigation pane choose **AMIs**, and locate the bucket name in the **Source** column.

Note

The `s3:CreateBucket` permission is only needed the first time that you copy an instance store-backed AMI to an individual Region. After that, the Amazon S3 bucket that is already created in the Region is used to store all future AMIs that you copy to that Region.

Copy an AMI

You can copy an AMI that you own or an AMI that was shared with you from another account. For the supported source and destination combinations, see Considerations.

Console

To copy an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the console navigation bar, select the Region that contains the AMI.
3. In the navigation pane, choose **AMIs** to display the list of AMIs available to you in the Region.
4. If you don't see the AMI you want to copy, choose a different filter. You can filter by AMIs **Owned by me**, **Private images**, **Public images**, and **Disabled images**.
5. Select the AMI to copy, and then choose **Actions**, **Copy AMI**.
6. On the **Copy Amazon Machine Image (AMI)** page, specify the following information:

    a. **AMI copy name**: A name for the new AMI. You can include the operating system information in the name because Amazon EC2 does not provide this information when displaying details about the AMI.

    b. **AMI copy description**: By default, the description includes information about the source AMI so that you can distinguish a copy from its original. You can change this description as needed.

    c. **Destination Region**: The Region in which to copy the AMI. For more information, see Cross-Region copying and Cross-account copying.

    d. **Copy tags**: Select this checkbox to include your user-defined AMI tags when copying the AMI. System tags (prefixed with `aws:`) and user-defined tags that are attached by other AWS accounts will not be copied.

    e. **Time-based copy**: You can specify whether the copy operation completes within a specific timeframe or on a best-effort basis, as follows:

        - To complete the copy within a specific timeframe:
            - Select **Enable time-based copy**.

    - For **Completion duration**, enter the number of minutes (in 15-minute increments) allowed for the copy operation. The completion duration applies to all snapshots associated with the AMI.

      For more information, see [Time-based copies](#) in the *Amazon EBS User Guide*.

  - To complete the copy on a best-effort basis:
    - Leave **Enable time-based copy** unselected.

f. (EBS-backed AMIs only) **Encrypt EBS snapshots of AMI copy**: Select this checkbox to encrypt the target snapshots, or to re-encrypt them using a different key. If encryption by default is enabled, the **Encrypt EBS snapshots of AMI copy** checkbox is selected and cannot be cleared. For more information, see [Encryption and copying](#).

g. (EBS-backed AMIs only) **KMS key**: The KMS key to used to encrypt the target snapshots.

h. **Tags**: You can tag the new AMI and the new snapshots with the same tags, or you can tag them with different tags.

  - To tag the new AMI and the new snapshots with the *same* tags, choose **Tag image and snapshots together**. The same tags are applied to the new AMI and every snapshot that is created.
  - To tag the new AMI and the new snapshots with *different* tags, choose **Tag image and snapshots separately**. Different tags are applied to the new AMI and the snapshots that are created. Note, however, that all the new snapshots that are created get the same tags; you can't tag each new snapshot with a different tag.

  To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

i. When you're ready to copy the AMI, choose **Copy AMI**.

  The initial status of the new AMI is `Pending`. The AMI copy operation is complete when the status is `Available`.

AWS CLI

To copy an AMI from one Region to another Region

Use the copy-image command. You must specify both the source and destination Regions. You specify the source Region using the `--source-region` parameter. You can specify the destination Region using the `--region` parameter (or omit this parameter to assume the default Region configured in your AWS CLI settings).

```
aws ec2 copy-image \
    --source-image-id ami-0abcdef1234567890 \
    --source-region us-west-2 \
    --name my-ami \
    --region us-east-1
```

When you encrypt a target snapshot during AMI copy, you must specify these additional parameters: `--encrypted` and `--kms-key-id`.

To copy an AMI from a Region to a Local Zone

Use the copy-image command. You must specify both the source and destination. You specify the source Region using the `--source-region` parameter. You specify the destination Local Zone using the `--destination-availability-zone` parameter (you can use `--destination-availability-zone-id` instead). Note that you can only copy an AMI from a Region to a Local Zone within that same Region.

```
aws ec2 copy-image \
    --source-image-id ami-0abcdef1234567890 \
    --source-region cn-north-1 \
    --destination-availability-zone cn-north-1-pkx-1a \
    --name my-ami \
    --region cn-north-1
```

To copy an AMI from a Local Zone to a Region

Use the copy-image command. You must specify both the source and destination. You specify the source Region using the `--source-region` parameter. You specify the destination Region using the `--region` parameter (or omit this parameter to assume the default Region configured in your AWS CLI settings). The source Local Zone is assumed from the location of the specified source AMI ID. Note that you can only copy an AMI from a Local Zone to its parent Region.

```
aws ec2 copy-image \
```

```
    --source-image-id ami-0abcdef1234567890 \
    --source-region cn-north-1 \
    --name my-ami \
    --region cn-north-1
```

To copy an AMI from one Local Zone to another Local Zone

Use the copy-image command. You must specify both the source and destination. You specify the source Region of the Local Zone using the `--source-region` parameter. You specify the destination Local Zone using the `--destination-availability-zone` parameter (you can use `--destination-availability-zone-id` instead). The source Local Zone is assumed from the location of the specified source AMI ID. You specify the parent Region of the destination Local Zone using the `--region` parameter (or omit this parameter to assume the default Region configured in your AWS CLI settings).

```
aws ec2 copy-image \
    --source-image-id ami-0abcdef1234567890 \
    --source-region cn-north-1 \
    --destination-availability-zone cn-north-1-pkx-1a \
    --name my-ami \
    --region cn-north-1
```

PowerShell

To copy an AMI from one Region to another Region

Use the Copy-EC2Image cmdlet. You must specify both the source and destination Regions. You specify the source Region using the `-SourceRegion` parameter. You can specify the destination Region using the `-Region` parameter or the Set-AWSDefaultRegion cmdlet.

```
Copy-EC2Image `
    -SourceImageId ami-0abcdef1234567890 `
    -SourceRegion us-west-2 `
    -Name my-ami `
    -Region us-east-1
```

When you encrypt a target snapshot during AMI copy, you must specify these additional parameters: `-Encrypted` and `-KmsKeyId`.

To copy an AMI from a Region to a Local Zone

Use the Copy-EC2Image cmdlet. You must specify both the source and destination. You specify the source Region using the -SourceRegion parameter. You specify the destination Local Zone using the -DestinationAvailabilityZone parameter (you can use -DestinationAvailabilityZoneId instead). Note that you can only copy an AMI from a Region to a Local Zone within that same Region.

```
Copy-EC2Image `
    -SourceImageId ami-0abcdef1234567890 `
    -SourceRegion cn-north-1 `
    -DestinationAvailabilityZone cn-north-1-pkx-1a `
    -Name my-ami `
    -Region cn-north-1
```

To copy an AMI from a Local Zone to a Region

Use the Copy-EC2Image cmdlet. You must specify both the source and destination. You specify the source Region using the -SourceRegion parameter. You specify the destination Region using the -Region parameter or the Set-AWSDefaultRegion cmdlet. The source Local Zone is assumed from the location of the specified source AMI ID. Note that you can only copy an AMI from a Local Zone to its parent Region.

```
Copy-EC2Image `
    -SourceImageId ami-0abcdef1234567890 `
    -SourceRegion cn-north-1 `
    -Name my-ami `
    -Region cn-north-1
```

To copy an AMI from one Local Zone to another Local Zone

Use the Copy-EC2Image cmdlet. You must specify both the source and destination. You specify the source Region of the Local Zone using the -SourceRegion parameter. You specify the destination Local Zone using the -DestinationAvailabilityZone parameter (you can use -DestinationAvailabilityZoneId instead). The source Local Zone is assumed from the location of the specified source AMI ID. You specify the parent Region of the destination Local Zone using the -Region parameter or the Set-AWSDefaultRegion cmdlet.

```
Copy-EC2Image `
    -SourceImageId ami-0abcdef1234567890 `
    -SourceRegion cn-north-1 `
    -DestinationAvailabilityZone cn-north-1-pkx-1a `
```

```
    -Name my-ami `
    -Region cn-north-1
```

Stop a pending AMI copy operation

You can stop a pending AMI copy using the following procedures.

Console

To stop an AMI copy operation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the destination Region from the Region selector.
3. In the navigation pane, choose **AMIs**.
4. Select the AMI to stop copying, and then choose **Actions**, **Deregister AMI**.
5. When asked for confirmation, choose **Deregister AMI**.

AWS CLI

To stop an AMI copy operation

Use the deregister-image command.

```
aws ec2 deregister-image --image-id ami-0abcdef1234567890
```

PowerShell

To stop an AMI copy operation using

Use the Unregister-EC2Image cmdlet.

```
Unregister-EC2Image -ImageId ami-0abcdef1234567890
```

How Amazon EC2 AMI copy works

Copying a source AMI results in an identical but distinct new AMI that we also refer to as the *target* AMI. The target AMI has its own unique AMI ID. You can change or deregister the source AMI with no effect on the target AMI. The reverse is also true.

With an EBS-backed AMI, each of its backing snapshots is copied to an identical but distinct target snapshot. If you copy an AMI to a new Region, the snapshots are complete (non-incremental) copies. If you encrypt unencrypted backing snapshots or encrypt them to a new KMS key, the snapshots are complete (non-incremental) copies. Subsequent copy operations of an AMI result in incremental copies of the backing snapshots.

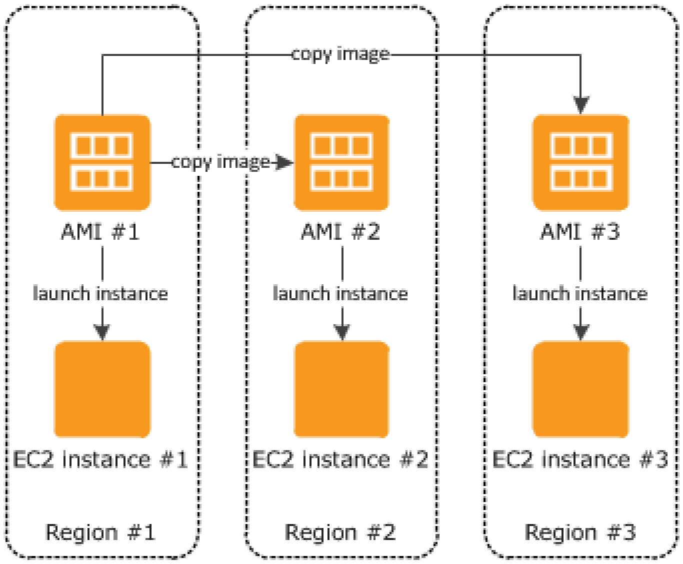
Contents

Cross-Region copying

Copying an AMI across geographically diverse Regions provides the following benefits:

- Consistent global deployment: Copying an AMI from one Region to another enables you to launch consistent instances in different Regions based on the same AMI.
- Scalability: You can more easily design and build global applications that meet the needs of your users, regardless of their location.
- Performance: You can increase performance by distributing your application, as well as locating critical components of your application in closer proximity to your users. You can also take advantage of Region-specific features, such as instance types or other AWS services.
- High availability: You can design and deploy applications across AWS Regions, to increase availability.

The following diagram shows the relationship between a source AMI and two copied AMIs in different Regions, as well as the EC2 instances launched from each. When you launch an instance from an AMI, it resides in the same Region where the AMI resides. If you make changes to the source AMI and want those changes to be reflected in the AMIs in the target Regions, you must recopy the source AMI to the target Regions.



When you first copy an instance store-backed AMI to a Region, we create an Amazon S3 bucket for the AMIs copied to that Region. All instance store-backed AMIs that you copy to that Region are stored in this bucket. The bucket names have the following format: amis-for-*account*-in-*region*-*hash*. For example: `amis-for-123456789012-in-us-east-2-yhjmxvp6`.

Prerequisite

Prior to copying an AMI, you must ensure that the contents of the source AMI are updated to support running in a different Region. For example, you should update any database connection strings or similar application configuration data to point to the appropriate resources. Otherwise, instances launched from the new AMI in the destination Region might still use the resources from the source Region, which can impact performance and cost.

Limitations

- Destination Regions are limited to 300 concurrent AMI copy operations. This also applies to time-based AMI copy operations.
- You can't copy a paravirtual (PV) AMI to a Region that does not support PV AMIs. For more information, see Virtualization types.

Cross-account copying

If an AMI from another AWS account is shared with your AWS account, you can copy the shared AMI. This is known as cross-account copying. The AMI that is shared with you is the source AMI.

When you copy the source AMI, you create a new AMI. The new AMI is often referred to as the target AMI.

AMI costs

- For a shared AMI, the account of the shared AMI is charged for the storage in the Region.
- If you copy an AMI that is shared with your account, you are the owner of the target AMI in your account.
  - The owner of the source AMI is charged standard Amazon EBS or Amazon S3 transfer fees.
  - You are charged for the storage of the target AMI in the destination Region.

Resource permissions

To copy an AMI that was shared with you from another account, the owner of the source AMI must grant you read permissions for the storage that backs the AMI, not just for the AMI itself. The storage is either the associated EBS snapshot (for an Amazon EBS-backed AMI) or an associated S3 bucket (for an instance store-backed AMI). If the shared AMI has encrypted snapshots, the owner must share the key or keys with you. For more information about granting resource permissions, for EBS snapshots, see Share an Amazon EBS snapshot with other AWS accounts in the *Amazon EBS User Guide*, and for S3 buckets, see Identity and access management for Amazon S3 in the *Amazon S3 User Guide*.

> **Note**
>
> Tags that are attached to the source AMI are not copied across accounts to the target AMI.

Time-based AMI copy operations

When you initiate a time-based AMI copy operation for an EBS-backed AMI with a single associated snapshot, it behaves in the same way as an **individual time-based snapshot copy operation**, and the same throughput limitations apply.

When you initiate a time-based AMI copy operation for an EBS-backed AMI with a multiple associated snapshots, it behaves in the same way as **concurrent time-based snapshot copy operations**, and the same throughput limitations apply. Each associated snapshot results in a separate snapshot copy request, each of which contributes to your cumulative snapshot copy throughput quota. The completion duration that you specify applies to each associated snapshot.

For more information, see [Time-based copies] in the *Amazon EBS User Guide*.

Encryption and copying

The following table shows encryption support for various AMI-copying scenarios. While it is possible to copy an unencrypted snapshot to yield an encrypted snapshot, you cannot copy an encrypted snapshot to yield an unencrypted one.

Scenario	Description	Supported
1	Unencrypted to unencrypted	Yes
2	Encrypted to encrypted	Yes
3	Unencrypted to encrypted	Yes
4	Encrypted to unencrypted	No

> **Note**
>
> Encrypting during the `CopyImage` action applies only to Amazon EBS-backed AMIs. Because an instance store-backed AMI does not use snapshots, you can't use copying to change its encryption status.

When you copy an AMI without specifying encryption parameters, the backing snapshot is copied with its original encryption status by default. Therefore, if the source AMI is backed by an unencrypted snapshot, the resulting target snapshot will also be unencrypted. Similarly, if the source AMI's snapshot is encrypted, the resulting target snapshot will also be encrypted by the same AWS KMS key. For AMIs backed by multiple snapshots, each target snapshot preserves the encryption state of its corresponding source snapshot.

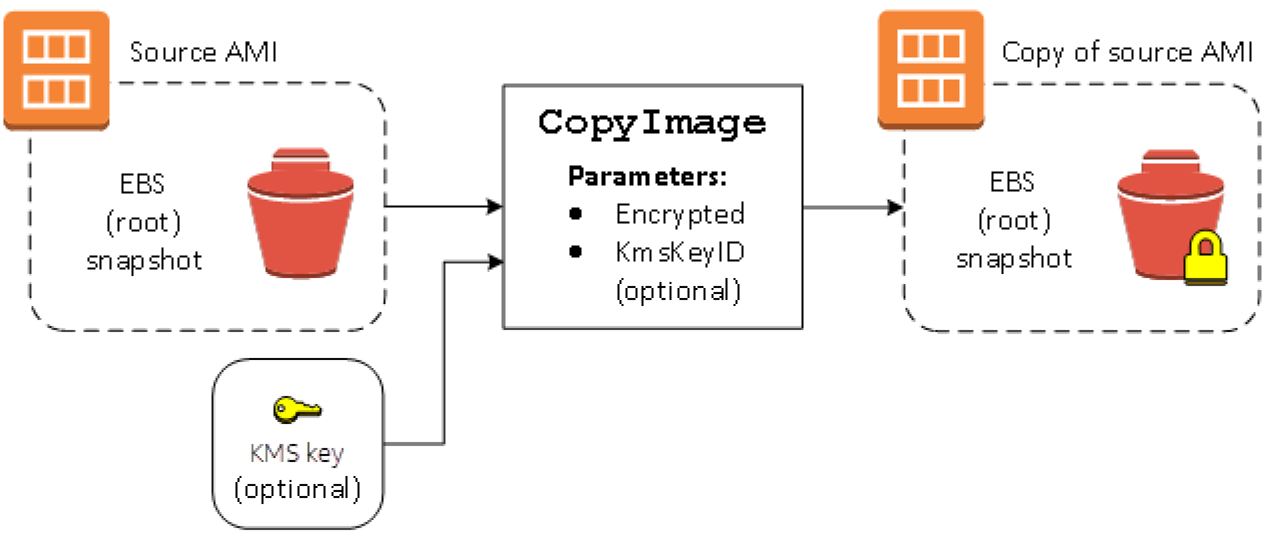
To change the encryption state of the target backing snapshots during an AMI copy, you can specify encryption parameters. The following example shows a non-default case, where encryption parameters are specified with the `CopyImage` action to change the target AMI's encryption state.

Copy an unencrypted source AMI to an encrypted target AMI

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The `CopyImage` action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

Note

Enabling encryption by default has the same effect as setting the `Encrypted` parameter to `true` for all snapshots in the AMI.



Setting the `Encrypted` parameter encrypts the single snapshot for this instance. If you do not specify the `KmsKeyId` parameter, the default customer managed key is used to encrypt the snapshot copy.

For more information about copying AMIs with encrypted snapshots, see Use encryption with EBS-backed AMIs.

Store and restore an AMI using S3

You can store an Amazon Machine Image (AMI) in an Amazon S3 bucket, copy the AMI to another S3 bucket, and then restore it from the S3 bucket. By storing and restoring an AMI using S3 buckets, you can copy AMIs from one AWS partition to another, for example, from the main commercial partition to the AWS GovCloud (US) partition. You can also make archival copies of AMIs by storing them in an S3 bucket.

The supported APIs for storing and restoring an AMI using S3 are `CreateStoreImageTask`, `DescribeStoreImageTasks`, and `CreateRestoreImageTask`.

`CopyImage` is the recommended API to use for copying AMIs *within* an AWS partition. However, `CopyImage` can't copy an AMI to *another* partition.

For information about the AWS partitions, see `partition` on the Amazon Resource Names (ARNs) page in the *IAM User Guide*.

> **Warning**
>
> Ensure that you comply with all applicable laws and business requirements when moving data between AWS partitions or AWS Regions, including, but not limited to, any applicable government regulations and data residency requirements.

Contents

Use cases

Use the store and restore APIs to do the following:

- Copy an AMI between AWS partitions
- Make archival copies of AMIs

Copy an AMI between AWS partitions

By storing and restoring an AMI using S3 buckets, you can copy an AMI from one AWS partition to another, or from one AWS Region to another. In the following example, you copy an AMI from the main commercial partition to the AWS GovCloud (US) partition, specifically from the `us-east-2` Region to the `us-gov-east-1` Region.

To copy an AMI from one partition to another, follow these steps:

- Store the AMI in an S3 bucket in the current Region by using `CreateStoreImageTask`. In this example, the S3 bucket is located in `us-east-2`.
- Monitor the progress of the store task by using `DescribeStoreImageTasks`. The object becomes visible in the S3 bucket when the task is completed.
- Copy the stored AMI object to an S3 bucket in the target partition using a procedure of your choice. In this example, the S3 bucket is located in `us-gov-east-1`.

> **Note**
>
> Because you need different AWS credentials for each partition, you can't copy an S3 object directly from one partition to another. The process for copying an S3 object across partitions is outside the scope of this documentation. We provide the following copy processes as examples, but you must use the copy process that meets your security requirements.
>
> - To copy one AMI across partitions, the copy process could be as straightforward as the following: Download the object from the source bucket to an intermediate host (for example, an EC2 instance or a laptop), and then upload the object from the intermediate host to the target bucket. For each stage of the process, use the AWS credentials for the partition.
> - For more sustained usage, consider developing an application that manages the copies, potentially using S3 multipart downloads and uploads.

- Restore the AMI from the S3 bucket in the target partition by using `CreateRestoreImageTask`. In this example, the S3 bucket is located in `us-gov-east-1`.
- Monitor the progress of the restore task by describing the AMI to check when its state becomes available. You can also monitor the progress percentages of the snapshots that make up the restored AMI by describing the snapshots.

Make archival copies of AMIs

You can make archival copies of AMIs by storing them in an S3 bucket. The AMI is packed into a single object in S3, and all of the AMI metadata (excluding sharing information) is preserved as part of the stored AMI. The AMI data is compressed as part of the storage process. AMIs that contain data that can easily be compressed will result in smaller objects in S3. To reduce costs, you can use less expensive S3 storage tiers. For more information, see Amazon S3 Storage Classes and Amazon S3 pricing

Limitations

- To store an AMI, your AWS account must either own the AMI and its snapshots, or the AMI and its snapshots must be shared directly with your account. You can't store an AMI if it is only publicly shared.
- Only EBS-backed AMIs can be stored using these APIs.
- Paravirtual (PV) AMIs are not supported.
- The size of an AMI (before compression) that can be stored is limited to 5,000 GB.
- Quota on store image requests: 1,200 GB of storage work (snapshot data) in progress.
- Quota on restore image requests: 600 GB of restore work (snapshot data) in progress.
- For the duration of the store task, the snapshots must not be deleted and the IAM principal doing the store must have access to the snapshots, otherwise the store process will fail.
- You can’t create multiple copies of an AMI in the same S3 bucket.
- An AMI that is stored in an S3 bucket can’t be restored with its original AMI ID. You can mitigate this by using AMI aliasing.
- Currently the store and restore APIs are only supported by using the AWS Command Line Interface, AWS SDKs, and Amazon EC2 API. You can’t store and restore an AMI using the Amazon EC2 console.

Costs

When you store and restore AMIs using S3, you are charged for the services that are used by the store and restore APIs, and for data transfer. The APIs use S3 and the EBS Direct API (used internally by these APIs to access the snapshot data). For more information, see Amazon S3 pricing and Amazon EBS pricing.

How AMI store and restore works

To store and restore an AMI using S3, you use the following APIs:

- `CreateStoreImageTask` – Stores the AMI in an S3 bucket

- `DescribeStoreImageTasks` – Provides the progress of the AMI store task
- `CreateRestoreImageTask` – Restores the AMI from an S3 bucket

How the APIs work

- CreateStoreImageTask
- DescribeStoreImageTasks
- CreateRestoreImageTask
- File paths

CreateStoreImageTask

The `CreateStoreImageTask` API stores an AMI as a single object in an S3 bucket.

The API creates a task that reads all of the data from the AMI and its snapshots, and then uses an S3 multipart upload to store the data in an S3 object. The API takes all of the components of the AMI, including most of the non-Region-specific AMI metadata, and all the EBS snapshots contained in the AMI, and packs them into a single object in S3. The data is compressed as part of the upload process to reduce the amount of space used in S3, so the object in S3 might be smaller than the sum of the sizes of the snapshots in the AMI.

If there are AMI and snapshot tags visible to the account calling this API, they are preserved.

The object in S3 has the same ID as the AMI, but with a `.bin` extension. The following data is also stored as S3 metadata tags on the S3 object: AMI name, AMI description, AMI registration date, AMI owner account, and a timestamp for the store operation.

The time it takes to complete the task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can track the progress of the task by calling the `DescribeStoreImageTasks` API.

The sum of the sizes of all the AMIs in progress is limited to 1,200 GB of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit. For example, if an AMI with 200 GB of snapshot data and another AMI with 400 GB of snapshot data are currently being stored, another request will be accepted, because the total in progress is 600 GB, which is less than the limit. But if a single AMI with 1,200 GB of snapshot data is currently being stored, further tasks are rejected until the task is completed.

DescribeStoreImageTasks

The `DescribeStoreImageTasks` API describes the progress of the AMI store tasks. You can describe tasks for specified AMIs. If you don't specify AMIs, you get a paginated list of all of the store image tasks that have been processed in the last 31 days.

For each AMI task, the response indicates if the task is `InProgress`, `Completed`, or `Failed`. For tasks `InProgress`, the response shows an estimated progress as a percentage.

Tasks are listed in reverse chronological order.

Currently, only tasks from the previous month can be viewed.

CreateRestoreImageTask

The `CreateRestoreImageTask` API starts a task that restores an AMI from an S3 object that was previously created by using a `CreateStoreImageTask` request.

The restore task can be performed in the same or a different Region in which the store task was performed.

The S3 bucket from which the AMI object will be restored must be in the same Region in which the restore task is requested. The AMI will be restored in this Region.

The AMI is restored with its metadata, such as the name, description, and block device mappings corresponding to the values of the stored AMI. The name must be unique for AMIs in the Region for this account. If you do not provide a name, the new AMI gets the same name as the original AMI. The AMI gets a new AMI ID that is generated at the time of the restore process.

The time it takes to complete the AMI restoration task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can view the progress of the task by describing the AMI (describe-images) or its EBS snapshots (describe-snapshots). If the task fails, the AMI and snapshots are moved to a failed state.

The sum of the sizes of all of the AMIs in progress is limited to 300 GB (based on the size after restoration) of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit.

File paths

You can use file paths when storing and restoring AMIs, in the following way:

- When storing an AMI in S3, the file path can be added to the bucket name. Internally, the system separates the path from the bucket name, and then adds the path to the object key that is generated to store the AMI. The full object path is shown in the response from the API call.
- When restoring the AMI, because an object key parameter is available, the path can be added to the beginning of the object key value.

Example: Bucket name with appended file path

When you store the AMI, specify the file path after the bucket name.

```
amzn-s3-demo-bucket/path1/path2
```

The following is the resulting object key.

```
path1/path2/ami-0abcdef1234567890.bin
```

When you restore the AMI, you specify both the bucket name and the object key. For examples, see the section called "Create a store image task".

Create a store image task

When you store an AMI in an S3 bucket, a store image task is created. You can use the store image task to monitor the progress and outcome of the process.

Contents

Securing your AMIs

It is important to ensure that the S3 bucket is configured with sufficient security to secure the content of the AMI and that the security is maintained for as long as the AMI objects remain in the bucket. If this can't be done, use of these APIs is not recommended. Ensure that public access to the S3 bucket is not allowed. We recommend enabling Server-side encryption for the S3 buckets in which you store the AMIs, although it's not required.

For information about how to set the appropriate security settings for your S3 buckets, review the following security topics:

- Blocking public access to your Amazon S3 storage
- Setting default server-side encryption behavior for Amazon S3 buckets
- What S3 bucket policy can I use to comply with the AWS Config rule s3-bucket-ssl-requests-only?
- Enabling Amazon S3 server access logging

When the AMI snapshots are copied to the S3 object, the data is then copied over TLS connections. You can store AMIs with encrypted snapshots, but the snapshots are decrypted as part of the store process.

Permissions for storing and restoring AMIs using S3

If your IAM principals will store or restore AMIs using Amazon S3, you need to grant them the required permissions.

The following example policy includes all of the actions that are required to allow an IAM principal to carry out the store and restore tasks.

You can also create IAM policies that grant principals access to specific resources only. For more example policies, see Access management for AWS resources in the *IAM User Guide*.

> **Note**
>
> If the snapshots that make up the AMI are encrypted, or if your account is enabled for encryption by default, your IAM principal must have permission to use the KMS key.

```

Create a store image task

To store an AMI in an S3 bucket, start by creating a store image task. The time it takes to complete the task depends on the size of the AMI. You can track the progress of the task until it either succeeds or fails.

AWS CLI

To create the store image task

Use the create-store-image-task command.

```
aws ec2 create-store-image-task \
    --image-id ami-0abcdef1234567890 \
    --bucket amzn-s3-demo-bucket
```

The following is example output.

```
{
```

```
  "ObjectKey": "ami-0abcdef1234567890.bin"
}
```

To describe the progress of the store image task

Use the describe-store-image-tasks command.

```
aws ec2 describe-store-image-tasks \
    --image-ids ami-0abcdef1234567890 \
    --query StoreImageTaskResults[].StoreTaskState \
    --output text
```

The following is example output.

```
InProgress
```

PowerShell

To create the store image task

Use the New-EC2StoreImageTask cmdlet.

```
New-EC2StoreImageTask `
    -ImageId ami-0abcdef1234567890 `
    -Bucket amzn-s3-demo-bucket
```

The following is example output.

```
ObjectKey         : ami-0abcdef1234567890.bin
```

To describe the progress of the store image task

Use the Get-EC2StoreImageTask cmdlet.

```
(Get-EC2StoreImageTask -ImageId ami-0abcdef1234567890).StoreTaskState
```

The following is example output.

```
InProgress
```

Create a restore image task

You must specify a name for the restored AMI. The name must be unique for AMIs in the Region for this account. The restored AMI gets a new AMI ID.

AWS CLI

To create a restore image task

Use the create-restore-image-task command.

```
aws ec2 create-restore-image-task \
    --object-key ami-0abcdef1234567890.bin \
    --bucket amzn-s3-demo-bucket \
    --name "my-restored-ami"
```

The following is example output.

```
{
   "ImageId": "ami-1234567890abcdef0"
}
```

PowerShell

To create a restore image task

Use the New-EC2RestoreImageTask cmdlet.

```
New-EC2RestoreImageTask `
    -ObjectKey ami-0abcdef1234567890.bin `
    -Bucket amzn-s3-demo-bucket `
    -Name "my-restored-ami"
```

The following is example output.

```
ImageId         : ami-1234567890abcdef0
```

Identify the source AMI used to create a new Amazon EC2 AMI

You can identify the source AMI used to create a new AMI by checking the **Source AMI ID** (console) or `sourceImageId` (AWS CLI) field on the new AMI. This field contains the ID of the original AMI that was copied to create the new AMI.

You can also find the Region where the source AMI was located by checking the **Source AMI Region** (console) or `sourceImageRegion` (AWS CLI) field.

Considerations

- The ID and Region of the source AMI only appear if the AMI was created by using the following API commands:
  - CreateImage – Creates an AMI from an instance.
  - CopyImage – Copies an AMI within the same Region or across Regions in the same partition.
  - CreateRestoreImageTask – Copies an AMI to another partition.

  If the AMI was created with any other API command, the ID and Region of the source AMI don't appear.
- For some older AMIs, the ID and Region of the source AMI might not be available.
- If the source AMI has been deleted, the ID and Region fields of the source AMI still appear on the new AMI.
- For AMIs created by using CreateImage (creates an AMI from an instance), the source AMI ID is the ID of the AMI used to launch the instance.

Console

To identify the source AMI used to create an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select the AMI to view its details.

   The source AMI information appears in the following fields: **Source AMI ID** and **Source AMI Region**

AWS CLI

To identify the source AMI used to create an AMI

Use the describe-images command and specify the ID and Region of the AMI.

```
aws ec2 describe-images \
    --region us-east-1 \
    --image-ids ami-0abcdef1234567890 \
    --query "Images[].{ID:SourceImageId,Region:SourceImageRegion}"
```

The following is example output.

```
[
    {
        "ID": "ami-0abcdef1234567890",
        "Region": "us-west-2"
    }
}
```

PowerShell

To identify the source AMI used to create an AMI

Use the Get-EC2Image cmdlet.

```
Get-EC2Image -ImageId ami-0abcdef1234567890 | Select SourceImageId,
 SourceImageRegion
```

The following is example output.

```
SourceImageId           SourceImageRegion
-------------           -----------------
ami-0abcdef1234567890 us-west-2
```

Manage and monitor AMI usage

AWS provides several features to help you manage and monitor your AMI usage effectively. You can track which accounts are using your shared AMIs, identify when your AMIs were last used, and discover which resources in your AWS account are referencing specific AMIs.

The following table provides an overview of the features for managing and monitoring AMI usage:

Feature	Use case	Key benefits
AMI usage reports	Gain visibility into which AWS accounts are using your AMIs and how much each AMI is being used.	• Identify the AWS accounts and resource types referencing your AMIs so that you can safely deregister or disable AMIs. • Identify unused AMIs for deregistration to reduce storage costs. • Identify your most used AMIs.
Last used tracking	Check when your AMI was last used.	• Identify unused AMIs so that you can safely deregister AMIs. • Identify unused AMIs for deregistration to reduce storage costs.
AMI reference check	Ensure your AWS resources are using the latest compliant AMIs.	• Audit the use of AMIs in your account. • Check where specific AMIs are being referenced. • Maintain compliance by updating your resources to reference the latest AMIs.

Topics

View your AMI usage

If you share your Amazon Machine Images (AMIs) with other AWS accounts—whether with specific AWS accounts, organizations, organizational units (OUs), or publicly—you can see how these AMIs are used by creating AMI usage reports. The reports provide visibility into:

- Which AWS accounts are using your AMIs in EC2 instances or launch templates
- How many EC2 instances or launch templates are referencing each AMI

AMI usage reports help you manage your AMIs more effectively by helping you:

- Identify the AWS accounts and resource types referencing your AMIs so that you can safely deregister or disable AMIs.
- Identify unused AMIs for deregistration to reduce storage costs.
- Identify your most used AMIs.

Contents

How AMI usage reports work

When you create an AMI usage report, you specify:

- The AMI to report on.
- The AWS accounts to check (specific accounts or all accounts).
- The resource types to check (EC2 instances, launch templates, or both).

- For launch templates, the number of versions to check (defaults to the 20 most recent versions).

Amazon EC2 creates a separate report for each AMI. Each report provides:

- A list of the AWS accounts using the AMI.
- A count of the resources referencing the AMI by resource type per account. Note that for launch templates, if an AMI is referenced in multiple versions of a launch template, the count is only 1.

> **Important**
>
> When you generate an AMI usage report, it might not contain the most recent activity. Instance activity from the past 24 hours and launch template activity from the past few days might not appear in the report.

Amazon EC2 automatically deletes a report 30 days after creation. You can download reports from the EC2 console to retain locally.

Create an AMI usage report

To view how your AMI is being used, you must first create an AMI usage report, specifying the accounts and resource types to report on. Once the report is created, you can view the contents of the report. You can also download the report from the EC2 console.

Console

To create an AMI usage report

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select an AMI and choose **Actions**, **AMI usage**, **View my AMI usage**.
4. On the **Create my AMI usage report** page, do the following:

   a. For **Resource types**, select one or more resource types to report on.

   b. For **Account IDs**, do one of the following:

      - Choose **Specify accounts IDs** and then choose **Add account ID** for each account to report on.

- Choose **Include all accounts** to report on all accounts.

c. Choose **Create my AMI usage report**.

5. On the AMI page, choose the **My AMI usage** tab.
6. Choose a report ID to view its details.

AWS CLI

To create an AMI usage report for a list of accounts

Use the create-image-usage-report command with the following required parameters:

- `--image-id` – The ID of the AMI to report on.
- `--resource-types` – The types of resources to check. In the following example, the resource types to check are EC2 instances and launch templates. In addition, the number of launch template versions to check is also specified (`version-depth=100`).

To report on specific accounts, use the `--account-ids` parameter to specify the ID of each account to report on.

```
aws ec2 create-image-usage-report \
    --image-id ami-0abcdef1234567890 \
    --account-ids 111122223333 444455556666 123456789012 \
    --resource-types ResourceType=ec2:Instance \
      'ResourceType=ec2:LaunchTemplate,ResourceTypeOptions=[{OptionName=version-
depth,OptionValues=100}]'
```

To create an AMI usage report of all accounts

To report on all accounts using the specified AMI, use the same command but omit the `--account-ids` parameter.

```
aws ec2 create-image-usage-report \
    --image-id ami-0abcdef1234567890 \
    --resource-types ResourceType=ec2:Instance \
      'ResourceType=ec2:LaunchTemplate,ResourceTypeOptions=[{OptionName=version-
depth,OptionValues=100}]'
```

The following is example output.

```
{
    "ReportId": "amiur-00b877d192f6b02d0"
}
```

To monitor the report creation status

Use the describe-image-usage-reports command and specify the report ID.

```
aws ec2 describe-image-usage-reports --report-ids amiur-00b877d192f6b02d0
```

The following is example output. The initial value of the `State` field is `pending`. To be able to view the report entries, the state must be `available`.

```
{
    "ImageUsageReports": [
        {
            "ImageId": "ami-0e9ae3dc21c2b3a64",
            "ReportId": "amiur-abcae3dc21c2b3999",
            "ResourceTypes": [
                {"ResourceType": "ec2:Instance"}
            ],
            "State": "pending",
            "CreationTime": "2025-09-29T13:27:12.322000+00:00",
            "ExpirationTime": "2025-10-28T13:27:12.322000+00:00"
        }
    ]
}
```

PowerShell

To create an AMI usage report for a list of accounts

Use the New-EC2ImageUsageReport cmdlet with the following required parameters:

- `-ImageId` – The ID of the AMI to report on.
- `-ResourceType` – The types of resources to check. In the following example, the resource types to check are EC2 instances and launch templates. In addition, the number of launch template versions to check is also specified (`'version-depth' = 100`).

To report on specific accounts, use the -AccountId parameter to specify the ID of each account to report on.

```
New-EC2ImageUsageReport `
    -ImageId ami-0abcdef1234567890 `
    -AccountId 111122223333 444455556666 123456789012 `
    -ResourceType @(
        @{ResourceType = 'ec2:Instance'},
        @{ResourceType = 'ec2:LaunchTemplate'ResourceTypeOptions = @{'version-depth'
 = 100}
        })
```

To create an AMI usage report of all accounts

To report on all accounts using the specified AMI, use the same command but omit the -AccountId parameter.

```
New-EC2ImageUsageReport `
    -ImageId ami-0abcdef1234567890 `
    -ResourceType @(
        @{ResourceType = 'ec2:Instance'},
        @{ResourceType = 'ec2:LaunchTemplate'ResourceTypeOptions = @{'version-depth'
 = 100}
        })
```

The following is example output.

```
ReportId
--------
amiur-00b877d192f6b02d0
```

To monitor the report creation status

Use the Get-EC2ImageUsageReport command and specify the report ID.

```
Get-EC2ImageUsageReport -ReportId amiur-00b877d192f6b02d0
```

The following is example output. The initial value of the State field is pending. To be able to view the report entries, the state must be available.

```
ImageUsageReports
-----------------
{@{ImageId=ami-0e9ae3dc21c2b3a64; ReportId=amiur-abcae3dc21c2b3999;
 ResourceTypes=System.Object[]; State=pending; CreationTime=2025-09-29;
 ExpirationTime=2025-10-28}}
```

View AMI usage reports

You can view all the usage reports you've created for an AMI in the past 30 days. Amazon EC2 automatically deletes a report 30 days after creation.

For each report, you can see the AWS accounts that are using the AMI, and for each account, a count of the resources referencing the AMI by resource type. You can also see when the report creation was initiated. This information is only available when the report is in the **Complete** (console) or `available` (AWS CLI) state.

> **Important**
>
> When you generate an AMI usage report, it might not contain the most recent activity. Instance activity from the past 24 hours and launch template activity from the past few days might not appear in the report.

Console

To view an AMI usage report

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select an AMI.
4. Choose the **My usage reports** tab.

   The report list shows:

   - All reports generated in the past 30 days for the selected AMI.
   - For each report, the **Report initiated time** column shows the date the report was created.
5. Choose the ID of a report to view its contents.

6. To go back to the **My usage reports** tab on the AMI details page, choose **View all reports for this AMI**.

AWS CLI

To list all the AMI usage reports for the specified AMI

Use the describe-image-usage-reports command and specify the ID of the AMI to get a list of its reports.

```
aws ec2 describe-image-usage-reports --image-ids ami-0abcdef1234567890
```

The following is example output. Each report ID is listed along with the resource types that were scanned and the report creation and expiration dates. You can use this information to identify the reports whose entries you want to view.

```
{
  "ImageUsageReports": [
    {
      "ImageId": "ami-0abcdef1234567890",
      "ReportId": "amiur-1111111111111111",
      "ResourceTypes": [
        {
          "ResourceType": "ec2:Instance"
        }
      ],
      "State": "available",
      "CreationTime": "2025-09-29T13:27:12.322000+00:00",
      "ExpirationTime": "2025-10-28T13:27:12.322000+00:00",
      "Tags": []
    },
    {
      "ImageId": "ami-0abcdef1234567890",
      "ReportId": "amiur-22222222222222222",
      "ResourceTypes": [
        {
          "ResourceType": "ec2:Instance"
        },
        {
          "ResourceType": "ec2:LaunchTemplate"
        }
      ],
```

```
      "State": "available",
      "CreationTime": "2025-10-01T13:27:12.322000+00:00",
      "ExpirationTime": "2025-10-30T13:27:12.322000+00:00",
      "Tags": []
    }
  ],
  "NextToken": "opaque"
}
```

To view the contents of an AMI usage report for the specified AMI

Use the [describe-image-usage-report-entries](#) command and specify the ID of the AMI. The response returns all the reports for the specified AMI, showing the accounts that have used the AMI and their resource counts.

```
aws ec2 describe-image-usage-report-entries --image-ids ami-0abcdef1234567890
```

The following is example output.

```
{
  "ImageUsageReportEntries": [
    {
      "ImageId": "ami-0abcdef1234567890",
      "ResourceType": "ec2:Instance",
      "AccountId": "123412341234",
      "UsageCount": 15,
      "ReportCreationTime": "2025-09-29T13:27:12.322000+00:00",
      "ReportId": "amiur-1111111111111111"
    },
    {
      "ImageId": "ami-0abcdef1234567890",
      "ResourceType": "ec2:Instance",
      "AccountId": "123412341234",
      "UsageCount": 2,
      "ReportCreationTime": "2025-10-01T13:27:12.322000+00:00",
      "ReportId": "amiur-22222222222222222"
    },
    {
      "ImageId": "ami-0abcdef1234567890",
      "ResourceType": "ec2:Instance",
      "AccountId": "001100110011",
      "UsageCount": 39,
```

```
      "ReportCreationTime": "2025-10-01T13:27:12.322000+00:00",
      "ReportId": "amiur-22222222222222222"
    }
  ],
  "NextToken": "opaque"
}
```

To view the contents of an AMI usage report for the specified report

Use the describe-image-usage-report-entries command and specify the ID of the report. The response returns all the entries for the specified report, showing the accounts that have used the AMI and their resource counts.

```
aws ec2 describe-image-usage-report-entries --report-ids amiur-11111111111111111
```

The following is example output.

```
{
  "ImageUsageReportEntries": [
    {
      "ImageId": "ami-0abcdef1234567890",
      "ResourceType": "ec2:Instance",
      "AccountId": "123412341234",
      "UsageCount": 15,
      "ReportCreationTime": "2025-09-29T13:27:12.322000+00:00",
      "ReportId": "amiur-11111111111111111"
    },
    {
      "ImageId": "ami-0abcdef1234567890",
      "ResourceType": "ec2:LaunchTemplate",
      "AccountId": "123412341234",
      "UsageCount": 4,
      "ReportCreationTime": "2025-09-29T13:27:12.322000+00:00",
      "ReportId": "amiur-11111111111111111"
    },
    {
      "ImageId": "ami-0abcdef1234567890",
      "ResourceType": "ec2:LaunchTemplate",
      "AccountId": "001100110011",
      "UsageCount": 2,
      "ReportCreationTime": "2025-09-29T13:27:12.322000+00:00",
      "ReportId": "amiur-11111111111111111"
```

```
    }
  ],
  "NextToken": "opaque"
}
```

PowerShell

To list all the AMI usage reports for the specified AMI

Use the Get-EC2ImageUsageReport cmdlet and specify the ID of the AMI to get a list of its reports.

```
Get-EC2ImageUsageReport -ImageId ami-0abcdef1234567890
```

The following is example output. Each report ID is listed along with the resource types that were scanned and the report creation and expiration dates. You can use this information to identify the reports whose entries you want to view.

```
@{
    ImageUsageReports = @(
        @{
            ImageId = "ami-0abcdef1234567890"
            ReportId = "amiur-1111111111111111"
            ResourceTypes = @(
                @{
                    ResourceType = "ec2:Instance"
                }
            )
            State = "available"

    }}
NextToken : opaque
```

Delete an AMI usage report

Amazon EC2 automatically deletes a report 30 days after it was created. You can delete it manually before that time.

Console

To delete an AMI usage report

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select an AMI.
4. Choose the **My AMI usage** tab.
5. Choose the option button next to the report to delete, and then choose **Delete**.

AWS CLI

To delete an AMI usage report

Use the delete-image-usage-report command and specify the ID of the report.

```
aws ec2 delete-image-usage-report --report-id amiur-0123456789abcdefg
```

PowerShell

To delete an AMI usage report

Use the Remove-EC2ImageUsageReport cmdlet and specify the ID of the report.

```
Remove-EC2ImageUsageReport -ReportId amiur-0123456789abcdefg
```

Check when an Amazon EC2 AMI was last used

Amazon EC2 automatically tracks the date and time when an AMI was last used to launch an instance. If you have an AMI that has not been used to launch an instance in a long time, consider whether the AMI is a good candidate for deregistration or deprecation.

Considerations

- When an AMI is used to launch an instance, there is a 24-hour delay before that usage is reported.
- You must be the owner of the AMI to get the last launched time.
- AMI usage data is available starting April 2017.

Console

To view the last launched time of an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the checkbox for the AMI.
5. On the **Details** tab, find **Last launched time**.

AWS CLI

To view the last launched time by describing the AMI

Use the describe-images command. If `LastLaunchedTime` is not present in the output, verify that you own the AMI.

```
aws ec2 describe-images \
    --image-id ami-0abcdef1234567890 \
    --query Images[].LastLaunchedTime \
    --output text
```

The following is example output.

```
2025-02-17T20:22:19Z
```

To view the last launched time attribute of an AMI

Use the describe-image-attribute command. You must be the owner of the specified AMI.

```
aws ec2 describe-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --attribute lastLaunchedTime \
    --query LastLaunchedTime.Value \
    --output text
```

The following is example output.

```
2025-02-17T20:22:19Z
```

PowerShell

To view the last launched time by describing the AMI

Use the Get-EC2Image cmdlet. If `LastLaunchedTime` is not present in the output, verify that you own the AMI.

```
(Get-EC2Image -ImageId ami-0abcdef1234567890).LastLaunchedTime
```

The following is example output.

```
2025-02-17T20:22:19Z
```

To view the last launched time attribute of an AMI

Use the Get-EC2ImageAttribute cmdlet. You must be the owner of the specified AMI.

```
(Get-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute LastLaunchedTime).LastLaunchedTime
```

The following is example output.

```
2025-02-17T20:22:19Z
```

Identify your resources referencing specified AMIs

You can identify your AWS resources that reference specified Amazon Machine Images (AMIs), regardless of whether the AMIs are public or private, or who owns them. This visibility helps you ensure your resources use the latest compliant AMIs.

Key benefits

Checking AMI references helps you:

- Audit the use of AMIs in your account.
- Check where specific AMIs are being referenced.
- Maintain compliance by updating your resources to reference the latest AMIs.

Topics

Supported resources

AMI references can be checked in:

- EC2 instances
- Launch templates
- SSM parameters
- Image Builder image recipes
- Image Builder container recipes

How AMI reference checks work

Basic operation

When you run an AMI reference check, you:

- Specify which AMIs to check.
- Choose which resource types to scan.
- Receive a list of your resources that reference the specified AMIs.

Resource type selection

In the console, you select the resource types to scan.

In the CLI, you specify resource types to scan using one or both of the following CLI parameters:

- `IncludeAllResourceTypes`: Scans all supported resource types.
- `ResourceTypes`: Scans your specified resource types.

Response scoping

You can scope the response for EC2 instances and launch templates by customizing the `ResourceTypeOptions` values using the `ResourceTypes` parameter. The console and `IncludeAllResourceTypes` parameter both use default option values. When `ResourceTypes` and `IncludeAllResourceTypes` are used together, the `ResourceTypes` option values take precedence over the defaults.

The following are the default values:

Resource type	Scoping option (`OptionName`)	Purpose	Default values for `OptionValue` and console
EC2 instances	`state-name`	Filter by instance state	`pending`, `running`, `shutting-down`, `terminated`, `stopping`, `stopped` (all states)
Launch templates	`version-depth`	Specify the number of launch template versions to check (starting from the most recent version)	`10` (most recent versions)

Required IAM permissions

To use the DescribeImageReferences API to identify your resources that are referencing specified AMIs, you need the following IAM permissions to describe the resources:

- `ec2:DescribeInstances`
- `ec2:DescribeLaunchTemplates`
- `ec2:DescribeLaunchTemplateVersions`
- `ssm:DescribeParameters`
- `ssm:GetParameters`

- `imagebuilder:ListImageRecipes`
- `imagebuilder:ListContainerRecipes`
- `imagebuilder:GetContainerRecipe`

Example IAM policy for using the DescribeImageReferences API

The following example policy grants you the permissions to use the DescribeImageReferences API, which includes the permissions to describe EC2 instances, launch templates, Systems Manager parameters, Image Builder image recipes, and Image Builder container recipes.

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": "ec2:DescribeImageReferences",
   "Resource": "*"
  },
  {
   "Effect": "Allow",
   "Action": [
    "ec2:DescribeInstances",
    "ec2:DescribeLaunchTemplates",
    "ec2:DescribeLaunchTemplateVersions",
    "ssm:DescribeParameters",
    "ssm:GetParameters",
    "imagebuilder:ListImageRecipes",
    "imagebuilder:ListContainerRecipes",
    "imagebuilder:GetContainerRecipe"
   ],
   "Resource": "*",
   "Condition": {
    "ForAnyValue:StringEquals": {
     "aws:CalledVia": [
      "ec2-images.amazonaws.com"
     ]
    }
   }
  }
 ]
}
```

> **Important**
>
> We strongly recommend using the AWS managed policy `AmazonEC2ImageReferencesAccessPolicy` instead of creating the policy yourself. Creating a custom IAM policy that provides only the required permissions requires time and expertise, and will require updates as new resource types become available.
> The `AmazonEC2ImageReferencesAccessPolicy` managed policy:
>
> - Grants all the permissions needed to use the DescribeImageReferences API (these include the permissions to describe EC2 instances, launch templates, Systems Manager parameters, and Image Builder container and image recipes).
> - Automatically supports new resource types as they become available (especially important when using the `IncludeAllResourceTypes` parameter).
>
> You can attach the `AmazonEC2ImageReferencesAccessPolicy` policy to your IAM identities (users, groups, and roles).
> To view the permissions included in this policy, see AmazonEC2ImageReferencesAccessPolicy in the *AWS Managed Policy Reference*.

Steps for checking AMI references

Use the following procedures to identify which of your AWS resources are referencing specified AMIs.

Console

To identify resources referencing specified AMIs

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select one or more AMIs to check for references.
4. Choose **Actions**, **AMI usage**, **View referenced resources**.
5. On the **View resources referencing selected AMIs** page:
    a. For **Resource types**, select one or more resource types.
    b. Choose **View resources**.

6. The **Resources referencing selected AMIs** section appears. The list displays the resources referencing the specified AMIs. Each row provides the following information:

   - **AMI ID** – The ID of the referenced AMI.
   - **Resource type** – The resource type of the resource referencing the AMI.
   - **Resource ID** – The ID of the resource referencing the AMI.

AWS CLI

To check AMI references for specific resource types

Use the describe-image-references command with the `--resource-types` parameter. The following example checks EC2 instances (scoping by instance state), launch templates (scoping to the 20 most recent launch template versions), and other specific resource types.

```
aws ec2 describe-image-references \
    --image-ids ami-0abcdef1234567890 ami-1234567890abcdef0 \
    --resource-types \
        'ResourceType=ec2:Instance,ResourceTypeOptions=[{OptionName=state-
name,OptionValues=[running,pending]}]' \
        'ResourceType=ec2:LaunchTemplate,ResourceTypeOptions=[{OptionName=version-
depth,OptionValues=[20]}]' \
        'ResourceType=ssm:Parameter' \
        'ResourceType=imagebuilder:ImageRecipe' \
        'ResourceType=imagebuilder:ContainerRecipe'
```

The following is example output.

```
{
    "ImageReferences": [
        {
            "ImageId": "ami-0abcdef1234567890",
            "ResourceType": "ec2:Instance",
            "Arn": "arn:aws:ec2:us-east-1:123456789012:instance/i-1234567890abcdef0"
        },
        {
            "ImageId": "ami-1234567890abcdef0",
            "ResourceType": "ec2:LaunchTemplate",
            "Arn": "arn:aws:ec2:us-east-1:123456789012:launch-template/
lt-1234567890abcdef0"
        }
```

```
    ]
}
```

To check AMI references for all the supported resource types

Use the describe-image-references command with the `--include-all-resource-types` parameter.

```
aws ec2 describe-image-references \
    --image-ids ami-0abcdef1234567890 ami-1234567890abcdef0 \
    --include-all-resource-types
```

To check AMI references for all supported resource types and specific options

Use the describe-image-references command with both the `--include-all-resource-types` and `--resource-types` parameters. This example checks all resource types while scoping the response for EC2 instances to running or pending instances.

```
aws ec2 describe-image-references \
    --image-ids ami-0abcdef1234567890 ami-1234567890abcdef0 \
    --include-all-resource-types \
    --resource-types
 'ResourceType=ec2:Instance,ResourceTypeOptions=[{OptionName=state-
name,OptionValues=[running,pending]}]'
```

PowerShell

To check AMI references for specific resource types

Use the Get-EC2ImageReference cmdlet with the `-ResourceType` parameter. The following example checks EC2 instances (scoping by instance state), launch templates (scoping to the 20 most recent launch template versions), and other specific resource types.

```
Get-EC2ImageReference `
    -ImageId 'ami-0abcdef1234567890', 'ami-1234567890abcdef0' `
    -ResourceType @(
        @{
            ResourceType = 'ec2:Instance'
            ResourceTypeOptions = @(
                @{
                    OptionName = 'state-name'
                    OptionValues = @('running', 'pending')
```

```
                }
            )
        },
        @{
            ResourceType = 'ec2:LaunchTemplate'
            ResourceTypeOptions = @(
                @{
                    OptionName = 'version-depth'
                    OptionValues = @('20')
                }
            )
        },
        @{
            ResourceType = 'ssm:Parameter'
        },
        @{
            ResourceType = 'imagebuilder:ImageRecipe'
        },
        @{
            ResourceType = 'imagebuilder:ContainerRecipe'
        }
    )
```

To check AMI references for all the supported resource types

Use the [Get-EC2ImageReference](#) cmdlet with the `-IncludeAllResourceTypes` parameter.

```
Get-EC2ImageReference `
    -ImageId 'ami-0abcdef1234567890', 'ami-1234567890abcdef0' `
    -IncludeAllResourceTypes
```

To check AMI references for all supported resource types and specific options

Use the [Get-EC2ImageReference](#) cmdlet with both the `-IncludeAllResourceTypes` and `-ResourceType` parameters. This example checks all resource types while scoping the response for EC2 instances to running or pending instances.

```
Get-EC2ImageReference `
    -ImageId 'ami-0abcdef1234567890', 'ami-1234567890abcdef0' `
    -IncludeAllResourceTypes `
    -ResourceType @(
        @{
```

```
            ResourceType = 'ec2:Instance'
            ResourceTypeOptions = @(
                @{
                    OptionName = 'state-name'
                    OptionValues = @('running', 'pending')
                }
            )
        }
    )
```

Deprecate an Amazon EC2 AMI

You can deprecate an AMI to indicate that it is out of date and should not be used. You can also specify a future deprecation date for an AMI, indicating when the AMI will be out of date. For example, you might deprecate an AMI that is no longer actively maintained, or you might deprecate an AMI that has been superseded by a newer version. By default, deprecated AMIs do not appear in AMI listings, preventing new users from using out-of-date AMIs. However, existing users and launch services, such as launch templates and Auto Scaling groups, can continue to use a deprecated AMI by specifying its ID. To delete the AMI so that users and services cannot use it, you must deregister it.

After an AMI is deprecated:

- For AMI users, the deprecated AMI does not appear in DescribeImages API calls unless you specify its ID or specify that deprecated AMIs must appear. AMI owners continue to see deprecated AMIs in DescribeImages API calls.
- For AMI users, the deprecated AMI is not available to select via the EC2 console. For example, a deprecated AMI does not appear in the AMI catalog in the launch instance wizard. AMI owners continue to see deprecated AMIs in the EC2 console.
- For AMI users, if you know the ID of a deprecated AMI, you can continue to launch instances using the deprecated AMI by using the API, CLI, or the SDKs.
- Launch services, such as launch templates and Auto Scaling groups, can continue to reference deprecated AMIs.
- EC2 instances that were launched using an AMI that is subsequently deprecated are not affected, and can be stopped, started, and rebooted.

You can deprecate both private and public AMIs.

Contents

Costs

When you deprecate an AMI, the AMI is not deleted. The AMI owner continues to pay for the AMI's snapshots. To stop paying for the snapshots, the AMI owner must delete the AMI by deregistering it.

Considerations

- To deprecate an AMI, you must be the owner of the AMI.
- AMIs that have not been used recently to launch an instance might be good candidates for deprecation or deregistering. For more information, see the section called “Check when an AMI was last used”.
- You can create Amazon Data Lifecycle Manager EBS-backed AMI policies to automate the deprecation of EBS-backed AMIs. For more information, see Create AMI lifecycle policies.
- By default, the deprecation date of all public AMIs is set to two years from the AMI creation date. You can set the deprecation date to earlier than two years. To cancel the deprecation date, or to move the deprecation to a later date, you must make the AMI private by only sharing it with specific AWS accounts.

Deprecate an AMI

You can deprecate an AMI on a specific date and time. You must be the owner of the AMI.

The upper limit for the deprecation date is 10 years from now, except for public AMIs, where the upper limit is 2 years from the creation date. You can't specify a date in the past.

Console

To deprecate an AMI on a specific date

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions**, **Manage AMI Deprecation**. You can select multiple AMIs to set the same deprecation date of several AMIs at once.
5. Select the **Enable** checkbox, and then enter the deprecation date and time.
6. Choose **Save**.

AWS CLI

To deprecate an AMI on a specific date

Use the enable-image-deprecation command. If you specify a value for seconds, Amazon EC2 rounds the seconds to the nearest minute.

```
aws ec2 enable-image-deprecation \
    --image-id ami-0abcdef1234567890 \
    --deprecate-at "2025-04-15T13:17:12.000Z"
```

PowerShell

To deprecate an AMI on a specific date

Use the Enable-EC2ImageDeprecation cmdlet. If you specify a value for seconds, Amazon EC2 rounds the seconds to the nearest minute.

```
Enable-EC2ImageDeprecation `
    -ImageId ami-0abcdef1234567890 `
    -DeprecateAt 2025-04-15T13:17:12.000Z
```

Describe deprecated AMIs

You can view the deprecation date and time of an AMI, and filter AMIs by deprecation date.

Console

To view the deprecation date of an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigator, choose **AMIs**, and then select the AMI.
3. Check the **Deprecation time** field (if you selected the checkbox next to the AMI, it's located on the **Details** tab). The field shows the deprecation date and time of the AMI. If the field is empty, the AMI is not deprecated.

To filter AMIs by deprecation date

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me** or **Private images** (private images include AMIs that are shared with you as well as owned by you).
4. In the Search bar, enter **`Deprecation time`** (as you enter the letters, the **Deprecation time** filter appears), and then choose an operator and a date and time.

AWS CLI

When you describe all AMIs, the results depend on whether you are an AMI user or the AMI owner.

- **AMI user** – By default, when you describe all AMIs, deprecated AMIs that are shared with you but not owned by you are excluded. To include deprecated AMIs in the results, specify the `--include-deprecated` option.
- **AMI owner** – When you describe all AMIs, all AMIs that you own, including deprecated AMIs, are included. You can't exclude deprecated AMIs that you own by using the `--no-include-deprecated` option.

To include deprecated AMIs when describing all AMIs for an account

Use the following describe-images command.

```
aws ec2 describe-images
    --owners 123456789012 \
```

```
    --include-deprecated
```

To describe the deprecated AMIs for your account

Use the following describe-images command.

```
aws ec2 describe-images \
    --owners self \
    --query "Images[?DeprecationTime!=null].ImageId" \
    --output text
```

The following is example output.

```
ami-0abcdef1234567890
```

To describe the deprecation date of an AMI

Use the following describe-images command. If `DeprecationTime` is not present in the output, the AMI is not deprecated or set to deprecate at a future date.

```
aws ec2 describe-images \
    --image-ids ami-0abcdef1234567890 \
    --query Images[].DeprecationTime \
    --output text
```

The following is example output.

```
2025-05-01T00:00:00.000Z
```

PowerShell

To list the deprecated AMIs for your account

Use the Get-EC2Image cmdlet.

```
(Get-EC2Image -Owner self | Where-Object {$_.DeprecationTime -ne $null}).ImageId
```

The following is example output.

```
ami-0abcdef1234567890
```

To describe the deprecation date of an AMI

Use the [Get-EC2Image](#) cmdlet. If `DeprecationTime` is not present in the output, the AMI is not deprecated or set to deprecate at a future date.

```
(Get-EC2Image -ImageId ami-0abcdef1234567890).DeprecationTime
```

The following is example output.

```
2025-05-01T00:00:00.000Z
```

Cancel AMI deprecation

You can cancel the deprecation of an AMI, which removes the deprecation date and time. You must be the AMI owner to perform this procedure.

Console

To cancel the deprecation of an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions**, **Manage AMI Deprecation**. You can select multiple AMIs to cancel the deprecation of several AMIs at once.
5. Clear the **Enable** checkbox, and then choose **Save**.

AWS CLI

To cancel the deprecation of an AMI

Use the following disable-image-deprecation command.

```
aws ec2 disable-image-deprecation --image-id ami-0abcdef1234567890
```

PowerShell

To cancel the deprecation of an AMI

Use the Disable-EC2ImageDeprecation cmdlet.

```
Disable-EC2ImageDeprecation -ImageId ami-0abcdef1234567890
```

Disable an Amazon EC2 AMI

You can disable an AMI to prevent it from being used for instance launches. You can't launch new instances from a disabled AMI. You can re-enable a disabled AMI so that it can be used again for instance launches.

You can disable both private and public AMIs.

To reduce storage costs for disabled EBS-backed AMIs that are rarely used, but which need to be retained long term, you can archive their associated snapshots. For more information, see Archive Amazon EBS snapshots in the *Amazon EBS User Guide*.

Contents

How AMI disable works

> **Warning**
>
> Disabling an AMI removes all its launch permissions.

When an AMI is disabled:

- The AMI's state changes to `disabled`.

- A disabled AMI can't be shared. If an AMI was public or previously shared, it is made private. If an AMI was shared with an AWS account, organization, or Organizational Unit, they lose access to the disabled AMI.
- A disabled AMI does not appear in [DescribeImages] API calls by default.
- A disabled AMI does not appear under the **Owned by me** console filter. To find disabled AMIs, use the **Disabled images** console filter.
- A disabled AMI is not available to select for instance launches in the EC2 console. For example, a disabled AMI does not appear in the AMI catalog in the launch instance wizard or when creating a launch template.
- Launch services, such as launch templates and Auto Scaling groups, can continue to reference disabled AMIs. Subsequent instance launches from a disabled AMI will fail, so we recommend updating launch templates and Auto Scaling groups to reference available AMIs only.
- EC2 instances that were previously launched using an AMI that is subsequently disabled are not affected, and can be stopped, started, and rebooted.
- You can't delete snapshots associated with disabled AMIs. Attempting to delete an associated snapshot results in the `snapshot is currently in use` error.

When an AMI is re-enabled:

- The AMI's state changes to `available`, and it can be used to launch instances.
- The AMI can be shared.
- AWS accounts, organizations, and Organizational Units that lost access to the AMI when it was disabled do not regain access automatically, but the AMI can be shared with them again.

Costs

When you disable an AMI, the AMI is not deleted. If the AMI is an EBS-backed AMI, you continue to pay for the AMI's EBS snapshots. If you want to keep the AMI, you might be able to reduce your storage costs by archiving the snapshots. For more information, see Archive Amazon EBS snapshots in the *Amazon EBS User Guide*. If you don't want to keep the AMI and its snapshots, you must deregister the AMI and delete the snapshots. For more information, see Deregister an AMI.

Prerequisites

To disable or re-enable an AMI, you must be the owner of the AMI.

Required IAM permissions

To disable and re-enable an AMI, you must have the following IAM permissions:

- `ec2:DisableImage`
- `ec2:EnableImage`

Disable an AMI

You can disable an AMI by using the EC2 console or the AWS Command Line Interface (AWS CLI). You must be the AMI owner to perform this procedure.

Console

To disable an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions**, **Disable AMI**. You can select multiple AMIs to disable at once.
5. In the **Disable AMI** window, choose **Disable AMI**.

AWS CLI

To disable an AMI

Use the following disable-image command.

```
aws ec2 disable-image --image-id ami-0abcdef1234567890
```

PowerShell

To disable an AMI

Use the Disable-EC2Image cmdlet.

```
Disable-EC2Image -ImageId ami-0abcdef1234567890
```

Describe disabled AMIs

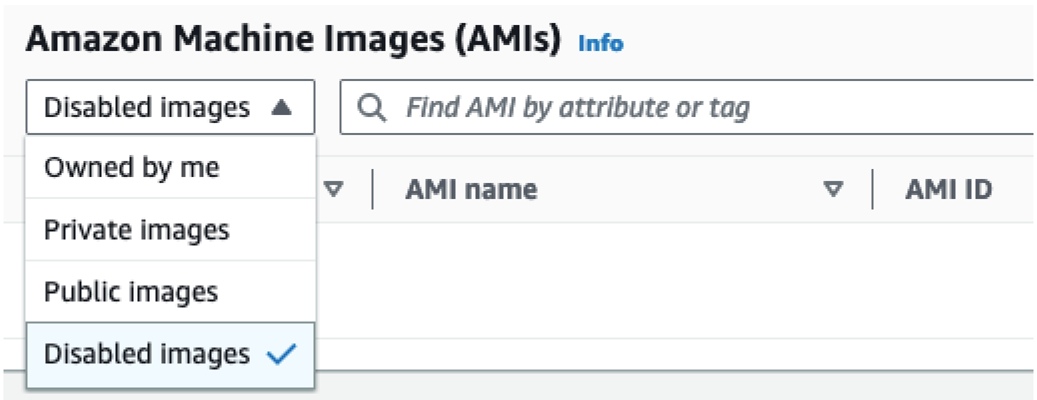
You can view disabled AMIs in the EC2 console and by using the AWS CLI.

You must be the AMI owner to view disabled AMIs. Because disabled AMIs are made private, you can't view disabled AMIs if you're not the owner.

Console

To view disabled AMIs

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **AMIs**.
3. From the filter bar, choose **Disabled images**.



AWS CLI

By default, when you describe all AMIs, the disabled AMIs are not included in the results. To include disabled AMIs in the results, specify the `--include-disabled` option. The `State` field for an AMI is `disabled` if the AMI is disabled.

To include disabled AMIs when describing all AMIs for an account

Use the following describe-images command.

```
aws ec2 describe-images \
    --owners 123456789012 \
    --include-disabled
```

To list the disabled AMIs for your account

Use the following describe-images command.

```
aws ec2 describe-images \
    --owners self \
    --include-disabled \
    --filters Name=state,Values=disabled \
    --query Images[].ImageId \
    --output text
```

The following is example output.

```
ami-0abcdef1234567890
```

To describe the status of an AMI

Use the following describe-images command. If `DeprecationTime` is not present in the output, the AMI is not deprecated or set to deprecate at a future date.

```
aws ec2 describe-images \
    --image-ids ami-0abcdef1234567890 \
    --query Images[].State \
    --output text
```

The following is example output.

```
disabled
```

PowerShell

By default, when you describe all AMIs, the disabled AMIs are not included in the results. To include disabled AMIs in the results, specify the `-IncludeDisabled` parameter. The `State` field for an AMI is `disabled` if the AMI is disabled.

To list the disabled AMIs for your account

Use the Get-EC2Image cmdlet.

```
(Get-EC2Image `
    -Owner self `
    -IncludeDisabled $true | Where-Object {$_.State -eq "disabled"}).ImageId
```

The following is example output.

```
ami-0abcdef1234567890
```

To describe the status of an AMI

Use the Get-EC2Image cmdlet.

```
(Get-EC2Image -ImageId ami-0abcdef1234567890).State.Value
```

The following is example output.

```
disabled
```

Re-enable a disabled AMI

You can re-enable a disabled AMI. You must be the AMI owner to perform this procedure.

Console

To re-enable a disabled AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **AMIs**.
3. From the filter bar, choose **Disabled images**.
4. Select the AMI, and then choose **Actions**, **Enable AMI**. You can select multiple AMIs to re-enable several AMIs at once.
5. In the **Enable AMI** window, choose **Enable**.

AWS CLI

To re-enable a disabled AMI

Use the following enable-image command.

```
aws ec2 enable-image --image-id ami-0abcdef1234567890
```

PowerShell

To re-enable a disabled AMI

Use the Enable-EC2Image cmdlet.

```
Enable-EC2Image -ImageId ami-0abcdef1234567890
```

Deregister an Amazon EC2 AMI

When you deregister an AMI, Amazon EC2 permanently deletes it. After you deregister an AMI, you can't use it to launch new instances. You might consider deregistering an AMI when you have finished using it.

To protect against accidental or malicious deregistering of an AMI, you can turn on deregistration protection. If you accidentally deregister an EBS-backed AMI, you can use the Recycle Bin to restore it only if you restore it within the allowed time period before it is permanently deleted.

When deregistering an AMI, you can optionally delete its associated snapshots at the same time. However, if a snapshot is associated with multiple AMIs, it won't be deleted even if specified for deletion, although the AMI will still be deregistered. Any snapshots not deleted will continue to incur storage costs.

Deregistering an AMI has no effect on any instances that were launched from the AMI. You can continue to use these instances. By default, deregistering an AMI also has no effect on any snapshots that were created during the AMI creation process. You'll continue to incur usage costs for these instances and storage costs for the snapshots. Therefore, to avoid incurring unnecessary costs, we recommend that you terminate any instances and delete any snapshots that you do not need. You can delete the snapshots either automatically during deregistration or manually after deregistration. For more information, see Avoid costs from unused resources.

For instances launched from an AMI that is subsequently deregistered, you can still view some high-level information about the AMI by using the `describe-instance-image-metadata` AWS CLI command. For more information, see describe-instance-image-metadata.

Contents

- Protect an Amazon EC2 AMI from deregistration

Considerations

- You can't deregister an AMI that is not owned by your account.
- You can't use Amazon EC2 to deregister an AMI that is managed by the AWS Backup service. Instead, use AWS Backup to delete the corresponding recovery points in the backup vault. For more information, see Deleting backups in the *AWS Backup Developer Guide*.

Deregister an AMI

You can deregister EBS-backed AMIs and instance store-backed AMIs. For EBS-backed AMIs, you can optionally delete the associated snapshots at the same time. However, if a snapshot is associated with other AMIs, it will not be deleted even if specified for deletion.

Console

To deregister an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. From the filter bar, choose **Owned by me** to list your available AMIs, or choose **Disabled images** to list your disabled AMIs.
4. Select the AMI to deregister.
5. Choose **Actions**, **Deregister AMI**.
6. (Optional) To delete the associated snapshots during deregistration, select the **Delete associated snapshots** checkbox.

   > **Note**
   >
   > If a snapshot is associated with other AMIs, it is not deleted, even if the checkbox is selected.

7. Choose **Deregister AMI**.

   It might take a few minutes before the console removes the AMI from the list. Choose **Refresh** to refresh the status.

AWS CLI

To deregister an AMI

Use the following deregister-image command.

```
aws ec2 deregister-image --image-id ami-0abcdef1234567890
```

To deregister an AMI and delete its associated snapshots

Use the following deregister-image command and specify the `--delete-associated-snapshots` parameter. Note that if a snapshot is associated with other AMIs, it is not deleted, even if you specify this parameter.

```
aws ec2 deregister-image \
    --image-id ami-0abcdef1234567890 \
    --delete-associated-snapshots
```

PowerShell

To deregister an AMI

Use the Unregister-EC2Image cmdlet.

```
Unregister-EC2Image -ImageId ami-0abcdef1234567890
```

To deregister an AMI and delete its associated snapshots

Use the Unregister-EC2Image cmdlet and specify the `-DeleteAssociatedSnapshots` parameter. Note that if a snapshot is associated with other AMIs, it is not deleted, even if you specify this parameter.

```
Unregister-EC2Image `
    -ImageId ami-0abcdef1234567890 `
    -DeleteAssociatedSnapshots
```

Avoid costs from unused resources

Deregistering an AMI doesn't, by default, delete all of the resources that are associated with the AMI. These resources include the snapshots for EBS-backed AMIs and the files in Amazon S3 for instance store-backed AMIs. When you deregister an AMI, you also don't terminate or stop any instances launched from the AMI.

You will continue to incur costs for storing the snapshots and files, and you will incur costs for any running instances.

To avoid incurring these types of unnecessary costs, we recommend deleting any resources that you don't need.

EBS-backed AMIs

- Delete the associated snapshots while deregistering the AMI. For more information, see Deregister an AMI.
- If you deregister an AMI without deleting its associated snaphots, you can manually delete the snapshots. The snapshot of the instance root volume created during AMI creation has the following description format:

```
Created by CreateImage(i-1234567890abcdef0) for ami-0abcdef1234567890
```

- If you no longer need the instances that were launched from the AMI, you can stop or terminate them. To list the instances, filter by the ID of the AMI.

Instance store-backed AMIs

- Delete the bundle in Amazon S3 by using the ec2-delete-bundle (AMI tools) command.
- If the Amazon S3 bucket is empty after you delete the bundle, and you have no further use for that bucket, you can delete the bucket.
- If you no longer need the instances that were launched from the AMI, you can terminate them. To list the instances, filter by the ID of the AMI.

Protect an Amazon EC2 AMI from deregistration

You can turn on *deregistration protection* on an AMI to prevent accidental or malicious deletion. When you turn on deregistration protection, the AMI can’t be deregistered by any user, regardless of their IAM permissions. If you want to deregister the AMI, you must first turn off the deregistration protection on it.

When you turn on deregistration protection on an AMI, you have the option to include a 24-hour cooldown period. This cooldown period is the time during which deregistration protection remains in effect after you turn it off. During this cooldown period, the AMI can't be deregistered. When the cooldown period ends, the AMI can be deregistered.

Deregistration protection is turned off by default on all existing and new AMIs.

Turn on deregistration protection

Use the following procedures to turn on deregistration protection.

Console

To turn on deregistration protection

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. From the filter bar, choose **Owned by me** to list your available AMIs, or choose **Disabled images** to list your disabled AMIs.
4. Select the AMI on which you want to turn on deregistration protection, and then choose **Actions**, **Manage AMI deregistration protection**.
5. In the **Manage AMI deregistration protection** dialog box, you can turn on deregistration protection with or without a cooldown period. Choose one of the following options:
   - **Enable with a 24-hour cooldown period** – With a cooldown period, the AMI can't be deregistered for 24 hours when deregistration protection is turned off.
   - **Enable without cooldown** – Without a cooldown period, the AMI can be deregistered immediately when deregistration protection is turned off.
6. Choose **Save**.

AWS CLI

To turn on deregistration protection

Use the enable-image-deregistration-protection command. To enable the optional cooldown period, include the `--with-cooldown` option.

```
aws ec2 enable-image-deregistration-protection \
    --image-id ami-0abcdef1234567890 \
    --with-cooldown
```

PowerShell

To turn on deregistration protection

Use the Enable-EC2ImageDeregistrationProtection cmdlet. To enable the optional cooldown period, set the `-WithCooldown` parameter to `true`.

```
Enable-EC2ImageDeregistrationProtection `
    -ImageId ami-0abcdef1234567890 `
    -WithCooldown $true
```

Turn off deregistration protection

Use the following procedures to turn off deregistration protection.

If you chose to include a 24-hour cooldown period when you turned on deregistration protection for the AMI, then, when you turn off deregistration protection, you won't immediately be able to deregister the AMI. The cooldown period is the 24-hour time period during which deregistration protection remains in effect even after you turn it off. During this cooldown period, the AMI can't be deregistered. After the cooldown period ends, the AMI can be deregistered.

Console

To turn off deregistration protection

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. From the filter bar, choose **Owned by me** to list your available AMIs, or choose **Disabled images** to list your disabled AMIs.
4. Select the AMI to turn off deregistration protection, and then choose **Actions**, **Manage AMI deregistration protection**.
5. In the **Manage AMI deregistration protection** dialog box, choose **Disable**.
6. Choose **Save**.

AWS CLI

To turn off deregistration protection

Use the disable-image-deregistration-protection command.

```
aws ec2 disable-image-deregistration-protection --image-id ami-0abcdef1234567890
```

PowerShell

To turn off deregistration protection

Use the Disable-EC2ImageDeregistrationProtection cmdlet.

```
Disable-EC2ImageDeregistrationProtection -ImageId ami-0abcdef1234567890
```

Instance launch behavior with Amazon EC2 boot modes

When a computer boots, the first software that it runs is responsible for initializing the platform and providing an interface for the operating system to perform platform-specific operations.

In Amazon EC2, two variants of the boot mode software are supported: Unified Extensible Firmware Interface (UEFI) and Legacy BIOS.

Possible boot mode parameters on an AMI

An AMI can have one of the following boot mode parameter values: `uefi`, `legacy-bios`, or `uefi-preferred`. The AMI boot mode parameter is optional. For AMIs with no boot mode parameter, the instances launched from these AMIs use the default boot mode value of the instance type.

Purpose of the AMI boot mode parameter

The AMI boot mode parameter signals to Amazon EC2 which boot mode to use when launching an instance. When the boot mode parameter is set to `uefi`, EC2 attempts to launch the instance on UEFI. If the operating system is not configured to support UEFI, the instance launch will be unsuccessful.

UEFI Preferred boot mode parameter

You can create AMIs that support both UEFI and Legacy BIOS by using the `uefi-preferred` boot mode parameter. When the boot mode parameter is set to `uefi-preferred`, and if the instance type supports UEFI, the instance is launched on UEFI. If the instance type does not support UEFI, the instance is launched on Legacy BIOS.

> **Warning**
>
> Some features, like UEFI Secure Boot, are only available on instances that boot on UEFI. When you use the `uefi-preferred` AMI boot mode parameter with an instance type that does not support UEFI, the instance will launch as Legacy BIOS and the UEFI-dependent feature will be disabled. If you rely on the availability of a UEFI-dependent feature, set your AMI boot mode parameter to `uefi`.

Default boot modes for instance types

- Graviton instance types: UEFI
- Intel and AMD instance types: Legacy BIOS

Zone support

UEFI boot is not supported in Wavelength Zones or AWS Outposts.

Boot mode topics

- Requirements to launch an EC2 instance in UEFI boot mode
- Determine the boot mode parameter of an Amazon EC2 AMI
- Determine the supported boot modes of an EC2 instance type
- Determine the boot mode of an EC2 instance
- Determine the boot mode of the operating system for your EC2 instance
- Set the boot mode of an Amazon EC2 AMI
- UEFI variables for Amazon EC2 instances
- UEFI Secure Boot for Amazon EC2 instances

Requirements to launch an EC2 instance in UEFI boot mode

The boot mode of an instance is determined by the configuration of the AMI, the operating system contained in it, and the instance type. To launch an instance in UEFI boot mode, you must meet the following requirements.

AMI

The AMI must be configured for UEFI as follows:

- **Operating system** – The operating system contained in the AMI must be configured to use UEFI; otherwise, the instance launch will fail. For more information, see Determine the boot mode of the operating system for your EC2 instance.
- **AMI boot mode parameter** – The boot mode parameter of the AMI must be set to `uefi` or `uefi-preferred`. For more information, see Determine the boot mode parameter of an Amazon EC2 AMI.

Linux – The following Linux AMIs support UEFI:

- Amazon Linux 2023
- Amazon Linux 2 (Graviton instance types only)

For other Linux AMIs, you must configure the AMI, import the AMI through VM Import/Export, or import the AMI through CloudEndure.

Windows – The following Windows AMIs support UEFI:

- Windows_Server-2025-* (except for AMIs with the `BIOS-` name prefix)
- TPM-Windows_Server-2022-English-Full-Base
- TPM-Windows_Server-2022-English-Core-Base
- TPM-Windows_Server-2019-English-Full-Base
- TPM-Windows_Server-2019-English-Core-Base
- TPM-Windows_Server-2016-English-Full-Base
- TPM-Windows_Server-2016-English-Core-Base

Instance type

All instances built on the AWS Nitro System support both UEFI and Legacy BIOS, except the following: bare metal instances, DL1, G4ad, P4, u-3tb1, u-6tb1, u-9tb1, u-12tb1, u-18tb1, u-24tb1, and VT1. For more information, see the section called “Instance type boot mode”.

The following table shows that the boot mode of an instance (indicated by the **Resulting instance boot mode** column) is determined by a combination of the boot mode parameter of the AMI (column 1), the boot mode configuration of the operating system contained in the AMI (column 2), and the boot mode support of the instance type (column 3).

AMI boot mode parameter	Operating system boot mode configuration	Instance type boot mode support	Resulting instance boot mode
UEFI	UEFI	UEFI	UEFI
Legacy BIOS	Legacy BIOS	Legacy BIOS	Legacy BIOS
UEFI Preferred	UEFI	UEFI	UEFI
UEFI Preferred	UEFI	UEFI and Legacy BIOS	UEFI
UEFI Preferred	Legacy BIOS	Legacy BIOS	Legacy BIOS
UEFI Preferred	Legacy BIOS	UEFI and Legacy BIOS	Legacy BIOS
No boot mode specified - ARM	UEFI	UEFI	UEFI
No boot mode specified - x86	Legacy BIOS	UEFI and Legacy BIOS	Legacy BIOS

Determine the boot mode parameter of an Amazon EC2 AMI

The AMI boot mode parameter is optional. An AMI can have one of the following boot mode parameter values: `uefi`, `legacy-bios`, or `uefi-preferred`.

Some AMIs don't have a boot mode parameter. When an AMI has no boot mode parameter, the instances launched from the AMI use the default value of the instance type, which is `uefi` on Graviton, and `legacy-bios` on Intel and AMD instance types.

Console

To determine the boot mode parameter of an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**, and then select the AMI.
3. Inspect the **Boot mode** field.

- A value of **uefi** indicates that the AMI supports UEFI.
- A value of **uefi-preferred** indicates that the AMI supports both UEFI and Legacy BIOS.
- If there is no value, the instances launched from the AMI use the default value of the instance type.

To determine the boot mode parameter of an AMI when launching an instance

When launching an instance using the launch instance wizard, at the step to select an AMI, inspect the **Boot mode** field. For more information, see Application and OS Images (Amazon Machine Image).

AWS CLI

To determine the boot mode parameter of an AMI

Use the describe-images command to determine the boot mode of an AMI.

```
aws ec2 describe-images \
    --region us-east-1 \
    --image-id ami-0abcdef1234567890 \
    --query Images[].BootMode \
    --output text
```

The following is example output.

```
uefi
```

In the output, a value of `uefi` indicates that the AMI supports UEFI. A value of `uefi-preferred` indicates that the AMI supports both UEFI and Legacy BIOS. If there is no value, the instances launched from the AMI use the default value of the instance type.

PowerShell

To determine the boot mode parameter of an AMI

Use the Get-EC2Image cmdlet to determine the boot mode of an AMI.

```
Get-EC2Image -Region us-east-1 `
    -ImageId ami-0abcdef1234567890 | Format-List Name, BootMode, TpmSupport
```

The following is example output.

```
Name        : TPM-Windows_Server-2016-English-Full-Base-2023.05.10
BootMode    : uefi
TpmSupport : v2.0
```

In the output, the value of `BootMode` indicates the boot mode of the AMI. A value of `uefi` indicates that the AMI supports UEFI. A value of `uefi-preferred` indicates that the AMI supports both UEFI and Legacy BIOS. If there is no value, the instances launched from the AMI use the default value of the instance type.

Determine the supported boot modes of an EC2 instance type

You can determine the supported boot modes of an instance type.

The Amazon EC2 console does not display the supported boot modes of an instance type.

AWS CLI

Use the describe-instance-types command to determine the supported boot modes of an instance type. The `--query` parameter filters the output to return only the supported boot modes.

The following example shows that the specified instance type supports both UEFI and Legacy BIOS boot modes.

```
aws ec2 describe-instance-types \
    --instance-types m5.2xlarge \
    --query "InstanceTypes[*].SupportedBootModes"
```

The following is example output.

```
[
    [
        "legacy-bios",
        "uefi"
    ]
]
```

The following example shows that `t2.xlarge` supports only Legacy BIOS.

```
aws ec2 describe-instance-types \
    --instance-types t2.xlarge \
    --query "InstanceTypes[*].SupportedBootModes"
```

The following is example output.

```
[
    [
        "legacy-bios"
    ]
]
```

PowerShell

Use the [Get-EC2InstanceType](#) cmdlet to determine the supported boot modes of an instance type.

The following example shows that `m5.2xlarge` supports both UEFI and Legacy BIOS boot modes.

```
Get-EC2InstanceType -InstanceType m5.2xlarge | Format-List InstanceType,
 SupportedBootModes
```

The following is example output.

```
InstanceType       : m5.2xlarge
SupportedBootModes : {legacy-bios, uefi}
```

The following example shows that `t2.xlarge` supports only Legacy BIOS.

```
Get-EC2InstanceType -InstanceType t2.xlarge | Format-List InstanceType,
 SupportedBootModes
```

The following is example output.

```
InstanceType       : t2.xlarge
SupportedBootModes : {legacy-bios}
```

To determine the instance types that support UEFI

You can determine the instance types that support UEFI. The Amazon EC2 console does not display the UEFI support of an instance type.

AWS CLI

The available instance types vary by AWS Region. To see the available instance types that support UEFI in a Region, use the [describe-instance-types](#) command. Include the `--filters` parameter to scope the results to the instance types that support UEFI and the `--query` parameter to scope the output to the value of `InstanceType`.

```
aws ec2 describe-instance-types \
    --filters Name=supported-boot-mode,Values=uefi \
    --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

PowerShell

The available instance types vary by AWS Region. To see the available instance types that support UEFI in a Region, use the [Get-EC2InstanceType](#) cmdlet.

```
Get-EC2InstanceType | `
 Where-Object {$_.SupportedBootModes -Contains "uefi"} | `
 Sort-Object InstanceType | `
 Format-Table InstanceType -GroupBy CurrentGeneration
```

To determine the instance types that support UEFI Secure Boot and persist non-volatile variables

Bare metal instances do not support UEFI Secure Boot and non-volatile variables, so these examples exclude them from the output. For information about UEFI Secure Boot, see [UEFI Secure Boot for Amazon EC2 instances](#).

AWS CLI

Use the [describe-instance-types](#) command, and exclude the bare metal instances from the output.

```
aws ec2 describe-instance-types \
    --filters Name=supported-boot-mode,Values=uefi Name=bare-metal,Values=false \
```

```
    --query "InstanceTypes[*].[InstanceType]" \
    --output text | sort
```

PowerShell

Use the Get-EC2InstanceType cmdlet, and exclude the bare metal instances from the output.

```
Get-EC2InstanceType | `
    Where-Object { `
        $_.SupportedBootModes -Contains "uefi" -and `
        $_.BareMetal -eq $False
        } | `
    Sort-Object InstanceType  | `
    Format-Table InstanceType, SupportedBootModes, BareMetal, `
        @{Name="SupportedArchitectures";
 Expression={$_.ProcessorInfo.SupportedArchitectures}}
```

Determine the boot mode of an EC2 instance

The boot mode of an instance is displayed in the **Boot mode** field in the Amazon EC2 console, and by the `currentInstanceBootMode` parameter in the AWS CLI.

When an instance is launched, the value for its boot mode parameter is determined by the value of the boot mode parameter of the AMI used to launch it, as follows:

- An AMI with a boot mode parameter of `uefi` creates an instance with a `currentInstanceBootMode` parameter of `uefi`.
- An AMI with a boot mode parameter of `legacy-bios` creates an instance with a `currentInstanceBootMode` parameter of `legacy-bios`.
- An AMI with a boot mode parameter of `uefi-preferred` creates an instance with a `currentInstanceBootMode` parameter of `uefi` if the instance type supports UEFI; otherwise, it creates an instance with a `currentInstanceBootMode` parameter of `legacy-bios`.
- An AMI with no boot mode parameter value creates an instance with a `currentInstanceBootMode` parameter value that is dependent on whether the AMI architecture is ARM or x86 and the supported boot mode of the instance type. The default boot mode is `uefi` on Graviton instance types, and `legacy-bios` on Intel and AMD instance types.

Console

To determine the boot mode of an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Details** tab, inspect the **Boot mode** field.

AWS CLI

To determine the boot mode of an instance

Use the describe-instances command to determine the boot mode of an instance. You can also determine the boot mode of the AMI that was used to the create the instance.

```
aws ec2 describe-instances \
    --region us-east-1 \
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[].Instances[].BootMode \
    --output text
```

The following is example output.

```
uefi
```

PowerShell

To determine the boot mode of an instance

Use the Get-EC2Image cmdlet to determine the boot mode of an instance. You can also determine the boot mode of the AMI that was used to the create the instance.

```
(Get-EC2Instance `
    -InstanceId i-1234567890abcdef0).Instances | Format-List BootMode,
 CurrentInstanceBootMode, InstanceType, ImageId
```

The following is example output.

```
BootMode                : uefi
CurrentInstanceBootMode : uefi
```

```
InstanceType                 : c5a.large
ImageId                      : ami-0abcdef1234567890
```

Determine the boot mode of the operating system for your EC2 instance

The boot mode of the AMI guides Amazon EC2 on which boot mode to use to boot an instance. To view whether the operating system of your instance is configured for UEFI, you need to connect to your instance using SSH (Linux instances) or RDP (Windows instances).

Use the instructions for your instance's operating system.

Linux

To determine the boot mode of the instance's operating system

1. Connect to your Linux instance using SSH.
2. To view the boot mode of the operating system, try one of the following:

   - Run the following command.

     ```
     [ec2-user ~]$ sudo /usr/sbin/efibootmgr
     ```

     Expected output from an instance booted in UEFI boot mode

     ```
     BootCurrent: 0001
     Timeout: 0 seconds
     BootOrder: 0000,0001
     Boot0000* UiApp
     Boot0001* UEFI Amazon Elastic Block Store vol-xyz
     ```

   - Run the following command to verify the existence of the `/sys/firmware/efi` directory. This directory exists only if the instance boots using UEFI. If this directory doesn't exist, the command returns `Legacy BIOS Boot Detected`.

     ```
     [ec2-user ~]$ [ -d /sys/firmware/efi ] && echo "UEFI Boot Detected" || echo
      "Legacy BIOS Boot Detected"
     ```

     Expected output from an instance booted in UEFI boot mode

```
UEFI Boot Detected
```

Expected output from an instance booted in Legacy BIOS boot mode

```
Legacy BIOS Boot Detected
```

- Run the following command to verify that EFI appears in the `dmesg` output.

```
[ec2-user ~]$ dmesg | grep -i "EFI"
```

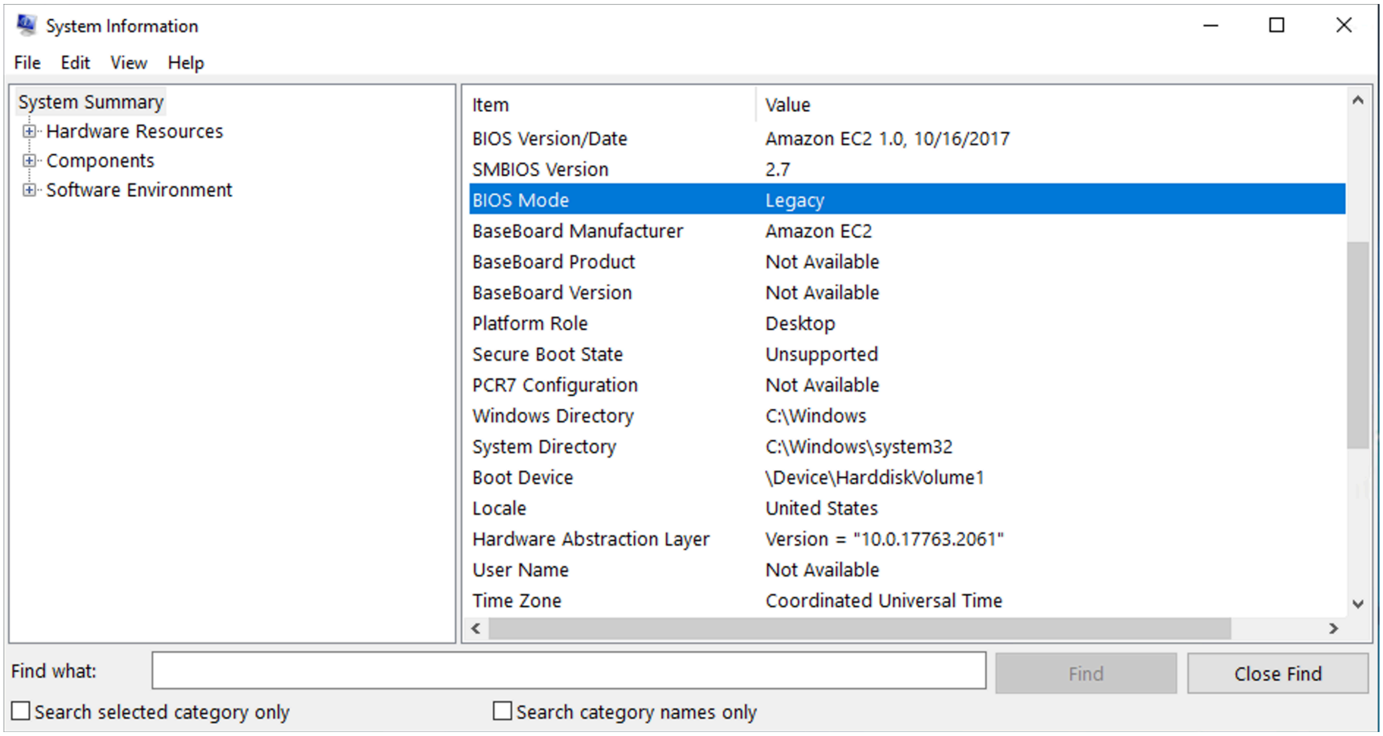
Expected output from an instance booted in UEFI boot mode

```
[    0.000000] efi: Getting EFI parameters from FDT:
[    0.000000] efi: EFI v2.70 by EDK II
```

Windows

To determine the boot mode of the instance's operating system

1. Connect to your Windows instance using RDP.
2. Go to **System Information** and check the **BIOS Mode** row.



Set the boot mode of an Amazon EC2 AMI

By default, an AMI inherits the boot mode of the EC2 instance used to create the AMI. For example, if you create an AMI from an EC2 instance running on Legacy BIOS, the boot mode of the new AMI is `legacy-bios`. If you create an AMI from an EC2 instance with a boot mode of `uefi-preferred`, the boot mode of the new AMI is `uefi-preferred`.

When you register an AMI, you can set the boot mode of the AMI to `uefi`, `legacy-bios`, or `uefi-preferred`.

When the AMI boot mode is set to `uefi-preferred`, the instance boots as follows:

- For instance types that support both UEFI and Legacy BIOS (for example, `m5.large`), the instance boots using UEFI.
- For instance types that support only Legacy BIOS (for example, `m4.large`), the instance boots using Legacy BIOS.

If you set the AMI boot mode to `uefi-preferred`, the operating system must support the ability to boot both UEFI and Legacy BIOS.

To convert an existing Legacy BIOS-based instance to UEFI, or an existing UEFI-based instance to Legacy BIOS, you must first modify the instance's volume and operating system to support the selected boot mode. Then, create a snapshot of the volume. Finally, create an AMI from the snapshot.

Considerations

- Setting the AMI boot mode parameter does not automatically configure the operating system for the specified boot mode. You must first make suitable modifications to the instance's volume and operating system to support booting using the selected boot mode. Otherwise, the resulting AMI is not usable. For example, if you are converting a Legacy BIOS-based Windows instance to UEFI, you can use the MBR2GPT tool from Microsoft to convert the system disk from MBR to GPT. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.
- You can't use the register-image command or the Register-EC2Image cmdlet to create an AMI that supports both NitroTPM and UEFI Preferred.
- Some features, like UEFI Secure Boot, are only available on instances that boot on UEFI. When you use the `uefi-preferred` AMI boot mode parameter with an instance type that does not support UEFI, the instance launches as Legacy BIOS and the UEFI-dependent feature is disabled. If you rely on the availability of a UEFI-dependent feature, set your AMI boot mode parameter to `uefi`.

AWS CLI

To set the boot mode of an AMI

1. Make suitable modifications to the instance's volume and operating system to support booting via the selected boot mode. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

   > **Warning**
   >
   > If you don't perform this step, the AMI will not be usable.

2. To find the volume ID of the instance, use the describe-instances command. You'll create a snapshot of this volume in the next step.

   ```
   aws ec2 describe-instances \
   ```

```
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[].Instances[].BlockDeviceMappings
```

The following is example output.

```
[
    [
        {
            "DeviceName": "/dev/xvda",
            "Ebs": {
                "AttachTime": "2024-07-11T01:05:51+00:00",
                "DeleteOnTermination": true,
                "Status": "attached",
                "VolumeId": "vol-1234567890abcdef0"
            }
        }
    ]
]
```

3. To create a snapshot of the volume, use the create-snapshot command. Use the volume ID from the previous step.

```
aws ec2 create-snapshot \
    --volume-id vol-01234567890abcdef \
    --description "my snapshot"
```

The following is example output.

```
{
    "Description": "my snapshot",
    "Encrypted": false,
    "OwnerId": "123456789012",
    "Progress": "",
    "SnapshotId": "snap-0abcdef1234567890",
    "StartTime": "",
    "State": "pending",
    "VolumeId": "vol-01234567890abcdef",
    "VolumeSize": 30,
    "Tags": []
}
```

4. Wait until the state of the snapshot is `completed` before you go to the next step. To get the state of the snapshot, use the [describe-snapshots](#) command with the snapshot ID from the previous step.

```
aws ec2 describe-snapshots \
    --snapshot-ids snap-0abcdef1234567890 \
    --query Snapshots[].State \
    --output text
```

   The following is example output.

```
completed
```

5. To create a new AMI, use the [register-image](#) command. Use the value of `SnapshotId` from the output of **CreateSnapshot**.

   - To set the boot mode to UEFI, add the `--boot-mode` parameter with a value of `uefi`.

```
aws ec2 register-image \
   --description "my image" \
   --name "my-image" \
   --block-device-mappings "DeviceName=/dev/
sda1,Ebs={SnapshotId=snap-0abcdef1234567890,DeleteOnTermination=true}" \
   --root-device-name /dev/sda1 \
   --virtualization-type hvm \
   --ena-support \
   --boot-mode uefi
```

   - To set the boot mode to `uefi-preferred`, set the value of `--boot-mode` to `uefi-preferred`

```
aws ec2 register-image \
   --description "my description" \
   --name "my-image" \
   --block-device-mappings "DeviceName=/dev/
sda1,Ebs={SnapshotId=snap-0abcdef1234567890,DeleteOnTermination=true}" \
   --root-device-name /dev/sda1 \
   --virtualization-type hvm \
   --ena-support \
   --boot-mode uefi-preferred
```

6. (Optional) To verify that the newly-created AMI has the boot mode that you specified, use the describe-images command.

```
aws ec2 describe-images \
    --image-id ami-1234567890abcdef0 \
    --query Images[].BootMode \
    --output text
```

The following is example output.

```
uefi
```

PowerShell

To set the boot mode of an AMI

1. Make suitable modifications to the instance's volume and operating system to support booting via the selected boot mode. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

> **Warning**
> If you don't perform this step, the AMI will not be usable.

2. To find the volume ID of the instance, use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance `
    -InstanceId i-1234567890abcdef0).Instances.BlockDeviceMappings.Ebs
```

The following is example output.

```
AssociatedResource  :
AttachTime          : 7/11/2024 1:05:51 AM
DeleteOnTermination : True
Operator            :
Status              : attached
VolumeId            : vol-01234567890abcdef
```

3. To create a snapshot of the volume, use the [New-EC2Snapshot](#) cmdlet. Use the volume ID from the previous step.

```
New-EC2Snapshot `
    -VolumeId vol-01234567890abcdef `
    -Description "my snapshot"
```

   The following is example output.

```
AvailabilityZone          :
Description               : my snapshot
Encrypted                 : False
FullSnapshotSizeInBytes   : 0
KmsKeyId                  :
OwnerId                   : 123456789012
RestoreExpiryTime         :
SnapshotId                : snap-0abcdef1234567890
SseType                   :
StartTime                 : 4/25/2025 6:08:59 PM
State                     : pending
StateMessage              :
VolumeId                  : vol-01234567890abcdef
VolumeSize                : 30
```

4. Wait until the state of the snapshot is `completed` before you go to the next step. To get the state of the snapshot, use the [Get-EC2Snapshot](#) cmdlet with the snapshot ID from the previous step.

```
(Get-EC2Snapshot `
    -SnapshotId snap-0abcdef1234567890).State.Value
```

   The following is example output.

```
completed
```

5. To create a new AMI, use the [Register-EC2Image](#) cmdlet. Use the value of `SnapshotId` from the output of **New-EC2Snapshot**.

   - To set the boot mode to UEFI, add the `-BootMode` parameter with a value of `uefi`.

```
$block = @{SnapshotId=snap-0abcdef1234567890}
```

```
Register-EC2Image `
    -Description "my image" `
    -Name "my-image" `
    -BlockDeviceMapping @{DeviceName="/dev/xvda";Ebs=$block} `
    -RootDeviceName /dev/xvda `
    -EnaSupport $true `
    -BootMode uefi
```

- To set the boot mode to `uefi-preferred`, set the value of `-BootMode` to `uefi-preferred`

```
$block = @{SnapshotId=snap-0abcdef1234567890}
Register-EC2Image `
    -Description "my image" `
    -Name "my-image" `
    -BlockDeviceMapping @{DeviceName="/dev/xvda";Ebs=$block} `
    -RootDeviceName /dev/xvda `
    -EnaSupport $true `
    -BootMode uefi-preferred
```

6. (Optional) To verify that the newly-created AMI has the boot mode that you specified, use the Get-EC2Image cmdlet.

```
(Get-EC2Image `
    -ImageId ami-1234567890abcdef0).BootMode.Value
```

The following is example output.

```
uefi
```

UEFI variables for Amazon EC2 instances

When you launch an instance where the boot mode is set to UEFI, a key-value store for variables is created. The store can be used by UEFI and the instance operating system for storing UEFI variables.

UEFI variables are used by the boot loader and the operating system to configure early system startup. They allow the operating system to manage certain settings of the boot process, like the boot order, or managing the keys for UEFI Secure Boot.

> **Warning**
>
> Anyone who can connect to the instance (and potentially any software running on the instance), or anyone with permissions to use the GetInstanceUefiData API on the instance can read the variables. You should never store sensitive data, such as passwords or personally identifiable information, in the UEFI variable store.

UEFI variable persistence

- For instances that were launched on or before May 10, 2022, UEFI variables are wiped on reboot or stop.
- For instances that are launched on or after May 11, 2022, UEFI variables that are marked as non-volatile are persisted on reboot and stop/start.
- Bare metal instances don't preserve UEFI non-volatile variables across instance stop/start operations.

UEFI Secure Boot for Amazon EC2 instances

UEFI Secure Boot builds on the long-standing secure boot process of Amazon EC2, and provides additional defense-in-depth that helps customers secure software from threats that persist across reboots. It ensures that the instance only boots software that is signed with cryptographic keys. The keys are stored in the key database of the UEFI non-volatile variable store. UEFI Secure Boot prevents unauthorized modification of the instance boot flow.

Contents

How UEFI Secure Boot works with Amazon EC2 instances

UEFI Secure Boot is a feature specified in UEFI, which provides verification about the state of the boot chain. It is designed to ensure that only cryptographically verified UEFI binaries are executed after the self-initialization of the firmware. These binaries include UEFI drivers and the main bootloader, as well as chain-loaded components.

UEFI Secure Boot specifies four key databases, which are used in a chain of trust. The databases are stored in the UEFI variable store.

The chain of trust is as follows:

Platform key (PK) database

The PK database is the root of trust. It contains a single public PK key that is used in the chain of trust for updating the key exchange key (KEK) database.

To change the PK database, you must have the private PK key to sign an update request. This includes deleting the PK database by writing an empty PK key.

Key exchange key (KEK) database

The KEK database is a list of public KEK keys that are used in the chain of trust for updating the signature (db) and denylist (dbx) databases.

To change the public KEK database, you must have the private PK key to sign an update request.

Signature (db) database

The db database is a list of public keys and hashes that are used in the chain of trust to validate all UEFI boot binaries.

To change the db database, you must have the private PK key or any of the private KEK keys to sign an update request.

Signature denylist (dbx) database

The dbx database is a list of public keys and binary hashes that are not trusted, and are used in the chain of trust as a revocation file.

The dbx database always takes precedence over all other key databases.

To change the dbx database, you must have the private PK key or any of the private KEK keys to sign an update request.

The UEFI Forum maintains a publicly available dbx for many known-bad binaries and certs at https://uefi.org/revocationlistfile.

Important

UEFI Secure Boot enforces signature validation on any UEFI binaries. To permit execution of a UEFI binary in UEFI Secure Boot, you sign it with any of the private db keys described above.

By default, UEFI Secure Boot is disabled and the system is in `SetupMode`. When the system is in `SetupMode`, all key variables can be updated without a cryptographic signature. When the PK is set, UEFI Secure Boot is enabled and the SetupMode is exited.

Requirements for UEFI Secure Boot on Amazon EC2

When you launch an Amazon EC2 instance with a supported AMI and a supported instance type, that instance will automatically validate UEFI boot binaries against its UEFI Secure Boot database. No additional configuration is required. You can also configure UEFI Secure Boot on an instance after launch.

Note

UEFI Secure Boot protects your instance and its operating system against boot flow modifications. If you create a new AMI from a source AMI that has UEFI Secure Boot enabled and modify certain parameters during the copy process, such as changing the `UefiData` within the AMI, you can disable UEFI Secure Boot.

Contents

Supported AMIs

Linux AMIs

To launch a Linux instance, the Linux AMI must have UEFI Secure Boot enabled.

Amazon Linux supports UEFI Secure Boot starting with AL2023 release 2023.1. However, UEFI Secure Boot isn't enabled in the default AMIs. For more information, see UEFI Secure Boot in the

AL2023 User Guide. Older versions of Amazon Linux AMIs aren't enabled for UEFI Secure Boot. To use a supported AMI, you must perform a number of configuration steps on your own Linux AMI. For more information, see Create a Linux AMI with custom UEFI Secure Boot keys.

Windows AMIs

To launch a Windows instance, the Windows AMI must have UEFI Secure Boot enabled. To find an AWS Windows AMI that's preconfigured for UEFI Secure Boot with Microsoft keys, see Find Windows Server AMIs configured with NitroTPM and UEFI Secure Boot in the *AWS Windows AMIs Reference*.

Currently, we do not support importing Windows with UEFI Secure Boot by using the import-image command.

Supported instance types

All virtualized instance types that support UEFI also support UEFI Secure Boot. For the instance types that support UEFI Secure Boot, see Requirements for UEFI boot mode.

> **Note**
>
> Bare metal instance types do not support UEFI Secure Boot.

Verify whether an Amazon EC2 instance is enabled for UEFI Secure Boot

You can use the following procedures to determine whether an Amazon EC2 is enabled for UEFI Secure Boot.

Linux instances

You can use the `mokutil` utility to verify whether a Linux instance is enabled for UEFI Secure Boot. If `mokutil` is not installed on your instance, you must install it. For the installation instructions for Amazon Linux 2, see Find and install software packages on an Amazon Linux 2 instance. For other Linux distributions, see their specific documentation.

To verify whether a Linux instance is enabled for UEFI Secure Boot

Connect to your instance and run the following command as `root` in a terminal window.

```
mokutil --sb-state
```

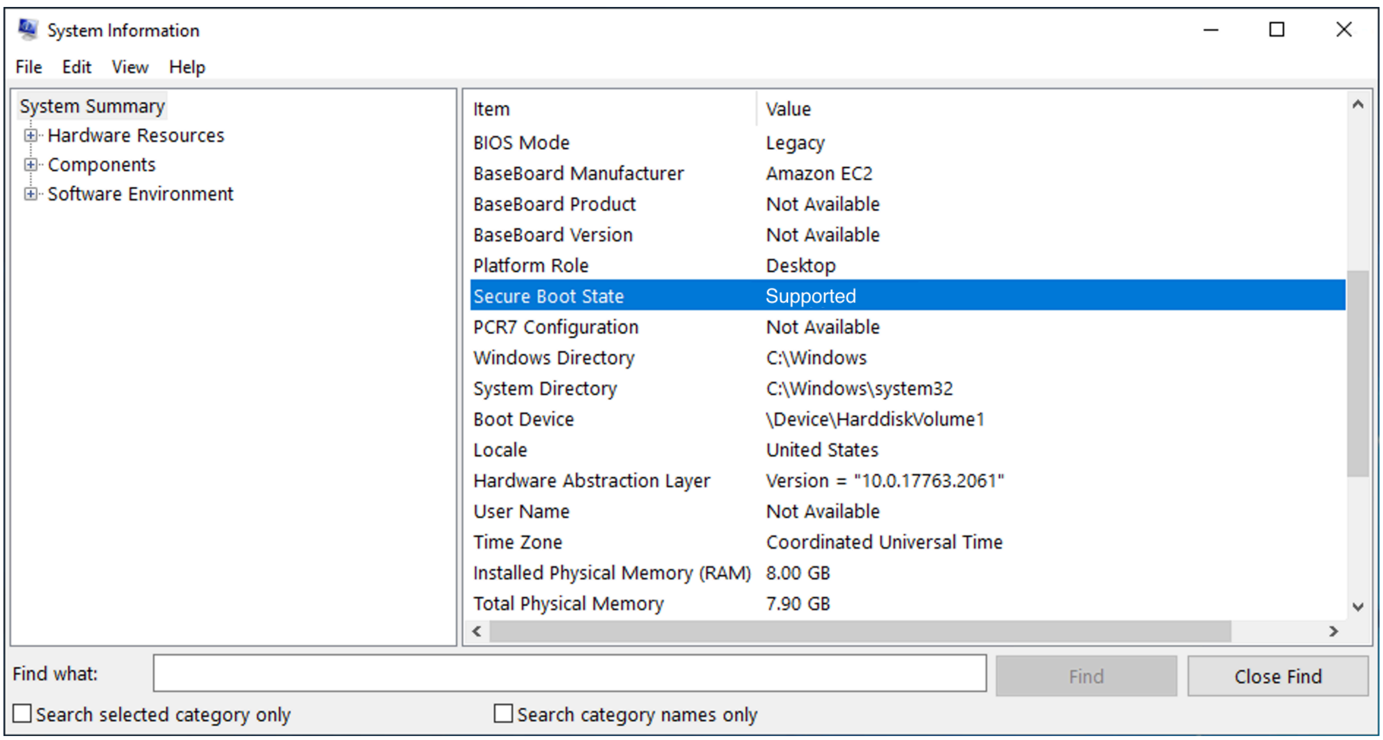
The following is example output.

- If UEFI Secure Boot is enabled, the output contains `SecureBoot enabled`.
- If UEFI Secure Boot is not enabled, the output contains `SecureBoot disabled` or `Failed to read SecureBoot`.

Windows instances

To verify whether a Windows instance is enabled for UEFI Secure Boot

1. Connect to your instance.
2. Open the msinfo32 tool.
3. Check the **Secure Boot State** field. If UEFI Secure Boot is enabled, the value is **Supported**, as shown in the following image.



You can also use the Windows PowerShell Cmdlet `Confirm-SecureBootUEFI` to check the the Secure Boot status. For more information about the cmdlet, see Confirm-SecureBootUEFI in the Microsoft Documentation.

Create a Linux AMI with custom UEFI Secure Boot keys

These instructions show you how to create a Linux AMI with UEFI Secure Boot and custom-made private keys. Amazon Linux supports UEFI Secure Boot starting with AL2023 release 2023.1. For more information, see [UEFI Secure Boot on AL2023](#) in the *Amazon Linux 2023 User Guide*.

> **Important**
>
> The following procedure is intended for **advanced users only**. You must have sufficient knowledge of SSL and Linux distribution boot flow to use these procedures.

Prerequisites

- The following tools will be used:
  - OpenSSL – https://www.openssl.org/
  - efivar – https://github.com/rhboot/efivar
  - efitools – https://git.kernel.org/pub/scm/linux/kernel/git/jejb/efitools.git/
  - get-instance-uefi-data command
- Your Linux instance must have been launched with a Linux AMI that supports UEFI boot mode, and have non-volatile data present.

Newly created instances without UEFI Secure Boot keys are created in `SetupMode`, which allows you to enroll your own keys. Some AMIs come preconfigured with UEFI Secure Boot and you cannot change the existing keys. If you want to change the keys, you must create a new AMI based on the original AMI.

You have two ways to propagate the keys in the variable store, which are described in Option A and Option B that follow. Option A describes how to do this from within the instance, mimicking the flow of real hardware. Option B describes how to create a binary blob, which is then passed as a base64-encoded file when you create the AMI. For both options, you must first create the three key pairs, which are used for the chain of trust.

To create a Linux AMI that supports UEFI Secure Boot, first create the three key pairs, and then complete either Option A or Option B, but not both:

- Task 1: Create key pairs
- Task 2 - Option A: Add keys to the variable store from within the instance

- Task 2 - Option B: Create a binary blob containing a pre-filled variable store

Task 1: Create key pairs

UEFI Secure Boot is based on the following three key databases, which are used in a chain of trust: the platform key (PK), the key exchange key (KEK), and the signature database (db).[1]

You create each key on the instance. To prepare the public keys in a format that is valid for the UEFI Secure Boot standard, you create a certificate for each key. DER defines the SSL format (binary encoding of a format). You then convert each certificate into a UEFI signature list, which is the binary format that is understood by UEFI Secure Boot. And finally, you sign each certificate with the relevant key.

Tasks

- Prepare to create the key pairs
- Key pair 1: Create the platform key (PK)
- Key pair 2: Create the key exchange key (KEK)
- Key pair 3: Create the signature database (db)
- Sign the boot image (kernel) with the private key

Prepare to create the key pairs

Before creating the key pairs, create a globally unique identifier (GUID) to be used in key generation.

1. Connect to the instance.
2. Run the following command in a shell prompt.

```
uuidgen --random > GUID.txt
```

Key pair 1: Create the platform key (PK)

The PK is the root of trust for UEFI Secure Boot instances. The private PK is used to update the KEK, which in turn can be used to add authorized keys to the signature database (db).

The X.509 standard is used for creating the key pair. For information about the standard, see X.509 on *Wikipedia*.

To create the PK

1. Create the key. You must name the variable PK.

```
openssl req -newkey rsa:4096 -nodes -keyout PK.key -new -x509 -sha256 -days 3650 -
subj "/CN=Platform key/" -out PK.crt
```

   The following parameters are specified:

   - `-keyout PK.key` – The private key file.
   - `-days 3650` – The number of days that the certificate is valid.
   - `-out PK.crt` – The certificate that is used to create the UEFI variable.
   - `CN=Platform key` – The common name (CN) for the key. You can enter the name of your own organization instead of *Platform key*.

2. Create the certificate.

```
openssl x509 -outform DER -in PK.crt -out PK.cer
```

3. Convert the certificate into a UEFI signature list.

```
cert-to-efi-sig-list -g "$(< GUID.txt)" PK.crt PK.esl
```

4. Sign the UEFI signature list with the private PK (self-signed).

```
sign-efi-sig-list -g "$(< GUID.txt)" -k PK.key -c PK.crt PK PK.esl PK.auth
```

Key pair 2: Create the key exchange key (KEK)

The private KEK is used to add keys to the db, which is the list of authorized signatures to boot on the system.

To create the KEK

1. Create the key.

```
openssl req -newkey rsa:4096 -nodes -keyout KEK.key -new -x509 -sha256 -days 3650 -
subj "/CN=Key Exchange Key/" -out KEK.crt
```

2. Create the certificate.

```
openssl x509 -outform DER -in KEK.crt -out KEK.cer
```

3. Convert the certificate into a UEFI signature list.

```
cert-to-efi-sig-list -g "$(< GUID.txt)" KEK.crt KEK.esl
```

4. Sign the signature list with the private PK.

```
sign-efi-sig-list -g "$(< GUID.txt)" -k PK.key -c PK.crt KEK KEK.esl KEK.auth
```

Key pair 3: Create the signature database (db)

The db list contains authorized keys that are authorized to be booted on the system. To modify the list, the private KEK is necessary. Boot images will be signed with the private key that is created in this step.

To create the db

1. Create the key.

```
openssl req -newkey rsa:4096 -nodes -keyout db.key -new -x509 -sha256 -days 3650 -
subj "/CN=Signature Database key/" -out db.crt
```

2. Create the certificate.

```
openssl x509 -outform DER -in db.crt -out db.cer
```

3. Convert the certificate into a UEFI signature list.

```
cert-to-efi-sig-list -g "$(< GUID.txt)" db.crt db.esl
```

4. Sign the signature list with the private KEK.

```
sign-efi-sig-list -g "$(< GUID.txt)" -k KEK.key -c KEK.crt db db.esl db.auth
```

Sign the boot image (kernel) with the private key

For Ubuntu 22.04, the following images require signatures.

```
/boot/efi/EFI/ubuntu/shimx64.efi
/boot/efi/EFI/ubuntu/mmx64.efi
/boot/efi/EFI/ubuntu/grubx64.efi
/boot/vmlinuz
```

To sign an image

Use the following syntax to sign an image.

```
sbsign --key db.key --cert db.crt --output /boot/vmlinuz /boot/vmlinuz
```

> **Note**
>
> You must sign all new kernels. */boot/vmlinuz* will usually symlink to the last installed kernel.

Refer to the documentation for your distribution to find out about your boot chain and required images.

[1] Thanks to the ArchWiki community for all of the work they have done. The commands for creating the PK, creating the KEK, creating the DB, and signing the image are from Creating keys, authored by the ArchWiki Maintenance Team and/or the ArchWiki contributors.

Task 2 - Option A: Add keys to the variable store from within the instance

After you have created the three key pairs, you can connect to your instance and add the keys to the variable store from within the instance by completing the following steps. Alternatively, complete the steps in the section called "Task 2 - Option B: Create a binary blob containing a pre-filled variable store".

Option A steps:

- Step 1: Launch an instance that will support UEFI Secure Boot
- Step 2: Configure an instance to support UEFI Secure Boot
- Step 3: Create an AMI from the instance

Step 1: Launch an instance that will support UEFI Secure Boot

When you launch an instance with the following prerequisites, the instance will then be ready to be configured to support UEFI Secure Boot. You can only enable support for UEFI Secure Boot on an instance at launch; you can't enable it later.

Prerequisites

- **AMI –** The Linux AMI must support UEFI boot mode. To verify that the AMI supports UEFI boot mode, the AMI boot mode parameter must be **uefi**. For more information, see Determine the boot mode parameter of an Amazon EC2 AMI.

  Note that AWS only provides Linux AMIs configured to support UEFI for Graviton-based instance types. AWS currently does not provide x86_64 Linux AMIs that support UEFI boot mode. You can configure your own AMI to support UEFI boot mode for all architectures. To configure your own AMI to support UEFI boot mode, you must perform a number of configuration steps on your own AMI. For more information, see Set the boot mode of an Amazon EC2 AMI.
- **Instance type –** All virtualized instance types that support UEFI also support UEFI Secure Boot. Bare metal instance types do not support UEFI Secure Boot. For the instance types that support UEFI Secure Boot, see Requirements for UEFI boot mode.
- Launch your instance after the release of UEFI Secure Boot. Only instances launched after May 10, 2022 (when UEFI Secure Boot was released) can support UEFI Secure Boot.

After you've launched your instance, you can verify that it is ready to be configured to support UEFI Secure Boot (in other words, you can proceed to Step 2) by checking whether UEFI data is present. The presence of UEFI data indicates that non-volatile data is persisted.

To verify whether your instance is ready for Step 2

Use the get-instance-uefi-data command and specify the instance ID.

```
aws ec2 get-instance-uefi-data --instance-id i-1234567890abcdef0
```

The instance is ready for Step 2 if UEFI data is present in the output. If the output is empty, the instance cannot be configured to support UEFI Secure Boot. This can happen if your instance was launched before UEFI Secure Boot support became available. Launch a new instance and try again.

Step 2: Configure an instance to support UEFI Secure Boot

Enroll the key pairs in your UEFI variable store on the instance

> **Warning**
>
> You must sign your boot images *after* you enroll the keys, otherwise you won't be able to boot your instance.

After you create the signed UEFI signature lists (PK, KEK, and db), they must be enrolled into the UEFI firmware.

Writing to the PK variable is possible only if:

- No PK is enrolled yet, which is indicated if the `SetupMode` variable is `1`. Check this by using the following command. The output is either `1` or `0`.

  ```
  efivar -d -n 8be4df61-93ca-11d2-aa0d-00e098032b8c-SetupMode
  ```
- The new PK is signed by the private key of the existing PK.

To enroll the keys in your UEFI variable store

The following commands must be run on the instance.

If SetupMode is enabled (the value is 1), the keys can be enrolled by running the following commands on the instance:

```
[ec2-user ~]$ efi-updatevar -f db.auth db
```

```
[ec2-user ~]$ efi-updatevar -f KEK.auth KEK
```

```
[ec2-user ~]$ efi-updatevar -f PK.auth PK
```

To verify that UEFI Secure Boot is enabled

To verify that UEFI Secure Boot is enabled, follow the steps in Verify whether an Amazon EC2 instance is enabled for UEFI Secure Boot.

You can now export your UEFI variable store with the get-instance-uefi-data CLI command, or you continue to the next step and sign your boot images to reboot into a UEFI Secure Boot-enabled instance.

Step 3: Create an AMI from the instance

To create an AMI from the instance, you can use the console or the `CreateImage` API, CLI, or SDKs. For the console instructions, see Create an Amazon EBS-backed AMI. For the API instructions, see CreateImage.

> **Note**
>
> The `CreateImage` API automatically copies the UEFI variable store of the instance to the AMI. The console uses the `CreateImage` API. After you launch instances using this AMI, the instances will have the same UEFI variable store.

Task 2 - Option B: Create a binary blob containing a pre-filled variable store

After you have created the three key pairs, you can create a binary blob containing a pre-filled variable store containing the UEFI Secure Boot keys. Alternatively, complete the steps in the section called "Task 2 - Option A: Add keys to the variable store from within the instance".

> **Warning**
>
> You must sign your boot images *before* you enroll the keys, otherwise you won't be able to boot your instance.

Option B steps:

- Step 1: Create a new variable store or update an existing one
- Step 2: Upload the binary blob on AMI creation

Step 1: Create a new variable store or update an existing one

You can create the variable store *offline* without a running instance by using the python-uefivars tool. The tool can create a new variable store from your keys. The script currently supports the EDK2 format, the AWS format, and a JSON representation that is easier to edit with higher-level tooling.

To create the variable store offline without a running instance

1. Download the tool at the following link.

```
https://github.com/awslabs/python-uefivars
```

2. Create a new variable store from your keys by running the following command. This will create a base64-encoded binary blob in *your_binary_blob*.bin. The tool also supports updating a binary blob via the `-I` parameter.

```
./uefivars.py -i none -o aws -O your_binary_blob.bin -P PK.esl -K KEK.esl --db
 db.esl --dbx dbx.esl
```

Step 2: Upload the binary blob on AMI creation

Use [register-image](https://docs.aws.amazon.com/cli/latest/reference/ec2/register-image.html) to pass your UEFI variable store data. For the `--uefi-data` parameter, specify your binary blob, and for the `--boot-mode` parameter, specify `uefi`.

```
aws ec2 register-image \
    --name uefi_sb_tpm_register_image_test \
    --uefi-data $(cat your_binary_blob.bin) \
    --block-device-mappings "DeviceName=/dev/sda1,Ebs=
 {SnapshotId=snap-0123456789example,DeleteOnTermination=true}" \
    --architecture x86_64 \
    --root-device-name /dev/sda1 \
    --virtualization-type hvm \
    --ena-support \
    --boot-mode uefi
```

Create the AWS binary blob for UEFI Secure Boot

You can use the following steps to customize the UEFI Secure Boot variables during AMI creation. The KEK that is used in these steps is current as of September 2021. If Microsoft updates the KEK, you must use the latest KEK.

To create the AWS binary blob

1. Create an empty PK signature list.

```
touch empty_key.crt
```

```
cert-to-efi-sig-list empty_key.crt PK.esl
```

2. Download the KEK certificates.

```
https://go.microsoft.com/fwlink/?LinkId=321185
```

3. Wrap the KEK certificates in a UEFI signature list (`siglist`).

```
sbsiglist --owner 77fa9abd-0359-4d32-bd60-28f4e78f784b --type x509 --output
 MS_Win_KEK.esl MicCorKEKCA2011_2011-06-24.crt
```

4. Download Microsoft's db certificates.

```
https://www.microsoft.com/pkiops/certs/MicWinProPCA2011_2011-10-19.crt
https://www.microsoft.com/pkiops/certs/MicCorUEFCA2011_2011-06-27.crt
```

5. Generate the db signature list.

```
sbsiglist --owner 77fa9abd-0359-4d32-bd60-28f4e78f784b --type x509 --output
 MS_Win_db.esl MicWinProPCA2011_2011-10-19.crt
sbsiglist --owner 77fa9abd-0359-4d32-bd60-28f4e78f784b --type x509 --output
 MS_UEFI_db.esl MicCorUEFCA2011_2011-06-27.crt
cat MS_Win_db.esl MS_UEFI_db.esl > MS_db.esl
```

6. The Unified Extensible Firmware Interface Forum no longer provides the DBX files. They are now provided by Microsoft on GitHub. Download the latest DBX update from the Microsoft Secure Boot updates repository at https://github.com/microsoft/secureboot_objects.

7. Unpack the signed update-binary.

   Create `SplitDbxContent.ps1` with the script content below. Alternatively, you can install the script from [PowerShell Gallery](#) using `Install-Script -Name SplitDbxContent`.

```

#>

<#
.DESCRIPTION
 Splits a DBX update package into the new DBX variable contents and the signature
 authorizing the change.
 To apply an update using the output files of this script, try:
 Set-SecureBootUefi -Name dbx -ContentFilePath .\content.bin -SignedFilePath .
\signature.p7 -Time 2010-03-06T19:17:21Z -AppendWrite'
.EXAMPLE
.\SplitDbxAuthInfo.ps1 DbxUpdate_x64.bin
#>

# Get file from script input
$file  = Get-Content -Encoding Byte $args[0]

# Identify file signature
$chop = $file[40..($file.Length - 1)]
if (($chop[0] -ne 0x30) -or ($chop[1] -ne 0x82 )) {
    Write-Error "Cannot find signature"
    exit 1
}

# Signature is known to be ASN size plus header of 4 bytes
```

```
$sig_length = ($chop[2] * 256) + $chop[3] + 4
$sig = $chop[0..($sig_length - 1)]

if ($sig_length -gt ($file.Length + 40)) {
    Write-Error "Signature longer than file size!"
    exit 1
}

# Content is everything else
$content = $file[0..39] + $chop[$sig_length..($chop.Length - 1)]

# Write signature and content to files
Set-Content -Encoding Byte signature.p7 $sig
Set-Content -Encoding Byte content.bin $content
```

Use the script to unpack the signed DBX files.

```
PS C:\Windows\system32> SplitDbxContent.ps1 .\dbx.bin
```

This produces two files — `signature.p7` and `content.bin`. Use `content.bin` in the next step.

8. Build a UEFI variable store using the `uefivars.py` script.

```
./uefivars.py -i none -o aws -O uefiblob-microsoft-keys-empty-pk.bin -P ~/PK.esl -K
 ~/MS_Win_KEK.esl --db ~/MS_db.esl  --dbx ~/content.bin
```

9. Check the binary blob and the UEFI variable store.

```
./uefivars.py -i aws -I uefiblob-microsoft-keys-empty-pk.bin -o json | less
```

10. You can update the blob by passing it to the same tool again.

```
./uefivars.py -i aws -I uefiblob-microsoft-keys-empty-pk.bin -o aws -O uefiblob-
microsoft-keys-empty-pk.bin -P ~/PK.esl -K ~/MS_Win_KEK.esl --db ~/MS_db.esl  --dbx
 ~/content.bin
```

Expected output

```
Replacing PK
Replacing KEK
```

```
Replacing db
Replacing dbx
```

Use encryption with EBS-backed AMIs

AMIs that are backed by Amazon EBS snapshots can take advantage of Amazon EBS encryption. Snapshots of both data and root volumes can be encrypted and attached to an AMI. You can launch instances and copy images with full EBS encryption support included. Encryption parameters for these operations are supported in all Regions where AWS KMS is available.

EC2 instances with encrypted EBS volumes are launched from AMIs in the same way as other instances. In addition, when you launch an instance from an AMI backed by unencrypted EBS snapshots, you can encrypt some or all of the volumes during launch.

Like EBS volumes, snapshots in AMIs can be encrypted by either your default AWS KMS key, or to a customer managed key that you specify. You must in all cases have permission to use the selected KMS key.

AMIs with encrypted snapshots can be shared across AWS accounts. For more information, see [Understand shared AMI usage in Amazon EC2](#).

Encryption with EBS-backed AMIs topics

- [Instance-launching scenarios](#)
- [Image-copying scenarios](#)

Instance-launching scenarios

Amazon EC2 instances are launched from AMIs using the `RunInstances` action with parameters supplied through block device mapping, either by means of the AWS Management Console or directly using the Amazon EC2 API or CLI. For more information, see [Block device mappings for volumes on Amazon EC2 instances](#). For examples of controlling block device mapping from the AWS CLI, see [Launch, List, and Terminate EC2 Instances](#).

By default, without explicit encryption parameters, a `RunInstances` action maintains the existing encryption state of an AMI's source snapshots while restoring EBS volumes from them. If encryption by default is enabled, all volumes created from the AMI (whether from encrypted or unencrypted snapshots) are encrypted. If encryption by default is not enabled, the instance maintains the encryption state of the AMI.

You can also launch an instance and simultaneously apply a new encryption state to the resulting volumes by supplying encryption parameters. Consequently, the following behaviors are observed:

Launch with no encryption parameters

- An unencrypted snapshot is restored to an unencrypted volume, unless encryption by default is enabled, in which case all the newly created volumes will be encrypted.
- An encrypted snapshot that you own is restored to a volume that is encrypted to the same KMS key.
- An encrypted snapshot that you do not own (for example, the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key.

The default behaviors can be overridden by supplying encryption parameters. The available parameters are `Encrypted` and `KmsKeyId`. Setting only the `Encrypted` parameter results in the following:

Instance launch behaviors with `Encrypted` set, but no `KmsKeyId` specified

- An unencrypted snapshot is restored to an EBS volume that is encrypted by your AWS account's default KMS key.
- An encrypted snapshot that you own is restored to an EBS volume encrypted by the same KMS key. (In other words, the `Encrypted` parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key. (In other words, the `Encrypted` parameter has no effect.)

Setting both the `Encrypted` and `KmsKeyId` parameters allows you to specify a non-default KMS key for an encryption operation. The following behaviors result:

Instance with both `Encrypted` and `KmsKeyId` set

- An unencrypted snapshot is restored to an EBS volume encrypted by the specified KMS key.
- An encrypted snapshot is restored to an EBS volume encrypted not to the original KMS key, but instead to the specified KMS key.

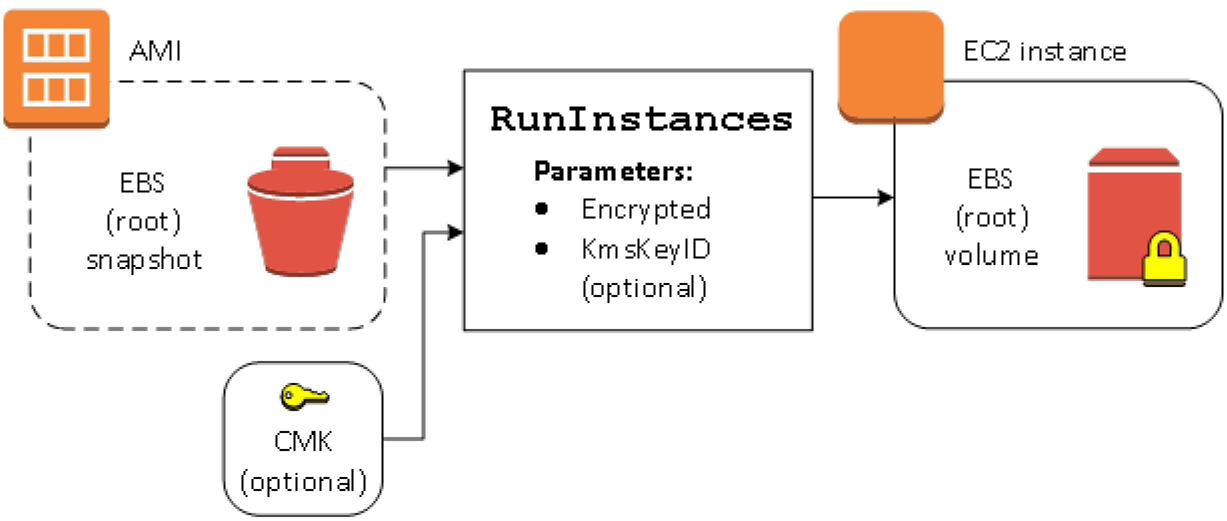
Submitting a `KmsKeyId` without also setting the `Encrypted` parameter results in an error.

The following sections provide examples of launching instances from AMIs using non-default encryption parameters. In each of these scenarios, parameters supplied to the `RunInstances` action result in a change of encryption state during restoration of a volume from a snapshot.

For information about using the console to launch an instance from an AMI, see Launch an Amazon EC2 instance.

Encrypt a volume during launch

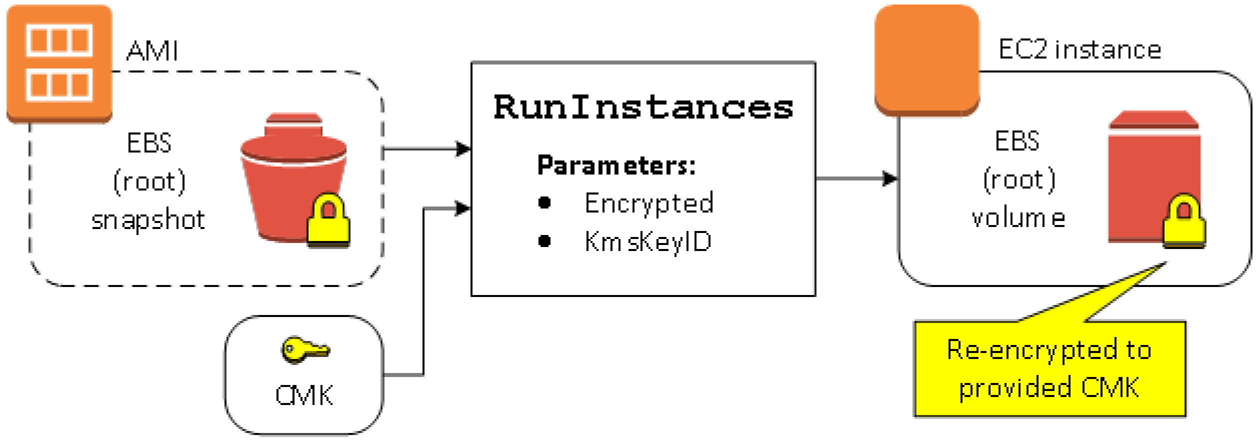
In this example, an AMI backed by an unencrypted snapshot is used to launch an EC2 instance with an encrypted EBS volume.



The `Encrypted` parameter alone results in the volume for this instance being encrypted. Providing a `KmsKeyId` parameter is optional. If no KMS key ID is specified, the AWS account's default KMS key is used to encrypt the volume. To encrypt the volume to a different KMS key that you own, supply the `KmsKeyId` parameter.

Re-encrypt a volume during launch

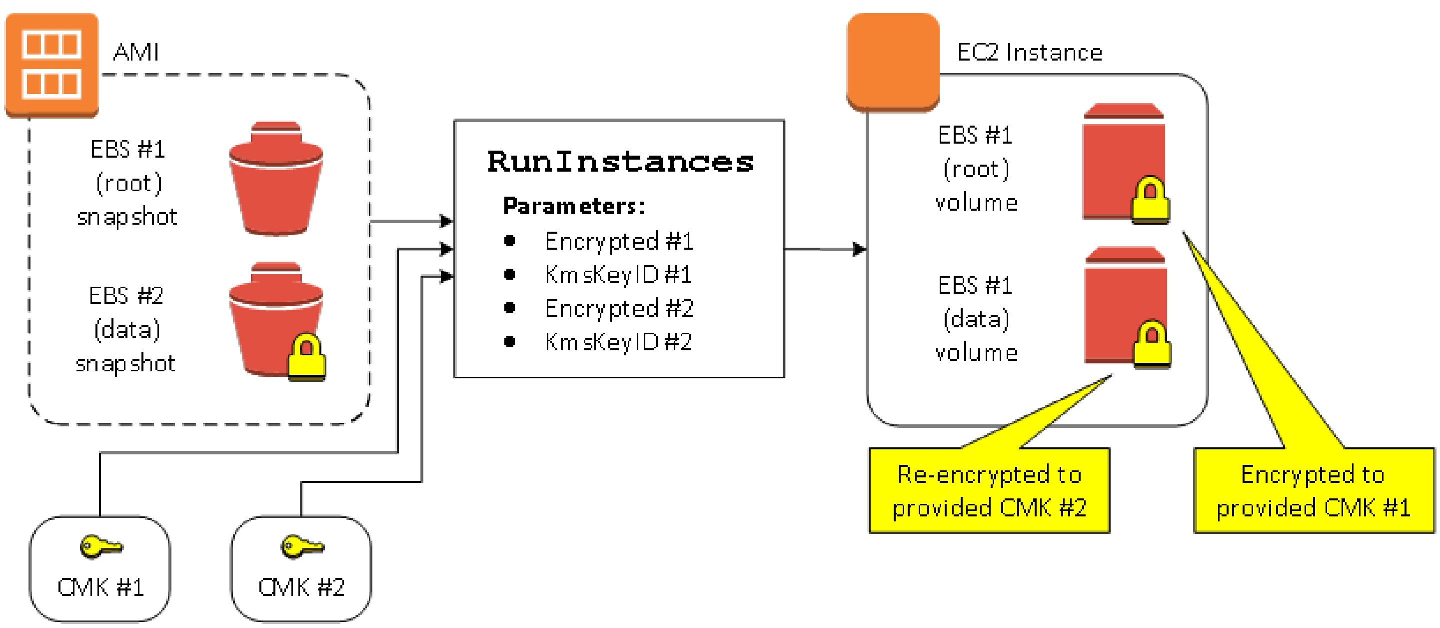
In this example, an AMI backed by an encrypted snapshot is used to launch an EC2 instance with an EBS volume encrypted by a new KMS key.



If you own the AMI and supply no encryption parameters, the resulting instance has a volume encrypted by the same KMS key as the snapshot. If the AMI is shared rather than owned by you, and you supply no encryption parameters, the volume is encrypted by your default KMS key. With encryption parameters supplied as shown, the volume is encrypted by the specified KMS key.

Change encryption state of multiple volumes during launch

In this more complex example, an AMI backed by multiple snapshots (each with its own encryption state) is used to launch an EC2 instance with a newly encrypted volume and a re-encrypted volume.



In this scenario, the `RunInstances` action is supplied with encryption parameters for each of the source snapshots. When all possible encryption parameters are specified, the resulting instance is the same regardless of whether you own the AMI.

Image-copying scenarios

Amazon EC2 AMIs are copied using the `CopyImage` action, either through the AWS Management Console or directly using the Amazon EC2 API or CLI.

By default, without explicit encryption parameters, a `CopyImage` action maintains the existing encryption state of an AMI's source snapshots during copy. You can also copy an AMI and simultaneously apply a new encryption state to its associated EBS snapshots by supplying encryption parameters. Consequently, the following behaviors are observed:

Copy with no encryption parameters

- An unencrypted snapshot is copied to another unencrypted snapshot, unless encryption by default is enabled, in which case all the newly created snapshots will be encrypted.
- An encrypted snapshot that you own is copied to a snapshot encrypted with the same KMS key.
- An encrypted snapshot that you do not own (that is, the AMI is shared with you) is copied to a snapshot that is encrypted by your AWS account's default KMS key.

All of these default behaviors can be overridden by supplying encryption parameters. The available parameters are `Encrypted` and `KmsKeyId`. Setting only the `Encrypted` parameter results in the following:

Copy-image behaviors with `Encrypted` set, but no `KmsKeyId` specified

- An unencrypted snapshot is copied to a snapshot encrypted by the AWS account's default KMS key.
- An encrypted snapshot is copied to a snapshot encrypted by the same KMS key. (In other words, the `Encrypted` parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is copied to a volume that is encrypted by your AWS account's default KMS key. (In other words, the `Encrypted` parameter has no effect.)

Setting both the `Encrypted` and `KmsKeyId` parameters allows you to specify a customer managed KMS key for an encryption operation. The following behaviors result:

Copy-image behaviors with both `Encrypted` and `KmsKeyId` set

- An unencrypted snapshot is copied to a snapshot encrypted by the specified KMS key.

- An encrypted snapshot is copied to a snapshot encrypted not to the original KMS key, but instead to the specified KMS key.

Submitting a `KmsKeyId` without also setting the `Encrypted` parameter results in an error.

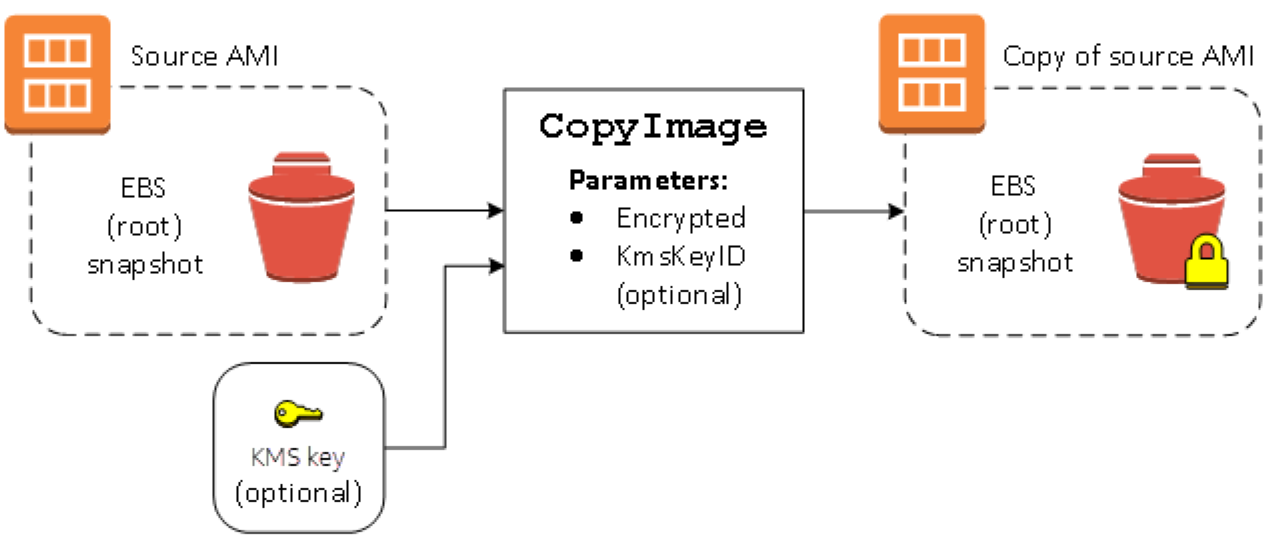
The following section provides an example of copying an AMI using non-default encryption parameters, resulting in a change of encryption state.

For detailed instructions using the console, see Copy an Amazon EC2 AMI.

Encrypt an unencrypted image during copy

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The `CopyImage` action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

> **Note**
>
> Enabling encryption by default has the same effect as setting the `Encrypted` parameter to `true` for all snapshots in the AMI.



Setting the `Encrypted` parameter encrypts the single snapshot for this instance. If you do not specify the `KmsKeyId` parameter, the default customer managed key is used to encrypt the snapshot copy.

> **Note**
>
> You can also copy an image with multiple snapshots and configure the encryption state of each individually.

Understand shared AMI usage in Amazon EC2

A shared AMI is an AMI that a developer created and made available for others to use. One of the easiest ways to get started with Amazon EC2 is to use a shared AMI that has the components you need and then add custom content. You can also create your own AMIs and share them with others.

You use a shared AMI at your own risk. Amazon can't vouch for the integrity or security of AMIs shared by other Amazon EC2 users. Therefore, you should treat shared AMIs as you would any foreign code that you might consider deploying in your own data center, and perform the appropriate due diligence. We recommend that you get an AMI from a trusted source, such as a verified provider.

Verified provider

In the Amazon EC2 console, public AMIs that are owned by Amazon or a verified Amazon partner are marked **Verified provider**.

You can also use the describe-images AWS CLI command to identify the public AMIs that come from a verified provider. Public images that are owned by Amazon or a verified partner have an aliased owner, which is either `amazon`, `aws-backup-vault`, or `aws-marketplace`. In the CLI output, these values appear for `ImageOwnerAlias`. Other users can't alias their AMIs. This enables you to easily find AMIs from Amazon or verified partners.

To become a verified provider, you must register as a seller on the AWS Marketplace. Once registered, you can list your AMI on the AWS Marketplace. For more information, see Getting started as a seller and AMI-based products in the *AWS Marketplace Seller Guide*.

Shared AMI topics

- Find shared AMIs to use for Amazon EC2 instances

- Prepare to use shared AMIs for Linux
- Control the discovery and use of AMIs in Amazon EC2 with Allowed AMIs
- Make your AMI publicly available for use in Amazon EC2
- Understand block public access for AMIs
- Share an AMI with organizations and organizational units
- Share an AMI with specific AWS accounts
- Cancel having an AMI shared with your AWS account
- Recommendations for creating shared Linux AMIs

If you're looking for information about other topics

- For information about creating an AMI, see the section called “Create an instance store-backed AMI” or the section called “Create an AMI”.
- For information about building, delivering, and maintaining your applications on the AWS Marketplace, see the AWS Marketplace Documentation.

Find shared AMIs to use for Amazon EC2 instances

You can use the Amazon EC2 console or the command line to find public or private shared AMIs to use with your Amazon EC2 instances.

AMIs are a Regional resource. When you search for a shared AMI (public or private), you must search for it from the same Region from which it is shared. To make an AMI available in a different Region, copy the AMI to the Region, and then share it. For more information, see Copy an Amazon EC2 AMI.

Console

The console provides an AMI filter field. You can also scope your searches using the filters provided in the **Search** field.

To find a shared or AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose one of the following options:

- **Private images** – Lists all AMIs that are shared with you.
- **Public images** – Lists all public AMIs.

4. (Optional) To display only the public images from Amazon, choose the **Search** field and then, from the menu options, choose **Owner alias**, then **=**, and then **amazon**.
5. (Optional) Add filters to scope your search to AMIs that meet your requirements.

To find a shared public AMI from a verified provider

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMI Catalog**.
3. Choose **Community AMIs**.
4. In the **Refine results** pane, select **Verified provider**. The **Verified provider** label indicates that the AMIs are from Amazon or a verified partner.

AWS CLI

Use the describe-images command to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

To list all public AMIs

The following command lists all public AMIs, including any public AMIs that you own.

```
aws ec2 describe-images --executable-users all
```

To list AMIs with explicit launch permissions

The following command lists the AMIs for which you have explicit launch permissions. This list does not include any AMIs that you own.

```
aws ec2 describe-images --executable-users self
```

To list AMIs owned by verified providers

The following command lists the AMIs owned by verified providers. Public AMIs owned by verified providers (either Amazon or verified partners) have an aliased owner, which appears as amazon, aws-backup-vault, or aws-marketplace in the account field. This helps you to easily find AMIs from verified providers. Other users can't alias their AMIs.

```
aws ec2 describe-images \
    --owners amazon aws-marketplace \
    --query 'Images[*].[ImageId]' \
    --output text
```

To list AMIs owned by an account

The following command lists the AMIs owned by the specified AWS account.

```
aws ec2 describe-images --owners 123456789012
```

To scope AMIs using a filter

To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only EBS-backed AMIs.

```
--filters "Name=root-device-type,Values=ebs"
```

PowerShell

Use the Get-EC2Image cmdlet (Tools for Windows PowerShell) to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

To list all public AMIs

The following command lists all public AMIs, including any public AMIs that you own.

```
Get-EC2Image -ExecutableUser all
```

To list AMIs with explicit launch permissions

The following command lists the AMIs for which you have explicit launch permissions. This list does not include any AMIs that you own.

```
Get-EC2Image -ExecutableUser self
```

To list AMIs owned by verified providers

The following command lists the AMIs owned by verified providers. Public AMIs owned by verified providers (either Amazon or verified partners) have an aliased owner, which appears as `amazon`, `aws-backup-vault`, or `aws-marketplace` in the account field. This helps you to easily find AMIs from verified providers. Other users can't alias their AMIs.

```
Get-EC2Image -Owner amazon aws-marketplace
```

To list AMIs owned by an account

The following command lists the AMIs owned by the specified AWS account.

```
Get-EC2Image -Owner 123456789012
```

To scope AMIs using a filter

To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only EBS-backed AMIs.

```
-Filter @{Name="root-device-type"; Values="ebs"}
```

Prepare to use shared AMIs for Linux

Before you use a shared AMI for Linux, take the following steps to confirm that there are no pre-installed credentials that would allow unwanted access to your instance by a third party and no pre-configured remote logging that could transmit sensitive data to a third party. Check the documentation for the Linux distribution used by the AMI for information about improving the security of the system.

To ensure that you don't accidentally lose access to your instance, we recommend that you initiate two SSH sessions and keep the second session open until you've removed credentials that you don't recognize and confirmed that you can still log into your instance using SSH.

1. Identify and disable any unauthorized public SSH keys. The only key in the file should be the key you used to launch the AMI. The following command locates `authorized_keys` files:

   ```
   [ec2-user ~]$ sudo find / -name "authorized_keys" -print -exec cat {} \;
   ```

2. Disable password-based authentication for the root user. Open the `sshd_config` file and edit the `PermitRootLogin` line as follows:

```
PermitRootLogin without-password
```

Alternatively, you can disable the ability to log into the instance as the root user:

```
PermitRootLogin No
```

Restart the sshd service.

3. Check whether there are any other users that are able to log in to your instance. Users with superuser privileges are particularly dangerous. Remove or lock the password of any unknown accounts.
4. Check for open ports that you aren't using and running network services listening for incoming connections.
5. To prevent preconfigured remote logging, you should delete the existing configuration file and restart the `rsyslog` service. For example:

```
[ec2-user ~]$ sudo rm /etc/rsyslog.conf
[ec2-user ~]$ sudo service rsyslog restart
```

6. Verify that all cron jobs are legitimate.

If you discover a public AMI that you feel presents a security risk, contact the AWS security team. For more information, see the AWS Security Center.

Control the discovery and use of AMIs in Amazon EC2 with Allowed AMIs

To control the discovery and use of Amazon Machine Images (AMIs) by users in your AWS account, you can use the *Allowed AMIs* feature. This feature allows you to specify criteria that AMIs must meet to be visible and available within your account. When the criteria are enabled, users launching instances will only see and have access to AMIs that comply with the specified criteria. For example, you can specify a list of trusted AMI providers as the criteria, and only AMIs from these providers will be visible and available for use.

Before enabling the Allowed AMIs settings, you can enable *audit mode* to preview which AMIs will or won't be visible and available for use. This lets you refine the criteria as needed to ensure that only the intended AMIs are visible and available to users in your account. Additionally, you can run the describe-instance-image-metadata command and filter the response to identify any instances that were launched with AMIs that don't meet the specified criteria. This information can guide your decision to either update your launch configurations to use compliant AMIs (for example, specifying a different AMI in a launch template) or adjust your criteria to allow these AMIs.

You specify the Allowed AMIs settings at the account level, either directly in the account or by using a declarative policy. These settings must be configured in each AWS Region where you want to control the discovery and use of AMIs. Using a declarative policy allows you to apply the settings across multiple Regions simultaneously, as well as across multiple accounts simultaneously. When a declarative policy is in use, you can't modify the settings directly within an account. This topic describes how to configure the settings directly within an account. For information about using declarative policies, see Declarative policies in the *AWS Organizations User Guide*.

> **Note**
>
> The Allowed AMIs feature only controls the discovery and use of public AMIs or AMIs shared with your account. It does not restrict the AMIs owned by your account. Regardless of the criteria you set, the AMIs created by your account are always discoverable and usable by users in your account.

Key benefits of Allowed AMIs

- **Compliance and security**: Users can only discover and use AMIs that meet the specified criteria, reducing the risk of non-compliant AMI usage.
- **Efficient management**: By reducing the number of allowed AMIs, managing the remaining ones becomes easier and more efficient.
- **Centralized account-level implementation**: Configure the Allowed AMIs settings at the account level, either directly within the account or through a declarative policy. This provides a centralized and efficient way to control AMI usage across the entire account.

Contents

How Allowed AMIs works

You control AMI access by specifying *criteria* in a JSON configuration. These criteria determine which AMIs can be discovered and used in your account. After defining your criteria, you enable them using the API or console. Once enabled, all AMIs are evaluated against the criteria. If an AMI matches at least one of the criteria, it is allowed in your account.

Topics

Allowed AMIs criteria

Currently, the only supported criteria are AMI providers. Valid values are aliases that are defined by AWS, and AWS account IDs, as follows:

- `amazon` – An alias that identifies AMIs created by AWS
- `aws-marketplace` – An alias that identifies AMIs created by verified providers in the AWS Marketplace
- `aws-backup-vault` – An alias that identifies backup AMIs that reside in logically air-gapped AWS Backup vault accounts. If you use the AWS Backup logically air-gapped vault feature, ensure this alias is included as an AMI provider.
- AWS account IDs – One or more 12-digit AWS account IDs
- `none` – Indicates that only AMIs created by your account can be discovered and used. Public or shared AMIs can't be discovered and used. If you specify `none`, you can't specify an alias or account ID.

JSON configuration

The core configuration for Allowed AMIs is the JSON configuration that defines the criteria for allowed AMIs. Here's an example that specifies two aliases and three AWS account IDs:

```
{
```

```
    "ImageCriteria": [
        {
            "ImageProviders": [
                "amazon",
                "aws-marketplace",
                "123456789012",
                "112233445566",
                "009988776655"
            ]
        }
    ]
}
```

How criteria are evaluated

The criteria in the JSON configuration are evaluated using an `or` condition. This means that an AMI only needs to match one of the specified providers in any `ImageCriteria` object to be considered allowed. For example, if you specify both `amazon` and an AWS account ID as providers, AMIs from either provider will be allowed.

Limits for the JSON configuration

- `ImageCriteria` objects: Maximum of 10 `ImageCriteria` objects can be specified in a single configuration.
- `ImageProviders` values: Maximum of 200 values across all `ImageCriteria` objects.

Example of limits

Consider the following example to illustrate these limits, where different `ImageProviders` lists are used to group the AMI provider accounts:

```
{
    "ImageCriteria": [
        {
            "ImageProviders": ["amazon", "aws-marketplace"]
        },
        {
            "ImageProviders": ["123456789012", "112233445566", "121232343454"]
        },
        {
            "ImageProviders": ["998877665555", "987654321098"]
        }
```

```
        // Up to 7 more ImageCriteria objects can be added
        // Up to 193 more ImageProviders values can be added
    ]
}
```

In this example:

- There are 3 `imageCriteria` objects (up to 7 more can be added to reach the limit of 10).
- There are 7 total `imageProviders` values across all objects (up to 193 more can be added to reach the limit of 200).

In this example, AMIs are allowed from any of the specified AMI providers in all of the `ImageCriteria` objects, since they are evaluated using an `or` condition.

Allowed AMIs operations

The Allowed AMIs feature has three operational modes for managing the image criteria: **enabled**, **disabled**, and **audit mode**. These allow you to enable or disable the image criteria, or review them as needed.

Enabled

When Allowed AMIs is enabled:

- The `ImageCriteria` are applied.
- Only allowed AMIs are discoverable in the EC2 console and by APIs that use images (for example, that describe, copy, store, or perform other actions that use images).
- Instances can only be launched using allowed AMIs.

Disabled

When Allowed AMIs is disabled:

- The `ImageCriteria` are not applied.
- No restrictions are placed on AMI discoverability or usage.

Audit mode

In audit mode:

- The `ImageCriteria` are applied, but no restrictions are placed on AMI discoverability or usage.
- In the EC2 console, for each AMI, the **Allowed image** field displays either **Yes** or **No** to indicate whether the AMI will be discoverable and available to users in the account when Allowed AMIs is enabled.
- In the command line, the response for the `describe-image` operation includes `"ImageAllowed": true` or `"ImageAllowed": false` to indicate whether the AMI will be discoverable and available to users in the account when Allowed AMIs is enabled.
- In the EC2 console, the AMI Catalog displays **Not allowed** next to AMIs that won't be discoverable or available to users in the account when Allowed AMIs is enabled.

Best practices for implementing Allowed AMIs

When implementing Allowed AMIs, consider these best practices to ensure a smooth transition and minimize potential disruptions to your AWS environment.

1. **Enable audit mode**

   Begin by enabling Allowed AMIs in audit mode. This mode allows you to see which AMIs would be affected by your criteria without actually restricting access, providing a risk-free evaluation period.

2. **Set Allowed AMIs criteria**

   Carefully establish which AMI providers align with your organization's security policies, compliance requirements, and operational needs.

   > **Note**
   >
   > We recommend specifying the `amazon` alias to allow AMIs created by AWS, ensuring that AWS managed services you use can continue to launch EC2 instances in your account.

3. **Check for impact on expected business processes**

   You can use the console or the CLI to identify any instances that were launched with AMIs that don't meet the specified criteria. This information can guide your decision to either update your launch configurations to use compliant AMIs (for example, specifying a different AMI in a launch template) or adjust your criteria to allow these AMIs.

Console: Use the ec2-instance-launched-with-allowed-ami AWS Config rule to check if running or stopped instances were launched with AMIs that meet your Allowed AMIs criteria. The rule is **NON_COMPLIANT** if an AMI doesn't meet the Allowed AMIs criteria, and **COMPLIANT** if it does. The rule only operates when the Allowed AMIs setting is set to **enabled** or **audit mode**.

CLI: Run the describe-instance-image-metadata command and filter the response to identify any instances that were launched with AMIs that don't meet the specified criteria.

For the console and CLI instructions, see Find instances launched from AMIs that aren't allowed.

4. **Enable Allowed AMIs**

   Once you've confirmed that the criteria will not adversely affect expected business processes, enable Allowed AMIs.

5. **Monitor instance launches**

   Continue to monitor instance launches from AMIs across your applications and the AWS managed services you use, such as Amazon EMR, Amazon ECR, Amazon EKS, and AWS Elastic Beanstalk. Check for any unexpected issues and make necessary adjustments to the Allowed AMIs criteria.

6. **Pilot new AMIs**

   To test third-party AMIs that do not comply with your current Allowed AMIs settings, AWS recommends the following approaches:

   - Use a separate AWS account: Create an account with no access to your business-critical resources. Ensure that the Allowed AMIs setting is not enabled in this account, or that the AMIs you want to test are explicitly allowed, so that you can test them.
   - Test in another AWS Region: Use a Region where the third-party AMIs are available, but where you have not yet enabled the Allowed AMIs settings.

   These approaches help ensure your business-critical resources remain secure while you test new AMIs.

Required IAM permissions

To use the Allowed AMIs feature, you need the following IAM permissions:

- `GetAllowedImagesSettings`

- `EnableAllowedImagesSettings`
- `DisableAllowedImagesSettings`
- `ReplaceImageCriteriaInAllowedImagesSettings`

Manage the settings for Allowed AMIs

You can manage the settings for Allowed AMIs. These settings are per Region per account.

Tasks

Enable Allowed AMIs

You can enable Allowed AMIs and specify Allowed AMIs criteria. We recommend that you begin in audit mode, which shows you which AMIs would be affected by the criteria without actually restricting access.

Console

To enable Allowed AMIs

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dashboard**.
3. Under **Account attributes** (top right), choose **Allowed AMIs**.
4. On the **Allowed AMIs** tab, choose **Manage**.
5. For **Allowed AMIs settings**, choose **Audit mode** or **Enabled**. We recommend that you begin in audit mode, test the criteria, and then return to this step to enable Allowed AMIs.
6. (Optional) For **AMI criteria**, enter the criteria in JSON format.
7. Choose **Update**.

AWS CLI

To enable Allowed AMIs

Use the enable-allowed-images-settings command.

```
aws ec2 enable-allowed-images-settings --allowed-images-settings-state enabled
```

To enable audit mode instead, specify `audit-mode` instead of `enabled`.

```
aws ec2 enable-allowed-images-settings --allowed-images-settings-state audit-mode
```

PowerShell

To enable Allowed AMIs

Use the Enable-EC2AllowedImagesSetting cmdlet.

```
Enable-EC2AllowedImagesSetting -AllowedImagesSettingsState enabled
```

To enable audit mode instead, specify `audit-mode` instead of `enabled`.

```
Enable-EC2AllowedImagesSetting -AllowedImagesSettingsState audit-mode
```

Set the Allowed AMIs criteria

After you enable Allowed AMIs, you can set or replace the Allowed AMIs criteria.

For the correct configuration and valid values, see JSON configuration and Allowed AMIs criteria.

Console

To set the Allowed AMIs criteria

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dashboard**.
3. Under **Account attributes** (top right), choose **Allowed AMIs**.
4. On the **Allowed AMIs** tab, choose **Manage**.

5. For **AMI criteria**, enter the criteria in JSON format.
6. Choose **Update**.

AWS CLI

To set the Allowed AMIs criteria

Use the replace-image-criteria-in-allowed-images-settings command as follows to allow AMIs from Amazon and the specified account.

```
aws ec2 replace-image-criteria-in-allowed-images-settings \
    --image-criteria ImageProviders=amazon,123456789012
```

PowerShell

To set the Allowed AMIs criteria

Use the Set-EC2ImageCriteriaInAllowedImagesSetting cmdlet as follows to allow AMIs from Amazon and the specified account.

```
$imageCriteria = New-Object Amazon.EC2.Model.ImageCriterionRequest
$imageCriteria.ImageProviders = @("amazon", "123456789012")
Set-EC2ImageCriteriaInAllowedImagesSetting -ImageCriterion $imageCriteria
```

Disable Allowed AMIs

You can disable Allowed AMIs as follows.

Console

To disable Allowed AMIs

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dashboard**.
3. Under **Account attributes** (top right), choose **Allowed AMIs**.
4. On the **Allowed AMIs** tab, choose **Manage**.
5. For **Allowed AMIs settings**, choose **Disabled**.
6. Choose **Update**.

AWS CLI

To disable Allowed AMIs

Use the disable-allowed-images-settings command.

```
aws ec2 disable-allowed-images-settings
```

PowerShell

To disable Allowed AMIs

Use the Disable-EC2AllowedImagesSetting cmdlet.

```
Disable-EC2AllowedImagesSetting
```

Get the Allowed AMIs criteria

You can get the current state of the Allowed AMIs setting and the Allowed AMIs criteria.

Console

To get the Allowed AMIs state and criteria

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dashboard**.
3. Under **Account attributes** (top right), choose **Allowed AMIs**.
4. On the **Allowed AMIs** tab, **Allowed AMIs settings** is set to **Enabled**, **Disabled**, or **Audit mode**.
5. If the state of Allowed AMIs is either **Enabled** or **Audit mode**, **AMI criteria**, displays the AMI criteria in JSON format.

AWS CLI

To get the Allowed AMIs state and criteria

Use the get-allowed-images-settings command.

```
aws ec2 get-allowed-images-settings
```

In the following example output, the state is `audit-mode` and the image provider list includes two providers (`amazon`, plus the specified account).

```
{
    "State": "audit-mode",
    "ImageCriteria": [
        {
            "ImageProviders": [
                "amazon",
                "123456789012"
            ]
        }
    ],
    "ManagedBy": "account"
}
```

PowerShell

To get the Allowed AMIs state and criteria

Use the Get-EC2AllowedImagesSetting cmdlet.

```
Get-EC2AllowedImagesSetting | `
    Select State, ManagedBy, @{Name='ImageProviders';
 Expression={($_.ImageCriteria.ImageProviders)}}
```

In the following example output, the state is `audit-mode` and the image provider list includes two providers (`amazon`, plus the specified account).

```
State      ManagedBy ImageProviders
-----      --------- --------------
audit-mode account   {amazon, 123456789012}
```

Find AMIs that are allowed

You can find the AMIs that are allowed or not allowed by the current Allowed AMIs criteria.

> **Note**
>
> Allowed AMIs must be in audit mode.

Console

To check whether an AMI meets the Allowed AMIs criteria

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select the AMI.
4. On the **Details** tab (if you selected the checkbox) or in the summary area (if you selected the AMI ID), find the **Allowed image** field.
   - **Yes –** The AMI meets the Allowed AMIs criteria. This AMI will be available to users in your account after you enable Allowed AMIs.
   - **No –** The AMI does not meet the Allowed AMIs criteria.
5. In the navigation pane, choose **AMI Catalog**.

   An AMI marked **Not allowed** indicates an AMI that does not meet the Allowed AMIs criteria. This AMI won't be visible or available to users in your account when Allowed AMIs is enabled.

AWS CLI

To check whether an AMI meets the Allowed AMIs criteria

Use the describe-images command.

```
aws ec2 describe-images \
    --image-id ami-0abcdef1234567890 \
    --query Images[].ImageAllowed \
    --output text
```

The following is example output.

```
True
```

To find AMIs that meet the Allowed AMIs criteria

Use the describe-images command.

```
aws ec2 describe-images \
```

```
    --filters "Name=image-allowed,Values=true" \
    --max-items 10 \
    --query Images[].ImageId
```

The following is example output.

```
ami-000eaaa8be2fd162a
ami-000f82db25e50de8e
ami-000fc21eb34c7a9a6
ami-0010b876f1287d7be
ami-0010b929226fe8eba
ami-0010957836340aead
ami-00112c992a47ba871
ami-00111759e194abcc1
ami-001112565ffcafa5e
ami-0011e45aaee9fba88
```

PowerShell

To check whether an AMI meets the Allowed AMIs criteria

Use the Get-EC2Image cmdlet.

```
(Get-EC2Image -ImageId ami-0abcdef1234567890).ImageAllowed
```

The following is example output.

```
True
```

To find AMIs that meet the Allowed AMIs criteria

Use the Get-EC2Image cmdlet.

```
Get-EC2Image `
    -Filter @{Name="image-allows";Values="true"} `
    -MaxResult 10 | `
    Select ImageId
```

The following is example output.

```
ami-000eaaa8be2fd162a
ami-000f82db25e50de8e
```

```
ami-000fc21eb34c7a9a6
ami-0010b876f1287d7be
ami-0010b929226fe8eba
ami-0010957836340aead
ami-00112c992a47ba871
ami-00111759e194abcc1
ami-001112565ffcafa5e
ami-0011e45aaee9fba88
```

Find instances launched from AMIs that aren't allowed

You can identify the instances that were launched using an AMI that does not meet the Allowed AMIs criteria.

Console

To check whether an instance was launched using an AMI that isn't allowed

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Details** tab, under **Instance details**, find **Allowed image**.

   - **Yes** – The AMI meets the Allowed AMIs criteria.
   - **No** – The AMI does not meet the Allowed AMIs criteria.

AWS CLI

To find instances launched using AMIs that aren't allowed

Use the describe-instance-image-metadata command with the `image-allowed` filter.

```
aws ec2 describe-instance-image-metadata \
    --filters "Name=image-allowed,Values=false" \
    --query "InstanceImageMetadata[*].[InstanceId,ImageMetadata.ImageId]" \
    --output table
```

The following is example output.

```
--------------------------------------------------
```

```
|          DescribeInstanceImageMetadata         |
+----------------------+------------------------+
|  i-08fd74f3f1595fdbd |  ami-09245d5773578a1d6  |
|  i-0b1bf24fd4f297ab9 |  ami-07cccf2bd80ed467f  |
|  i-026a2eb590b4f7234 |  ami-0c0ec0a3a3a4c34c0  |
|  i-006a6a4e8870c828f |  ami-0a70b9d193ae8a799  |
|  i-0781e91cfeca3179d |  ami-00c257e12d6828491  |
|  i-02b631e2a6ae7c2d9 |  ami-0bfddf4206f1fa7b9  |
+----------------------+------------------------+
```

PowerShell

To find instances launched using AMIs that aren't allowed

Use the Get-EC2InstanceImageMetadata cmdlet.

```
Get-EC2InstanceImageMetadata `
    -Filter @{Name="image-allowed";Values="false"} | `
    Select InstanceId, @{Name='ImageId'; Expression={($_.ImageMetadata.ImageId)}}
```

The following is example output.

```
InstanceId          ImageId
----------          -------
i-08fd74f3f1595fdbd ami-09245d5773578a1d6
i-0b1bf24fd4f297ab9 ami-07cccf2bd80ed467f
i-026a2eb590b4f7234 ami-0c0ec0a3a3a4c34c0
i-006a6a4e8870c828f ami-0a70b9d193ae8a799
i-0781e91cfeca3179d ami-00c257e12d6828491
i-02b631e2a6ae7c2d9 ami-0bfddf4206f1fa7b9
```

AWS Config

You can add the **ec2-instance-launched-with-allowed-ami** AWS Config rule, configure it for your requirements, and then use it to evaluate your instances.

For more information, see Adding AWS Config rules and ec2-instance-launched-with-allowed-ami in the *AWS Config Developer Guide*.

Make your AMI publicly available for use in Amazon EC2

You can make your AMI publicly available by sharing it with all AWS accounts.

If you want to prevent the public sharing of your AMIs, you can enable *block public access for AMIs*. This blocks any attempts to make an AMI public, helping to prevent unauthorized access and potential misuse of AMI data. Note that enabling block public access does not affect your AMIs that are already publicly available; they remain publicly available. For more information, see Understand block public access for AMIs.

To allow only specific accounts to use your AMI to launch instances, see Share an AMI with specific AWS accounts.

Contents

Considerations

Consider the following before making an AMI public.

- **Ownership** – To make an AMI public, your AWS account must own the AMI.
- **Region** – AMIs are a Regional resource. When you share an AMI, it is available only in the Region from which you shared it. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see Copy an Amazon EC2 AMI.
- **Block public access** – To publicly share an AMI, block public access for AMIs must be disabled in each Region in which the AMI will be publicly shared. After you've publicly shared the AMI, you can re-enable block public access for AMIs to prevent further public sharing of your AMIs.
- **Some AMIs can't be made public** – If your AMI includes one of the following components, you can't make it public (but you can share the AMI with specific AWS accounts):
  - Encrypted volumes
  - Snapshots of encrypted volumes
  - Product codes
- **Avoid exposing sensitive data** – To avoid exposing sensitive data when you share an AMI, read the security considerations in Recommendations for creating shared Linux AMIs and follow the recommended actions.
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can’t delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from the instance they launched.

- **Automatic deprecation –** By default, the deprecation date of all public AMIs is set to two years from the AMI creation date. You can set the deprecation date to earlier than two years. To cancel the deprecation date, or to move the deprecation to a later date, you must make the AMI private by only sharing it with specific AWS accounts.
- **Remove obsolete AMIs –** After a public AMI reaches its deprecation date, if no new instances were launched from the AMI for six or more months, AWS eventually removes the public sharing property so that obsolete AMIs don't appear in the public AMI lists.
- **Billing –** You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

Share an AMI with all AWS accounts (share publicly)

After you make an AMI public, it is available in **Community AMIs** in the console, which you can access from the **AMI Catalog** in the left navigator in the EC2 console or when launching an instance using the console. Note that it can take a short while for an AMI to appear in **Community AMIs** after you make it public.

Console

To make an AMI public

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI from the list, and then choose **Actions**, **Edit AMI permissions**.
4. Under **AMI availability**, choose **Public**.
5. Choose **Save changes**.

AWS CLI

Each AMI has a `launchPermission` property that controls which AWS accounts, besides the owner's, are allowed to use that AMI to launch instances. By modifying the `launchPermission` property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts), or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the `all` group. You can specify both public and explicit launch permissions.

To make an AMI public

1. Use the modify-image-attribute command as follows to add the `all` group to the `launchPermission` list for the specified AMI.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --launch-permission "Add=[{Group=all}]"
```

2. To verify the launch permissions of the AMI, use the describe-image-attribute command.

```
aws ec2 describe-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --attribute launchPermission
```

3. (Optional) To make the AMI private again, remove the `all` group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --launch-permission "Remove=[{Group=all}]"
```

PowerShell

Each AMI has a `launchPermission` property that controls which AWS accounts, besides the owner's, are allowed to use that AMI to launch instances. By modifying the `launchPermission` property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts), or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the `all` group. You can specify both public and explicit launch permissions.

To make an AMI public

1. Use the Edit-EC2ImageAttribute command as follows to add the `all` group to the `launchPermission` list for the specified AMI.

```
Edit-EC2ImageAttribute `
```

```
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission `
    -OperationType add `
    -UserGroup all
```

2. To verify the launch permissions of the AMI, use the following Get-EC2ImageAttribute command.

```
Get-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission
```

3. (Optional) To make the AMI private again, remove the `all` group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
Edit-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission `
    -OperationType remove `
    -UserGroup all
```

Understand block public access for AMIs

To prevent the public sharing of your AMIs, you can enable *block public access for AMIs* at the account level.

When block public access is enabled, any attempt to make an AMI public is automatically blocked. However, if you already have public AMIs, they remain publicly available.

To publicly share AMIs, you must disable block public access. When you’re done sharing, it's best practice to re-enable block public access to prevent any unintended public sharing of your AMIs.

Note

This setting is configured at the account level, either directly in the account or by using a declarative policy. It must be configured in each AWS Region where you want to prevent the public sharing of your AMIs. Using a declarative policy allows you to apply the setting across multiple Regions simultaneously, as well as across multiple accounts simultaneously. When a declarative policy is in use, you can't modify the setting directly within an account. This topic describes how to configure the setting directly within an account. For information about using declarative policies, see Declarative policies in the *AWS Organizations User Guide.*

You can restrict IAM permissions to an administrator user so that only they can enable or disable block public access for AMIs.

Topics

- Default settings
- Manage the block public access setting for AMIs

Default settings

The **Block public access for AMIs** setting is either enabled or disabled by default depending on whether your account is new or existing, and whether you have public AMIs. The following table lists the default settings:

AWS account	Block public access for AMIs default setting
New accounts	Enabled
Existing accounts with no public AMIs [1]	Enabled
Existing accounts with one or more public AMIs	Disabled

[1] If your account had one or more public AMIs on or after July 15, 2023, **Block public access for AMIs** is disabled by default for your account, even if you subsequently made all the AMIs private.

Manage the block public access setting for AMIs

You can manage the block public access setting for your AMIs to control whether they can be publicly shared. You can enable, disable, or view the current block public access state for your AMIs using the Amazon EC2 console or the AWS CLI.

View the block public access state for AMIs

To see whether the public sharing of your AMIs is blocked in your account, you can view the state for block public access for AMIs. You must view the state in each AWS Region in which you want to see whether the public sharing of your AMIs is blocked.

Required permissions

To get the current block public access setting for AMIs, you must have the `GetImageBlockPublicAccessState` IAM permission.

Console

To view the block public access state for AMIs in the specified Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar (at the top of the screen), select the Region in which to view the block public access state for AMIs.
3. If the dashboard is not displayed, in the navigation pane, choose **EC2 Dashboard**.
4. Under **Account attributes**, choose **Data protection and security**.
5. Under **Block public access for AMIs**, check the **Public access** field. The value is either **New public sharing blocked** or **New public sharing allowed**.

AWS CLI

To get the block public access state for AMIs

Use the get-image-block-public-access-state command. The value is either `block-new-sharing` or `unblocked`.

Example: For a specific Region

```
aws ec2 get-image-block-public-access-state --region us-east-1
```

The `ManagedBy` field indicates the entity that configured the setting. In this example, `account` indicates that the setting was configured directly in the account. A value of `declarative-policy` would mean the setting was configured by a declarative policy. For more information, see Declarative policies in the *AWS Organizations User Guide*.

```
{
    "ImageBlockPublicAccessState": "block-new-sharing",
    "ManagedBy": "account"
}
```

Example: For all Regions in your account

```
echo -e "Region   \t Public Access State" ; \
echo -e "-------------- \t ----------------------" ; \
for region in $(
    aws ec2 describe-regions \
        --region us-east-1 \
        --query "Regions[*].[RegionName]" \
        --output text
    );
    do (output=$(
        aws ec2 get-image-block-public-access-state \
            --region $region \
            --output text)
        echo -e "$region \t $output"
    );
done
```

The following is example output.

```
Region           Public Access State
--------------   ----------------------
ap-south-1       block-new-sharing
eu-north-1       unblocked
eu-west-3        block-new-sharing
...
```

PowerShell

To get the block public access state for AMIs

Use the Get-EC2ImageBlockPublicAccessState cmdlet. The value is either `block-new-sharing` or `unblocked`.

Example: For a specific Region

```
Get-EC2ImageBlockPublicAccessState -Region us-east-1
```

The following is example output.

```
block-new-sharing
```

Example: For all Regions in your account

```
(Get-EC2Region).RegionName | `
    ForEach-Object {
        [PSCustomObject]@{
            Region   = $_
            PublicAccessState = (Get-EC2ImageBlockPublicAccessState -Region $_)
        }
} | `
Format-Table -AutoSize
```

The following is example output.

```
Region         PublicAccessState
------         -----------------
ap-south-1     block-new-sharing
eu-north-1     block-new-sharing
eu-west-3      block-new-sharing
...
```

Enable block public access for AMIs

To prevent the public sharing of your AMIs, enable block public access for AMIs at the account level. You must enable block public access for AMIs in each AWS Region in which you want to prevent the public sharing of your AMIs. If you already have public AMIs, they will remain publicly available.

Required permissions

To enable the block public access setting for AMIs, you must have the `EnableImageBlockPublicAccess` IAM permission.

Considerations

- It can take up to 10 minutes to configure this setting. During this time, if you describe the public access state, the response is `unblocked`. When the configuration is completed, the response is `block-new-sharing`.

Console

To enable block public access for AMIs in the specified Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar (at the top of the screen), select the Region in which to enable block public access for AMIs.
3. If the dashboard is not displayed, in the navigation pane, choose **EC2 Dashboard**.
4. Under **Account attributes**, choose **Data protection and security**.
5. Under **Block public access for AMIs**, choose **Manage**.
6. Select the **Block new public sharing** checkbox, and then choose **Update**.

AWS CLI

To enable block public access for AMIs

Use the enable-image-block-public-access command.

Example: For a specific Region

```
aws ec2 enable-image-block-public-access \
--region us-east-1 \
--image-block-public-access-state block-new-sharing
```

The following is example output.

```
{
    "ImageBlockPublicAccessState": "block-new-sharing"
}
```

Example: For all Regions in your account

```
echo -e "Region   \t Public Access State" ; \
echo -e "-------------- \t ----------------------" ; \
for region in $(
    aws ec2 describe-regions \
        --region us-east-1 \
        --query "Regions[*].[RegionName]" \
        --output text
```

```
    );
    do (output=$(
        aws ec2 enable-image-block-public-access \
            --region $region \
            --image-block-public-access-state block-new-sharing \
            --output text)
        echo -e "$region \t $output"
    );
done
```

The following is example output.

```
Region            Public Access State
--------------    ----------------------
ap-south-1        block-new-sharing
eu-north-1        block-new-sharing
eu-west-3         block-new-sharing
...
```

PowerShell

To enable block public access for AMIs

Use the Enable-EC2ImageBlockPublicAccess command.

Example: For a specific Region

```
Enable-EC2ImageBlockPublicAccess `
    -Region us-east-1 `
    -ImageBlockPublicAccessState block-new-sharing
```

The following is example output.

```
Value
-----
block-new-sharing
```

Example: For all Regions in your account

```
(Get-EC2Region).RegionName | `
    ForEach-Object {
    [PSCustomObject]@{
```

```
        Region            = $_
        PublicAccessState = (
        Enable-EC2ImageBlockPublicAccess `
         -Region $_ `
         -ImageBlockPublicAccessState block-new-sharing)
    }
} | `
Format-Table -AutoSize
```

The following is example output.

```
Region          PublicAccessState
------          -----------------
ap-south-1      block-new-sharing
eu-north-1      block-new-sharing
eu-west-3       block-new-sharing
...
```

Disable block public access for AMIs

To allow the users in your account to publicly share your AMIs, disable block public access at the account level. You must disable block public access for AMIs in each AWS Region in which you want to allow the public sharing of your AMIs.

Required permissions

To disable the block public access setting for AMIs, you must have the `DisableImageBlockPublicAccess` IAM permission.

Considerations

- It can take up to 10 minutes to configure this setting. During this time, if you describe the public access state, the response is `block-new-sharing`. When the configuration is completed, the response is `unblocked`.

Console

To disable block public access for AMIs in the specified Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. From the navigation bar (at the top of the screen), select the Region in which to disable block public access for AMIs.
3. If the dashboard is not displayed, in the navigation pane, choose **EC2 Dashboard**.
4. Under **Account attributes**, choose **Data protection and security**.
5. Under **Block public access for AMIs**, choose **Manage**.
6. Clear the **Block new public sharing** checkbox, and then choose **Update**.
7. Enter **`confirm`** when prompted for confirmation, and then choose **Allow public sharing**.

AWS CLI

To disable block public access for AMIs

Use the disable-image-block-public-access command.

Example: For a specific Region

```
aws ec2 disable-image-block-public-access --region us-east-1
```

The following is example output.

```
{
   "ImageBlockPublicAccessState": "unblocked"
}
```

Example: For all Regions in your account

```
echo -e "Region   \t Public Access State" ; \
echo -e "-------------- \t ----------------------" ; \
for region in $(
    aws ec2 describe-regions \
        --region us-east-1 \
        --query "Regions[*].[RegionName]" \
        --output text
    );
    do (output=$(
        aws ec2 disable-image-block-public-access \
            --region $region \
            --output text)
```

```
        echo -e "$region \t $output"
    );
done
```

The following is example output.

```
Region            Public Access State
--------------    ----------------------
ap-south-1        unblocked
eu-north-1        unblocked
eu-west-3         unblocked
...
```

PowerShell

To disable block public access for AMIs

Use the Disable-EC2ImageBlockPublicAccess cmdlet.

Example: For a specific Region

```
Disable-EC2ImageBlockPublicAccess -Region us-east-1
```

The following is example output.

```
Value
-----
unblocked
```

Example: For all Regions in your account

```
(Get-EC2Region).RegionName | `
    ForEach-Object {
    [PSCustomObject]@{
        Region            = $_
        PublicAccessState = (Disable-EC2ImageBlockPublicAccess -Region $_)
    }
} | `
Format-Table -AutoSize
```

The following is example output.

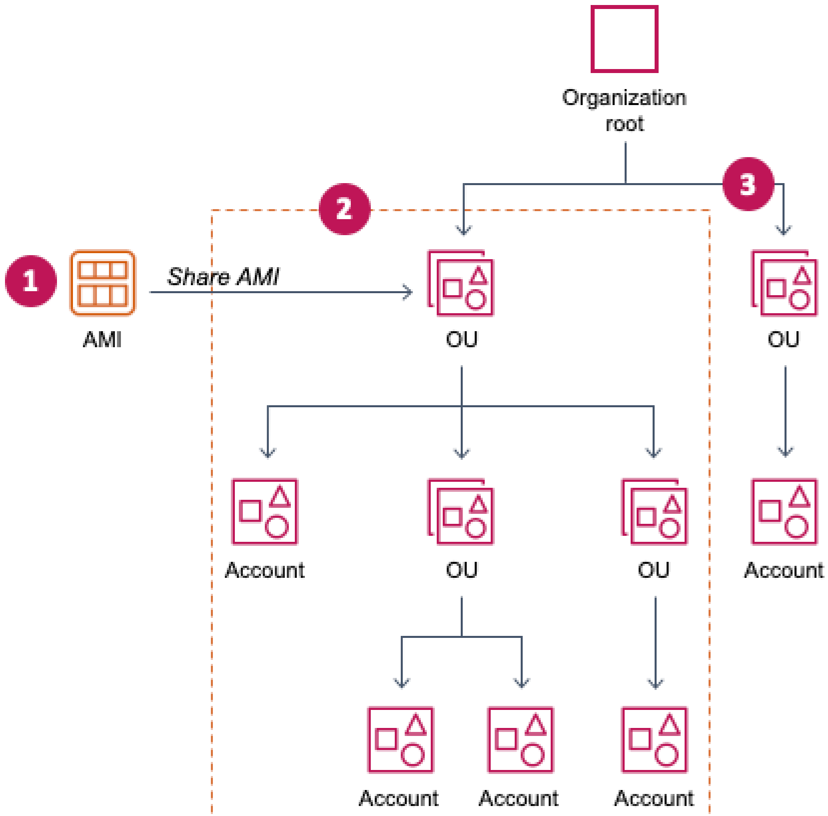
```
Region          PublicAccessState
------          -----------------
ap-south-1      unblocked
eu-north-1      unblocked
eu-west-3       unblocked
...
```

Share an AMI with organizations and organizational units

AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage. You can share an AMI with an organization or an organizational unit (OU) that you have created, in addition to sharing it with specific accounts.

An organization is an entity that you create to consolidate and centrally manage your AWS accounts. You can organize the accounts in a hierarchical, tree-like structure, with a root at the top and organizational units nested under the organization root. Each account can be added directly to the root, or placed in one of the OUs in the hierarchy. For more information, see AWS Organizations terminology and concepts in the *AWS Organizations User Guide*.

When you share an AMI with an organization or an OU, all of the children accounts gain access to the AMI. For example, in the following diagram, the AMI is shared with a top-level OU (indicated by the arrow at the number **1**). All of the OUs and accounts that are nested underneath that top-level OU (indicated by the dotted line at number **2**) also have access to the AMI. The accounts in the organization and OU outside the dotted line (indicated by the number **3**) do not have access to the AMI because they are not children of the OU that the AMI is shared with.



Topics

- Considerations
- Get the ARN of an organization or organizational unit
- Allow organizations and OUs to use a KMS key
- Manage AMI sharing with an organization or OU

Considerations

Consider the following when sharing AMIs with specific organizations or organizational units.

- **Ownership** – To share an AMI, your AWS account must own the AMI.
- **Sharing limits** – The AMI owner can share an AMI with any organization or OU, including organizations and OUs that they're not a member of.

  For the maximum number of entities to which an AMI can be shared within a Region, see the Amazon EC2 service quotas.

- **Tags** – You can't share user-defined tags (tags that you attach to an AMI). When you share an AMI, your user-defined tags are not available to any AWS account in an organization or OU with which the AMI is shared.
- **ARN format** – When you specify an organization or OU in a command, make sure to use the correct ARN format. You'll get an error if you specify only the ID, for example, if you specify only `o-123example` or `ou-1234-5example`.

  Correct ARN formats:

  - Organization ARN: `arn:aws:organizations::111122223333:organization/organization-id`
  - OU ARN: `arn:aws:organizations::111122223333:ou/organization-id/ou-id`

  Where:

  - *`111122223333`* is an example of the 12-digit account ID for the management account. If you don't know the management account number, you can describe the organization or the organizational unit to get the ARN, which includes the management account number. For more information, see Get the ARN of an organization or organizational unit.
  - *`organization-id`* is the organization ID, for example, `o-123example`.
  - *`ou-id`* is the organizational unit ID, for example, `ou-1234-5example`.

  For more information about the format of ARNs, see Amazon Resource Names (ARNs) in the *IAM User Guide*.
- **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.
  - The encrypted snapshots must be encrypted with a customer managed key. You can't share AMIs that are backed by snapshots that are encrypted with the default AWS managed key.
  - If you share an AMI that is backed by encrypted snapshots, you must allow the organizations or OUs to use the customer managed keys that were used to encrypt the snapshots. For more information, see Allow organizations and OUs to use a KMS key.
- **Region** – AMIs are a Regional resource. When you share an AMI, it is available only in the Region from which you shared it. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see Copy an Amazon EC2 AMI.
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from the instance they launched.

- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

Get the ARN of an organization or organizational unit

The organization and the organizational unit ARNs contain the 12-digit management account number. If you don't know the management account number, you can describe the organization and the organizational unit to get the ARN for each. In the following examples, `123456789012` is the account ID of the management account.

Required permissions

Before you can get the ARNs, you must have the permission to describe organizations and organizational units. The following policy provides the necessary permission.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "organizations:Describe*"
            ],
            "Resource": "*"
        }
    ]
}
```

AWS CLI

To get the ARN of an organization

Use the describe-organization command. Add the `--query` option to return only the organization ARN.

```
aws organizations describe-organization --query 'Organization.Arn'
```

The following is example output.

```
"arn:aws:organizations::123456789012:organization/o-1234567abc"
```

To get the ARN of an organizational unit

Use the describe-organizational-unit command. Use the `--query` parameter to return only the organizational unit ARN.

```
aws organizations describe-organizational-unit \
    --organizational-unit-id ou-a123-b4567890 \
    --query 'OrganizationalUnit.Arn'
```

The following is example output.

```
"arn:aws:organizations::123456789012:ou/o-1234567abc/ou-a123-b4567890"
```

PowerShell

To get the ARN of an organization

Use the Get-ORGOrganization cmdlet.

```
(Get-ORGOrganization).Arn
```

The following is example output.

```
arn:aws:organizations::123456789012:organization/o-1234567abc
```

To get the ARN of an organizational unit

Use the Get-ORGOrganizationalUnit cmdlet.

```
(Get-ORGOrganizationalUnit -OrganizationalUnitId "ou-a123-b4567890").Arn
```

The following is example output.

```
arn:aws:organizations::123456789012:ou/o-1234567abc/ou-a123-b4567890
```

Allow organizations and OUs to use a KMS key

If you share an AMI that is backed by encrypted snapshots, you must also allow the organizations or organizational units (OUs) to use the KMS keys that were used to encrypt the snapshots.

> **Note**
>
> The encrypted snapshots must be encrypted with a *customer managed* key. You can't share AMIs that are backed by snapshots that are encrypted with the default AWS managed key.

To control access to the KMS key, in the key policy you can use the `aws:PrincipalOrgID` and `aws:PrincipalOrgPaths` condition keys to allow only specific principals permission to the specified actions. A principal can be a user, IAM role, federated user, or AWS account root user.

The condition keys are used as follows:

- `aws:PrincipalOrgID` – Allows any principal belonging to the organization represented by the specified ID.
- `aws:PrincipalOrgPaths` – Allows any principal belonging to the OUs represented by the specified paths.

To give an organization (including the OUs and accounts that belong to it) permission to use a KMS key, add the following statement to the key policy.

```
{
    "Sid": "Allow access for organization root",
    "Effect": "Allow",
    "Principal": "*",
    "Action": [
        "kms:Describe*",
        "kms:List*",
        "kms:Get*",
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:CreateGrant"
    ],
    "Resource": "*",
```

```
    "Condition": {
        "StringEquals": {
            "aws:PrincipalOrgID": "o-123example"
        }
    }
}
```

To give specific OUs (and the accounts that belong to it) permission to use a KMS key, you can use a policy similar to the following example.

```
{
        "Sid": "Allow access for specific OUs and their descendants",
        "Effect": "Allow",
        "Principal": "*",
        "Action": [
            "kms:Describe*",
            "kms:List*",
            "kms:Get*",
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncrypt*",
            "kms:GenerateDataKey*",
            "kms:CreateGrant"
        ],
        "Resource": "*",
        "Condition": {
            "StringEquals": {
                "aws:PrincipalOrgID": "o-123example"
            },
            "ForAnyValue:StringLike": {
                "aws:PrincipalOrgPaths": [
                    "o-123example/r-ab12/ou-ab12-33333333/*",
                    "o-123example/r-ab12/ou-ab12-22222222/*"
                ]
            }
        }
}
```

For more example condition statements, see aws:PrincipalOrgID and aws:PrincipalOrgPaths in the *IAM User Guide*.

For information about cross-account access, see Allowing users in other accounts to use a KMS key in the *AWS Key Management Service Developer Guide*.

Manage AMI sharing with an organization or OU

You can manage AMI sharing with organizations and organization units (OU) to control whether they can launch Amazon EC2 instances.

View the organizations and OUs with which an AMI is shared

You can find the organizations and OUs with which you've shared your AMI.

Console

To check with which organizations and OUs you've shared your AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**.

   To find AMIs that are shared with you, see Find shared AMIs to use for Amazon EC2 instances.

AWS CLI

To check with which organizations and OUs you've shared your AMI

Use the describe-image-attribute command with the `launchPermission` attribute.

```
aws ec2 describe-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --attribute launchPermission
```

The following is an example response.

```
{
    "ImageId": "ami-0abcdef1234567890",
    "LaunchPermissions": [
        {
            "OrganizationalUnitArn": "arn:aws:organizations::111122223333:ou/
o-123example/ou-1234-5example"
        }
```

```
    ]
}
```

PowerShell

To check with which organizations and OUs you've shared your AMI

Use the Get-EC2ImageAttribute cmdlet.

```
Get-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission
```

Share an AMI with an organization or OU

You can share an AMI with an organization or OU.

> **Note**
>
> You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see Allow organizations and OUs to use a KMS key.

Console

To share an AMI with an organization or an OU

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions**, **Edit AMI permissions**.
4. Under **AMI availability**, choose **Private**.
5. Next to **Shared organizations/OUs**, choose **Add organization/OU ARN**.
6. For **Organization/OU ARN**, enter the organization ARN or OU ARN with which you want to share the AMI, and then choose **Share AMI**. Note that you must specify the full ARN, not just the ID.

To share this AMI with multiple organizations or OUs, repeat this step until you have added all of the required organizations or OUs.

7. Choose **Save changes** when you're done.
8. (Optional) To view the organizations or OUs with which you have shared the AMI, select the AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**. To find AMIs that are shared with you, see Find shared AMIs to use for Amazon EC2 instances.

AWS CLI

To share an AMI with an organization

Use the modify-image-attribute command to grant launch permissions for the specified AMI to the specified organization.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --launch-permission
 "Add=[{OrganizationArn=arn:aws:organizations::123456789012:organization/
o-123example}]"
```

To share an AMI with an OU

The modify-image-attribute command grants launch permissions for the specified AMI to the specified OU. Note that you must specify the full ARN, not just the ID.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --launch-permission
 "Add=[{OrganizationalUnitArn=arn:aws:organizations::123456789012:ou/o-123example/
ou-1234-5example}]"
```

PowerShell

Use the Edit-EC2ImageAttribute command (Tools for Windows PowerShell) to share an AMI as shown in the following examples.

To share an AMI with an organization or an OU

The following command grants launch permissions for the specified AMI to the specified organization.

```
Edit-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission `
    -OperationType add `
    -OrganizationArn "arn:aws:organizations::123456789012:organization/o-123example"
```

To stop sharing an AMI with an organization or OU

The following command removes launch permissions for the specified AMI from the specified organization:

```
Edit-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission `
    -OperationType remove `
    -OrganizationArn "arn:aws:organizations::123456789012:organization/o-123example"
```

To stop sharing an AMI with all organizations, OUs, and AWS accounts

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
Reset-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission
```

Stop sharing an AMI with an organization or OU

You can stop sharing an AMI with an organization or OU.

> **Note**
>
> You can't stop sharing an AMI with a specific account if it's in an organization or OU with which an AMI is shared. If you try to stop sharing the AMI by removing launch permissions

for the account, Amazon EC2 returns a success message. However, the AMI continues to be shared with the account.

Console

To stop sharing an AMI with an organization or OU

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions**, **Edit AMI permissions**.
4. Under **Shared organizations/OUs**, select the organizations or OUs with which you want to stop sharing the AMI, and then choose **Remove selected**.
5. Choose **Save changes** when you're done.
6. (Optional) To confirm that you have stopped sharing the AMI with the organizations or OUs, select the AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**.

AWS CLI

To stop sharing an AMI with an organization or OU

Use the modify-image-attribute command. This example removes launch permissions for the specified AMI from the specified organization.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --launch-permission
 "Remove=[{OrganizationArn=arn:aws:organizations::123456789012:organization/
o-123example}]"
```

To stop sharing an AMI with all organizations, OUs, and AWS accounts

Use the reset-image-attribute command. This example removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 reset-image-attribute \
```

```
    --image-id ami-0abcdef1234567890 \
    --attribute launchPermission
```

PowerShell

To stop sharing an AMI with an organization or OU

Use the Edit-EC2ImageAttribute cmdlet. This example removes launch permissions for the specified AMI from the specified organization.

```
Edit-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission `
    -OperationType remove `
    -OrganizationArn "arn:aws:organizations::123456789012:organization/o-123example"
```

To stop sharing an AMI with all organizations, OUs, and AWS accounts

Use the Reset-EC2ImageAttribute cmdlet. This example removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
Reset-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute LaunchPermission
```

Share an AMI with specific AWS accounts

You can share an AMI with specific AWS accounts without making the AMI public. All you need are the AWS account IDs.

An AWS account ID is a 12-digit number, such as `012345678901`, that uniquely identifies an AWS account. For more information, see View AWS account identifiers in the *AWS Account Management Reference Guide*.

Considerations

Consider the following when sharing AMIs with specific AWS accounts.

- **Ownership** – To share an AMI, your AWS account must own the AMI.

- **Sharing limits** – For the maximum number of entities to which an AMI can be shared within a Region, see the Amazon EC2 service quotas.
- **Tags** – You can't share user-defined tags (tags that you attach to an AMI). When you share an AMI, your user-defined tags are not available to any AWS account that the AMI is shared with.
- **Snapshots** – You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. You can share only the AMI itself; the system provides the instance access to the referenced EBS snapshots for the launch. However, you must share any KMS keys used to encrypt snapshots that an AMI references. For more information, see Share an Amazon EBS snapshot in the *Amazon EBS User Guide*.
- **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.
  - The encrypted snapshots must be encrypted with a KMS key. You can’t share AMIs that are backed by snapshots that are encrypted with the default AWS managed key.
  - If you share an AMI that is backed by encrypted snapshots, you must allow the AWS accounts to use the KMS keys that were used to encrypt the snapshots. For more information, see Allow organizations and OUs to use a KMS key. To set up the key policy that you need to launch Auto Scaling instances when you use a customer managed key for encryption, see Required AWS KMS key policy for use with encrypted volumes in the *Amazon EC2 Auto Scaling User Guide*.
- **Region** – AMIs are a Regional resource. When you share an AMI, it is only available in that Region. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see Copy an Amazon EC2 AMI.
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can’t delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from their instance.
- **Copying shared AMIs** – If users in another account want to copy a shared AMI, you must grant them read permissions for the storage that backs the AMI. For more information, see Cross-account copying.
- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

Console

To grant explicit launch permissions

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions**, **Edit AMI permissions**.
4. Choose **Private**.
5. Under **Shared accounts**, choose **Add account ID**.
6. For **AWS account ID**, enter the AWS account ID with which you want to share the AMI, and then choose **Share AMI**.

   To share this AMI with multiple accounts, repeat Steps 5 and 6 until you have added all the required account IDs.
7. Choose **Save changes** when you are done.
8. (Optional) To view the AWS account IDs with which you have shared the AMI, select the AMI in the list, and choose the **Permissions** tab. To find AMIs that are shared with you, see Find shared AMIs to use for Amazon EC2 instances.

AWS CLI

Use the modify-image-attribute command to share an AMI as shown in the following examples.

To grant explicit launch permissions

The following example grants launch permissions for the specified AMI to the specified AWS account.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --launch-permission "Add=[{UserId=123456789012}]"
```

To remove launch permissions for an account

The following example removes launch permissions for the specified AMI from the specified AWS account.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --launch-permission "Remove=[{UserId=123456789012}]"
```

To remove all launch permissions

The following example removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 reset-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --attribute launchPermission
```

PowerShell

Use the Edit-EC2ImageAttribute command (Tools for Windows PowerShell) to share an AMI as shown in the following examples.

To grant explicit launch permissions

The following example grants launch permissions for the specified AMI to the specified AWS account.

```
Edit-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission `
    -OperationType add `
    -UserId "123456789012"
```

To remove launch permissions for an account

The following example removes launch permissions for the specified AMI from the specified AWS account.

```
Edit-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission -OperationType remove `
    -UserId "123456789012"
```

To remove all launch permissions

The following exaple removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
Reset-EC2ImageAttribute `
```

```
    -ImageId ami-0abcdef1234567890 `
    -Attribute launchPermission
```

Cancel having an AMI shared with your AWS account

An Amazon Machine Image (AMI) can be shared with specific AWS accounts by adding the accounts to the AMI's launch permissions. If an AMI has been shared with your AWS account and you no longer want it shared with your account, you can remove your account from the AMI's launch permissions. You do this by running the `cancel-image-launch-permission` AWS CLI command. When running this command, your AWS account is removed from the launch permissions for the specified AMI. To find the AMIs that are shared with your AWS account, see Find shared AMIs to use for Amazon EC2 instances.

You might cancel having an AMI shared with your account, for example, to reduce the likelihood of launching an instance with an unused or deprecated AMI that was shared with you. When you cancel having an AMI shared with your account, it no longer appears in any AMI lists in the EC2 console or in the output for describe-images.

Topics

Limitations

- You can remove your account from the launch permissions of an AMI that is shared with your AWS account only. You can't use `cancel-image-launch-permission` to remove your account from the launch permissions of an AMI shared with an organization or organizational unit (OU) or to remove access to public AMIs.
- You can't permanently remove your account from the launch permissions of an AMI. An AMI owner can share an AMI with your account again.
- AMIs are a Regional resource. When running `cancel-image-launch-permission`, you must specify the Region in which the AMI is located. Either specify the Region in the command, or use the AWS_DEFAULT_REGION environment variable.
- Only the AWS CLI and SDKs support removing your account from the launch permissions of an AMI. The EC2 console does not currently support this action.

Cancel having an AMI shared with your account

> **Note**
>
> After you cancel having an AMI shared with your account, you can't undo it. To regain access to the AMI, the AMI owner must share it with your account.

AWS CLI

To cancel having an AMI shared with your account

Use the cancel-image-launch-permission command.

```
aws ec2 cancel-image-launch-permission \
    --image-id ami-0abcdef1234567890 \
    --region us-east-1
```

PowerShell

To cancel having an AMI shared with your account

Use the Stop-EC2ImageLaunchPermission cmdlet.

```
Stop-EC2ImageLaunchPermission `
    -ImageId ami-0abcdef1234567890 `
    -Region us-east-1
```

Recommendations for creating shared Linux AMIs

Use the following guidelines to reduce the attack surface and improve the reliability of the AMIs you create.

> **Important**
>
> No list of security guidelines can be exhaustive. Build your shared AMIs carefully and take time to consider where you might expose sensitive data.

Contents

If you are building AMIs for AWS Marketplace, see Best practices for building AMIs in the *AWS Marketplace Seller Guide* for guidelines, policies, and best practices.

For additional information about sharing AMIs safely, see the following articles:

- How To Share and Use Public AMIs in A Secure Manner
- Public AMI Publishing: Hardening and Clean-up Requirements

Disable password-based remote logins for the root user

Using a fixed root password for a public AMI is a security risk that can quickly become known. Even relying on users to change the password after the first login opens a small window of opportunity for potential abuse.

To solve this problem, disable password-based remote logins for the root user.

To disable password-based remote logins for the root user

1. Open the `/etc/ssh/sshd_config` file with a text editor and locate the following line:

   ```
   #PermitRootLogin yes
   ```

2. Change the line to:

   ```
   PermitRootLogin without-password
   ```

   The location of this configuration file might differ for your distribution, or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

Disable local root access

When you work with shared AMIs, a best practice is to disable direct root logins. To do this, log into your running instance and issue the following command:

```
[ec2-user ~]$ sudo passwd -l root
```

> **Note**
>
> This command does not impact the use of `sudo`.

Remove SSH host key pairs

If you plan to share an AMI derived from a public AMI, remove the existing SSH host key pairs located in `/etc/ssh`. This forces SSH to generate new unique SSH key pairs when someone launches an instance using your AMI, improving security and reducing the likelihood of "man-in-the-middle" attacks.

Remove all of the following key files that are present on your system.

- ssh_host_dsa_key
- ssh_host_dsa_key.pub
- ssh_host_key
- ssh_host_key.pub
- ssh_host_rsa_key
- ssh_host_rsa_key.pub
- ssh_host_ecdsa_key
- ssh_host_ecdsa_key.pub
- ssh_host_ed25519_key
- ssh_host_ed25519_key.pub

You can securely remove all of these files with the following command.

```
[ec2-user ~]$ sudo shred -u /etc/ssh/*_key /etc/ssh/*_key.pub
```

> **Warning**
>
> Secure deletion utilities such as **shred** might not remove all copies of a file from your storage media. Hidden copies of files may be created by journalling file systems (including Amazon Linux default ext4), snapshots, backups, RAID, and temporary caching. For more information, see the [shred documentation](#).

> **Important**
>
> If you forget to remove the existing SSH host key pairs from your public AMI, our routine auditing process notifies you and all customers running instances of your AMI of the potential security risk. After a short grace period, we mark the AMI private.

Install public key credentials

After configuring the AMI to prevent logging in using a password, you must make sure users can log in using another mechanism.

Amazon EC2 allows users to specify a public-private key pair name when launching an instance. When a valid key pair name is provided to the `RunInstances` API call (or through the command line API tools), the public key (the portion of the key pair that Amazon EC2 retains on the server after a call to `CreateKeyPair` or `ImportKeyPair`) is made available to the instance through an HTTP query against the instance metadata.

To log in through SSH, your AMI must retrieve the key value at boot and append it to `/root/.ssh/authorized_keys` (or the equivalent for any other user account on the AMI). Users can launch instances of your AMI with a key pair and log in without requiring a root password.

Many distributions, including Amazon Linux and Ubuntu, use the `cloud-init` package to inject public key credentials for a configured user. If your distribution does not support `cloud-init`, you can add the following code to a system start-up script (such as `/etc/rc.local`) to pull in the public key you specified at launch for the root user.

Note

In the following example, the IP address http://169.254.169.254/ is a link-local address and is valid only from the instance.

IMDSv2

```
if [ ! -d /root/.ssh ] ; then
        mkdir -p /root/.ssh
        chmod 700 /root/.ssh
fi
# Fetch public key using HTTP
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-
token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-
data/public-keys/0/openssh-key > /tmp/my-key
if [ $? -eq 0 ] ; then
        cat /tmp/my-key >> /root/.ssh/authorized_keys
        chmod 700 /root/.ssh/authorized_keys
        rm /tmp/my-key
fi
```

IMDSv1

```
if [ ! -d /root/.ssh ] ; then
        mkdir -p /root/.ssh
        chmod 700 /root/.ssh
fi
# Fetch public key using HTTP
curl http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key > /tmp/my-key
if [ $? -eq 0 ] ; then
        cat /tmp/my-key >> /root/.ssh/authorized_keys
        chmod 700 /root/.ssh/authorized_keys
        rm /tmp/my-key
fi
```

This can be applied to any user; you do not need to restrict it to the `root` user.

> **Note**
>
> Rebundling an instance based on this AMI includes the key with which it was launched. To prevent the key's inclusion, you must clear out (or delete) the `authorized_keys` file or exclude this file from rebundling.

Disable sshd DNS checks (optional)

Disabling sshd DNS checks slightly weakens your sshd security. However, if DNS resolution fails, SSH logins still work. If you do not disable sshd checks, DNS resolution failures prevent all logins.

To disable sshd DNS checks

1. Open the `/etc/ssh/sshd_config` file with a text editor and locate the following line:

    ```
    #UseDNS yes
    ```

2. Change the line to:

    ```
    UseDNS no
    ```

> **Note**
>
> The location of this configuration file can differ for your distribution or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

Remove sensitive data

We recommend against storing sensitive data or software on any AMI that you share. Users who launch a shared AMI might be able to rebundle it and register it as their own. Follow these guidelines to help you to avoid some easily overlooked security risks:

- We recommend using the `--exclude` *`directory`* option on `ec2-bundle-vol` to skip any directories and subdirectories that contain secret information that you would not like to include in your bundle. In particular, exclude all user-owned SSH public/private key pairs and SSH `authorized_keys` files when bundling the image. The Amazon public AMIs store these in

/root/.ssh for the root user, and /home/*user_name*/.ssh/ for regular users. For more information, see ec2-bundle-vol.

- Always delete the shell history before bundling. If you attempt more than one bundle upload in the same AMI, the shell history contains your access key. The following example should be the last command you run before bundling from within the instance.

```
[ec2-user ~]$ shred -u ~/.*history
```

> **Warning**
>
> The limitations of **shred** described in the warning above apply here as well.
> Be aware that bash writes the history of the current session to the disk on exit. If you log out of your instance after deleting ~/.bash_history, and then log back in, you will find that ~/.bash_history has been re-created and contains all of the commands you ran during your previous session.
> Other programs besides bash also write histories to disk, Use caution and remove or exclude unnecessary dot-files and dot-directories.

- Bundling a running instance requires your private key and X.509 certificate. Put these and other credentials in a location that is not bundled (such as the instance store).

Monitor AMI events using Amazon EventBridge

When the state of an Amazon Machine Image (AMI) changes, Amazon EC2 generates an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events). The events are sent to the default EventBridge event bus in JSON format. You can use Amazon EventBridge to detect and react to these events. You do this by creating rules in EventBridge that trigger an action in response to an event. For example, you can create an EventBridge rule that detects when the AMI creation process has completed and then invokes an Amazon SNS topic to send an email notification to you.

Amazon EC2 generates an `EC2 AMI State Change` event when an AMI enters any of the following states:

- `available`
- `failed`

- deregistered
- disabled

Events are generated on a best effort basis.

The following table lists the AMI operations and the states that an AMI can enter. In the table, **Yes** indicates the states that the AMI can enter when the corresponding operation runs.

AMI operations	available	failed	deregistered	disabled
CopyImage	Yes	Yes		
CreateImage	Yes	Yes		
CreateRes toreImageTask	Yes	Yes		
DeregisterImage			Yes	
DisableImage				Yes
EnableImage	Yes			
RegisterImage	Yes	Yes		

EC2 AMI State Change events

- Event details
- available events
- failed events
- deregistered events
- disabled events

Event details

You can use the following fields in the event to create rules that trigger an action:

`"source": "aws.ec2"`

Identifies that the event is from Amazon EC2.

`"detail-type": "EC2 AMI State Change"`

Identifies the event name.

`"detail": { "ImageId": "ami-0abcdef1234567890", "State": "available", }`

Provides the AMI ID and the state of the AMI (`available`, `failed`, `deregistered`, or `disabled`).

For more information, see the following in the *Amazon EventBridge User Guide*:

- Amazon EventBridge events
- Amazon EventBridge event patterns
- Amazon EventBridge rules

For a tutorial about how to create a Lambda function and an EventBridge rule that runs the Lambda function, see Tutorial: Log the state of an Amazon EC2 instance using EventBridge in the *AWS Lambda Developer Guide*.

available events

The following is an example of an event that Amazon EC2 generates when the AMI enters the `available` state following a successful `CreateImage`, `CopyImage`, `RegisterImage`, `CreateRestoreImageTask`, or `EnableImage` operation.

`"State": "available"` indicates that the operation was successful.

```
{
    "version": "0",
    "id": "example-9f07-51db-246b-d8b8441bcdf0",
    "detail-type": "EC2 AMI State Change",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": ["arn:aws:ec2:us-east-1::image/ami-0abcdef1234567890"],
```

```
    "detail": {
        "RequestId": "example-9dcc-40a6-aa77-7ce457d5442b",
        "ImageId": "ami-0abcdef1234567890",
        "State": "available",
        "ErrorMessage": ""
    }
}
```

failed events

The following is an example of an event that Amazon EC2 generates when the AMI enters the `failed` state following a failed `CreateImage`, `CopyImage`, `RegisterImage`, or `CreateRestoreImageTask` operation.

The following fields provide pertinent information:

- `"State": "failed"` – Indicates that the operation failed.
- `"ErrorMessage": ""` – Provides the reason for the failed operation.

```
{
    "version": "0",
    "id": "example-9f07-51db-246b-d8b8441bcdf0",
    "detail-type": "EC2 AMI State Change",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": ["arn:aws:ec2:us-east-1::image/ami-0abcdef1234567890"],
    "detail": {
        "RequestId": "example-9dcc-40a6-aa77-7ce457d5442b",
        "ImageId": "ami-0abcdef1234567890",
        "State": "failed",
        "ErrorMessage": "Description of failure"
    }
}
```

deregistered events

The following is an example of an event that Amazon EC2 generates when the AMI enters the `deregistered` state following a successful `DeregisterImage` operation. If the operation fails, no event is generated. Any failure is known immediately because `DeregisterImage` is a synchronous operation.

`"State": "deregistered"` indicates that the `DeregisterImage` operation was successful.

```
{
    "version": "0",
    "id": "example-9f07-51db-246b-d8b8441bcdf0",
    "detail-type": "EC2 AMI State Change",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": ["arn:aws:ec2:us-east-1::image/ami-0abcdef1234567890"],
    "detail": {
        "RequestId": "example-9dcc-40a6-aa77-7ce457d5442b",
        "ImageId": "ami-0abcdef1234567890",
        "State": "deregistered",
        "ErrorMessage": ""
    }
}
```

disabled events

The following is an example of an event that Amazon EC2 generates when the AMI enters the `disabled` state following a successful `DisableImage` operation. If the operation fails, no event is generated. Any failure is known immediately because `DisableImage` is a synchronous operation.

`"State": "disabled"` indicates that the `DisableImage` operation was successful.

```
{
    "version": "0",
    "id": "example-9f07-51db-246b-d8b8441bcdf0",
    "detail-type": "EC2 AMI State Change",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": ["arn:aws:ec2:us-east-1::image/ami-0abcdef1234567890"],
    "detail": {
        "RequestId": "example-9dcc-40a6-aa77-7ce457d5442b",
        "ImageId": "ami-0abcdef1234567890",
```

```
        "State": "disabled",
        "ErrorMessage": ""
    }
}
```

Understand AMI billing information

There are many Amazon Machine Images (AMIs) to choose from when launching your instances, and they support a variety of operating system platforms and features. To understand how the AMI you choose when launching your instance affects the bottom line on your AWS bill, you can research the associated operating system platform and billing information. Do this before you launch any On-Demand or Spot Instances, or purchase a Reserved Instance.

Here are two examples of how researching your AMI in advance can help you choose the AMI that best suits your needs:

- For Spot Instances, you can use the AMI **Platform details** to confirm that the AMI is supported for Spot Instances.
- When purchasing a Reserved Instance, you can make sure that you select the operating system platform (**Platform**) that maps to the AMI **Platform details**.

For more information about instance pricing, see Amazon EC2 pricing.

Contents

AMI billing information fields

The following fields provide billing information associated with an AMI:

Platform details

    The platform details associated with the billing code of the AMI. For example, `Red Hat Enterprise Linux`.

Usage operation

The operation of the Amazon EC2 instance and the billing code that is associated with the AMI. For example, `RunInstances:0010`. **Usage operation** corresponds to the lineitem/Operation column on your AWS Cost and Usage Report (CUR) and in the AWS Price List API.

You can view these fields on the **Instances** or **AMIs** page in the Amazon EC2 console, or in the response that is returned by the describe-images or Get-EC2Image command.

Sample data: usage operation by platform

The following table lists some of the platform details and usage operation values that can be displayed on the **Instances** or **AMIs** pages in the Amazon EC2 console, or in the response that is returned by the describe-images or Get-EC2Image command.

Platform details	Usage operation [2]
Linux/UNIX	RunInstances
Red Hat BYOL Linux	RunInstances:00g0 [3]
Red Hat Enterprise Linux	RunInstances:0010
Red Hat Enterprise Linux with HA	RunInstances:1010
Red Hat Enterprise Linux with SQL Server Standard and HA	RunInstances:1014
Red Hat Enterprise Linux with SQL Server Enterprise and HA	RunInstances:1110
Red Hat Enterprise Linux with SQL Server Standard	RunInstances:0014
Red Hat Enterprise Linux with SQL Server Web	RunInstances:0210
Red Hat Enterprise Linux with SQL Server Enterprise	RunInstances:0110

Platform details	Usage operation [2]
SQL Server Enterprise	RunInstances:0100
SQL Server Standard	RunInstances:0004
SQL Server Web	RunInstances:0200
SUSE Linux	RunInstances:000g
Ubuntu Pro	RunInstances:0g00
Windows	RunInstances:0002
Windows BYOL	RunInstances:0800
Windows with SQL Server Enterprise [1]	RunInstances:0102
Windows with SQL Server Standard [1]	RunInstances:0006
Windows with SQL Server Web [1]	RunInstances:0202

[1] If two software licenses are associated with an AMI, the **Platform details** field shows both.

[2] If you are running Spot Instances, the lineitem/Operation on your AWS Cost and Usage Report might be different from the **Usage operation** value that is listed here. For example, if `lineitem/Operation` displays `RunInstances:0010:SV006`, it means that Amazon EC2 is running Red Hat Enterprise Linux Spot Instance-hour in US East (N. Virginia) in Zone 6.

[3] This appears as RunInstances (Linux/UNIX) in your usage reports.

Finding AMI billing and usage details

The following properties can help you verify AMI charges on your bill:

- **Platform details**
- **Usage operation**
- **AMI ID**

Console

To find the AMI billing information for an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select the AMI.
4. On the **Details** tab, find **Platform details** and **Usage operation**.

To find the AMI billing information for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Details** tab, expand **Instance details** and find **Platform details** and **Usage operation**.

AWS CLI

To find the AMI billing information for an AMI

Use the describe-images command.

```
aws ec2 describe-images \
    --image-ids ami-0abcdef1234567890 \
    --query "Images[].
{PlatformDetails:PlatformDetails,UsageOperation:UsageOperation}"
```

The following is example output for a Linux AMI.

```
[
    {
        "PlatformDetails": "Linux/UNIX",
        "UsageOperation": "RunInstances"
    }
]
```

To find the AMI billing information for an instance

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query "Reservations[].Instances[].
{PlatformDetails:PlatformDetails,UsageOperation:UsageOperation}"
```

The following is example output for a Windows instance.

```
[
    {
        "PlatformDetails": "Windows",
        "UsageOperation": "RunInstances:0002"
    }
]
```

PowerShell

To find the AMI billing information for an AMI

Use the Get-EC2Image cmdlet.

```
Get-EC2Image `
    -ImageId ami-0abcdef1234567890 | `
    Format-List PlatformDetails, UsageOperation
```

The following is example output for a Linux AMI.

```
PlatformDetails : Linux/UNIX
```

```
UsageOperation  : RunInstances
```

To find the AMI billing information for an instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance `
    -InstanceId i-1234567890abcdef0).Instances | `
    Format-List PlatformDetails, UsageOperation
```

The following is example output for a Windows instance.

```
PlatformDetails : Windows
UsageOperation  : RunInstances:0002
```

Verify AMI charges on your bill

To ensure that you're not incurring unplanned costs, you can verify that the billing information for an instance in your AWS Cost and Usage Report (CUR) matches the billing information that's associated with the AMI that you used to launch the instance.

To verify the billing information, find the instance ID in your CUR and check the corresponding value in the `lineitem/Operation` column. That value should match the value for **Usage operation** that's associated with the AMI.

For example, the AMI `ami-0123456789EXAMPLE` has the following billing information:

- **Platform details** = `Red Hat Enterprise Linux`
- **Usage operation** = `RunInstances:0010`

If you launched an instance using this AMI, you can find the instance ID in your CUR, and check the corresponding value in the `lineitem/Operation` column. In this example, the value should be `RunInstances:0010`.

AMI quotas in Amazon EC2

The following quotas apply to creating and sharing AMIs. The quotas apply per AWS Region.

Quota name	Description	Default quota per Region
AMIs	The maximum number of public and private AMIs allowed per Region. These include available, pending, and disabled AMIs, and AMIs in the Recycle Bin.	50,000
Public AMIs	The maximum number of public AMIs, including public AMIs in the Recycle Bin, allowed per Region.	5
AMI sharing	The maximum number of entities (organizations, organizational units (OUs), and accounts) that an AMI can be shared with in a Region. Note that if you share an AMI with an organization or OU, the number of accounts in the organization or OU does not count towards the quota.	1,000

If you exceed your quotas and you want to create or share more AMIs, you can do the following:

- If you exceed your total AMIs or public AMIs quota, consider deregistering unused images.
- If you exceed your public AMIs quota, consider making one or more public AMIs private.
- If you exceed your AMI sharing quota, consider sharing your AMIs with an organization or OU instead of separate accounts.
- Request a quota increase for AMIs.

Request a quota increase for AMIs

If you need more than the default quota for AMIs, you can request a quota increase.

To request a quota increase for AMIs

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.
2. In the navigation pane, choose **AWS services**.
3. Choose **Amazon Elastic Compute Cloud (Amazon EC2)** from the list, or type the name of the service in the search box.
4. Choose the AMI quota to request an increase. The AMI quotas you can select are:
   - AMIs
   - Public AMIs
   - AMI sharing
5. Choose **Request quota increase**.
6. For **Change quota value**, enter the new quota value, and then choose **Request**.

To view any pending or recently resolved requests, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number under **Support Center case number**. Choose the case number to open the ticket for your request.

After the request is resolved, the **Applied quota value** for the quota is set to the new value.

For more information, see the Service Quotas User Guide.

Amazon EC2 instances

An Amazon EC2 instance is a virtual server in the AWS cloud environment. You have full control over your instance, from the time that you first start it (referred to as launching an instance) until you delete it (referred to as terminating an instance). You can choose from a variety of operating systems when you launch your instance. You can connect to your instance and customize it to meet your needs. For example, you can configure the operating system, install operating system updates, and install applications on your instance.

Amazon EC2 provides a wide range of instance types. You can choose an instance type that provides the compute resources, memory, storage, and network performance that you need to run your applications.

With Amazon EC2, you pay only for what you use. Billing for your instance starts when you launch your instance and it transitions to the running state. Billing stops when you stop your instance and resumes when you start your instance. When you terminate your instance, billing stops when it transitions to the shutting down state.

Amazon EC2 provides features that you can use to optimize the performance and the cost of your instances. For example, you can use Amazon EC2 Fleet or Amazon EC2 Auto Scaling to scale your capacity up or down as your instance utilization changes. You can reduce the costs for your instances using Spot Instances or Savings Plans.

A *managed instance* is managed by a service provider, such as Amazon EKS Auto Mode. You can't directly modify the settings of a managed instance. Managed instances are identified by a **true** value in the **Managed** field. For more information, see [Amazon EC2 managed instances].

Features and tasks

- [Amazon EC2 instance types]
- [Amazon EC2 managed instances]
- [Amazon EC2 billing and purchasing options]
- [Store instance launch parameters in Amazon EC2 launch templates]
- [Launch an Amazon EC2 instance]
- [Connect to your EC2 instance]
- [Amazon EC2 instance state changes]

Amazon EC2 instance types

When you launch an instance, the *instance type* that you specify determines the hardware of the host computer used for your instance. Each instance type offers different compute, memory, and storage capabilities, and is grouped in an instance family based on these capabilities. Select an instance type based on the requirements of the application or software that you plan to run on your instance. For more information about features and use cases, see Amazon EC2 Instance Types.

Amazon EC2 dedicates some resources of the host computer, such as CPU, memory, and instance storage, to a particular instance. Amazon EC2 shares other resources of the host computer, such as the network and the disk subsystem, among instances. If each instance on a host computer tries to use as much of one of these shared resources as possible, each receives an equal share of that resource. However, when a resource is underused, an instance can consume a higher share of that resource while it's available.

Each instance type provides higher or lower minimum performance from a shared resource. For example, instance types with high I/O performance have a larger allocation of shared resources. Allocating a larger share of shared resources also reduces the variance of I/O performance. For most applications, moderate I/O performance is more than enough. However, for applications that require greater or more consistent I/O performance, consider an instance type with higher I/O performance.

Contents

Available instance types

Amazon EC2 provides a wide selection of instance types optimized to fit different use cases. Instance types comprise varying combinations of CPU, memory, storage, and networking capacity and give you the flexibility to choose the appropriate mix of resources for your applications. Each instance type includes one or more instance sizes, allowing you to scale your resources to the requirements of your target workload.

Instance type naming conventions

Names are based on instance family, generation, processor family, capabilities, and size. For more information, see Naming conventions in the *Amazon EC2 Instance Types Guide*.

Find an instance type

To determine which instance types meet your requirements, such as supported Regions, compute resources, or storage resources, see Find an Amazon EC2 instance type and Amazon EC2 instance type specifications in the *Amazon EC2 Instance Types Guide*.

Hardware specifications

For detailed instance type specifications, see Specifications in the *Amazon EC2 Instance Types Guide*. For pricing information, see Amazon EC2 On-Demand Pricing.

To determine which instance type best meets your needs, we recommend that you launch an instance and use your own benchmark application. Because you pay by the instance second, it's convenient and inexpensive to test multiple instance types before making a decision. If your needs change, even after you make a decision, you can change the instance type later. For more information, see Amazon EC2 instance type changes.

Hypervisor type

Amazon EC2 supports the following hypervisors: Xen and Nitro.

Nitro-based instances

- **General purpose:** M5 | M5a | M5ad | M5d | M5dn | M5n | M5zn | M6a | M6g | M6gd | M6i | M6id | M6idn | M6in | M7a | M7g | M7gd | M7i | M7i-flex | M8g | M8gd | M8i | M8i-flex | T3 | T3a | T4g
- **Compute optimized:** C5 | C5a | C5ad | C5d | C5n | C6a | C6g | C6gd | C6gn | C6i | C6id | C6in | C7a | C7g | C7gd | C7gn | C7i | C7i-flex | C8g | C8gd | C8gn
- **Memory optimized:** R5 | R5a | R5ad | R5b | R5d | R5dn | R5n | R6a | R6g | R6gd | R6i | R6idn | R6in | R6id | R7a | R7g | R7gd | R7i | R7iz | R8g | R8gd | R8i | R8i-flex | U-3tb1 | U-6tb1 | U-9tb1 | U-12tb1 | U-18tb1 | U-24tb1 | U7i-6tb | U7i-8tb | U7i-12tb | U7in-16tb | U7in-24tb | U7in-32tb | U7inh-32tb | X2gd | X2idn | X2iedn | X2iezn | X8g | z1d
- **Storage optimized:** D3 | D3en | I3en | I4g | I4i | I7i | I7ie | I8g | I8ge | Im4gn | Is4gen
- **Accelerated computing:** DL1 | DL2q | F2 | G4ad | G4dn | G5 | G5g | G6 | G6e | G6f | Gr6 | Gr6f | Inf1 | Inf2 | P3dn | P4d | P4de | P5 | P5e | P5en | P6-B200 | P6e-GB200 | Trn1 | Trn1n | Trn2 | Trn2u | VT1
- **High-performance computing:** Hpc6a | Hpc6id | Hpc7a | Hpc7g
- **Previous generation:** A1

For more information about the supported versions of Nitro hypervisor, see Network feature support in the *Amazon EC2 Instance Types Guide*.

Xen-based instances

- **General purpose**: M1 | M2 | M3 | M4 | T1 | T2

- **Compute optimized**: C1 | C3 | C4
- **Memory optimized**: R3 | R4 | X1 | X1e
- **Storage optimized**: D2 | H1 | I2 | I3
- **Accelerated computing**: F1 | G3 | P2 | P3

AMI virtualization types

The virtualization type of your instance is determined by the AMI that you use to launch it. Current generation instance types support hardware virtual machine (HVM) only. Some previous generation instance types support paravirtual (PV) and some AWS Regions support PV instances. For more information, see Virtualization types.

For best performance, we recommend that you use an HVM AMI. In addition, HVM AMIs are required to take advantage of enhanced networking. HVM virtualization uses hardware-assist technology provided by the AWS platform. With HVM virtualization, the guest VM runs as if it were on a native hardware platform, except that it still uses PV network and storage drivers for improved performance.

Processors

EC2 instances support a variety of processors.

Processors

- Intel processors
- AMD processors
- AWS Graviton processors
- AWS Trainium
- AWS Inferentia

Intel processors

Amazon EC2 instances that run on Intel processors might include the following processor features. Not all instances that run on Intel processors support all of these processor features. For information about which features are available for each instance type, see Amazon EC2 Instance types.

- **Intel AES New Instructions (AES-NI)** — Intel AES-NI encryption instruction set improves upon the original Advanced Encryption Standard (AES) algorithm to provide faster data protection and greater security. All current generation EC2 instances support this processor feature.
- **Intel Advanced Vector Extensions (Intel AVX, Intel AVX2, and Intel AVX-512)** — Intel AVX and Intel AVX2 are 256-bit, and Intel AVX-512 is a 512-bit instruction set extension designed for applications that are Floating Point (FP) intensive. Intel AVX instructions improve performance for applications like image and audio/video processing, scientific simulations, financial analytics, and 3D modeling and analysis. These features are only available on instances launched with HVM AMIs.
- **Intel Turbo Boost Technology** — Intel Turbo Boost Technology processors automatically run cores faster than the base operating frequency.
- **Intel Deep Learning Boost (Intel DL Boost)** — Accelerates AI deep learning use cases. The 2nd Gen Intel Xeon Scalable processors extend Intel AVX-512 with a new Vector Neural Network Instruction (VNNI/INT8) that significantly increases deep learning inference performance over previous generation Intel Xeon Scalable processors (with FP32) for image recognition/segmentation, object detection, speech recognition, language translation, recommendation systems, reinforcement learning, and more. VNNI may not be compatible with all Linux distributions.

  The following instances support VNNI: `M5n`, `R5n`, `M5dn`, `M5zn`, `R5b`, `R5dn`, `D3`, `D3en`, and `C6i`. `C5` and `C5d` instances support VNNI for only `12xlarge`, `24xlarge`, and `metal` instances.

Confusion can result from industry naming conventions for 64-bit CPUs. Chip manufacturer Advanced Micro Devices (AMD) introduced the first commercially successful 64-bit architecture based on the Intel x86 instruction set. Consequently, the architecture is widely referred to as AMD64 regardless of the chip manufacturer. Windows and several Linux distributions follow this practice. This explains why the internal system information on an instance running Ubuntu or Windows displays the CPU architecture as AMD64 even though the instances are running on Intel hardware.

AMD processors

Amazon EC2 instances that run on AMD EPYC processors can help you optimize both cost and performance for your workloads. These instances might support the following processor features. Not all instances that run on AMD processors support all of these processor features. For information about which features are available for each instance type, see Amazon EC2 Instance types.

- AMD Secure Memory Encryption (SME)
- AMD Transparent Single Key Memory Encryption (TSME)
- AMD Advanced Vector Extensions (AVX)
- AMD Secure Encrypted Virtualization-Secure Nested Paging (SEV-SNP)
- Vector Neural Network Instructions (VNNI)
- BFloat16

AWS Graviton processors

AWS Graviton is a family of processors designed to deliver the best price performance for your workloads running on Amazon EC2 instances.

For more information, see Getting started with Graviton.

AWS Trainium

Instances powered by AWS Trainium are purpose built for high-performance, cost-effective deep learning training. You can use these instances to train natural language processing, computer vision, and recommender models used across a broad set of applications, such as speech recognition, recommendation, fraud detection, and image and video classification. Use your existing workflows in popular ML frameworks, such as PyTorch and TensorFlow.

AWS Inferentia

Instances powered by AWS Inferentia are designed to accelerate machine learning. They provide high performance and low latency machine learning inference. These instances are optimized for deploying deep learning (DL) models for applications, such as natural language processing, object detection and classification, content personalization and filtering, and speech recognition.

There are a variety of ways that you can get started:

- Use SageMaker AI, a fully-managed service that is the easiest way to get started with machine learning models. For more information, see Get Started with SageMaker AI in the *Amazon SageMaker AI Developer Guide*.
- Launch an Inf1 or Inf2 instance using the Deep Learning AMI. For more information, see AWS Inferentia with DLAMI in the *AWS Deep Learning AMIs Developer Guide*.
- Launch an Inf1 or Inf2 instance using your own AMI and install the AWS Neuron SDK, which enables you to compile, run, and profile deep learning models for AWS Inferentia.

- Launch a container instance using an Inf1 or Inf2 instance and an Amazon ECS-optimized AMI. For more information, see Amazon Linux 2 (Inferentia) AMIs in the *Amazon Elastic Container Service Developer Guide*.
- Create an Amazon EKS cluster with nodes running Inf1 instances. For more information, see Inferentia support in the Amazon EKS User Guide.

Find an Amazon EC2 instance type

Before you can launch an instance, you must select an instance type to use. The instance type that you choose might depend on the resources that your workload requires, such as compute, memory, or storage resources. It can be beneficial to identify several instance types that might suit your workload and evaluate their performance in a test environment. There is no substitute for measuring the performance of your application under load.

You can get suggestions and guidance for EC2 instance types using the EC2 instance type finder. For more information, see the section called "EC2 instance type finder".

If you already have running EC2 instances, you can use AWS Compute Optimizer to get recommendations about the instance types that you should use to improve performance, save money, or both. For more information, see the section called "Compute Optimizer recommendations".

Tasks

- Find an instance type using the console
- Describe an instance type using the AWS CLI
- Find an instance type using the AWS CLI
- Find an instance type using the Tools for PowerShell

Find an instance type using the console

You can find an instance type that meets your needs using the Amazon EC2 console.

To find an instance type using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.

3. In the navigation pane, choose **Instance Types**.
4. (Optional) Choose the preferences (gear) icon to select which instance type attributes to display, such as **On-Demand Linux pricing**, and then choose **Confirm**. Alternatively, select the name of an instance type to open its details page and view all attributes available through the console. The console does not display all the attributes available through the API or the command line.
5. Use the instance type attributes to filter the list of displayed instance types to only the instance types that meet your needs. For example, you can filter on the following attributes:

   - **Availability zones** – The name of the Availability Zone, Local Zone, or Wavelength Zone. For more information, see the section called "Regions and Zones".
   - **vCPUs** or **Cores** – The number of vCPUs or cores.
   - **Memory (GiB)** – The memory size, in GiB.
   - **Network performance** – The network performance, in Gigabits.
   - **Local instance storage** – Indicates whether the instance type has local instance storage (`true` | `false`).
6. (Optional) To see a side-by-side comparison, select the checkbox for multiple instance types. The comparison is displayed at the bottom of the screen.
7. (Optional) To save the list of instance types to a comma-separated values (.csv) file for further review, choose **Actions**, **Download list CSV**. The file includes all instance types that match the filters you set.
8. (Optional) To launch instances using an instance type that meet your needs, select the checkbox for the instance type and choose **Actions**, **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

Describe an instance type using the AWS CLI

You can use the describe-instance-types command to describe a specific instance type.

To fully describe an instance type

The following command displays all available details for the specified instance type. The output is lengthy, so it is omitted here.

```
aws ec2 describe-instance-types \
    --instance-types t2.micro \
```

```
    --region us-east-2
```

The describe an instance type and filter the output

The following command displays the networking details for the specified instance type.

```
aws ec2 describe-instance-types \
    --instance-types t2.micro \
    --region us-east-2 \
    --query "InstanceTypes[].NetworkInfo"
```

The following is example output.

```
[
    {
        "NetworkPerformance": "Low to Moderate",
        "MaximumNetworkInterfaces": 2,
        "MaximumNetworkCards": 1,
        "DefaultNetworkCardIndex": 0,
        "NetworkCards": [
            {
                "NetworkCardIndex": 0,
                "NetworkPerformance": "Low to Moderate",
                "MaximumNetworkInterfaces": 2,
                "BaselineBandwidthInGbps": 0.064,
                "PeakBandwidthInGbps": 1.024
            }
        ],
        "Ipv4AddressesPerInterface": 2,
        "Ipv6AddressesPerInterface": 2,
        "Ipv6Supported": true,
        "EnaSupport": "unsupported",
        "EfaSupported": false,
        "EncryptionInTransitSupported": false,
        "EnaSrdSupported": false
    }
]
```

The following command displays the available memory for the specified instance type.

```
aws ec2 describe-instance-types \
    --instance-types t2.micro \
```

```
    --region us-east-2 \
    --query "InstanceTypes[].MemoryInfo"
```

The following is example output.

```
[
    {
        "SizeInMiB": 1024
    }
]
```

Find an instance type using the AWS CLI

You can use the describe-instance-types and describe-instance-type-offerings commands to find the instance types that meet your needs.

Examples

- Example 1: Find an instance type by Availability Zone
- Example 2: Find an instance type by available memory size
- Example 3: Find an instance type by available instance storage
- Example 4: Find an instance type that supports hibernation

Example 1: Find an instance type by Availability Zone

The following example displays only the instance types offered in the specified Availability Zone.

```
aws ec2 describe-instance-type-offerings \
    --location-type "availability-zone" \
    --filters "Name=location,Values=us-east-2a" \
    --region us-east-2 \
    --query "InstanceTypeOfferings[*].[InstanceType]" --output text | sort
```

The output is a list of instance types, sorted alphabetically. The following is the start of the output only.

```
a1.2xlarge
a1.4xlarge
a1.large
```

```
a1.medium
a1.metal
a1.xlarge
c4.2xlarge
    ...
```

Example 2: Find an instance type by available memory size

The following example displays only current generation instance types with 64 GiB (65536 MiB) of memory.

```
aws ec2 describe-instance-types \
    --filters "Name=current-generation,Values=true" "Name=memory-info.size-in-mib,Values=65536" \
    --region us-east-2 \
    --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

The output is a list of instance types, sorted alphabetically. The following is the start of the output only.

```
c5a.8xlarge
c5ad.8xlarge
c6a.8xlarge
c6g.8xlarge
c6gd.8xlarge
c6gn.8xlarge
c6i.8xlarge
c6id.8xlarge
c6in.8xlarge
    ...
```

Example 3: Find an instance type by available instance storage

The following example displays the total size of instance storage for all R7 instances with instance store volumes.

```
aws ec2 describe-instance-types \
    --filters "Name=instance-type,Values=r7*" "Name=instance-storage-supported,Values=true" \
    --region us-east-2 \
    --query "InstanceTypes[].[InstanceType, InstanceStorageInfo.TotalSizeInGB]" \
```

```
    --output table
```

The following is example output.

```
---------------------------
|  DescribeInstanceTypes  |
+----------------+--------+
|  r7gd.xlarge   |  237   |
|  r7gd.8xlarge  |  1900  |
|  r7gd.16xlarge |  3800  |
|  r7gd.medium   |  59    |
|  r7gd.4xlarge  |  950   |
|  r7gd.2xlarge  |  474   |
|  r7gd.metal    |  3800  |
|  r7gd.large    |  118   |
|  r7gd.12xlarge |  2850  |
+----------------+--------+
```

Example 4: Find an instance type that supports hibernation

The following example displays the instance types that support hibernation.

```
aws ec2 describe-instance-types \
    --filters "Name=hibernation-supported,Values=true" \
    --region us-east-2 \
    --query "InstanceTypes[*].[InstanceType]" \
    --output text | sort
```

The output is a list of instance types, sorted alphabetically. The following is the start of the output only.

```
c4.2xlarge
c4.4xlarge
c4.8xlarge
c4.large
c4.xlarge
c5.12xlarge
c5.18xlarge
c5.2xlarge
c5.4xlarge
c5.9xlarge
```

```
...
```

Find an instance type using the Tools for PowerShell

You can use the Get-EC2InstanceType and Get-EC2InstanceTypeOffering cmdlets to find the instance types that meet your needs.

Examples

- Find an instance type by Availability Zone
- Find an instance type by available memory size
- Find an instance type by available instance storage
- Find an instance type that supports hibernation

Find an instance type by Availability Zone

The following example displays only the instance types offered in the specified Availability Zone.

```
(Get-EC2InstanceTypeOffering `
    -LocationType "availability-zone" `
    -Region us-east-2 `
    -Filter @{Name="location"; Values="us-east-2a"}).InstanceType | Sort-Object `
```

Find an instance type by available memory size

The following example displays only current generation instance types with 64 GiB (65536 MiB) of memory.

```
(Get-EC2InstanceType `
    -Filter @{Name="current-generation"; Values="true"},
            @{Name="memory-info.size-in-mib"; Values="65536"}).InstanceType | Sort-
Object
```

Find an instance type by available instance storage

The following example displays the total size of instance storage for all R7 instances with instance store volumes.

```
Get-EC2InstanceType `
```

```
    -Filter @{Name="instance-type"; Values="r7*"},
            @{Name="instance-storage-supported"; Values="true"} | `
     Select InstanceType, @{Name="TotalSizeInGB";
 Expression={($_.InstanceStorageInfo.TotalSizeInGB)}}
```

The following is example output.

```
InstanceType  TotalSizeInGB
------------  -------------
r7gd.8xlarge           1900
r7gd.16xlarge          3800
r7gd.xlarge             237
r7gd.4xlarge            950
r7gd.medium              59
r7gd.2xlarge            474
r7gd.large              118
r7gd.metal             3800
r7gd.12xlarge          2850
```

Find an instance type that supports hibernation

The following example displays the instance types that support hibernation.

```
(Get-EC2InstanceType `
    -Filter @{Name="hibernation-supported"; Values="true"}).InstanceType | Sort-Object
```

Get recommendations from EC2 instance type finder

EC2 instance type finder considers your use case, workload type, CPU manufacturer preference, and how you prioritize price and performance, as well as additional parameters that you can specify. It then uses this data to provide suggestions and guidance for Amazon EC2 instance types that are best suited to your new workloads.

With so many instance types available, finding the right instance types for your workload can be time-consuming and complex. By using the EC2 instance type finder, you can remain up to date with the latest instance types and achieve the best price-performance for your workloads.

You can get suggestions and guidance for EC2 instance types using the Amazon EC2 console. You can also go directly to Amazon Q to ask for instance type advice. For more information, see the Amazon Q Developer User Guide.

If you're looking for instance type recommendations for an *existing* workload, use AWS Compute Optimizer. For more information, see Get EC2 instance recommendations from Compute Optimizer.

Use the EC2 instance type finder

In the Amazon EC2 console, you can get instance type suggestions from the EC2 instance type finder in the launch instance wizard, when creating a launch template, or on the **Instance types** page.

Use the following instructions to get suggestions and guidance for EC2 instance types using the EC2 instance type finder in the Amazon EC2 console. To view an animation of the steps, see View an animation: Get instance type suggestions using the EC2 instance type finder.

To get instance type suggestions using the EC2 instance type finder

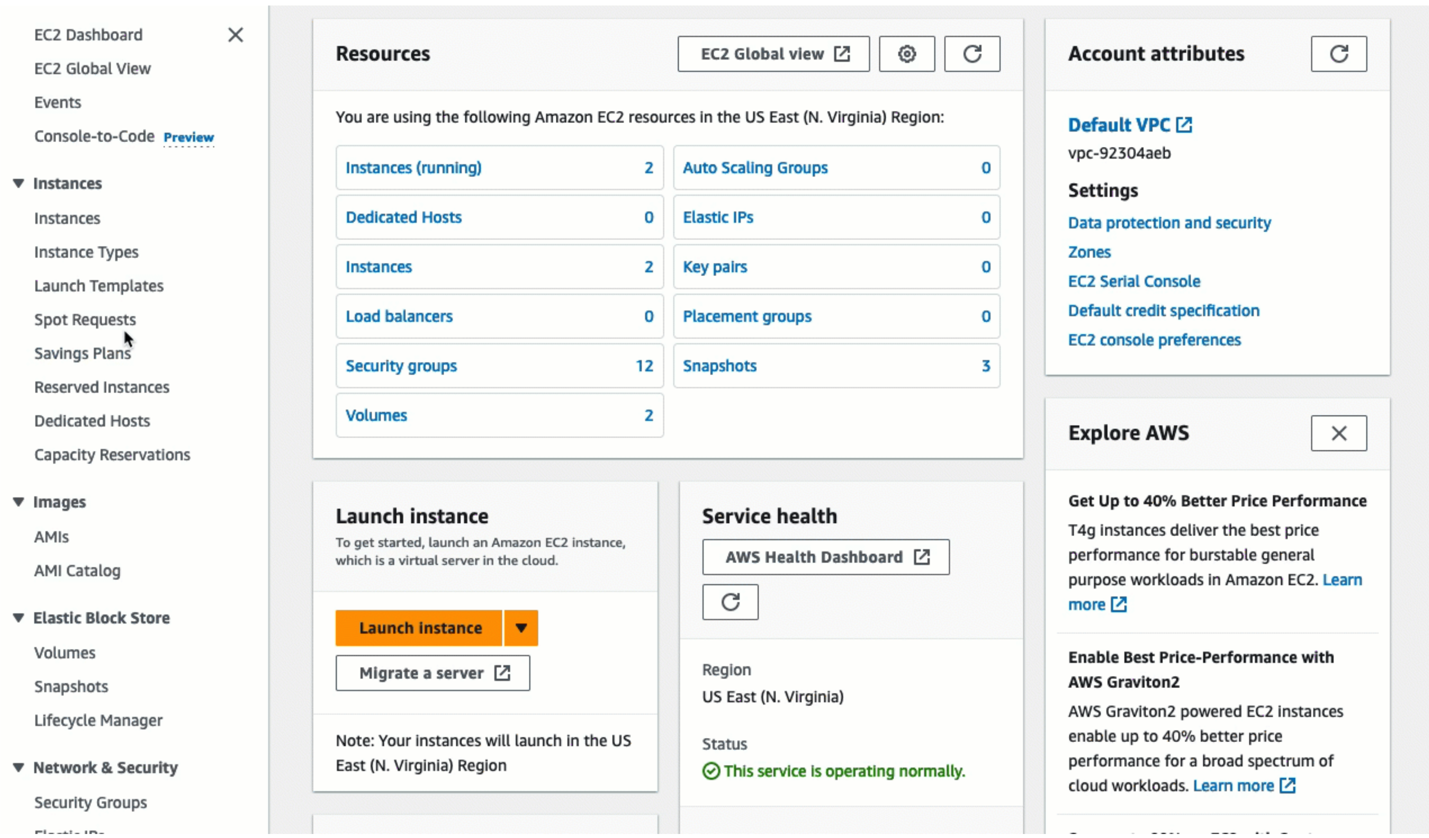
1. Start your process using any of the following:
   - Follow the procedure to launch an instance. Next to **Instance type**, choose the **Get advice** link.
   - Follow the procedure to create a launch template. Next to **Instance type**, choose the **Get advice** link.
   - In the navigation pane, choose **Instance Types**, and then choose the **Instance type finder** button.
2. In the **Get advice on instance type selection** screen, do the following:
   a. Specify your instance type requirements by selecting options for **Workload type**, **Use case**, **Priority**, and **CPU manufacturers**.
   b. (Optional) To specify more detailed requirements for your workload, do the following:
      i. Expand **Advanced parameters**.
      ii. To add a parameter, select a parameter, choose **Add**, and specify a value for the parameter. Repeat for each additional parameter that you want to add. To indicate no minimum or maximum value, leave the field empty.
      iii. To remove a parameter after adding it, choose the **X** next to the parameter.
   c. Choose **Get instance type advice**.

      Amazon EC2 provides you with suggestions for instance families matching your specified requirements.

3. To view the details of each instance type within the suggested instance families, choose **View recommended instance family details**.
4. Select an instance type that meets your requirements, and then choose **Actions**, **Launch instance** or **Actions**, **Create launch template**.

   Alternatively, if you started the process in the launch instance wizard or the launch template page, and you prefer to go back to your original flow, make note of the instance type you'd like to use. Then, in the launch instance wizard or launch template, for **Instance type**, choose the instance type, and complete the procedure to launch an instance or create a launch template.

View an animation: Get instance type suggestions using the EC2 instance type finder



Get EC2 instance recommendations from Compute Optimizer

AWS Compute Optimizer provides Amazon EC2 recommendations to help you improve performance, save money, or both. You can use these recommendations to decide whether to change to a new instance type.

To make recommendations, Compute Optimizer analyzes your existing instance specifications and utilization metrics. The compiled data is then used to recommend which Amazon EC2 instance types are best able to handle the existing workload. Recommendations are returned along with per-hour instance pricing. For more information, see Amazon EC2 instance metrics in the *AWS Compute Optimizer User Guide*.

Contents

Requirements

To get recommendations from Compute Optimizer, you must first opt in to Compute Optimizer. For more information, see Getting started with AWS Compute Optimizer in the *AWS Compute Optimizer User Guide*.

Compute Optimizer generates recommendations for some instance types, but not all instance types. If you're using an unsupported instance type, Compute Optimizer will not generate recommendations. For the list of supported instance types, see Amazon EC2 instance requirements in the *AWS Compute Optimizer User Guide*.

Finding classifications

Compute Optimizer classifies its findings for EC2 instances as follows:

- **Under-provisioned** – An EC2 instance is considered under-provisioned when at least one specification of your instance, such as CPU, memory, or network, does not meet the performance requirements of your workload. Under-provisioned EC2 instances might lead to poor application performance.
- **Over-provisioned** – An EC2 instance is considered over-provisioned when at least one specification of your instance, such as CPU, memory, or network, can be sized down while still meeting the performance requirements of your workload, and when no specification is under-provisioned. Over-provisioned EC2 instances might lead to unnecessary infrastructure cost.
- **Optimized** – An EC2 instance is considered optimized when all specifications of your instance, such as CPU, memory, and network, meet the performance requirements of your workload, and the instance is not over-provisioned. An optimized EC2 instance runs your workloads with

optimal performance and infrastructure cost. For optimized instances, Compute Optimizer might sometimes recommend a new generation instance type.

- **None** – There are no recommendations for this instance. This might occur if you've been opted in to Compute Optimizer for less than 12 hours, or when the instance has been running for less than 30 hours, or when the instance type is not supported by Compute Optimizer.

View recommendations

After you opt in to Compute Optimizer, you can view the findings that Compute Optimizer generates for your EC2 instances in the Amazon EC2 console. You can then access the Compute Optimizer console to view the recommendations. If you recently opted in, findings might not be reflected in the EC2 console for up to 12 hours.

To view recommendations for an instance using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Choose the instance ID to open the instance detail page.
4. On the instance detail page, in the top summary section, locate **AWS Compute Optimizer finding**. If there is a finding, we display the finding classification and a link to view the details. Otherwise, we display **No recommendations available for this instance.**
5. If there is a finding, choose **View detail**. This opens the **Recommendations for EC2 instances** page in the Compute Optimizer console. The current instance type is labeled **Current**. There are also up to three instance type recommendations, labeled **Option 1**, **Option 2**, and **Option 3**. This page also shows recent CloudWatch metric data for the instance.

To view recommendations for all instances in all Regions

You can view recommendations for all of your Amazon EC2 instances in all Regions using the Compute Optimizer console. For more information, see Viewing EC2 instances recommendations and Viewing EC2 instance details in the *AWS Compute Optimizer User Guide*.

Considerations for evaluating recommendations

When you receive a recommendation, you must decide whether to act on it. Before changing an instance type, consider the following:

- The recommendations don't forecast your usage. Recommendations are based on your historical usage over the most recent 14-day time period. Be sure to choose an instance type that is expected to meet your future resource needs.
- Focus on the graphed metrics to determine whether actual usage is lower than instance capacity. You can also view metric data (average, peak, percentile) in CloudWatch to further evaluate your EC2 instance recommendations. For example, notice how CPU percentage metrics change during the day and whether there are peaks that need to be accommodated. For more information, see Viewing Available Metrics in the *Amazon CloudWatch User Guide*.
- Compute Optimizer might supply recommendations for burstable performance instances, which are T3, T3a, and T2 instances. If you periodically burst above the baseline, make sure that you can continue to do so based on the vCPUs of the new instance type. For more information, see Key concepts for burstable performance instances.
- If you've purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.
- Consider conversions to newer generation instances, where possible.
- When migrating to a different instance family, make sure the current instance type and the new instance type are compatible, for example, in terms of virtualization, architecture, or network type. For more information, see Compatibility for changing the instance type.
- Finally, consider the performance risk rating that's provided for each recommendation. Performance risk indicates the amount of effort you might need to spend in order to validate whether the recommended instance type meets the performance requirements of your workload. We also recommend rigorous load and performance testing before and after making any changes.

Amazon EC2 instance type changes

As your needs change, you might find that your instance is over-utilized (the instance type is too small) or under-utilized (the instance type is too large). If this is the case, you can resize your instance by changing its instance type. For example, if your `t2.micro` instance is too small for its workload, you can increase its size by changing it to a bigger T2 instance type, such as `t2.large`. Or you can change it to another instance type, such as `m5.large`. You might also want to change from a previous generation to a current generation instance type to take advantage of some features, such as support for IPv6.

If you want a recommendation for an instance type that is best able to handle your existing workload, you can use AWS Compute Optimizer. For more information, see Get EC2 instance recommendations from Compute Optimizer.

When you change the instance type, you'll start paying the rate of the new instance type. For the on-demand rates of all instance types, see Amazon EC2 On-Demand Pricing.

To add additional storage to your instance without changing the instance type, add an EBS volume to the instance. For more information, see Attach an Amazon EBS volume to an instance in the *Amazon EBS User Guide*.

Which instructions to follow?

There are different instructions for changing the instance type. The instructions to use depend on the instance's root volume, and whether the instance type is compatible with the instance's current configuration. For information about how compatibility is determined, see Compatibility for changing the instance type.

Use the following table to determine which instructions to follow.

Root volume	Compatibility	Use these instructions
EBS	Compatible	Change the instance type
EBS	Not compatible	Migrate to a new instance type
Instance store	Not applicable	Migrate to a new instance type

Compatibility for changing the instance type

You can change the instance type only if the instance's current configuration is compatible with the instance type that you want. If the instance type that you want is not compatible with the instance's current configuration, you must launch a new instance with a configuration that is compatible with the instance type, and then migrate your application to the new instance.

Compatibility is determined through the following:

Virtualization type

Linux AMIs use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). If an instance was launched from a PV AMI, you can't change to an instance type that is HVM only. For more information, see Virtualization types. To check the virtualization type of your instance, check the **Virtualization** value on the details pane of the **Instances** screen in the Amazon EC2 console.

Architecture

AMIs are specific to the architecture of the processor, so you must select an instance type with the same processor architecture as the current instance type. For example:

- If the current instance type has a processor based on the Arm architecture, you are limited to the instance types that support a processor based on the Arm architecture, such as C6g and M6g.
- The following instance types are the only instance types that support 32-bit AMIs: `t2.nano`, `t2.micro`, `t2.small`, `t2.medium`, `c3.large`, `t1.micro`, `m1.small`, `m1.medium`, and `c1.medium`. If you are changing the instance type of a 32-bit instance, you are limited to these instance types.

Network adapters

If you switch from a driver for one network adapter to another, the network adapter settings are reset when the operating system creates the new adapter. To reconfigure the settings, you might need access to a local account with administrator permissions. The following are examples of moving from one network adapter to another:

- AWS PV (T2 instances) to Intel 82599 VF (M4 instances)
- Intel 82599 VF (most M4 instances) to ENA (M5 instances)
- ENA (M5 instances) to high-bandwidth ENA (M5n instances)

Enhanced networking

Instance types that support enhanced networking require the necessary drivers installed. For example, Nitro-based instances require EBS-backed AMIs with the Elastic Network Adapter (ENA) drivers installed. To change from an instance type that does not support enhanced networking to an instance type that supports enhanced networking, you must install the ENA drivers or ixgbevf drivers on the instance, as appropriate.

> **Note**
>
> When you resize an instance with ENA Express enabled, the new instance type must also support ENA Express. For a list of instance types that support ENA Express, see Supported instance types for ENA Express.
>
> To change from an instance type that supports ENA Express to an instance type that does not support it, ensure that ENA Express is not currently enabled before you resize the instance.

NVMe

EBS volumes are exposed as NVMe block devices on Nitro-based instances. If you change from an instance type that does not support NVMe to an instance type that supports NVMe, you must first install the NVMe drivers on your instance. Also, the device names for devices that you specify in the block device mapping are renamed using NVMe device names (`/dev/nvme[0-26]n1`).

[Linux instances] Therefore, to mount file systems at boot time using `/etc/fstab`, you must use UUID/Label instead of device names.

Volume limit

The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see Amazon EBS volume limits for Amazon EC2 instances.

You can only change to an instance type or instance size that supports the same number or a larger number of volumes than is currently attached to the instance. If you change to an instance type or instance size that does not support the number of currently attached volumes, the request fails. For example, if you change from an `m7i.4xlarge` instance with 32 attached volumes to an `m6i.4xlarge`, which supports a maximum of 27 volumes, the request fails.

NitroTPM

If you launched the instance using an AMI with NitroTPM enabled and an instance type that supports NitroTPM, the instance launches with NitroTPM enabled. You can only change to an instance type that also supports NitroTPM.

Change the instance type for your Amazon EC2 instance

Use the following instructions to change the instance type of an Amazon EBS-backed instance if the instance type that you need is compatible with the current configuration of your instance. For more information, see the section called "Compatibility".

Considerations

- You must stop your instance before you can change its instance type. Ensure that you plan for downtime while your instance is stopped. Stopping the instance and changing its instance type might take a few minutes, and restarting your instance might take a variable amount of time depending on your application's startup scripts. For more information, see Stop and start Amazon EC2 instances.
- When you stop and start an instance, we move the instance to new hardware. If your instance has a public IPv4 address, that is not an Elastic IP, we release the address and give your instance a new public IPv4 address. For more information on IP address behavior throughout the lifecycle of an instance, see Differences between instance states.
- You can't change the instance type of a Spot Instance.
- [Windows instances] We recommend that you update the AWS PV driver package before changing the instance type. For more information, see the section called "Upgrade PV drivers".
- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and might terminate it and launch a replacement instance. To prevent this, you can suspend the scaling processes for the group while you're changing the instance type. For more information, see Suspending and resuming a process for an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.
- When you change the instance type of an instance with NVMe instance store volumes, the updated instance might have additional instance store volumes, because all NVMe instance store volumes are available even if they are not specified in the AMI or instance block device mapping. Otherwise, the updated instance has the same number of instance store volumes that you specified when you launched the original instance.
- The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. You can't change to an instance type or instance size that does not support the number of volumes that are already attached to your instance. For more information, see Amazon EBS volume limits for Amazon EC2 instances.
- [Linux instances] You can use the `AWSSupport-MigrateXenToNitroLinux` runbook to migrate compatible Linux instances from a Xen instance type to a Nitro instance type. For more

information, see [AWSSupport-MigrateXenToNitroLinux runbook]() in the *AWS Systems Manager Automation runbook reference*.

- [Windows instances] For additional guidance on migrating compatible Windows instances from a Xen instance type to a Nitro instance type, see [Migrate to latest generation instance types]().

To change the instance type of an Amazon EBS-backed instance

1. (Optional) If the new instance type requires drivers that are not installed on the existing instance, you must connect to your instance and install the drivers first. For more information, see [Compatibility for changing the instance type]().
2. [Windows instances] If you configured your Windows instance to use [static IP addressing]() and you change from an instance type that doesn't support enhanced networking to an instance type that does support enhanced networking, you might get a warning about a potential IP address conflict when you reconfigure static IP addressing. To prevent this, enable DHCP on the network interface for your instance before you change the instance type. From your instance, open the **Network and Sharing Center**, open **Internet Protocol Version 4 (TCP/IPv4) Properties** for the network interface, and choose **Obtain an IP address automatically**. Change the instance type and reconfigure static IP addressing on the network interface.
3. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
4. In the navigation pane, choose **Instances**.
5. Select the instance and choose **Instance state**, **Stop instance**. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
6. With the instance still selected, choose **Actions**, **Instance settings**, **Change instance type**. This option is grayed out if the instance state is not `stopped`.
7. On the **Change instance type** page, do the following:

   a. For **Instance type**, select the instance type that you want.

      If the instance type is not in the list, then it's not compatible with the configuration of your instance. Instead, use the following instructions: [Migrate to a new instance type by launching a new EC2 instance]().

   b. (Optional) If the instance type that you selected supports EBS optimization, select **EBS-optimized** to enable EBS optimization, or deselect **EBS-optimized** to disable EBS optimization.

If the instance type that you selected is EBS optimized by default, **EBS-optimized** is selected and you can't deselect it.

c. (Optional) Configure vCPU options on the new instance type.

When you change the instance type of an existing instance, Amazon EC2 applies the CPU option settings from the existing instance to the new instance, if possible. If the new instance type doesn't support those settings, the CPU options are reset to **None**. This option uses the default number of vCPUs for the new instance type.

If the instance type that you selected supports vCPU configuration, select **Specify CPU options** in the **Advanced details** panel to configure vCPUs for your new instance type.

d. Choose **Change** to accept the new settings.

8. To start the instance, select the instance and choose **Instance state**, **Start instance**. It can take a few minutes for the instance to enter the `running` state. If your instance won't start, see Troubleshoot changing the instance type.

9. [Windows instances] If your instance runs Windows Server 2016 or Windows Server 2019 with EC2Launch v1, connect to your Windows instance and run the following EC2Launch PowerShell script to configure the instance after the instance type is changed.

> **Important**
>
> The administrator password will reset when you enable the initialize instance EC2 Launch script. You can modify the configuration file to disable the administrator password reset by specifying it in the settings for the initialization tasks. For steps on how to disable password reset, see Configure initialization tasks (EC2Launch) or Change settings (EC2Launch v2).

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -
Schedule
```

Migrate to a new instance type by launching a new EC2 instance

You can change the instance type of an EC2 instance only if it is an EBS-backed instance with a configuration that is compatible with the new instance type that you want. Otherwise, if the configuration or your instance is not compatible with the new instance type, or it is an instance store-based instance, you must launch a replacement instance that is compatible with the instance type that you want. For more information about how compatibility is determined, see Compatibility for changing the instance type.

Overview of the migration process

- Back up the data on the original instance.
- Launch a new instance with a configuration that is compatible with the new instance type that you want, attaching any EBS volumes that were attached to your original instance.
- Install your application on your new instance.
- Restore any data.
- If the original instance has an Elastic IP address, you must associate it with your new instance to ensure that your users can continue to use your application without interruption.

To migrate an instance to a new instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Back up any data that you still need as follows:
    - Connect to your instance and copy the data on your instance store volumes to persistent storage.
    - Create snapshots of your EBS volumes so that you can create new volumes with the same data, or detach the volumes from the original instance so that you can attach them to the new instance.
3. In the navigation pane, choose **Instances**.
4. Choose **Launch instances**. When you configure the instance, do the following:
    a. Select an AMI that supports the instance type that you want. For example, you must select an AMI that supports the processor type of the new instance type. Also, current generation instance types require an HVM AMI.
    b. Select the new instance type that you want. If the instance type that you want isn't available, then it's not compatible with the configuration of the AMI that you selected.
    c. If you want to allow the same traffic to reach the new instance, select the same VPC and security group that are used with the original instance.

d. When you're done configuring your new instance, complete the steps to select a key pair and launch your instance. It can take a few minutes for the instance to enter the `running` state.

5. If you backed up data to an EBS snapshot, create a volume from the snapshot and then attach the volume to the new instance.

   To move an EBS volume from the original instance to the new instance, detach the volume from the original instance and then attach the volume to the new instance.

6. Install your application and any required software on the new instance.
7. Restore any data that you backed up from the instance store volumes of the original instance.
8. If the original instance has an Elastic IP address, assign it to the new instance as follows:

   a. In the navigation pane, choose **Elastic IPs**.
   b. Select the Elastic IP address that is associated with the original instance and choose **Actions**, **Disassociate Elastic IP address**. When prompted for confirmation, choose **Disassociate**.
   c. With the Elastic IP address still selected, choose **Actions**, **Associate Elastic IP address**.
   d. For **Resource type**, choose **Instance**.
   e. For **Instance**, choose the new instance.
   f. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
   g. Choose **Associate**.

9. (Optional) You can terminate the original instance if it's no longer needed. Select the instance, verify that you are about to terminate the original instance and not the new instance (for example, check the name or launch time), and then choose **Instance state**, **Terminate instance**.

Troubleshoot changing the instance type

Use the following information to help diagnose and fix issues that you might encounter when changing the instance type.

Instance won't start after changing instance type

Possible cause: Requirements for new instance type not met

If your instance won't boot, it is possible that one of the requirements for the new instance type was not met. For more information, see Why is my Linux instance not booting after I changed its type?

Possible cause: AMI does not support instance type

If you use the EC2 console to change the instance type, only the instance types that are supported by the selected AMI are available. However, if you use the AWS CLI to launch an instance, you can specify an incompatible AMI and instance type. If the AMI and instance type are incompatible, the instance can't start. For more information, see Compatibility for changing the instance type.

Possible cause: Instance is in cluster placement group

If your instance is in a cluster placement group and, after changing the instance type, the instance fails to start, try the following:

1. Stop all the instances in the cluster placement group.
2. Change the instance type of the affected instance.
3. Start all the instances in the cluster placement group.

Application or website not reachable from the internet after changing instance type

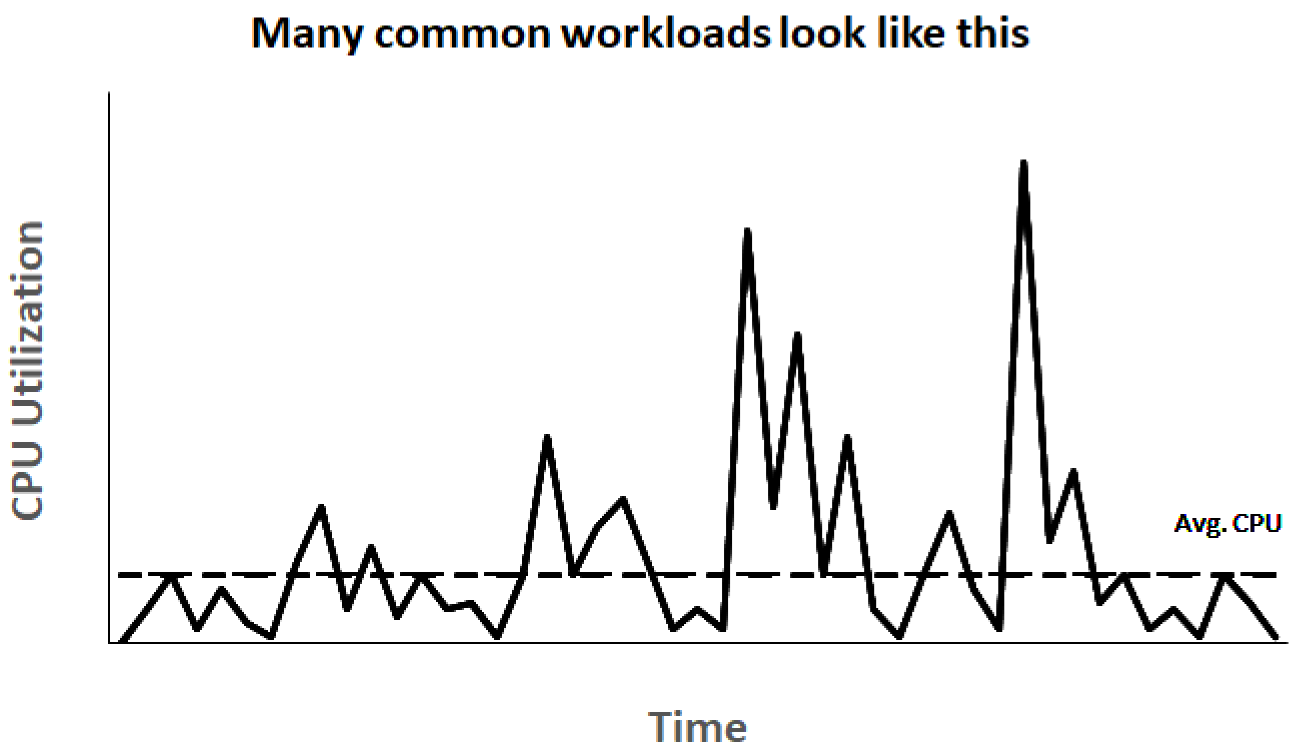
Possible cause: Public IPv4 address is released

When you change the instance type, you must first stop the instance. When you stop an instance, we release the public IPv4 address and give your instance a new public IPv4 address.

To retain the public IPv4 address between instance stops and starts, we recommend that you use an Elastic IP address, at no extra cost provided your instance is running. For more information, see Elastic IP addresses.

Burstable performance instances

Many general purpose workloads are on average not busy, and do not require a high level of sustained CPU performance. The following graph illustrates the CPU utilization for many common workloads that customers run in the AWS Cloud today.



These low-to-moderate CPU utilization workloads lead to wastage of CPU cycles and, as a result, you pay for more than you use. To overcome this, you can leverage the low-cost burstable general purpose instances, which are the T instances.

The T instance family provides a baseline CPU performance with the ability to burst above the baseline at any time for as long as required. The baseline CPU is defined to meet the needs of the majority of general purpose workloads, including large-scale micro-services, web servers, small and medium databases, data logging, code repositories, virtual desktops, development and test environments, and business-critical applications. The T instances offer a balance of compute, memory, and network resources, and provide you with the most cost-effective way to run a broad spectrum of general purpose applications that have a low-to-moderate CPU usage. They can save you up to 15% in costs when compared to M instances, and can lead to even more cost savings with smaller, more economical instance sizes, offering as low as 2 vCPUs and 0.5 GiB of memory. The smaller T instance sizes, such as nano, micro, small, and medium, are well suited for workloads that need a small amount of memory and do not expect high CPU usage.

Note

This topic describes burstable CPU. For information about burstable network performance, see Amazon EC2 instance network bandwidth.

EC2 burstable instance types

The EC2 burstable instances consist of T4g, T3a, and T3 instance types, and the previous generation T2 instance types.

The T4g instance types are the latest generation of burstable instances. They provide the best price for performance, and provide you with the lowest cost of all the EC2 instance types. The T4g instance types are powered by Arm-based AWS Graviton2 processors with extensive ecosystem support from operating systems vendors, independent software vendors, and popular AWS services and applications.

The following table summarizes the key differences between the burstable instance types.

Type	Description	Processor family
Latest generation		
T4g	Lowest cost EC2 instance type with up to 40% higher price/ performance and 20% lower costs vs T3	AWS Graviton2 processors with Arm Neoverse N1 cores
T3a	Lowest cost x86-based instances with 10% lower costs vs T3 instances	AMD 1st gen EPYC processors
T3	Best peak price/performance for x86 workloads with up to 30% lower price/performance vs previous generation T2 instances	Intel Xeon Scalable (Skylake, Cascade Lake processors)
Previous generation		

Type	Description	Processor family
T2	Previous generation burstable instances	Intel Xeon processors

For information about instance pricing and additional specifications, see Amazon EC2 Pricing and Amazon EC2 Instance Types. For information about burstable network performance, see Amazon EC2 instance network bandwidth.

If your created your AWS account before July 15, 2025 and it's less than 12 months old, you can use a `t2.micro` instance for free (or a `t3.micro` instance in Regions where `t2.micro` is unavailable) within certain usage limits. If you created your AWS account on or after July 15, 2025, you can use `t3.micro`, `t3.small`, `t4g.micro`, `t4g.small` instance types for 6 months or until your credits are used up. For more information, see AWS Free Tier.

Supported purchasing options for T instances

- On-Demand Instances
- Reserved Instances
- Dedicated Instances (T3 only)
- Dedicated Hosts (T3 only, in `standard` mode only)
- Spot Instances

For more information, see Amazon EC2 billing and purchasing options.

Contents

Best practices

Follow these best practices to get the maximum benefit from burstable performance instances.

- Ensure that the instance size you choose passes the minimum memory requirements of your operating system and applications. Operating systems with graphical user interfaces that consume significant memory and CPU resources (for example, Windows) might require a `t3.micro` or larger instance size for many use cases. As the memory and CPU requirements of your workload grow over time, you have the flexibility with the T instances to scale to larger instance sizes of the same instance type, or to select another instance type.
- Enable AWS Compute Optimizer for your account and review the Compute Optimizer recommendations for your workload. Compute Optimizer can help assess whether instances should be upsized to improve performance or downsized for cost savings. Compute Optimizer may also recommend a different instance type based on your scenario. For more information, see Viewing EC2 instance recommendations in the *AWS Compute Optimizer User Guide*.

Key concepts for burstable performance instances

Traditional Amazon EC2 instance types provide fixed CPU resources, while burstable performance instances provide a baseline level of CPU utilization with the ability to burst CPU utilization above the baseline level. This ensures that you pay only for baseline CPU plus any additional burst CPU usage resulting in lower compute costs. The baseline utilization and ability to burst are governed by CPU credits. Burstable performance instances are the only instance types that use credits for CPU usage.

Each burstable performance instance continuously earns credits when it stays below the CPU baseline, and continuously spends credits when it bursts above the baseline. The amount of credits earned or spent depends on the CPU utilization of the instance:

- If the CPU utilization is below baseline, then credits earned are greater than credits spent.
- If the CPU utilization is equal to baseline, then credits earned are equal to credits spent.
- If the CPU utilization is higher than baseline, then credits spent are higher than credits earned.

When the credits earned are greater than credits spent, then the difference is called accrued credits, which can be used later to burst above baseline CPU utilization. Similarly, when the credits spent are more than credits earned, then the instance behavior depends on the credit configuration mode—Standard mode or Unlimited mode.

In Standard mode, when credits spent are more than credits earned, the instance uses the accrued credits to burst above baseline CPU utilization. If there are no accrued credits remaining, then the instance gradually comes down to baseline CPU utilization and cannot burst above baseline until it accrues more credits.

In Unlimited mode, if the instance bursts above baseline CPU utilization, then the instance first uses the accrued credits to burst. If there are no accrued credits remaining, then the instance spends surplus credits to burst. When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a flat additional rate per vCPU-hour.

Contents

Key concepts and definitions

The following key concepts and definitions are applicable to burstable performance instances.

CPU utilization

CPU utilization is the percentage of allocated EC2 compute units that are currently in use on the instance. This metric measures the percentage of allocated CPU cycles that are being utilized on an instance. The CPU Utilization CloudWatch metric shows CPU usage per instance and not CPU usage per core. The baseline CPU specification of an instance is also based on the CPU usage per instance. To measure CPU utilization using the AWS Management Console or the AWS CLI, see Get statistics for a specific instance.

CPU credit

A unit of vCPU-time.

Examples:

1 CPU credit = 1 vCPU * 100% utilization * 1 minute.

1 CPU credit = 1 vCPU * 50% utilization * 2 minutes

1 CPU credit = 2 vCPU * 25% utilization * 2 minutes

Baseline utilization

The baseline utilization is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as the baseline. Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows: Baseline utilization % = (number of credits earned/number of vCPUs)/60 minutes.

For the baseline utilization of each burstable performance instance type, see the credit table.

Earned credits

Credits earned continuously by an instance when it is running.

Number of credits earned per hour = % baseline utilization * number of vCPUs * 60 minutes

Example:

A t3.nano with 2 vCPUs and a baseline utilization of 5% earns 6 credits per hour, calculated as follows:

2 vCPUs * 5% baseline * 60 minutes = 6 credits per hour

Spent or used credits

Credits used continuously by an instance when it is running.

CPU credits spent per minute = Number of vCPUs * CPU utilization * 1 minute

Accrued credits

Unspent CPU credits when an instance uses fewer credits than is required for baseline utilization. In other words, accrued credits = (Earned credits – Used credits) below baseline.

Example:

If a t3.nano is running at 2% CPU utilization, which is below its baseline of 5% for an hour, the accrued credits is calculated as follows:

Accrued CPU credits = (Earned credits per hour – Used credits per hour) = 6 – 2 vCPUs * 2% CPU utilization * 60 minutes = 6 – 2.4 = 3.6 accrued credits per hour

Credit accrual limit

Depends on the instance size but in general is equal to the number of maximum credits earned in 24 hours.

Example:

For t3.nano, the credit accrual limit = 24 * 6 = 144 credits

Launch credits

Only applicable for T2 instances configured for Standard mode. Launch credits are a limited number of CPU credits that are allocated to a new T2 instance so that, when launched in Standard mode, it can burst above the baseline.

Surplus credits

Credits that are spent by an instance after it depletes its accrued credit balance. The surplus credits are designed for burstable instances to sustain high performance for an extended period of time, and are only used in Unlimited mode. The surplus credits balance is used to determine how many credits were used by the instance for bursting in Unlimited mode.

Standard mode

Credit configuration mode, which allows an instance to burst above the baseline by spending credits it has accrued in its credit balance.

Unlimited mode

Credit configuration mode, which allows an instance to burst above the baseline by sustaining high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour.

The following table summarizes the key credit differences between the burstable instance types.

Type	Type of CPU credits supported	Credit configuration modes	Accrued CPU credits lifespan between instance starts and stops
Latest generation			
T4g	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
T3a	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
T3	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
Previous generation			
T2	Earned credits, Accrued credits, Spent credits, Launch credits (Standard mode only), Surplus credits (Unlimited mode only)	Standard (default), Unlimited	0 days (credits are lost when an instance stops)

> **Note**
>
> Unlimited mode is not supported for T3 instances that are launched on a Dedicated Host.

Earn CPU credits

Each burstable performance instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. The accounting process for whether credits are accrued or spent also happens at a millisecond-level resolution, so you don't have to worry about overspending CPU credits; a short burst of CPU uses a small fraction of a CPU credit.

If a burstable performance instance uses fewer CPU resources than is required for baseline utilization (such as when it is idle), the unspent CPU credits are accrued in the CPU credit balance. If a burstable performance instance needs to burst above the baseline utilization level, it spends the accrued credits. The more credits that a burstable performance instance has accrued, the more time it can burst beyond its baseline when more CPU utilization is needed.

The following table lists the burstable performance instance types, the rate at which CPU credits are earned per hour, the maximum number of earned CPU credits that an instance can accrue, the number of vCPUs per instance, and the baseline utilization as a percentage of a full core (using a single vCPU).

Instance type	CPU credits earned per hour	Maximum earned credits that can be accrued*	vCPUs***	Baseline utilization per vCPU
T2				
`t2.nano`	3	72	1	5%
`t2.micro`	6	144	1	10%
`t2.small`	12	288	1	20%
`t2.medium`	24	576	2	20%**
`t2.large`	36	864	2	30%**
`t2.xlarge`	54	1296	4	22.5%**

Instance type	CPU credits earned per hour	Maximum earned credits that can be accrued*	vCPUs***	Baseline utilization per vCPU
`t2.2xlarge`	81.6	1958.4	8	17%**
T3				
`t3.nano`	6	144	2	5%**
`t3.micro`	12	288	2	10%**
`t3.small`	24	576	2	20%**
`t3.medium`	24	576	2	20%**
`t3.large`	36	864	2	30%**
`t3.xlarge`	96	2304	4	40%**
`t3.2xlarge`	192	4608	8	40%**
T3a				
`t3a.nano`	6	144	2	5%**
`t3a.micro`	12	288	2	10%**
`t3a.small`	24	576	2	20%**
`t3a.medium`	24	576	2	20%**
`t3a.large`	36	864	2	30%**
`t3a.xlarge`	96	2304	4	40%**
`t3a.2xlarge`	192	4608	8	40%**
T4g				

Instance type	CPU credits earned per hour	Maximum earned credits that can be accrued*	vCPUs***	Baseline utilization per vCPU
t4g.nano	6	144	2	5%**
t4g.micro	12	288	2	10%**
t4g.small	24	576	2	20%**
t4g.medium	24	576	2	20%**
t4g.large	36	864	2	30%**
t4g.xlarge	96	2304	4	40%**
t4g.2xlarge	192	4608	8	40%**

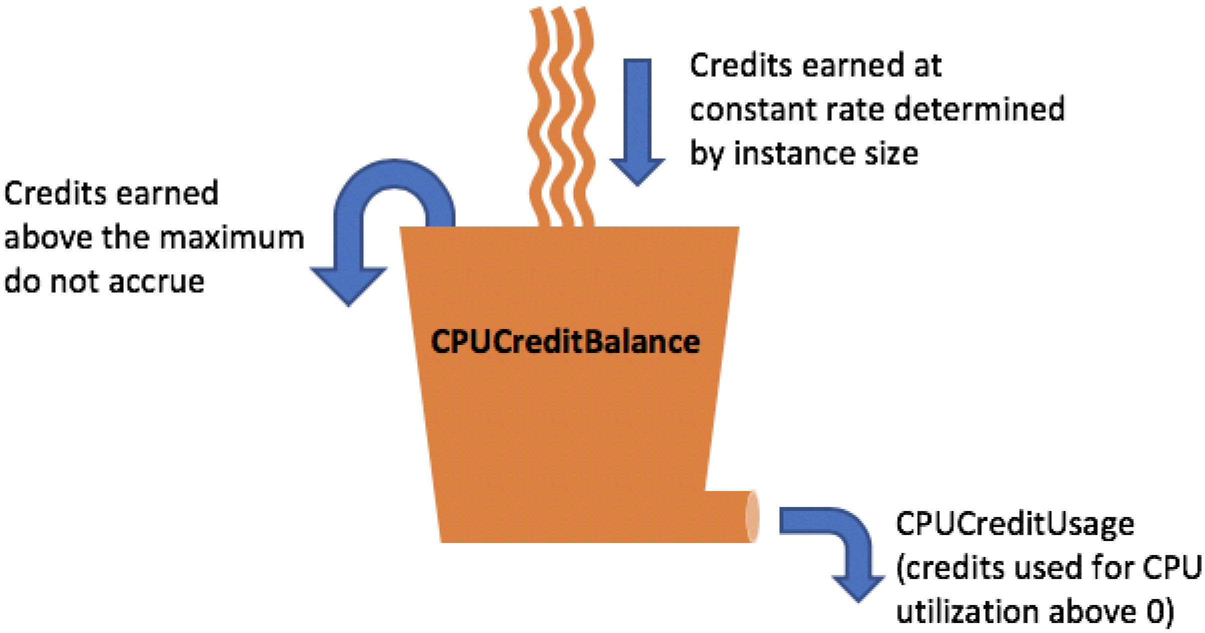
* The number of credits that can be accrued is equivalent to the number of credits that can be earned in a 24-hour period.
** The percentage baseline utilization in the table is per vCPU. In CloudWatch, CPU utilization is shown per vCPU. For example, the CPU utilization for a `t3.large` instance operating at the baseline level is shown as 30% in CloudWatch CPU metrics. For information about how to calculate the baseline utilization, see Baseline utilization.
*** Each vCPU is a thread of either an Intel Xeon core or an AMD EPYC core, except for T2 and T4g instances.

CPU credit earn rate

The number of CPU credits earned per hour is determined by the instance size. For example, a `t3.nano` earns six credits per hour, while a `t3.small` earns 24 credits per hour. The preceding table lists the credit earn rate for all instances.

CPU credit accrual limit

While earned credits never expire on a running instance, there is a limit to the number of earned credits that an instance can accrue. The limit is determined by the CPU credit balance limit. After the limit is reached, any new credits that are earned are discarded, as indicated by the following image. The full bucket indicates the CPU credit balance limit, and the spillover indicates the newly earned credits that exceed the limit.



The CPU credit balance limit differs for each instance size. For example, a `t3.micro` instance can accrue a maximum of 288 earned CPU credits in the CPU credit balance. The preceding table lists the maximum number of earned credits that each instance can accrue.

T2 Standard instances also earn launch credits. Launch credits do not count towards the CPU credit balance limit. If a T2 instance has not spent its launch credits, and remains idle over a 24-hour period while accruing earned credits, its CPU credit balance appears as over the limit. For more information, see Launch credits.

T4g, T3a, and T3 instances do not earn launch credits. These instances launch as `unlimited` by default, and therefore can burst immediately upon start without any launch credits. T3 instances launched on a Dedicated Host launch as `standard` by default; `unlimited` mode is not supported for T3 instances on a Dedicated Host.

Accrued CPU credits life span

CPU credits on a running instance do not expire.

For T2, the CPU credit balance does not persist between instance stops and starts. If you stop a T2 instance, the instance loses all its accrued credits.

For T4g, T3a, and T3, the CPU credit balance persists for seven days after an instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

For more information, see `CPUCreditBalance` in the CloudWatch metrics table.

Baseline utilization

The *baseline utilization* is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as *the baseline*.

Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows:

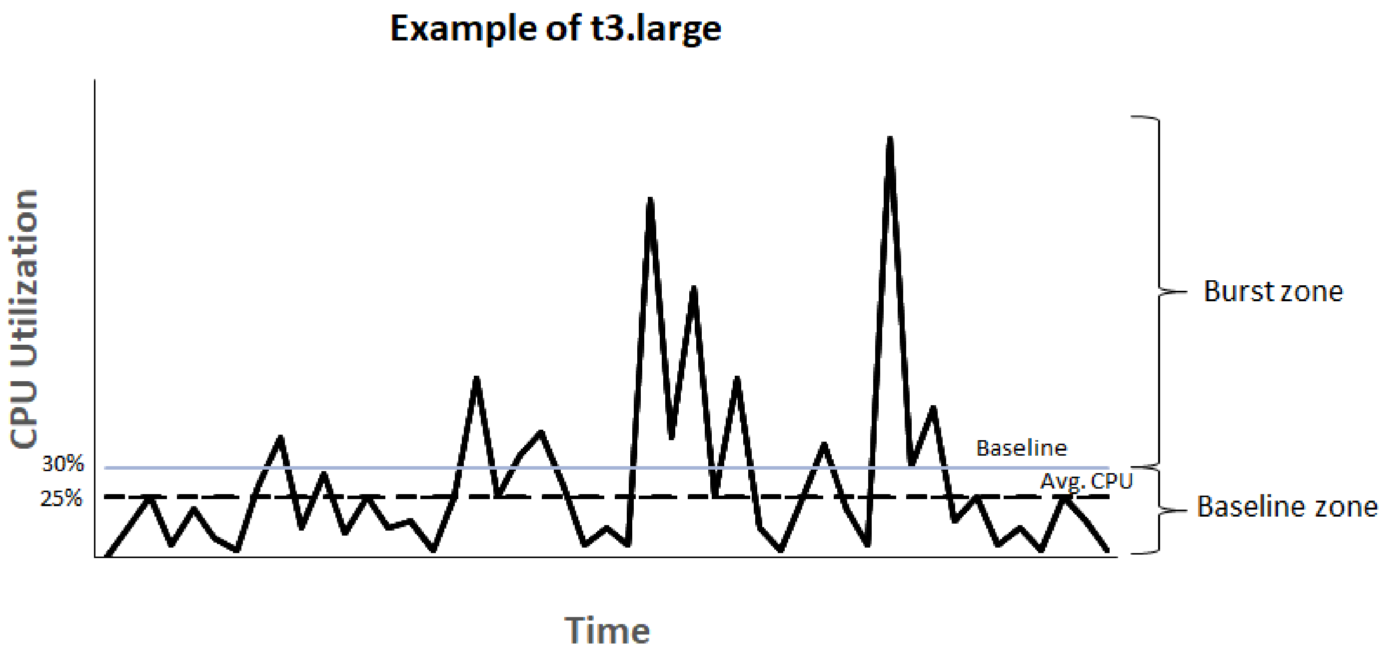
```
(number of credits earned/number of vCPUs)/60 minutes = % baseline
utilization
```

For example, a `t3.nano` instance, with 2 vCPUs, earns 6 credits per hour, resulting in a baseline utilization of 5% , which is calculated as follows:

```
(6 credits earned/2 vCPUs)/60 minutes = 5% baseline utilization
```

A `t3.large` instance, with 2 vCPUs, earns 36 credits per hour, resulting in a baseline utilization of 30% (`(36/2)/60`).

The following graph provides an example of a `t3.large` with an average CPU utilization below the baseline.



Unlimited mode for burstable performance instances

A burstable performance instance configured as `unlimited` can sustain high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter.

For the vast majority of general-purpose workloads, instances configured as `unlimited` provide ample performance without any additional charges. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour. For information about pricing, see [Amazon EC2 pricing] and [T2/T3/T4 Unlimited Mode Pricing].

If your created your AWS account before July 15, 2025 and you use a `t2.micro` or `t3.micro` instance under the [AWS Free Tier] offer and use it in `unlimited` mode, charges might apply if your average utilization over a rolling 24-hour period exceeds the [baseline utilization] of the instance.

T4g, T3a, and T3 instances launch as `unlimited` by default (unless you [change the default]). If the average CPU usage over a 24-hour period exceeds the baseline, you incur charges for surplus credits. If you launch Spot Instances as `unlimited` and plan to use them immediately and for a short duration, with no idle time for accruing CPU credits, you incur charges for surplus credits. We recommend that you launch your Spot Instances in [standard] mode to avoid paying higher costs.

For more information, see Surplus credits can incur charges and Launch burstable performance instances.

> **Note**
>
> T3 instances launched on a Dedicated Host launch as `standard` by default; `unlimited` mode is not supported for T3 instances on a Dedicated Host.

Contents

Unlimited mode concepts for burstable instances

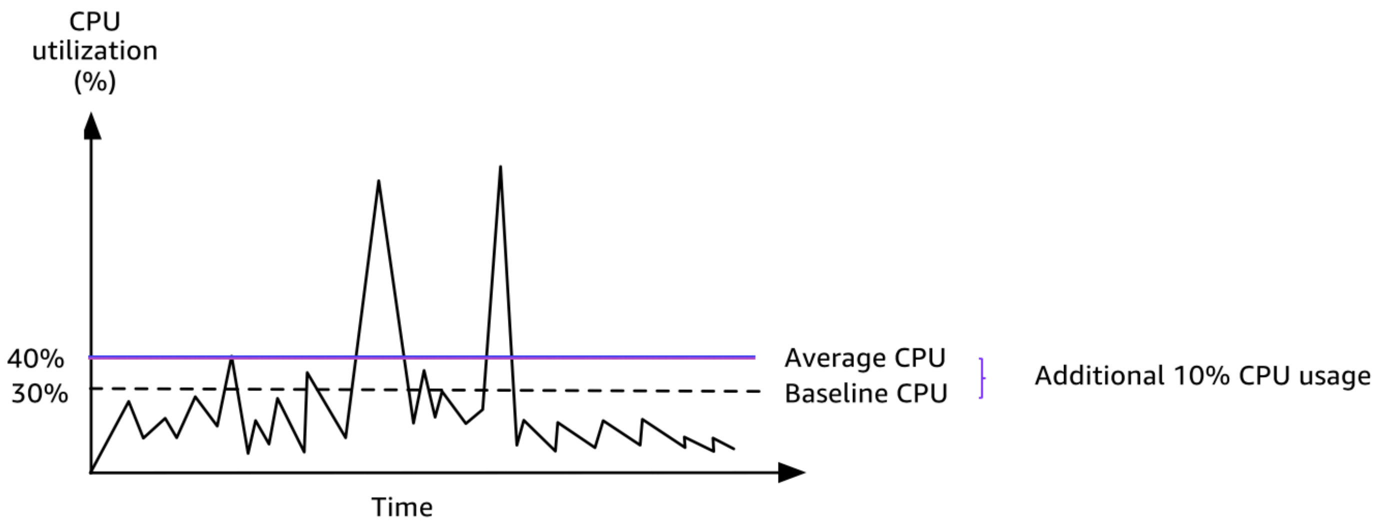
The `unlimited` mode is a credit configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can set `unlimited` as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

How Unlimited burstable performance instances work

If a burstable performance instance configured as `unlimited` depletes its CPU credit balance, it can spend *surplus* credits to burst beyond the baseline. When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the

CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a flat additional rate per vCPU-hour.

The following graph shows the CPU usage of a `t3.large`. The baseline CPU utilization for a `t3.large` is 30%. If the instance runs at 30% CPU utilization or less on average over a 24-hour period, there is no additional charge because the cost is already covered by the instance hourly price. However, if the instance runs at 40% CPU utilization on average over a 24-hour period, as shown in the graph, the instance is billed for the additional 10% CPU usage at a flat additional rate per vCPU-hour.



For more information about the baseline utilization per vCPU for each instance type and how many credits each instance type earns, see the credit table.

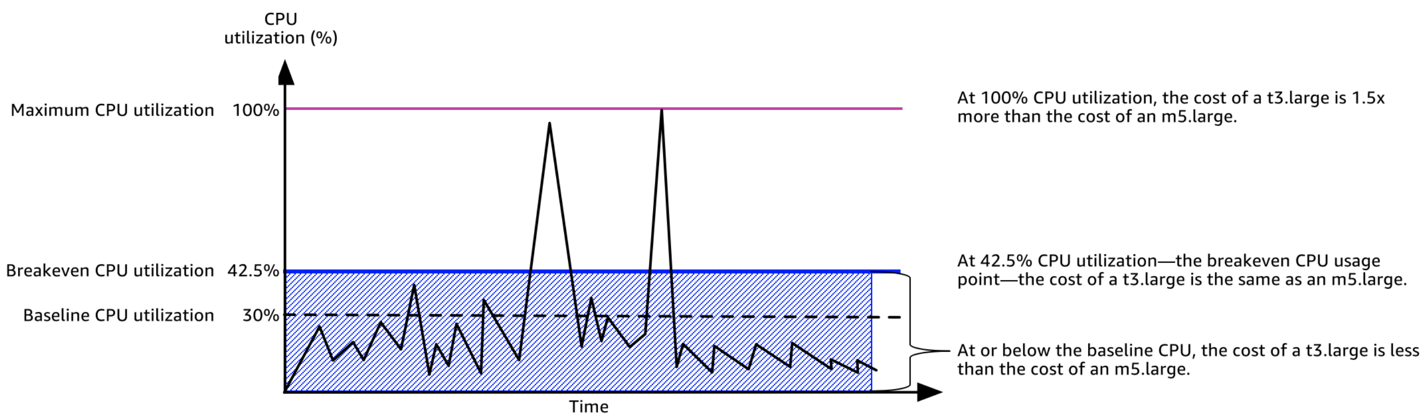
When to use unlimited mode versus fixed CPU

When determining whether you should use a burstable performance instance in `unlimited` mode, such as T3, or a fixed performance instance, such as M5, you need to determine the breakeven CPU usage. The breakeven CPU usage for a burstable performance instance is the point at which a burstable performance instance costs the same as a fixed performance instance. The breakeven CPU usage helps you determine the following:

- If the average CPU usage over a 24-hour period is at or below the breakeven CPU usage, use a burstable performance instance in `unlimited` mode so that you can benefit from the lower price of a burstable performance instance while getting the same performance as a fixed performance instance.

- If the average CPU usage over a 24-hour period is above the breakeven CPU usage, the burstable performance instance will cost more than the equivalently-sized fixed performance instance. If a T3 instance continuously bursts at 100% CPU, you end up paying approximately 1.5 times the price of an equivalently-sized M5 instance.

The following graph shows the breakeven CPU usage point where a `t3.large` costs the same as an `m5.large`. The breakeven CPU usage point for a `t3.large` is 42.5%. If the average CPU usage is at 42.5%, the cost of running the `t3.large` is the same as an `m5.large`, and is more expensive if the average CPU usage is above 42.5%. If the workload needs less than 42.5% average CPU usage, you can benefit from the lower price of the `t3.large` while getting the same performance as an `m5.large`.



The following table shows how to calculate the breakeven CPU usage threshold so that you can determine when it's less expensive to use a burstable performance instance in `unlimited` mode or a fixed performance instance. The columns in the table are labeled A through K.

Instance type	vCPUs	T3 price*/ hour	M5 price*/ hour	Price difference	T3 baseline utilization per vCPU (%)	Charge per vCPU hour for surplus credits	Charge per vCPU minute	Additional burst minutes available per vCPU	Additional CPU % available	Breakeven CPU %
A	B	C	D	E = D - C	F	G	H = G / 60	I = E / H	J = (I /	K = F + J

Instance type	vCPUs	T3 price*/ hour	M5 price*/ hour	Price difference	T3 baseline utilization per vCPU (%)	Charge per vCPU hour for surplus credits	Charge per vCPU minute	Additional burst minutes available per vCPU	Additional CPU % available	Breakeven CPU %
									60) / B	
t3.large	2	$0.0835	$0.096	$0.0125	30%	$0.05	$0.00083	15	12.5%	42.5%

* Price is based on us-east-1 and Linux OS.

The table provides the following information:

- Column A shows the instance type, `t3.large`.
- Column B shows the number of vCPUs for the `t3.large`.
- Column C shows the price of a `t3.large` per hour.
- Column D shows the price of an `m5.large` per hour.
- Column E shows the price difference between the `t3.large` and the `m5.large`.
- Column F shows the baseline utilization per vCPU of the `t3.large`, which is 30%. At the baseline, the hourly cost of the instance covers the cost of the CPU usage.
- Column G shows the flat additional rate per vCPU-hour that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column H shows the flat additional rate per vCPU-minute that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column I shows the number of additional minutes that the `t3.large` can burst per hour at 100% CPU while paying the same price per hour as an `m5.large`.
- Column J shows the additional CPU usage (in %) over baseline that the instance can burst while paying the same price per hour as an `m5.large`.

- Column K shows the breakeven CPU usage (in %) that the `t3.large` can burst without paying more than the `m5.large`. Anything above this, and the `t3.large` costs more than the `m5.large`.

The following table shows the breakeven CPU usage (in %) for T3 instance types compared to the similarly-sized M5 instance types.

T3 instance type	Breakeven CPU usage (in %) for T3 compared to M5
`t3.large`	42.5%
`t3.xlarge`	52.5%
`t3.2xlarge`	52.5%

Surplus credits can incur charges

If the average CPU utilization of an instance is at or below the baseline, the instance incurs no additional charges. Because an instance earns a maximum number of credits in a 24-hour period (for example, a `t3.micro` instance can earn a maximum of 288 credits in a 24-hour period), it can spend surplus credits up to that maximum without being charged.

However, if CPU utilization stays above the baseline, the instance cannot earn enough credits to pay down the surplus credits that it has spent. The surplus credits that are not paid down are charged at a flat additional rate per vCPU-hour. For information about the rate, see T2/T3/T4g Unlimited Mode Pricing.

Surplus credits that were spent earlier are charged when any of the following occurs:

- The spent surplus credits exceed the maximum number of credits the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour.
- The instance is stopped or terminated.
- The instance is switched from `unlimited` to `standard`.

Spent surplus credits are tracked by the CloudWatch metric `CPUSurplusCreditBalance`. Surplus credits that are charged are tracked by the CloudWatch metric `CPUSurplusCreditsCharged`. For more information, see Additional CloudWatch metrics for burstable performance instances.

No launch credits for T2 Unlimited instances

T2 Standard instances receive launch credits, but T2 Unlimited instances do not. A T2 Unlimited instance can burst beyond the baseline at any time with no additional charge, as long as its average CPU utilization is at or below the baseline over a rolling 24-hour window or its lifetime, whichever is shorter. As such, T2 Unlimited instances do not require launch credits to achieve high performance immediately after launch.

If a T2 instance is switched from `standard` to `unlimited`, any accrued launch credits are removed from the `CPUCreditBalance` before the remaining `CPUCreditBalance` is carried over.

T4g, T3a, and T3 instances never receive launch credits because they launch in Unlimited mode by default, and therefore can burst immediately upon start. The Unlimited mode credit configuration enables T4g, T3a, and T3 instances to use as much CPU as needed to burst beyond the baseline and for as long as needed.

Enable unlimited mode

You can switch from `unlimited` to `standard`, and from `standard` to `unlimited`, at any time on a running or stopped instance. For more information, see Configure the credit specification at launch and Manage the credit specification of a burstable performance instance.

You can set `unlimited` as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option. For more information, see Manage the default credit specification for an account.

You can check whether your burstable performance instance is configured as `unlimited` or `standard` using the Amazon EC2 console or the AWS CLI. For more information, see Configure burstable performance instances.

What happens to credits when switching between Unlimited and Standard

`CPUCreditBalance` is a CloudWatch metric that tracks the number of credits accrued by an instance. `CPUSurplusCreditBalance` is a CloudWatch metric that tracks the number of surplus credits spent by an instance.

When you change an instance configured as `unlimited` to `standard`, the following occurs:

- The `CPUCreditBalance` value remains unchanged and is carried over.
- The `CPUSurplusCreditBalance` value is immediately charged.

When a `standard` instance is switched to `unlimited`, the following occurs:

- The `CPUCreditBalance` value containing accrued earned credits is carried over.
- For T2 Standard instances, any launch credits are removed from the `CPUCreditBalance` value, and the remaining `CPUCreditBalance` value containing accrued earned credits is carried over.

Monitor credit usage

To see if your instance is spending more credits than the baseline provides, you can use CloudWatch metrics to track usage, and you can set up hourly alarms to be notified of credit usage. For more information, see [Monitor CPU credits for burstable instances](#).

Unlimited mode examples for burstable instances

The following examples explain credit use for instances that are configured as `unlimited`.

Examples

- [Example 1: Explain credit use with T3 Unlimited](#)
- [Example 2: Explain credit use with T2 Unlimited](#)

Example 1: Explain credit use with T3 Unlimited

In this example, you see the CPU utilization of a `t3.nano` instance launched as `unlimited`, and how it spends *earned* and *surplus* credits to sustain CPU utilization.

A `t3.nano` instance earns 144 CPU credits over a rolling 24-hour period, which it can redeem for 144 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric `CPUCreditBalance`), it can spend *surplus* CPU credits—that it has *not yet earned*—to burst for as long as it needs. Because a `t3.nano` instance earns a maximum of 144 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 144 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its `CPUCreditBalance`. The following workflow references the numbered points on the graph:

P1 – At 0 hours on the graph, the instance is launched as `unlimited` and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, `CPUCreditUsage` is at 0, and the `CPUCreditBalance` value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the `CPUCreditBalance` value cannot exceed its maximum of 144 credits.

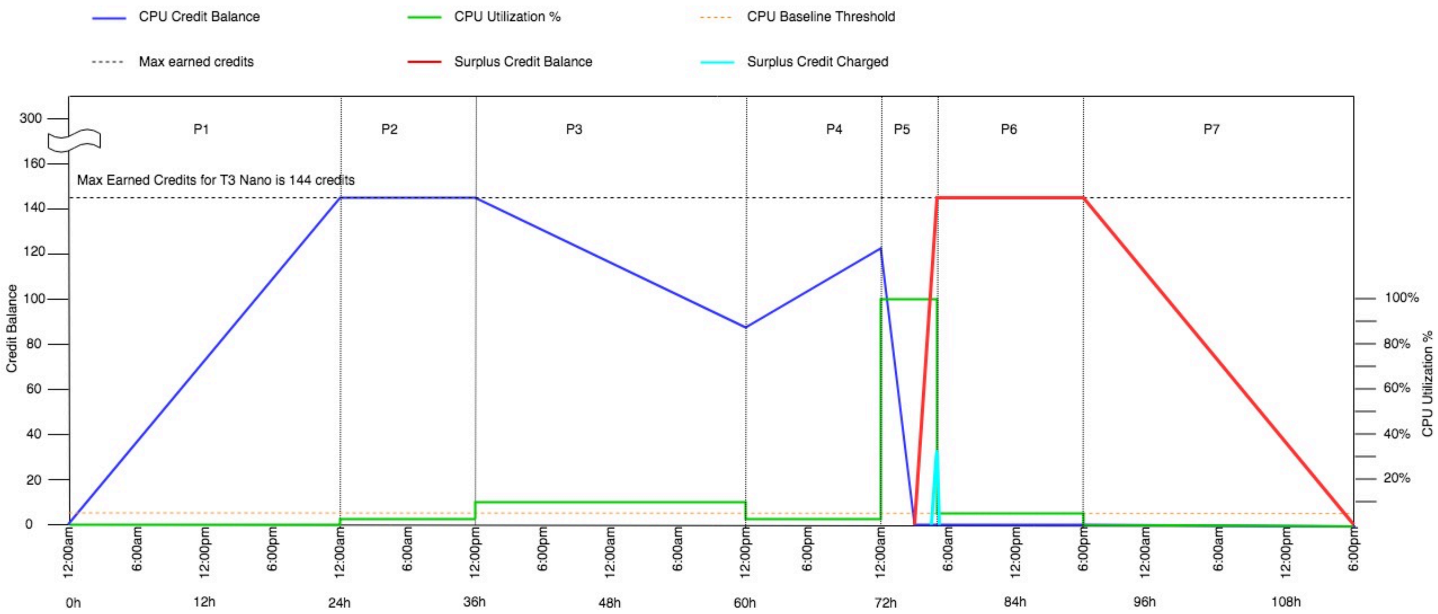
P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the `CPUCreditBalance` value reduces to 86.4 credits.

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the `CPUCreditBalance` value increases to 122 credits.

P5 – For the next 5 hours, the instance bursts at 100% CPU utilization, and spends a total of 570 credits to sustain the burst. About an hour into this period, the instance depletes its entire `CPUCreditBalance` of 122 credits, and starts to spend surplus credits to sustain the high CPU utilization, totaling 448 surplus credits in this period (570-122=448). When the `CPUSurplusCreditBalance` value reaches 144 CPU credits (the maximum a `t3.nano` instance can earn in a 24-hour period), any surplus credits spent thereafter cannot be offset by earned credits. The surplus credits spent thereafter amounts to 304 credits (448-144=304), which results in a small additional charge at the end of the hour for 304 credits.

P6 – For the next 13 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends, with no excess to pay down the `CPUSurplusCreditBalance`. The `CPUSurplusCreditBalance` value remains at 144 credits.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it uses to pay down the `CPUSurplusCreditBalance`.



Example 2: Explain credit use with T2 Unlimited

In this example, you see the CPU utilization of a `t2.nano` instance launched as `unlimited`, and how it spends *earned* and *surplus* credits to sustain CPU utilization.

A `t2.nano` instance earns 72 CPU credits over a rolling 24-hour period, which it can redeem for 72 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric `CPUCreditBalance`), it can spend *surplus* CPU credits—that it has *not yet earned*—to burst for as long as it needs. Because a `t2.nano` instance earns a maximum of 72 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 72 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its `CPUCreditBalance`. You can assume that, at the start of the time line in the graph, the instance has an accrued credit balance equal to the maximum number of credits it can earn in 24 hours. The following workflow references the numbered points on the graph:

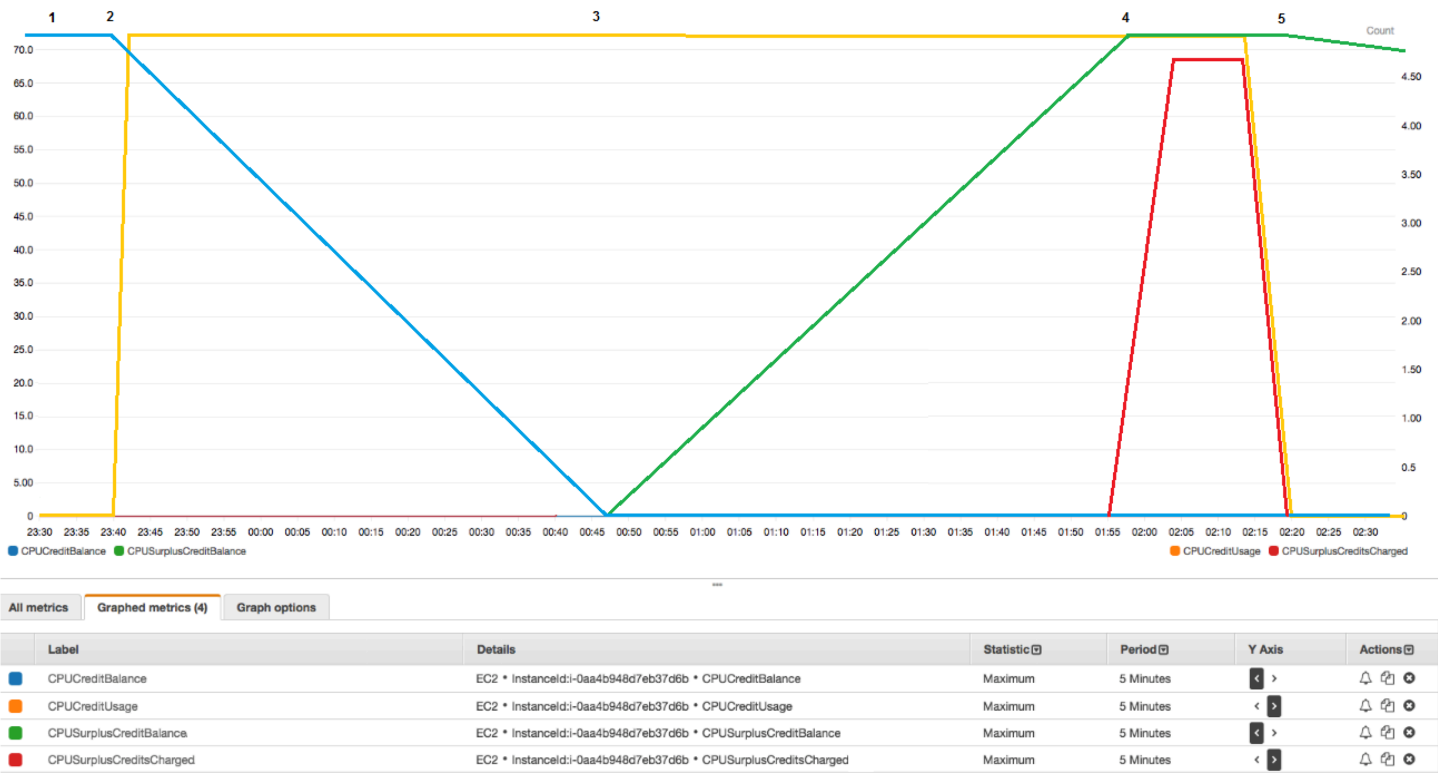
1 – In the first 10 minutes, `CPUCreditUsage` is at 0, and the `CPUCreditBalance` value remains at its maximum of 72.

2 – At 23:40, as CPU utilization increases, the instance spends CPU credits and the `CPUCreditBalance` value decreases.

3 – At around 00:47, the instance depletes its entire `CPUCreditBalance`, and starts to spend surplus credits to sustain high CPU utilization.

4 – Surplus credits are spent until 01:55, when the `CPUSurplusCreditBalance` value reaches 72 CPU credits. This is equal to the maximum a `t2.nano` instance can earn in a 24-hour period. Any surplus credits spent thereafter cannot be offset by earned credits within the 24-hour period, which results in a small additional charge at the end of the hour.

5 – The instance continues to spend surplus credits until around 02:20. At this time, CPU utilization falls below the baseline, and the instance starts to earn credits at 3 credits per hour (or 0.25 credits every 5 minutes), which it uses to pay down the `CPUSurplusCreditBalance`. After the `CPUSurplusCreditBalance` value reduces to 0, the instance starts to accrue earned credits in its `CPUCreditBalance` at 0.25 credits every 5 minutes.



Calculating the bill (Linux instance)

Surplus credits cost $0.05 per vCPU-hour. The instance spent approximately 25 surplus credits between 01:55 and 02:20, which is equivalent to 0.42 vCPU-hours. Additional charges for this instance are 0.42 vCPU-hours x $0.05/vCPU-hour = $0.021, rounded to $0.02. Here is the month-end bill for this T2 Unlimited instance:

Amazon Elastic Compute Cloud running Linux/UNIX		
$0.0058 per On Demand Linux t2.nano Instance Hour	720.000 Hrs	$4.18

Amazon Elastic Compute Cloud T2 CPU Credits		
$0.05 per vCPU-Hour of T2 CPU credits	0.420 vCPU-Hours	$0.02

Calculating the bill (Windows instance)

Surplus credits cost $0.096 per vCPU-hour. The instance spent approximately 25 surplus credits between 01:55 and 02:20, which is equivalent to 0.42 vCPU-hours. Additional charges for this instance are 0.42 vCPU-hours x $0.096/vCPU-hour = $0.04032, rounded to $0.04. Here is the month-end bill for this T2 Unlimited instance:

Amazon Elastic Compute Cloud running Windows		
$0.0081 per On Demand Windows t2.nano Instance Hour	720.000 Hrs	$5.83

Amazon Elastic Compute Cloud T2 CPU Credits		
$0.096 per vCPU-Hour of T2 CPU credits	0.420 vCPU-Hours	$0.04

You can set billing alerts to be notified every hour of any accruing charges, and take action if required.

Standard mode for burstable performance instances

A burstable performance instance configured as `standard` is suited to workloads with an average CPU utilization that is consistently below the baseline CPU utilization of the instance. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. If the instance is running low on accrued credits, CPU utilization is gradually lowered to the baseline level, so that the instance does not experience a sharp performance drop-off when its accrued CPU credit balance is depleted. For more information, see Key concepts for burstable performance instances.

Contents

Standard mode concepts for burstable instances

The `standard` mode is a configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can set `standard` as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

How standard burstable performance instances work

When a burstable performance instance configured as `standard` is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. For T2 Standard, when the instance is stopped, it loses all its accrued credits, and its credit balance is reset to zero. When it is restarted, it receives a new set of launch credits, and begins to accrue earned credits. For T4g, T3a, and T3 Standard instances, the CPU credit balance persists for seven days after the instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

T2 Standard instances receive two types of CPU credits: *earned credits* and *launch credits*. When a T2 Standard instance is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. At start, it has not yet earned credits for a good startup experience; therefore, to provide a good startup experience, it receives launch credits at start, which it spends first while it accrues earned credits.

T4g, T3a, and T3 instances do not receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a, and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

Launch credits

T2 Standard instances get 30 launch credits per vCPU at launch or start, and T1 Standard instances get 15 launch credits. For example, a `t2.micro` instance has one vCPU and gets 30 launch credits, while a `t2.xlarge` instance has four vCPUs and gets 120 launch credits. Launch credits are designed to provide a good startup experience to allow instances to burst immediately after launch before they have accrued earned credits.

Launch credits are spent first, before earned credits. Unspent launch credits are accrued in the CPU credit balance, but do not count towards the CPU credit balance limit. For example, a `t2.micro` instance has a CPU credit balance limit of 144 earned credits. If it is launched and remains idle for 24 hours, its CPU credit balance reaches 174 (30 launch credits + 144 earned credits), which is over the limit. However, after the instance spends the 30 launch credits, the credit balance cannot exceed 144. For more information about the CPU credit balance limit for each instance size, see the credit table.

The following table lists the initial CPU credit allocation received at launch or start, and the number of vCPUs.

Instance type	Launch credits	vCPUs
`t1.micro`	15	1
`t2.nano`	30	1
`t2.micro`	30	1
`t2.small`	30	1
`t2.medium`	60	2
`t2.large`	60	2
`t2.xlarge`	120	4
`t2.2xlarge`	240	8

Launch credit limits

There is a limit to the number of times T2 Standard instances can receive launch credits. The default limit is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. For example, the limit is reached when one instance is stopped and started 100 times within a 24-hour period, or when 100 instances are launched within a 24-hour period, or other combinations that equate to 100 starts. New accounts may have a lower limit, which increases over time based on your usage.

> **Tip**
>
> To ensure that your workloads always get the performance they need, switch to [Unlimited mode for burstable performance instances]() or consider using a larger instance size.

Differences between launch credits and earned credits

The following table lists the differences between launch credits and earned credits.

	Launch credits	Earned credits
Credit earn rate	T2 Standard instances get 30 launch credits per vCPU at launch or start. If a T2 instance is switched from `unlimited` to `standard`, it does not get launch credits at the time of switching.	Each T2 instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. For more information about the number of CPU credits earned per instance size, see the [credit table]().
Credit earn limit	The limit for receiving launch credits is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. New accounts may have a lower limit, which increases over time based on your usage.	A T2 instance cannot accrue more credits than the CPU credit balance limit. If the CPU credit balance has reached its limit, any credits that are earned after the limit is reached are discarded. Launch credits do not count towards the limit. For more information about the CPU credit

	Launch credits	Earned credits
		balance limit for each T2 instance size, see the credit table.
Credit use	Launch credits are spent first, before earned credits.	Earned credits are spent only after all launch credits are spent.
Credit expiration	When a T2 Standard instance is running, launch credits do not expire. When a T2 Standard instance stops or is switched to T2 Unlimited, all launch credits are lost.	When a T2 instance is running, earned credits that have accrued do not expire. When the T2 instance stops, all accrued earned credits are lost.

The number of accrued launch credits and accrued earned credits is tracked by the CloudWatch metric `CPUCreditBalance`. For more information, see `CPUCreditBalance` in the CloudWatch metrics table.

Standard mode examples for burstable instances

The following examples explain credit use when instances are configured as `standard`.

Examples

- Example 1: Explain credit use with T3 Standard
- Example 2: Explain credit use with T2 Standard

Example 1: Explain credit use with T3 Standard

In this example, you see how a `t3.nano` instance launched as `standard` earns, accrues, and spends *earned* credits. You see how the credit balance reflects the accrued *earned* credits.

A running `t3.nano` instance earns 144 credits every 24 hours. Its credit balance limit is 144 earned credits. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the credit table.

You might launch a T3 Standard instance and use it immediately. Or, you might launch a T3 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance reaches it limit, which is the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

The following workflow references the numbered points on the graph:

P1 – At 0 hours on the graph, the instance is launched as `standard` and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, `CPUCreditUsage` is at 0, and the `CPUCreditBalance` value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the `CPUCreditBalance` value cannot exceed its maximum of 144 credits. Any credits that are earned in excess of the limit are discarded.

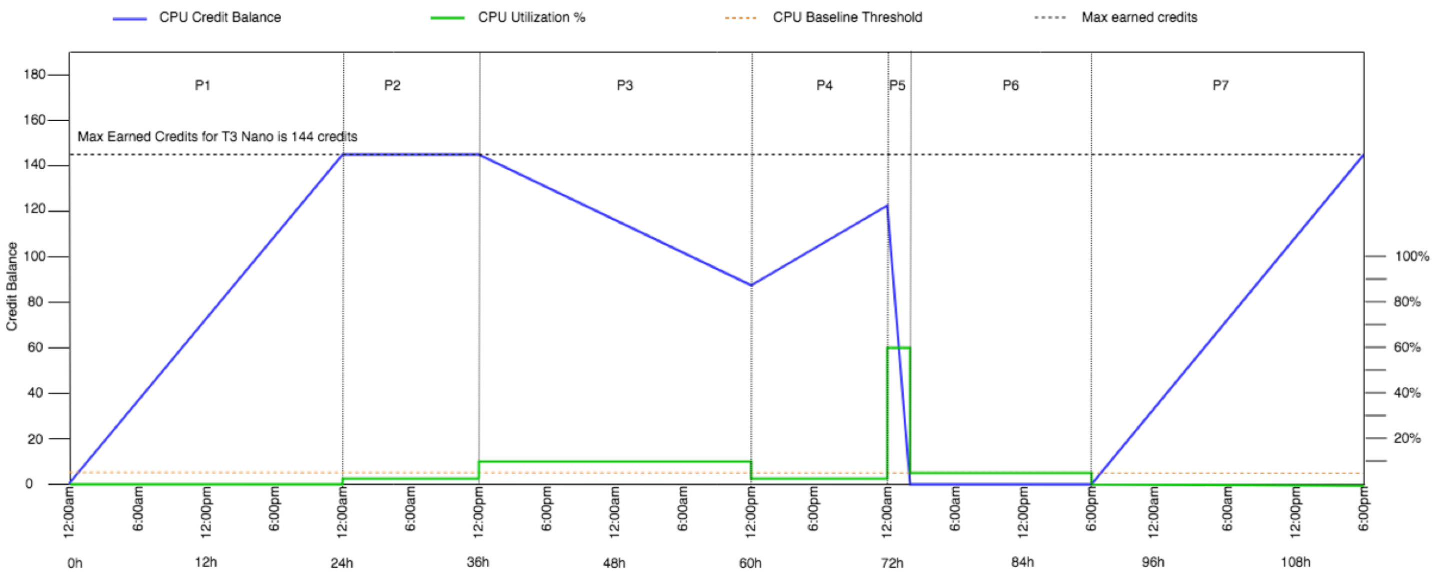
P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the `CPUCreditBalance` value reduces to 86.4 credits.

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the `CPUCreditBalance` value increases to 122 credits.

P5 – For the next two hours, the instance bursts at 60% CPU utilization, and depletes its entire `CPUCreditBalance` value of 122 credits. At the end of this period, with the `CPUCreditBalance` at zero, CPU utilization is forced to drop to the baseline utilization level of 5%. At the baseline, the instance earns as many credits as it spends.

P6 – For the next 14 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends. The `CPUCreditBalance` value remains at 0.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it accrues in its `CPUCreditBalance`.



Example 2: Explain credit use with T2 Standard

In this example, you see how a `t2.nano` instance launched as `standard` earns, accrues, and spends *launch* and *earned* credits. You see how the credit balance reflects not only accrued *earned* credits, but also accrued *launch* credits.

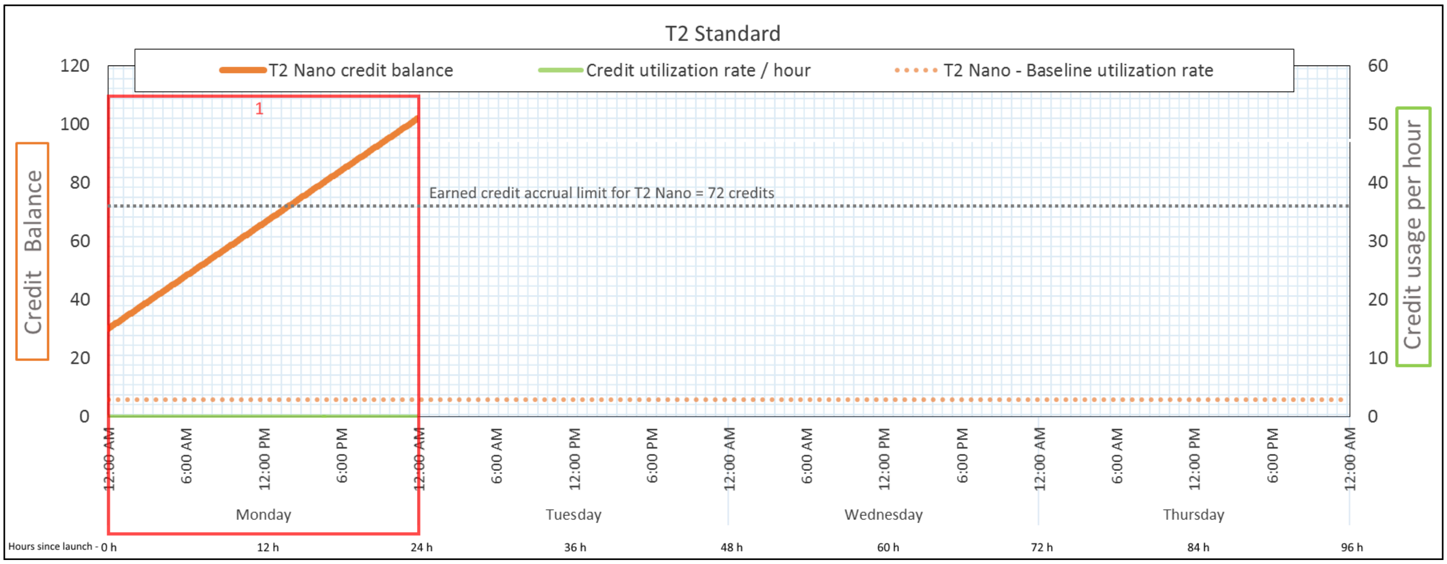
A `t2.nano` instance gets 30 launch credits when it is launched, and earns 72 credits every 24 hours. Its credit balance limit is 72 earned credits; launch credits do not count towards the limit. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the credit table. For more information about limits, see Launch credit limits.

You might launch a T2 Standard instance and use it immediately. Or, you might launch a T2 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance appears to exceed its limit because the balance reflects both accrued earned credits and accrued launch credits. However, after CPU is used, the launch credits are spent first. Thereafter, the limit always reflects the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

Period 1: 1 – 24 hours

At 0 hours on the graph, the T2 instance is launched as `standard` and immediately gets 30 launch credits. It earns credits while in the running state. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. At approximately 14 hours after launch, the credit balance is 72 (30 launch credits + 42 earned credits), which is equivalent to what the instance can earn in 24 hours. At 24 hours after launch, the credit balance exceeds 72 credits because the unspent launch credits are accrued in the credit balance—the credit balance is 102 credits: 30 launch credits + 72 earned credits.



Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	0 credits per 24 hours
Credit Balance	102 credits (30 launch credits + 72 earned credits)

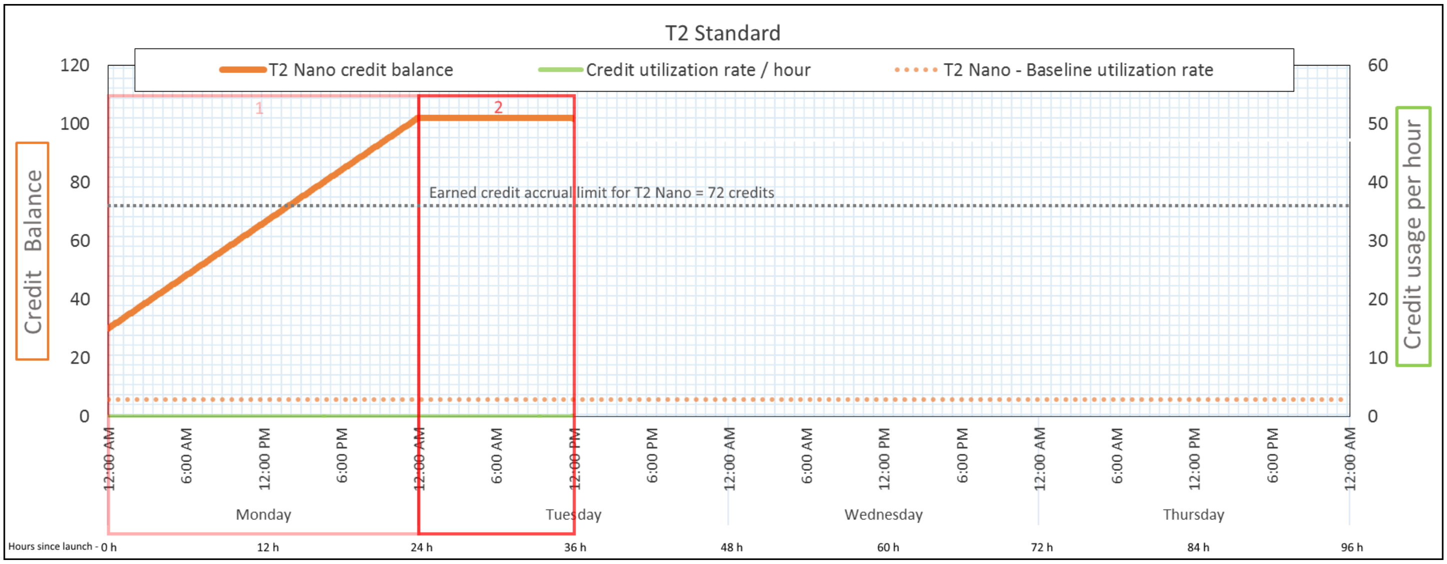
Conclusion

If there is no CPU utilization after launch, the instance accrues more credits than what it can earn in 24 hours (30 launch credits + 72 earned credits = 102 credits).

In a real-world scenario, an EC2 instance consumes a small number of credits while launching and running, which prevents the balance from reaching the maximum theoretical value in this example.

Period 2: 25 – 36 hours

For the next 12 hours, the instance continues to remain idle and earn credits, but the credit balance does not increase. It plateaus at 102 credits (30 launch credits + 72 earned credits). The credit balance has reached its limit of 72 accrued earned credits, so newly earned credits are discarded.



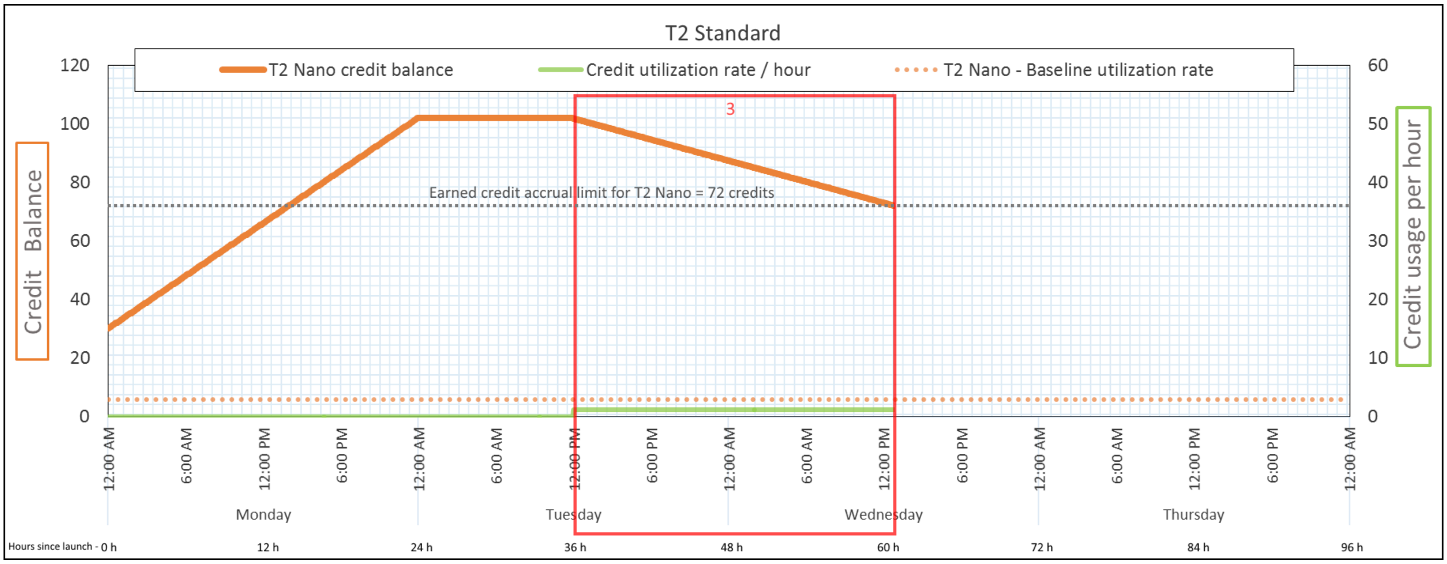
Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours (3 credits per hour)
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	102 credits (30 launch credits + 72 earned credits)—balance is unchanged

Conclusion

An instance constantly earns credits, but it cannot accrue more earned credits if the credit balance has reached its limit. After the limit is reached, newly earned credits are discarded. Launch credits do not count towards the credit balance limit. If the balance includes accrued launch credits, the balance appears to be over the limit.

Period 3: 37 – 61 hours

For the next 25 hours, the instance uses 2% CPU, which requires 30 credits. In the same period, it earns 75 credits, but the credit balance decreases. The balance decreases because the accrued *launch* credits are spent first, while newly earned credits are discarded because the credit balance is already at its limit of 72 earned credits.



Credit Spend Rate	28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—30 credits over 25 hours
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	72 credits (30 launch credits were spent; 72 earned credits remain unspent)

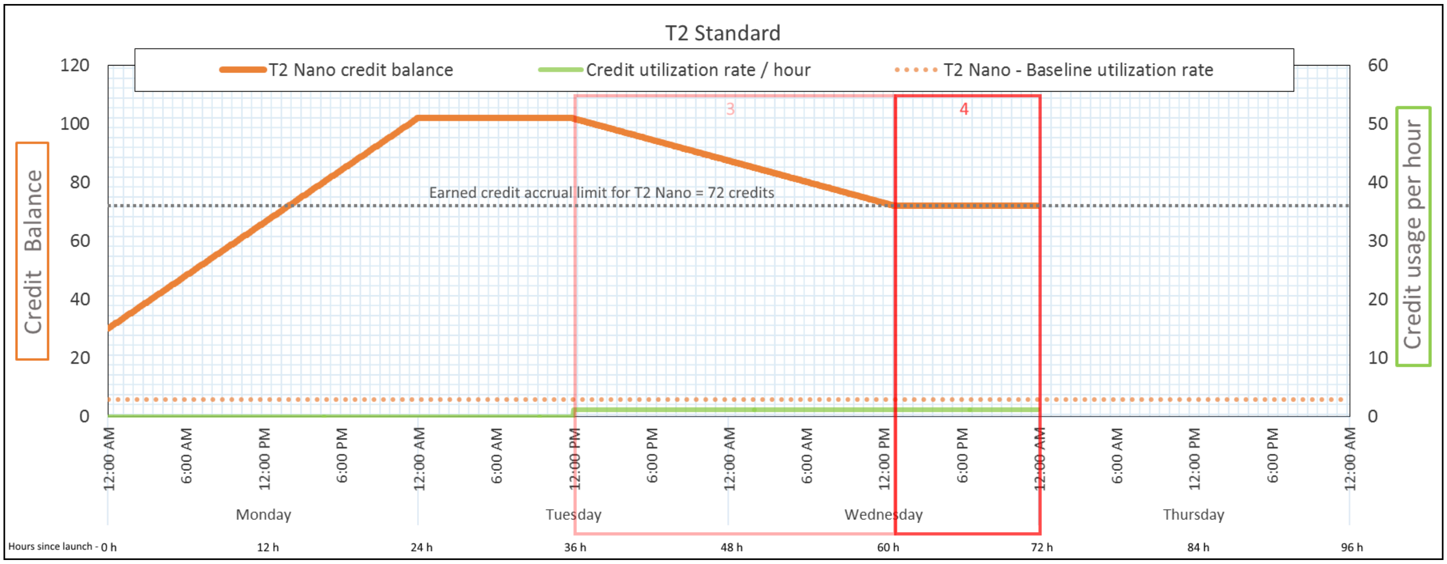
Conclusion

An instance spends launch credits first, before spending earned credits. Launch credits do not count towards the credit limit. After the launch credits are spent, the balance can never go higher than what can be earned in 24 hours. Furthermore, while an instance is running, it cannot get more launch credits.

Period 4: 62 – 72 hours

For the next 11 hours, the instance uses 2% CPU, which requires 13.2 credits. This is the same CPU utilization as in the previous period, but the balance does not decrease. It stays at 72 credits.

The balance does not decrease because the credit earn rate is higher than the credit spend rate. In the time that the instance spends 13.2 credits, it also earns 33 credits. However, the balance limit is 72 credits, so any earned credits that exceed the limit are discarded. The balance plateaus at 72 credits, which is different from the plateau of 102 credits during Period 2, because there are no accrued launch credits.



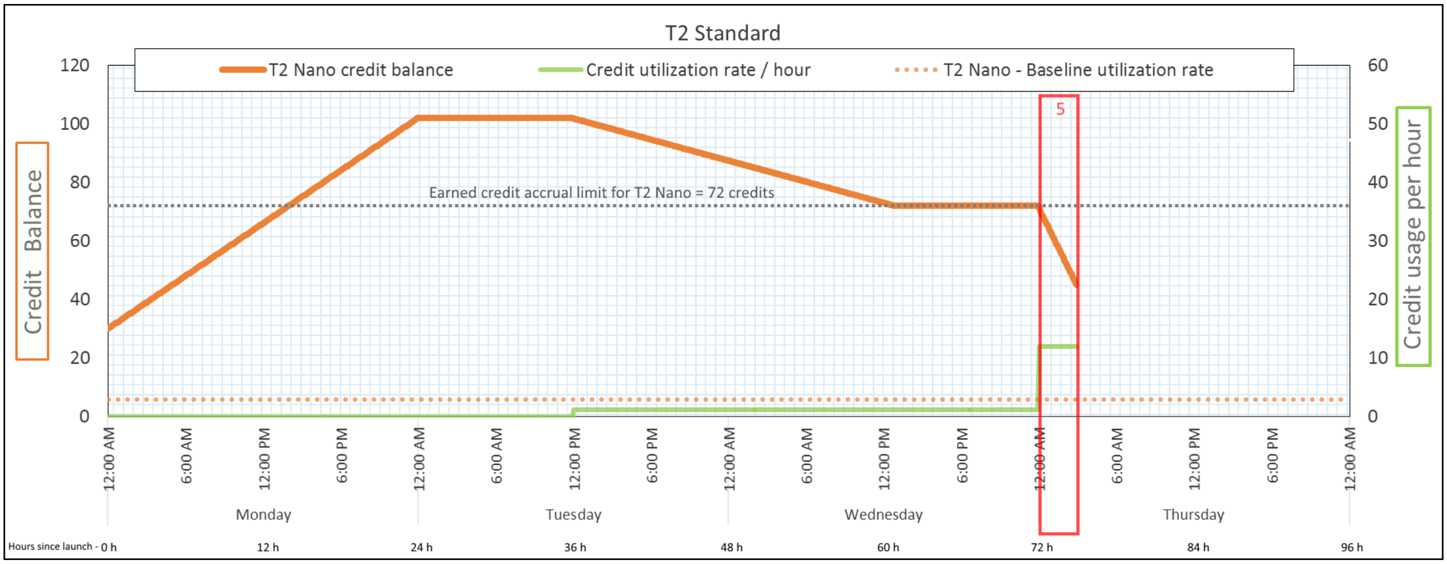
Credit Spend Rate	28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—13.2 credits over 11 hours
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	43.2 credits per 24 hours (60% of credit earn rate)
Credit Balance	72 credits (0 launch credits, 72 earned credits)—balance is at its limit

Conclusion

After launch credits are spent, the credit balance limit is determined by the number of credits that an instance can earn in 24 hours. If the instance earns more credits than it spends, newly earned credits over the limit are discarded.

Period 5: 73 – 75 hours

For the next three hours, the instance bursts at 20% CPU utilization, which requires 36 credits. The instance earns nine credits in the same three hours, which results in a net balance decrease of 27 credits. At the end of three hours, the credit balance is 45 accrued earned credits.



Credit Spend Rate	288 credits per 24 hours (12 credits per hour, 20% CPU utilization, 400% of credit earn rate)—36 credits over 3 hours
Credit Earn Rate	72 credits per 24 hours (9 credits over 3 hours)
Credit Discard Rate	0 credits per 24 hours
Credit Balance	45 credits (previous balance (72) - spent credits (36) + earned credits (9))—balance decreases at a rate of 216 credits per 24 hours (spend rate 288/24 + earn rate 72/24 = balance decrease rate 216/24)

Conclusion

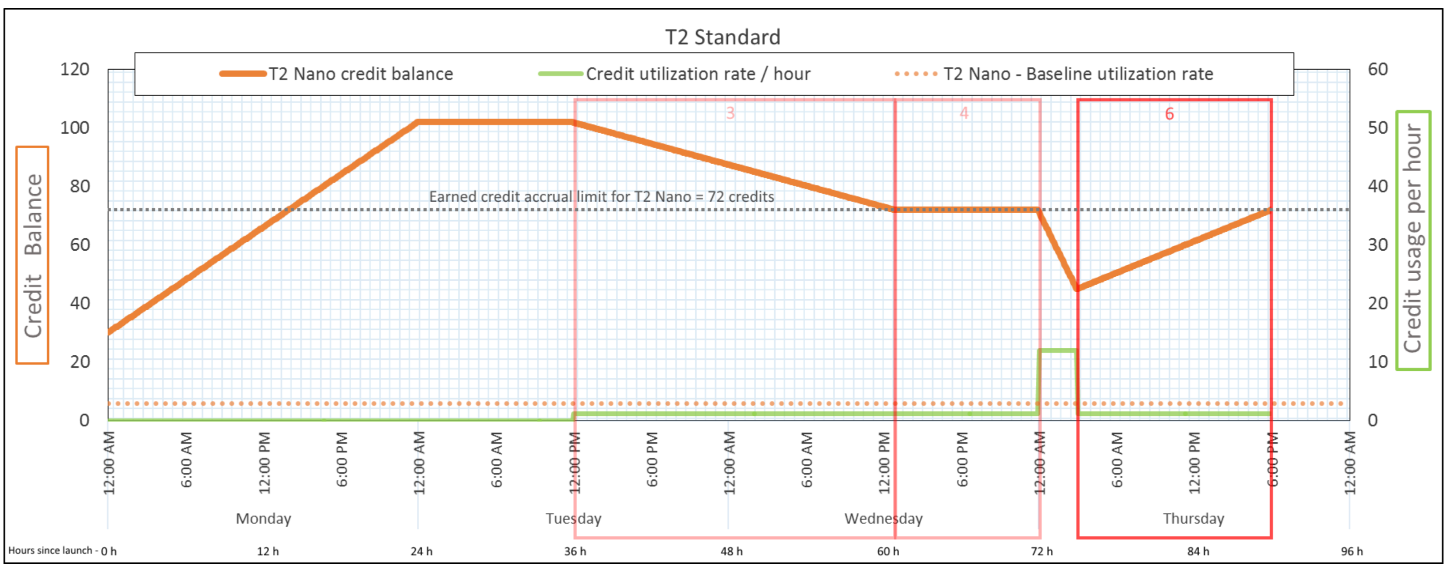
If an instance spends more credits than it earns, its credit balance decreases.

Period 6: 76 – 90 hours

For the next 15 hours, the instance uses 2% CPU, which requires 18 credits. This is the same CPU utilization as in Periods 3 and 4. However, the balance increases in this period, whereas it decreased in Period 3 and plateaued in Period 4.

In Period 3, the accrued launch credits were spent, and any earned credits that exceeded the credit limit were discarded, resulting in a decrease in the credit balance. In Period 4, the instance spent fewer credits than it earned. Any earned credits that exceeded the limit were discarded, so the balance plateaued at its maximum of 72 credits.

In this period, there are no accrued launch credits, and the number of accrued earned credits in the balance is below the limit. No earned credits are discarded. Furthermore, the instance earns more credits than it spends, resulting in an increase in the credit balance.



Credit Spend Rate	28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—18 credits over 15 hours
Credit Earn Rate	72 credits per 24 hours (45 credits over 15 hours)
Credit Discard Rate	0 credits per 24 hours

Credit Balance	72 credits (balance increases at a rate of 43.2 credits per 24 hours—change rate = spend rate 28.8/24 + earn rate 72/24)

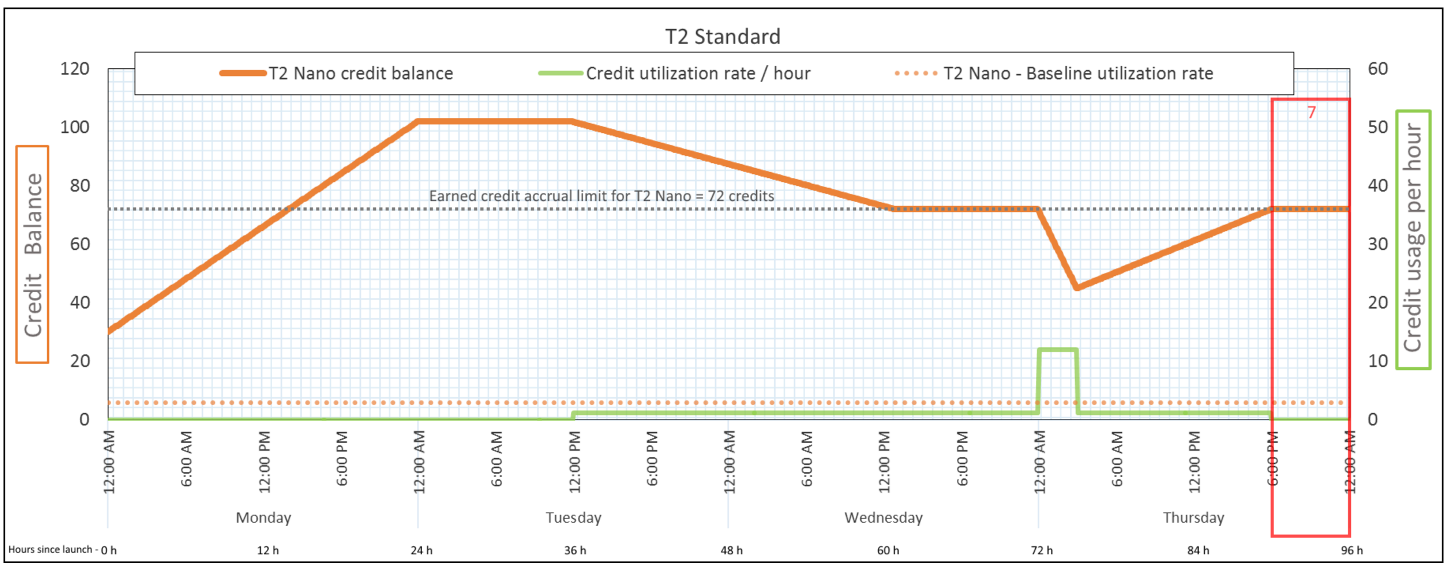
Conclusion

If an instance spends fewer credits than it earns, its credit balance increases.

Period 7: 91 – 96 hours

For the next six hours, the instance remains idle—CPU utilization is 0%—and no credits are spent. This is the same CPU utilization as in Period 2, but the balance does not plateau at 102 credits—it plateaus at 72 credits, which is the credit balance limit for the instance.

In Period 2, the credit balance included 30 accrued launch credits. The launch credits were spent in Period 3. A running instance cannot get more launch credits. After its credit balance limit is reached, any earned credits that exceed the limit are discarded.



Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	72 credits (0 launch credits, 72 earned credits)

Conclusion

An instance constantly earns credits, but cannot accrue more earned credits if the credit balance limit has been reached. After the limit is reached, newly earned credits are discarded. The credit balance limit is determined by the number of credits that an instance can earn in 24 hours. For more information about credit balance limits, see the credit table.

Configure burstable performance instances

The steps for launching, monitoring, and modifying burstable performance instances (T instances) are similar. The key difference is the default credit specification when they launch.

Each T instance family comes with the following *default credit specification*:

- T4g, T3a, and T3 instances launch as `unlimited`
- T3 instances on a Dedicated Host can only launch as `standard`
- T2 instances launch as `standard`

You can change the default credit specification for the account.

Tasks

- Configure the credit specification at launch
- Configure an Auto Scaling group to set the credit specification as unlimited
- Manage the credit specification of a burstable performance instance
- Manage the default credit specification for an account

Configure the credit specification at launch

You can launch your T instances with a credit specification of `unlimited` or `standard`.

The following procedures describe how to use the EC2 console or the AWS CLI. For information about using an Auto Scaling group, see Configure an Auto Scaling group to set the credit specification as unlimited.

Console

To configure the credit specification of an instance at launch

1. Follow the procedure to launch an instance.

2. Under **Instance type**, select a T instance type.
3. Expand **Advanced details**. For **Credit specification**, select a credit specification.
4. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**.

AWS CLI

To set the credit specification of an instance at launch

Use the run-instances command with the `--credit-specification` option.

```
--credit-specification CpuCredits=unlimited
```

PowerShell

To set the credit specification of an instance at launch

Use the New-EC2Instance cmdlet with the `-CreditSpecification_CpuCredit` parameter.

```
-CreditSpecification_CpuCredit unlimited
```

Configure an Auto Scaling group to set the credit specification as unlimited

When T instances are launched or started, they require CPU credits for a good bootstrapping experience. If you use an Auto Scaling group to launch your instances, we recommend that you configure your instances as `unlimited`. If you do, the instances use surplus credits when they are automatically launched or restarted by the Auto Scaling group. Using surplus credits prevents performance restrictions.

Create a launch template

You must use a *launch template* for launching instances as `unlimited` in an Auto Scaling group. A launch configuration does not support launching instances as `unlimited`.

Console

To create a launch template that sets the credit specification

1. Follow the Create a launch template using advanced settings procedure in the *Amazon EC2 Auto Scaling User Guide*.

2. In **Launch template contents**, for **Instance type**, choose an instance size.
3. To launch instances as `unlimited` in an Auto Scaling group, under **Advanced details**, for **Credit specification**, choose **Unlimited**.
4. When you've finished defining the launch template parameters, choose **Create launch template**.

AWS CLI

To create a launch template that sets the credit specification

Use the create-launch-template command.

```
aws ec2 create-launch-template \
    --launch-template-name my-launch-template \
    --version-description FirstVersion \
    --launch-template-data CreditSpecification={CpuCredits=unlimited}
```

PowerShell

To create a launch template that sets the credit specification

Use the New-EC2LaunchTemplate cmdlet. Define the credit specification for the launch template data as follows.

```
$creditSpec = New-Object Amazon.EC2.Model.CreditSpecificationRequest
$creditSpec.CpuCredits = "unlimited"
$launchTemplateData = New-Object Amazon.EC2.Model.RequestLaunchTemplateData
$launchTemplateData.CreditSpecification = $creditSpec
```

Associate an Auto Scaling group with a launch template

To associate the launch template with an Auto Scaling group, create the Auto Scaling group using the launch template, or add the launch template to an existing Auto Scaling group.

Console

To create an Auto Scaling group using a launch template

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose **Auto Scaling Groups**, **Create Auto Scaling group**.
4. Choose **Launch Template**, select your launch template, and then choose **Next Step**.
5. Complete the fields for the Auto Scaling group. When you've finished reviewing your configuration settings on the **Review page**, choose **Create Auto Scaling group**. For more information, see Creating an Auto Scaling Group Using a Launch Template in the *Amazon EC2 Auto Scaling User Guide*.

To add a launch template to an existing Auto Scaling group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose **Auto Scaling Groups**.
4. From the Auto Scaling group list, select an Auto Scaling group, and choose **Actions**, **Edit**.
5. On the **Details** tab, for **Launch Template**, choose a launch template, and then choose **Save**.

AWS CLI

To create an Auto Scaling group using a launch template

Use the create-auto-scaling-group command and specify the `--launch-template` parameter.

To add a launch template to an existing Auto Scaling group

Use the update-auto-scaling-group command and specify the `--launch-template` parameter.

PowerShell

To create an Auto Scaling group using a launch template

Use the New-ASAutoScalingGroup cmdlet and specify the `-LaunchTemplate_LaunchTemplateId` or `-LaunchTemplate_LaunchTemplateName` parameter.

To add a launch template to an existing Auto Scaling group

Use the Update-ASAutoScalingGroup cmdlet and specify the -LaunchTemplate_LaunchTemplateId or -LaunchTemplate_LaunchTemplateName parameter.

Manage the credit specification of a burstable performance instance

You can switch the credit specification of a running or stopped T instance at any time between `unlimited` and `standard`.

Note that in `unlimited` mode, an instance can spend surplus credits, which might incur an additional charge. For more information, see Surplus credits can incur charges.

Console

To manage the credit specification of an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**.
3. (Optional) Select an instance. On its **Details** tab, find **Credit specification**. The value is either `unlimited` or `standard`.
4. (Optional) To modify the credit specification for multiple instances at the same time, select them all.
5. Choose **Actions**, **Instance settings**, **Change credit specification**. This option is enabled only if you selected a T instance.
6. For **Unlimited mode**, select or clear the checkbox next to each instance ID.

AWS CLI

To get the credit specification of an instance

Use the describe-instance-credit-specifications command. If you do not specify an instance ID, all instances with the credit specification of `unlimited` are returned. The output would also include instances that were previously configured with the `unlimited` credit specification. For example, if you resize a T3 instance to an M4 instance, while it is configured as `unlimited`, Amazon EC2 returns the M4 instance.

```
aws ec2 describe-instance-credit-specifications \
```

```
    --instance-id i-1234567890abcdef0 \
    --query InstanceCreditSpecifications[].CpuCredits \
    --output text
```

The following is example output.

```
unlimited
```

To set the credit specification of an instance

Use the modify-instance-credit-specification command.

```
aws ec2 modify-instance-credit-specification \
    --region us-east-1 \
    --instance-credit-specification
 "InstanceId=i-1234567890abcdef0,CpuCredits=unlimited"
```

PowerShell

To get the credit specification of an instance

Use the Get-EC2CreditSpecification cmdlet.

```
(Get-EC2CreditSpecification `
    -InstanceId i-1234567890abcdef0).CpuCredits
```

The following is example output.

```
unlimited
```

To set the credit specification of an instance

Use the Edit-EC2InstanceCreditSpecification cmdlet.

```
Edit-EC2InstanceCreditSpecification `
    -Region us-east-1 `
    -InstanceCreditSpecification @({InstanceId="i-1234567890abcdef0"
 CpuCredits="unlimited"})
```

Manage the default credit specification for an account

Each T instance family comes with a default credit specification. You can change the default credit specification for each T instance family at the account level per AWS Region. The valid values for the default credit specification are `unlimited` and `standard`.

If you use the launch instance wizard in the EC2 console to launch instances, the value you select for the credit specification overrides the account-level default credit specification. If you use the AWS CLI to launch instances, all new T instances in the account launch using the default credit specification. The credit specification for existing running or stopped instances is not affected.

Consideration

The default credit specification for an instance family can be modified only once in a rolling 5-minute period, and up to four times in a rolling 24-hour period.

Console

To manage the default credit specification

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. On the left navigation pane, choose **EC2 Dashboard**.
4. From **Account attributes**, choose **Default credit specification**.
5. Choose **Manage**.
6. For each instance family, choose **Unlimited** or **Standard**, and then choose **Update**.

AWS CLI

To get the default credit specification

Use the get-default-credit-specification command.

```
aws ec2 get-default-credit-specification \
    --region us-east-1 \
    --instance-family t2 \
    --query InstanceFamilyCreditSpecifications[].CpuCredits \
    --output text
```

The following is example output.

```
standard
```

To set the default credit specification

Use the modify-default-credit-specification command. The following example sets the value to `unlimited`.

```
aws ec2 modify-default-credit-specification \
    --region us-east-1 \
    --instance-family t2 \
    --cpu-credits unlimited
```

PowerShell

To get the default credit specification

Use the Get-EC2DefaultCreditSpecification cmdlet.

```
(Get-EC2DefaultCreditSpecification `
    -Region us-east-1 `
    -InstanceFamily t2).CpuCredits
```

The following is example output.

```
standard
```

To set the default credit specification

Use the Edit-EC2DefaultCreditSpecification cmdlet. The following example sets the value to `unlimited`.

```
Edit-EC2DefaultCreditSpecification `
    -Region us-east-1 `
    -InstanceFamily t2 `
    -CpuCredit unlimited
```

Monitor CPU credits for burstable instances

EC2 sends metrics to Amazon CloudWatch. You can see the CPU credit metrics in the Amazon EC2 per-instance metrics of the CloudWatch console or by using the AWS CLI to list the metrics for each instance. For more information, see CloudWatch metrics that are available for your instances.

Contents

Additional CloudWatch metrics for burstable performance instances

Burstable performance instances have these additional CloudWatch metrics, which are updated every five minutes:

- `CPUCreditUsage` – The number of CPU credits spent during the measurement period.
- `CPUCreditBalance` – The number of CPU credits that an instance has accrued. This balance is depleted when the CPU bursts and CPU credits are spent more quickly than they are earned.
- `CPUSurplusCreditBalance` – The number of surplus CPU credits spent to sustain CPU utilization when the `CPUCreditBalance` value is zero.
- `CPUSurplusCreditsCharged` – The number of surplus CPU credits exceeding the maximum number of CPU credits that can be earned in a 24-hour period, and thus attracting an additional charge.

The last two metrics apply only to instances configured as `unlimited`.

The following table describes the CloudWatch metrics for burstable performance instances. For more information, see CloudWatch metrics that are available for your instances.

Metric	Description
`CPUCreditUsage`	The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes).

Metric	Description
	CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the `Sum` statistic instead of the `Average` statistic. Units: Credits (vCPU-minutes)
`CPUCreditBalance`	The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the `CPUCreditBalance` also includes the number of launch credits that have been accrued. Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit. The credits in the `CPUCreditBalance` are available for the instance to spend to burst beyond its baseline CPU utilization. When an instance is running, credits in the `CPUCreditBalance` do not expire. When a T4g, T3a or T3 instance stops, the `CPUCreditBalance` value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the `CPUCreditBalance` value does not persist, and all accrued credits are lost. CPU credit metrics are available at a five-minute frequency only. Units: Credits (vCPU-minutes)

Metric	Description
CPUSurplusCreditBalance	The number of surplus credits that have been spent by an `unlimited` instance when its `CPUCreditBalance` value is zero. The `CPUSurplusCreditBalance` value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge. Units: Credits (vCPU-minutes)
CPUSurplusCreditsCharged	The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge. Spent surplus credits are charged when any of the following occurs: • The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour. • The instance is stopped or terminated. • The instance is switched from `unlimited` to `standard`. Units: Credits (vCPU-minutes)

Calculate CPU credit usage

The CPU credit usage of instances is calculated using the instance CloudWatch metrics described in the preceding table.

Amazon EC2 sends the metrics to CloudWatch every five minutes. A reference to the *prior* value of a metric at any point in time implies the previous value of the metric, sent *five minutes ago*.

Calculate CPU credit usage for Standard instances

- The CPU credit balance increases if CPU utilization is below the baseline, when the credits spent are less than the credits earned in the prior five-minute interval.
- The CPU credit balance decreases if CPU utilization is above the baseline, when the credits spent are more than the credits earned in the prior five-minute interval.

Mathematically, this is captured by the following equation:

Example

```
CPUCreditBalance = prior CPUCreditBalance + [Credits earned per hour * (5/60) -
 CPUCreditUsage]
```

The size of the instance determines the number of credits that the instance can earn per hour and the number of earned credits that it can accrue in the credit balance. For information about the number of credits earned per hour, and the credit balance limit for each instance size, see the credit table.

Example

This example uses a `t3.nano` instance. To calculate the `CPUCreditBalance` value of the instance, use the preceding equation as follows:

- `CPUCreditBalance` – The current credit balance to calculate.
- `prior CPUCreditBalance` – The credit balance five minutes ago. In this example, the instance had accrued two credits.
- `Credits earned per hour` – A `t3.nano` instance earns six credits per hour.
- `5/60` – Represents the five-minute interval between CloudWatch metric publication. Multiply the credits earned per hour by 5/60 (five minutes) to get the number of credits that the instance earned in the past five minutes. A `t3.nano` instance earns 0.5 credits every five minutes.
- `CPUCreditUsage` – How many credits the instance spent in the past five minutes. In this example, the instance spent one credit in the past five minutes.

Using these values, you can calculate the `CPUCreditBalance` value:

Example

```
CPUCreditBalance = 2 + [0.5 - 1] = 1.5
```

Calculate CPU credit usage for Unlimited instances

When a burstable performance instance needs to burst above the baseline, it always spends accrued credits before spending surplus credits. When it depletes its accrued CPU credit balance, it can spend surplus credits to burst CPU for as long as it needs. When CPU utilization falls below the baseline, surplus credits are always paid down before the instance accrues earned credits.

We use the term `Adjusted balance` in the following equations to reflect the activity that occurs in this five-minute interval. We use this value to arrive at the values for the `CPUCreditBalance` and `CPUSurplusCreditBalance` CloudWatch metrics.

Example

```
Adjusted balance = [prior CPUCreditBalance - prior CPUSurplusCreditBalance] + [Credits
 earned per hour * (5/60) - CPUCreditUsage]
```

A value of `0` for `Adjusted balance` indicates that the instance spent all its earned credits for bursting, and no surplus credits were spent. As a result, both `CPUCreditBalance` and `CPUSurplusCreditBalance` are set to `0`.

A positive `Adjusted balance` value indicates that the instance accrued earned credits, and previous surplus credits, if any, were paid down. As a result, the `Adjusted balance` value is assigned to `CPUCreditBalance`, and the `CPUSurplusCreditBalance` is set to `0`. The instance size determines the [maximum number of credits](#) that it can accrue.

Example

```
CPUCreditBalance = min [max earned credit balance, Adjusted balance]
CPUSurplusCreditBalance = 0
```

A negative `Adjusted balance` value indicates that the instance spent all its earned credits that it accrued and, in addition, also spent surplus credits for bursting. As a result, the `Adjusted balance` value is assigned to `CPUSurplusCreditBalance` and `CPUCreditBalance` is set to `0`. Again, the instance size determines the [maximum number of credits](#) that it can accrue.

Example

```
CPUSurplusCreditBalance = min [max earned credit balance, -Adjusted balance]
CPUCreditBalance = 0
```

If the surplus credits spent exceed the maximum credits that the instance can accrue, the surplus credit balance is set to the maximum, as shown in the preceding equation. The remaining surplus credits are charged as represented by the `CPUSurplusCreditsCharged` metric.

Example

```
CPUSurplusCreditsCharged = max [-Adjusted balance - max earned credit balance, 0]
```

Finally, when the instance terminates, any surplus credits tracked by the `CPUSurplusCreditBalance` are charged. If the instance is switched from `unlimited` to `standard`, any remaining `CPUSurplusCreditBalance` is also charged.

Performance acceleration with GPU instances

GPU-based instances provide access to NVIDIA GPUs with thousands of compute cores. You can use these instances to accelerate scientific, engineering, and rendering applications by leveraging the CUDA or Open Computing Language (OpenCL) parallel computing frameworks. You can also use them for graphics applications, including game streaming, 3-D application streaming, and other graphics workloads.

Before you can activate or optimize a GPU-based instance, you must install the appropriate drivers, as follows:

- To install NVIDIA drivers on an instance with an attached NVIDIA GPU, such as a P3 or G4dn instance, see NVIDIA drivers.
- To install AMD drivers on an instance with an attached AMD GPU, such as a G4ad instance, see AMD drivers.

Contents

Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances

To activate the GRID Virtual Applications on GPU-based instances that have NVIDIA GPUs (NVIDIA GRID Virtual Workstation is enabled by default), you must define the product type for the driver. The process that you use depends on the operating system of your instance.

Linux instances

To activate GRID Virtual Applications on your Linux instances

1. Create the `/etc/nvidia/gridd.conf` file from the provided template file.

```
[ec2-user ~]$ sudo cp /etc/nvidia/gridd.conf.template /etc/nvidia/gridd.conf
```

2. Open the `/etc/nvidia/gridd.conf` file in your favorite text editor.
3. Find the `FeatureType` line, and set it equal to `0`. Then add a line with `IgnoreSP=TRUE`.

```
FeatureType=0 IgnoreSP=TRUE
```

4. Save the file and exit.
5. Reboot the instance to pick up the new configuration.

```
[ec2-user ~]$ sudo reboot
```

Windows instances

To activate GRID Virtual Applications on your Windows instances

1. Run **regedit.exe** to open the registry editor.
2. Navigate to `HKEY_LOCAL_MACHINE\SOFTWARE\NVIDIA Corporation\Global\GridLicensing`.
3. Open the context (right-click) menu on the right pane and choose **New**, **DWORD**.
4. For **Name**, enter **FeatureType** and type `Enter`.
5. Open the context (right-click) menu on **FeatureType** and choose **Modify**.
6. For **Value data**, enter `0` for NVIDIA GRID Virtual Applications and choose **OK**.
7. Open the context (right-click) menu on the right pane and choose **New**, **DWORD**.

8. For **Name**, enter **IgnoreSP** and type `Enter`.
9. Open the context (right-click) menu on **IgnoreSP** and choose **Modify**.
10. For **Value data**, type 1 and choose **OK**.
11. Close the registry editor.

Optimize GPU settings on Amazon EC2 instances

There are several GPU setting optimizations that you can perform to achieve the best performance on NVIDIA GPU instances. With some of these instance types, the NVIDIA driver uses an autoboost feature, which varies the GPU clock speeds. By disabling autoboost and setting the GPU clock speeds to their maximum frequency, you can consistently achieve the maximum performance with your GPU instances.

Optimize GPU settings on Linux

1. Configure the GPU settings to be persistent. This command can take several minutes to run.

```
[ec2-user ~]$ sudo nvidia-persistenced
```

2. [G3, and P2 instances only] Disable the autoboost feature for all GPUs on the instance.

```
[ec2-user ~]$ sudo nvidia-smi --auto-boost-default=0
```

3. Set all GPU clock speeds to their maximum frequency. Use the memory and graphics clock speeds specified in the following commands.

   Some versions of the NVIDIA driver do not support setting the application clock speed, and display the error `"Setting applications clocks is not supported for GPU..."`, which you can ignore.

   - G3 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 2505,1177
```

   - G4dn instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 5001,1590
```

   - G5 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 6250,1710
```

- G6 and Gr6 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 6251,2040
```

- G6e instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 9001,2520
```

- P2 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 2505,875
```

- P3 and P3dn instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 877,1530
```

- P4d instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 1215,1410
```

- P4de instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 1593,1410
```

- P5 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 2619,1980
```

Optimize GPU settings on Windows

1. Open a PowerShell window and navigate to the NVIDIA installation folder.

```
PS C:\> cd "C:\Windows\System32\DriverStore\FileRepository\nvgridsw_aws.inf_*\"
```

2. [G3, and P2 instances only] Disable the autoboost feature for all GPUs on the instance.

```
PS C:\> .\nvidia-smi --auto-boost-default=0
```

3. Set all GPU clock speeds to their maximum frequency. Use the memory and graphics clock speeds specified in the following commands.

   Some versions of the NVIDIA driver do not support setting the application clock speed, and display the error `"Setting applications clocks is not supported for GPU..."`, which you can ignore.

   - G3 instances:

     ```
     PS C:\> .\nvidia-smi -ac "2505,1177"
     ```

   - G4dn instances:

     ```
     PS C:\> .\nvidia-smi -ac "5001,1590"
     ```

   - G5 instances:

     ```
     PS C:\> .\nvidia-smi -ac "6250,1710"
     ```

   - G6 and Gr6 instances:

     ```
     PS C:\> .\nvidia-smi -ac "6251,2040"
     ```

   - G6e instances:

     ```
     PS C:\> .\nvidia-smi -ac "9001,2520"
     ```

   - P2 instances:

     ```
     PS C:\> .\nvidia-smi -ac "2505,875"
     ```

   - P3 and P3dn instances:

     ```
     PS C:\> .\nvidia-smi -ac "877,1530"
     ```

Set up Dual 4K displays on G4ad Linux instances

After you launch a G4ad instance, you can set up dual 4K displays.

To install the AMD drivers and configure dual screens

1. Connect to your Linux instance to get the PCI Bus address of the GPU you want to target for dual 4K (2x4k):

```
lspci -vv | grep -i amd
```

   You will get output similar to the following:

```
00:1e.0 Display controller: Advanced Micro Devices, Inc. [*AMD*/ATI] Device 7362 (rev
 c3)
Subsystem: Advanced Micro Devices, Inc. [AMD/ATI] Device 0a34
```

2. Note the PCI bus address is 00:1e.0 in the above output. Create a file named `/etc/modprobe.d/amdgpu.conf` and add:

```
options amdgpu virtual_display=0000:00:1e.0,2
```

3. To install the AMD drivers on Linux, see AMD drivers for your EC2 instance. If you already have the AMD GPU driver installed, you will need to rebuild the amdgpu kernel modules through dkms.

4. Use the below xorg.conf file to define the dual (2x4K) screen topology and save the file in `/etc/X11/xorg.conf`:

```
~$ cat /etc/X11/xorg.conf
Section "ServerLayout"
    Identifier     "Layout0"
    Screen          0 "Screen0"
    Screen        1 "Screen1"
    InputDevice     "Keyboard0" "CoreKeyboard"
    InputDevice     "Mouse0" "CorePointer"
    Option          "Xinerama" "1"
EndSection
Section "Files"
    ModulePath "/opt/amdgpu/lib64/xorg/modules/drivers"
    ModulePath "/opt/amdgpu/lib/xorg/modules"
    ModulePath "/opt/amdgpu-pro/lib/xorg/modules/extensions"
    ModulePath "/opt/amdgpu-pro/lib64/xorg/modules/extensions"
    ModulePath "/usr/lib64/xorg/modules"
    ModulePath "/usr/lib/xorg/modules"
EndSection
```

```
Section "InputDevice"
    # generated from default
    Identifier     "Mouse0"

```

5. Set up DCV by following the instructions in setting up an interactive desktop.
6. After the DCV set up is complete, reboot.
7. Confirm that the driver is functional:

   ```
   dmesg | grep amdgpu
   ```

   The response should look like the following:

   ```
   Initialized amdgpu
   ```

8. You should see in the output for `DISPLAY=:0 xrandr -q` that you have 2 virtual displays connected:

```
~$ DISPLAY=:0 xrandr -q
Screen 0: minimum 320 x 200, current 3840 x 1080, maximum 16384 x 16384

 720x480  59.94
640x480  59.94 59.94
```

9. When you connect into DCV, change the resolution to 2x4K, confirming the dual monitor support is registered by DCV.

Set up an interactive desktop for Linux

After you confirm that your Linux instance has the AMD GPU driver installed and amdgpu is in use, you can install an interactive desktop manager. We recommend the MATE desktop environment for the best compatibility and performance.

Prerequisite

Open a text editor and save the following as a file named `xorg.conf`. You'll need this file on your instance.

```
Section "ServerLayout"
Identifier     "Layout0"
Screen          0 "Screen0"
InputDevice     "Keyboard0" "CoreKeyboard"
InputDevice     "Mouse0" "CorePointer"
EndSection
Section "Files"
ModulePath "/opt/amdgpu/lib64/xorg/modules/drivers"
ModulePath "/opt/amdgpu/lib/xorg/modules"
ModulePath "/opt/amdgpu-pro/lib/xorg/modules/extensions"
ModulePath "/opt/amdgpu-pro/lib64/xorg/modules/extensions"
ModulePath "/usr/lib64/xorg/modules"
ModulePath "/usr/lib/xorg/modules"
EndSection

```

To set up an interactive desktop on Amazon Linux 2

1. Install the EPEL repository.

   ```
   [ec2-user ~]$ sudo amazon-linux-extras install epel -y
   ```

2. Install the MATE desktop.

```
[ec2-user ~]$ sudo amazon-linux-extras install mate-desktop1.x -y
[ec2-user ~]$ sudo yum groupinstall "MATE Desktop" -y
[ec2-user ~]$ sudo systemctl disable firewalld
```

3. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.
4. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

5. (Optional) Install the Amazon DCV server to use Amazon DCV as a high-performance display protocol, and then connect to a Amazon DCV session using your preferred client.

To set up an interactive desktop on Ubuntu

1. Install the MATE desktop.

```
$ sudo apt install xorg-dev ubuntu-mate-desktop -y
$ sudo apt purge ifupdown -y
```

2. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.
3. Reboot the instance.

```
$ sudo reboot
```

4. Install the AMF encoder for the appropriate version of Ubuntu.

```
$ sudo apt install ./amdgpu-pro-20.20-*/amf-amdgpu-pro_20.20-*_amd64.deb
```

5. (Optional) Install the Amazon DCV server to use Amazon DCV as a high-performance display protocol, and then connect to a Amazon DCV session using your preferred client.
6. After the DCV installation give the DCV User video permissions:

```
$ sudo usermod -aG video dcv
```

To set up an interactive desktop on CentOS

1. Install the EPEL repository.

```
$ sudo yum update -y
$ sudo yum install epel-release -y
```

2. Install the MATE desktop.

```
$ sudo yum groupinstall "MATE Desktop" -y
$ sudo systemctl disable firewalld
```

3. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.
4. Reboot the instance.

```
$ sudo reboot
```

5. (Optional) Install the Amazon DCV server to use Amazon DCV as a high-performance display protocol, and then connect to a Amazon DCV session using your preferred client.

Get started with GPU accelerated instances

The latest generation of GPU accelerated instance types, such as those shown in the following list deliver the highest performance capabilities for deep learning and high performance computing (HPC) applications. Select the instance type link to learn more about its capabilities.

- P6 family
- P5 family

For a complete list of instance type specifications for accelerated instance types, see Accelerated computing in the *Amazon EC2 Instance Types* reference.

Software configuration

The easiest way to get started with the latest generation GPU accelerated instance types is to launch an instance from an AWS Deep Learning AMI that's preconfigured with all of the required software. For the latest AWS Deep Learning AMIs for use with GPU accelerated instance types, see P6 Supported DLAMI in the *AWS Deep Learning AMIs Developer Guide*.

If you need to build a custom AMI to launch instances that host deep learning or HPC applications, we recommend that you install the following minimum software versions on top of your base image.

Instance type	NVIDIA driver	CUDA	NVIDIA GDRCopy	EFA installer	NCCL	EFA K8s [1]
P5	530	12.1	2.3	1.24.1	2.18.3	0.4.4
P5.4xlarge	530	12.1	2.3	1.43.1 [2]	2.18.3	0.4.4
P5e	550	12.1	2.3	1.24.1	2.18.3	0.5.5
P5en	550	12.1	2.3	1.24.1	2.18.3	0.5.6
P6-B200	570	12.8	2.5	1.4.1	2.26.2-1	0.5.10

[1] The **EFA K8s** column contains the minimum recommended version for `aws-efa-k8s-device-plugin`.

[2] There is compatibility issue that affects `P5.4xlarge` instances when GPU-to-GPU communication uses Elastic Fabric Adapter (EFA) and the NVIDIA Collective Communications Library (NCCL). To mitigate the issue, set the environment variable `FI_HMEM_DISABLE_P2P` to `1`, and ensure that you install EFA version 1.43.1 or newer.

> **Note**
>
> If you use version 1.4.1 of the EFA installer, the `aws-ofi-nccl plugin` comes with it. For earlier versions of the EFA installer, use `aws-ofi-nccl plugin` version `1.7.2-aws` or later.

We also recommend that you configure the instance to not use deeper C-states. For more information, see High performance and low latency by limiting deeper C-states in the *Amazon Linux 2 User Guide*. The latest AWS Deep Learning Base GPU AMIs are preconfigured to not use deeper C-states.

For networking and Elastic Fabric Adapter (EFA) configuration see Maximize network bandwidth on Amazon EC2 instances with multiple network cards.

Amazon EC2 Mac instances

EC2 Mac instances are ideal for developing, building, testing, and signing applications for Apple platforms, such as iPhone, iPad, Mac, Vision Pro, Apple Watch, Apple TV, and Safari. You can connect to your Mac instance using SSH or Apple Remote Desktop (ARD).

> **Note**
>
> The **unit of billing** is the **dedicated host**. The instances running on that host have no additional charge.

Amazon EC2 Mac instances natively support the macOS operating system.

- EC2 x86 Mac instances (`mac1.metal`) are built on 2018 Mac mini hardware powered by 3.2 GHz Intel eighth-generation (Coffee Lake) Core i7 processors.
- EC2 M1 Mac instances (`mac2.metal`) are built on 2020 Mac mini hardware powered by Apple silicon M1 processors.
- EC2 M1 Ultra Mac instances (`mac2-m1ultra.metal`) are built on 2022 Mac Studio hardware powered by Apple silicon M1 Ultra processors.
- EC2 M2 Mac instances (`mac2-m2.metal`) are built on 2023 Mac mini hardware powered by Apple silicon M2 processors.
- EC2 M2 Pro Mac instances (`mac2-m2pro.metal`) are built on 2023 Mac mini hardware powered by Apple silicon M2 Pro processors.

Amazon EC2 Mac Dedicated Hosts support Dedicated Host auto recovery and reboot-based host maintenance.

Contents

- Launch a Mac instance using the AWS Management Console or the AWS CLI
- Connect to your Mac instance using SSH or a GUI
- Update the operating system and software on Amazon EC2 Mac instances
- Increase the size of an EBS volume on your Mac instance
- Stop or terminate your Amazon EC2 Mac instance
- Configure System Integrity Protection for Amazon EC2 Mac instances
- Find supported macOS versions for your Amazon EC2 Mac Dedicated Host
- Subscribe to macOS AMI notifications
- Retrieve macOS AMI IDs using AWS Systems Manager Parameter Store API
- Amazon EC2 macOS AMIs release notes

Considerations

The following considerations apply to Mac instances:

- Mac instances are available only as bare metal instances on Dedicated Hosts, with a minimum allocation period of 24 hours before you can release the Dedicated Host. You can launch one Mac instance per Dedicated Host. You can share the Dedicated Host with the AWS accounts or organizational units within your AWS organization, or the entire AWS organization.
- Mac instances are available in different AWS Regions. For a list of Mac instance availability in each of the AWS Regions, see Amazon EC2 instance types by Region.
- Mac instances are available only as On-Demand Instances. They are not available as Spot Instances or Reserved Instances. You can save money on Mac instances by purchasing a Savings Plan.
- The compatibility of different Mac instance types with specific macOS Amazon Machine Images (AMIs) varies. For more information, see Amazon EC2 macOS AMIs release notes.
- EBS hotplug is supported.
- AWS does not manage or support the internal SSD on the Apple hardware. We strongly recommend that you use Amazon EBS volumes instead. EBS volumes provide the same elasticity, availability, and durability benefits on Mac instances as they do on any other EC2 instance.
- We recommend using an Amazon EBS volume with 10,000 IOPS and 400 MiB/s throughput with Mac instances for optimal performance. For more information, see Amazon EBS volume types in the *Amazon EBS User Guide*.

- Mac instances support Amazon EC2 Auto Scaling.
- On x86 Mac instances, automatic software updates are disabled. We recommend that you apply updates and test them on your instance before you put the instance into production. For more information, see Update the operating system and software on Amazon EC2 Mac instances.
- When you stop or terminate a Mac instance, a scrubbing workflow is performed on the Dedicated Host. For more information, see Stop or terminate your Amazon EC2 Mac instance.
- **Important**

  Apple Intelligence features are not available when booting Mac hardware from an external volume. As EC2 Mac instances boot from external EBS volumes by default, they do not support Apple Intelligence features.
- **Warning**

  Do not use FileVault. If you enable FileVault, the host fails to boot because the partitions are locked. If data encryption is required, use Amazon EBS encryption to avoid boot issues and performance impact. With Amazon EBS encryption, encryption operations occur on the host servers, ensuring the security of both data-at-rest and data-in-transit between the instances and their attached EBS storage. For more information, see Amazon EBS encryption in the *Amazon EBS User Guide*.

Instance readiness

After you launch a Mac instance, you'll need to wait until the instance is ready before you can connect to it. For an AWS vended AMI with a x86 Mac instance or a Apple silicon Mac instance, the launch time can range from approximately 6 minutes to 20 minutes. Depending on the chosen Amazon EBS volume sizes, the inclusion of additional scripts to *user data*, or additional loaded software on a custom macOS AMI, the launch time might increase.

You can use a small shell script, like the one below, to poll the describe-instance-status API to know when the instance is ready to be connected to. In the following command, replace the example instance ID with your own.

```
for i in $(seq 1 200); do aws ec2 describe-instance-status --instance-ids=i-1234567890abcdef0 \
    --query='InstanceStatuses[0].InstanceStatus.Status'; sleep 5; done;
```

EC2 macOS AMIs

Amazon EC2 macOS is designed to provide a stable, secure, and high-performance environment for developer workloads running on Amazon EC2 Mac instances. EC2 macOS AMIs includes packages that enable easy integration with AWS, such as launch configuration tools and popular AWS libraries and tools.

For more information about EC2 macOS AMIs, see Amazon EC2 macOS AMIs release notes.

AWS provides updated EC2 macOS AMIs on a regular basis that include updates to packages owned by AWS and the latest fully-tested macOS version. Additionally, AWS provides updated AMIs with the latest minor version updates or major version updates as soon as they can be fully tested and vetted. If you do not need to preserve data or customizations to your Mac instances, you can get the latest updates by launching a new instance using the current AMI and then terminating the previous instance. Otherwise, you can choose which updates to apply to your Mac instances.

For information about how to subscribe to macOS AMI notifications, see Subscribe to macOS AMI notifications.

EC2 macOS Init

EC2 macOS Init is used to initialize EC2 Mac instances at launch. It uses priority groups to run logical groups of tasks at the same time.

The launchd plist file is `/Library/LaunchDaemons/com.amazon.ec2.macos-init.plist`. The files for EC2 macOS Init are located in `/usr/local/aws/ec2-macos-init`.

For more information, see https://github.com/aws/ec2-macos-init.

Amazon EC2 System Monitor for macOS

Amazon EC2 System Monitor for macOS provides CPU utilization metrics to Amazon CloudWatch. It sends these metrics to CloudWatch over a custom serial device in 1-minute periods. You can enable or disable this agent as follows. It is enabled by default.

```
sudo setup-ec2monitoring [enable | disable]
```

> **Note**
>
> Amazon EC2 System Monitor for macOS is not currently supported on Apple silicon Mac instances.

For more information about hardware specifications and network performance of Mac instances, see General purpose instances.

Launch a Mac instance using the AWS Management Console or the AWS CLI

EC2 Mac instances require a Dedicated Host. You first need to allocate a host to your account, and then launch the instance onto the host.

You can launch a Mac instance using the AWS Management Console or the AWS CLI.

Launch a Mac instance using the console

To launch a Mac instance onto a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Allocate the Dedicated Host, as follows:
   a. In the navigation pane, choose **Dedicated Hosts**.
   b. Choose **Allocate Dedicated Host** and then do the following:
      i. For **Instance family**, choose **mac1**, **mac2**, **mac2-m2**, **mac2-m2pro**, or **mac2-m1ultra**. If the instance family doesn't appear in the list, it's not supported in the currently selected Region.
      ii. For **Instance type**, choose **mac1.metal**, **mac2.metal**, **mac2-m2.metal**, **mac2-m2pro.metal**, or **mac2-m1ultra.metal** based on the instance family chosen.
      iii. For **Availability Zone**, choose the Availability Zone for the Dedicated Host.
      iv. For **Quantity**, keep **1**.
      v. Choose **Allocate**.

3. Launch the instance on the host, as follows:

   a. Select the Dedicated Host that you created and then do the following:

      i. Choose **Actions**, **Launch instance(s) onto host**.
      ii. Under **Application and OS Images (Amazon Machine Image)**, select a macOS AMI.
      iii. Under **Instance type**, select the appropriate instance type (**mac1.metal**, **mac2.metal**, **mac2-m2.metal**, **mac2-m2pro.metal**, or **mac2-m1ultra.metal**).
      iv. Under **Advanced details**, verify that **Tenancy**, **Tenancy host by**, and **Tenancy host ID** are preconfigured based on the Dedicated Host you created. Update **Tenancy affinity** as needed.
      v. Complete the wizard, specifying EBS volumes, security groups, and key pairs as needed.
      vi. In the **Summary** panel, choose **Launch instance**.

   b. A confirmation page lets you know that your instance is launching. Choose **View all instances** to close the confirmation page and return to the console. The initial state of an instance is `pending`. The instance is ready when its state changes to `running` and it passes status checks.

Launch a Mac instance using the AWS CLI

Allocate the Dedicated Host

Use the following [allocate-hosts](#) command to allocate a Dedicated Host for your Mac instance, replacing the `instance-type` with either `mac1.metal`, `mac2.metal`, `mac2-m2.metal`, `mac2-m2pro.metal`, or `mac2-m1ultra.metal`, and the `region` and `availability-zone` with the appropriate ones for your environment.

```
aws ec2 allocate-hosts --region us-east-1 --instance-type mac1.metal --availability-zone us-east-1b --auto-placement "on" --quantity 1
```

Launch the instance on the host

Use the following [run-instances](#) command to launch a Mac instance, again replacing the `instance-type` with either `mac1.metal`, `mac2.metal`, `mac2-m2.metal`, `mac2-m2pro.metal`, or `mac2-m1ultra.metal`, and the `region` and `availability-zone` with the ones used previously.

```
aws ec2 run-instances --region us-east-1 --instance-type mac1.metal --placement
 Tenancy=host --image-id ami_id --key-name my-key-pair
```

The initial state of an instance is `pending`. The instance is ready when its state changes to `running` and it passes status checks. Use the following [describe-instance-status](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-instance-status.html) command to display status information for your instance.

```
aws ec2 describe-instance-status --instance-ids i-017f8354e2dc69c4f
```

The following is example output for an instance that is running and has passed status checks.

```
{
    "InstanceStatuses": [
        {
            "AvailabilityZone": "us-east-1b",
            "InstanceId": "i-017f8354e2dc69c4f",
            "InstanceState": {
                "Code": 16,
                "Name": "running"
            },
            "InstanceStatus": {
                "Details": [
                    {
                        "Name": "reachability",
                        "Status": "passed"
                    }
                ],
                "Status": "ok"
            },
            "SystemStatus": {
                "Details": [
                    {
                        "Name": "reachability",
                        "Status": "passed"
                    }
                ],
                "Status": "ok"
            }
        }
    ]
}
```

Connect to your Mac instance using SSH or a GUI

You can connect to your Mac instance using SSH or a graphical user interface (GUI).

Multiple users can access the OS simultaneously. Typically there is a 1:1 user:GUI session, due to the built-in Screen Sharing service on port 5900. Using SSH within macOS supports multiple sessions up until the "Max Sessions" limit in the `sshd_config` file.

Connect to your instance using SSH

Amazon EC2 Mac instances do not allow remote root SSH by default. The ec2-user account is configured to log in remotely using SSH. The ec2-user account also has **sudo** privileges. After you connect to your instance, you can add other users.

To support connecting to your instance using SSH, launch the instance using a key pair and a security group that allows SSH access, and ensure that the instance has internet connectivity. You provide the `.pem` file for the key pair when you connect to the instance.

Use the following procedure to connect to your Mac instance using an SSH client. If you receive an error while attempting to connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

To connect to your instance using SSH

1. Verify that your local computer has an SSH client installed by entering **ssh** at the command line. If your computer doesn't recognize the command, search for an SSH client for your operating system and install it.
2. Get the public DNS name of your instance. Using the Amazon EC2 console, you can find the public DNS name on both the **Details** and the **Networking** tabs. Using the AWS CLI, you can find the public DNS name using the describe-instances command.
3. Locate the `.pem` file for the key pair that you specified when you launched the instance.
4. Connect to your instance using the following **ssh** command, specifying the public DNS name of the instance and the `.pem` file.

```
ssh -i /path/key-pair-name.pem ec2-user@instance-public-dns-name
```

Password authentication is disabled to prevent brute-force password attacks. Before you make changes to the SSH configuration, open `/usr/local/aws/ec2-macos-init/init.toml` and set `secureSSHDConfig` to `false`.

Connect to your instance's graphical user interface (GUI)

Use the following procedure to connect to your instance's GUI using VNC, Apple Remote Desktop (ARD), or the Apple Screen Sharing application (included with macOS).

> **Note**
>
> macOS 10.14 and later only allows control if Screen Sharing is enabled through System Preferences.

To connect to your instance using ARD client or VNC client

1. Verify that your local computer has an ARD client or a VNC client that supports ARD installed. On macOS, you can leverage the built-in Screen Sharing application. Otherwise, search for ARD for your operating system and install it.
2. From your local computer, connect to your instance using SSH.
3. Set up a password for the ec2-user account using the **passwd** command as follows.

```
[ec2-user ~]$ sudo passwd ec2-user
```

4. Install and start macOS Screen Sharing using the following command.

```
[ec2-user ~]$ sudo launchctl enable system/com.apple.screensharing
sudo launchctl load -w /System/Library/LaunchDaemons/com.apple.screensharing.plist
```

5. Disconnect from your instance by typing **exit** and pressing Enter.
6. From your computer, connect to your instance using the following **ssh** command. In addition to the options shown in the previous section, use the **-L** option to enable port forwarding and forward all traffic on local port 5900 to the ARD server on the instance.

```
ssh -L 5900:localhost:5900 -i /path/key-pair-name.pem ec2-user@instance-public-dns-name
```

7. From your local computer, use the ARD client or VNC client that supports ARD to connect to `localhost:5900`. For example, use the Screen Sharing application on macOS as follows:

a. Open **Finder** and select **Go**.

b. Select **Connect to Server**.

c. In the **Server Address** field, enter `vnc://localhost:5900`.

d. Log in as prompted, using **`ec2-user`** as the username and the password that you created for the ec2-user account.

Modify macOS screen resolution on Mac instances

After you connect to your EC2 Mac instance using ARD or a VNC client that supports ARD, you can modify the screen resolution of your macOS environment using any of the publicly available macOS tools or utilities, such as displayplacer.

To modify the screen resolution using displayplacer

1. Install displayplacer.

```
[ec2-user ~]$ brew tap jakehilborn/jakehilborn && brew install displayplacer
```

2. Show the current screen information and possible screen resolutions.

```
[ec2-user ~]$ displayplacer list
```

3. Apply the desired screen resolution.

```
[ec2-user ~]$ displayplacer "id:<screenID> res:<width>x<height> origin:(0,0)
 degree:0"
```

For example:

```
RES="2560x1600"
displayplacer "id:69784AF1-CD7D-B79B-E5D4-60D937407F68 res:${RES} scaling:off
 origin:(0,0) degree:0"
```

Update the operating system and software on Amazon EC2 Mac instances

The following topic explains how to update the operating system and software on Apple silicon Mac instances (Mac2, Mac2-m1ultra, Mac2-m2, Mac2-m2pro) and x86 Mac instances (Mac1).

> **Warning**
>
> Installation of beta or preview macOS versions is only available on Apple silicon Mac instances. Amazon EC2 doesn't qualify beta or preview macOS versions and doesn't ensure instances will remain functional after an update to a pre-production macOS version. Attempting to install beta or preview macOS versions on Amazon EC2 x86 Mac instances will lead to degradation of your Amazon EC2 Mac Dedicated Host when you stop or terminate your instances, and will prevent you from starting or launching a new instance on that host.

> **Note**
>
> If you perform an in-place macOS update before AWS releases an official AMI, the update applies to the selected host only. If you have other hosts, or if you launch new hosts, you must perform the same update process on those hosts as well. Each macOS version requires a minimum firmware version on the underlying Apple Mac hardware. The in-place update only updates the firmware on the selected host and doesn't transfer to other existing or new hosts. To check which macOS versions are compatible with your Amazon EC2 Mac Dedicated Host, see Find supported macOS versions for your Amazon EC2 Mac Dedicated Host.

Update software on Apple silicon Mac instances

Prerequisites

Due to an update in the network driver configuration, ENA driver version 1.0.2 isn't compatible with macOS 13.3 and later. If you want to install any beta, preview, or production macOS version 13.3 or later and have not installed the latest ENA driver, use the following procedure to install a new version of the driver.

To install a new version of the ENA driver

1. In a Terminal window, connect to your Apple silicon Mac instance using SSH.
2. Update Homebrew and download the ENA application into the `Applications` file using the following command.

   ```
   [ec2-user ~]$ brew update
   ```

   ```
   [ec2-user ~]$ brew install amazon-ena-ethernet-dext
   ```

3. Disconnect from your instance by typing **exit** and pressing return.
4. Use the VNC client to activate the ENA application.

   a. Setup the VNC client using Connect to your instance's graphical user interface (GUI).

   b. Once you have connected to your instance using the Screen Sharing application, go to the **Applications** folder and open the ENA application.

   c. Choose **Activate**

   d. To confirm the driver was activated correctly, run the following command in the Terminal window. The output of the command shows that the old driver is in the terminating state and the new driver is in the activated state.

   ```
   systemextensionsctl list;
   ```

   e. After you restart the instance, only the new driver will be present.

Perform the software update

On Apple silicon Mac instances, you must complete several steps to perform an in-place operating system update. This includes delegating ownership of the Amazon EBS root volume to the EBS root volume administrative user. You can choose to do this either automatically using an Amazon EC2 API, or you can do it manually by running the commands on your instance.

Automated volume ownership delegation (Recommended)

Considerations

- It can take between 30 and 90 minutes for the volume ownership delegation task to complete. During this time, the instance is unreachable.

- The following macOS versions are supported:
  - **Mac2 | Mac2-m1ultra** — macOS Ventura (version 13.0 or later)
  - **Mac2-m2 | Mac2-m2pro** — macOS Ventura (version 13.2 or later)
- Instances must have only one bootable volume, and each attached volume can have only one additional admin user.

Step 1: Set a password and enable the secure token for the EBS root volume administrative user

You must set a password and enable the secure token for the Amazon EBS root volume administrative user (`ec2-user`).

> **Note**
>
> The password and secure token are set the first time you connect to an Apple silicon Mac instance using the GUI. If you previously connected to the instance using the GUI, you **do not** need to perform these steps.

1. Connect to the instance using SSH.
2. Set the password for the `ec2-user` user.

   ```
   $ sudo /usr/bin/dscl . -passwd /Users/ec2-user
   ```

3. Enable the secure token for the `ec2-user` user. For `-oldPassword`, specify the same password from the previous step. For `-newPassword`, specify a different password. The following command assumes that you have your old and new passowords saved in `.txt` files.

   ```
   $ sysadminctl -oldPassword `cat old_password.txt` -newPassword `cat
    new_password.txt`
   ```

4. Verify that the secure token is enabled.

   ```
   $ sysadminctl -secureTokenStatus ec2-user
   ```

Step 2: Delegate ownership of the Amazon EBS root volume to the EBS root volume administrative user

To delegate ownership, you must create a volume ownership delegation task.

1. Use the create-delegate-mac-volume-ownership-task command to create the task. For `--instance-id`, specify the ID of the instance. For `--mac-credentials`, specify the following credentials:

   - **Internal disk administrative user**
     - **Username** — Only the default administrative user (`aws-managed-user`) is supported and it is used by default. You can't specify a different administrative user.
     - **Password** — If you did not change the default password for `aws-managed-user`, specify the default password, which is *blank*. Otherwise, specify your password.
   - **Amazon EBS root volume administrative user**
     - **Username** — If you did not change the default administrative user, specify `ec2-user`. Otherwise, specify the username for your administrative user.
     - **Password** — Specify the password that you set for root volume admin user in Step 1 above.

   ```
   aws ec2 create-delegate-mac-volume-ownership-task \
   --instance-id i-1234567890abcdef0 \
   --mac-credentials file://mac-credentials.json
   ```

   The following is the contents of the `mac-credentials.json` file referenced in the preceding examples.

   ```
   {
     "internalDiskPassword":"internal-disk-admin_password",
     "rootVolumeUsername":"root-volume-admin_username",
     "rootVolumepassword":"root-volume-admin_password"
   }
   ```

2. Wait for the volume ownership delegation task to complete and for the instance to return to a healthy state. Use the describe-mac-modification-tasks command. For `--mac-modification-task-id`, specify the ID of the volume ownership delegation task from the previous step.

```
aws ec2 describe-mac-modification-tasks \
--mac-modification-task-id task-id
```

3. After the volume ownership delegation task completes, continue to Step 3.

Step 3: Update the software

After you have delegated ownership of the Amazon EBS root volume, follow the steps described in Update software on x86 Mac instances (below) to update the software.

Manual volume ownership delegation

As you work through this procedure, you create two passwords. One password is for the Amazon EBS root volume administrative user (`ec2-user`), and the other password is for the internal disk administrative user (`aws-managed-user`). Remember these passwords since you will use them as you work through the procedure.

> **Note**
>
> With this procedure on macOS Big Sur, you can only perform minor updates such as updating from macOS Big Sur 11.7.3 to macOS Big Sur 11.7.4. For macOS Monterey or above, you can perform major software updates.

To access the internal disk

1. From your local computer, in the Terminal, connect to your Apple silicon Mac instance using SSH with the following command. For more information, see Connect to your instance using SSH.

```
ssh -i /path/key-pair-name.pem ec2-user@instance-public-dns-name
```

2. Install and start macOS Screen Sharing using the following command.

```
[ec2-user ~]$ sudo launchctl enable system/com.apple.screensharing
sudo launchctl load -w /System/Library/LaunchDaemons/
com.apple.screensharing.plist
```

3. Set a password for `ec2-user` with the following command. Remember the password as you will use it later.

```
[ec2-user ~]$ sudo /usr/bin/dscl . -passwd /Users/ec2-user
```

4. Disconnect from the instance by typing **exit** and pressing return.
5. From your local computer, in the Terminal, reconnect to your instance with an SSH tunnel to the VNC port using the following command.

```
ssh -i /path/key-pair-name.pem -L 5900:localhost:5900 ec2-user@instance-public-dns-name
```

> **Note**
>
> Do not exit this SSH session until the following VNC connection and GUI steps are completed. When the instance is restarted, the connection will close automatically.

6. From your local computer, connect to `localhost:5900` using the following steps:
   a. Open **Finder** and select **Go**.
   b. Select **Connect to Server**.
   c. In the **Server Address** field, enter `vnc://localhost:5900`.
7. In the macOS window, connect to the remote session of the Apple silicon Mac instance as `ec2-user` with the password you created in Step 3.
8. Access the internal disk, named **InternalDisk**, using one of the following options.
   a. For macOS Ventura or above: Open **System Settings**, select **General** in the left pane, then **Startup Disk** at the lower right of the pane.
   b. For macOS Monterey or below: Open **System Preferences**, select **Startup Disk**, then unlock the pane by choosing the lock icon in the lower left of the window.

> **Troubleshooting tip**
>
> If you need to mount the internal disk, run the following command in the Terminal.
>
> ```
> APFSVolumeName="InternalDisk" ; SSDContainer=$(diskutil list | grep
>  "Physical Store disk0" -B 3 | grep "/dev/disk" | awk {'print $1'} ) ;
>  diskutil apfs addVolume $SSDContainer APFS $APFSVolumeName
> ```

9. Choose the internal disk, named **InternalDisk**, and select **Restart**. Select **Restart** again when prompted.

> **Important**
>
> If the internal disk is named **Macintosh HD** instead of **InternalDisk**, your instance needs to be stopped and restarted so the dedicated host can be updated. For more information, see [Stop or terminate your Amazon EC2 Mac instance](#).

Use the following procedure to delegate ownership to the administrative user. When you reconnect to your instance with SSH, you boot from the internal disk using the special administrative user (`aws-managed-user`). The initial password for `aws-managed-user` is blank, so you need to overwrite it on your first connection. Then, you need to repeat the steps to install and start macOS Screen Sharing since the boot volume has changed.

To delegate ownership to the administrator on an Amazon EBS volume

1. From your local computer, in the Terminal, connect to your Apple silicon Mac instance using the following command.

```
ssh -i /path/key-pair-name.pem aws-managed-user@instance-public-dns-name
```

2. When you receive the warning `WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED!`, use one of the following commands to resolve this issue.

   a. Clear out the known hosts using the following command. Then, repeat the previous step.

   ```
   rm ~/.ssh/known_hosts
   ```

   b. Add the following to the SSH command in the previous step.

   ```
   -o UserKnownHostsFile=/dev/null -o StrictHostKeyChecking=no
   ```

3. Set the password for `aws-managed-user` with the following command. The `aws-managed-user` initial password is blank, so you need to overwrite it on your first connection.

a.
```
[aws-managed-user ~]$ sudo /usr/bin/dscl . -passwd /Users/aws-managed-
user password
```

b. When you receive the prompt, `Permission denied. Please enter user's old password:`, press enter.

> **Troubleshooting tip**
>
> If you get the error `passwd: DS error: eDSAuthFailed`, use the following command.
>
> ```
> [aws-managed-user ~]$ sudo passwd aws-managed-user
> ```

4. Install and start macOS Screen Sharing using the following command.

```
[aws-managed-user ~]$ sudo launchctl enable system/com.apple.screensharing
sudo launchctl load -w /System/Library/LaunchDaemons/
com.apple.screensharing.plist
```

5. Disconnect from the instance by typing **exit** and pressing return.
6. From your local computer, in the Terminal, reconnect to your instance with an SSH tunnel to the VNC port using the following command.

```
ssh -i /path/key-pair-name.pem -L 5900:localhost:5900 aws-managed-user@instance-
public-dns-name
```

7. From your local computer, connect to `localhost:5900` using the following steps:

   a. Open **Finder** and select **Go**.

   b. Select **Connect to Server**.

   c. In the **Server Address** field, enter `vnc://localhost:5900`.

8. In the macOS window, connect to the remote session of the Apple silicon Mac instance as `aws-managed-user` with the password you created in Step 3.

> **Note**
>
> When prompted to sign in with your Apple ID, select **Set Up Later**.

9. Access the Amazon EBS volume using one of the following options.

   a. For macOS Ventura or later: Open **System Settings**, select **General** in the left pane, then **Startup Disk** at the lower right of the pane.

   b. For macOS Monterey or earlier: Open **System Preferences**, select **Startup Disk**, then unlock the pane using the lock icon in the lower left of the window.

   > **Note**
   >
   > Until the reboot takes place, when prompted for an administrator password, use the password you set above for `aws-managed-user`. This password might be different from the one you set for `ec2-user` or the default administrator account on your instance. The following instructions specify when to use your instance's administrator password.

10. Select the Amazon EBS volume (the volume not named **InternalDisk** in the **Startup Disk** window) and choose **Restart**.

    > **Note**
    >
    > If you have multiple bootable Amazon EBS volumes attached to your Apple silicon Mac instance, be sure to use a unique name for each volume.

11. Confirm the restart, then choose **Authorize Users** when prompted.

12. On the **Authorize user on this volume** pane, verify that the administrative user (`ec2-user` by default) is selected, then select **Authorize**.

13. Enter the `ec2-user` password you created in Step 3 of the previous procedure, then select **Continue**.

14. Enter the password for the special administrative user (`aws-managed-user`) when prompted.

15. From your local computer, in the Terminal, reconnect to your instance using SSH with username `ec2-user`.

> **Troubleshooting tip**
>
> If you get the warning `WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED!`, run the following command and reconnect to your instance using SSH.
>
> ```
> rm ~/.ssh/known_hosts
> ```

16. To perform the software update, use the commands under Update software on x86 Mac instances.

Update software on x86 Mac instances

On x86 Mac instances, you can install operating system updates from Apple using the `softwareupdate` command.

To install operating system updates from Apple on x86 Mac instances

1. List the packages with available updates using the following command.

   ```
   [ec2-user ~]$ softwareupdate --list
   ```

2. Install all updates or only specific updates. To install specific updates, use the following command.

   ```
   [ec2-user ~]$ sudo softwareupdate --install label
   ```

   To install all updates instead, use the following command.

   ```
   [ec2-user ~]$ sudo softwareupdate --install --all --restart
   ```

System administrators can use AWS Systems Manager to roll out pre-approved operating system updates on x86 Mac instances. For more information, see the AWS Systems Manager User Guide.

You can use Homebrew to install updates to packages in the EC2 macOS AMIs, so that you have the latest version of these packages on your instances. You can also use Homebrew to install and run common macOS applications on Amazon EC2 macOS. For more information, see the Homebrew Documentation.

To install updates using Homebrew

1. Update Homebrew using the following command.

```
[ec2-user ~]$ brew update
```

2. List the packages with available updates using the following command.

```
[ec2-user ~]$ brew outdated
```

3. Install all updates or only specific updates. To install specific updates, use the following command.

```
[ec2-user ~]$ brew upgrade package name
```

To install all updates instead, use the following command.

```
[ec2-user ~]$ brew upgrade
```

Increase the size of an EBS volume on your Mac instance

You can increase the size of your Amazon EBS volumes on your Mac instance. For more information, see Amazon EBS Elastic Volumes in the *Amazon EBS User Guide*.

After you increase the size of the volume, you must increase the size of your APFS container as follows.

Make increased disk space available for use

1. Determine if a restart is required. If you resized an existing EBS volume on a running Mac instance, you must reboot the instance to make the new size available. If disk space modification was done during launch time, a reboot will not be required.

View current status of disk sizes:

```
[ec2-user ~]$  diskutil list external physical
/dev/disk0 (external, physical):
   #:                       TYPE NAME                    SIZE       IDENTIFIER
   0:                  GUID_partition_scheme            *322.1 GB    disk0
   1:                  EFI EFI                           209.7 MB    disk0s1
```

```
   2:                  Apple_APFS Container disk2        321.9 GB     disk0s2
```

2. Copy and paste the following command.

```
[ec2-user ~]$ PDISK=$(diskutil list physical external | head -n1 | cut -d" " -f1)
APFSCONT=$(diskutil list physical external | grep "Apple_APFS" | tr -s " " | cut -
d" " -f8)
yes | sudo diskutil repairDisk $PDISK
```

3. Copy and paste the following command.

```
[ec2-user ~]$ sudo diskutil apfs resizeContainer $APFSCONT 0
```

Stop or terminate your Amazon EC2 Mac instance

When you stop a Mac instance, the instance remains in the `stopping` state for about 15 minutes before it enters the `stopped` state.

When you stop or terminate a Mac instance, Amazon EC2 performs a scrubbing workflow on the underlying Dedicated Host to erase the internal SSD, to clear the persistent NVRAM variables, and to update to the latest device firmware. This ensures that Mac instances provide the same security and data privacy as other EC2 Nitro instances. It also allows you to run the latest macOS AMIs. During the scrubbing workflow, the Dedicated Host temporarily enters the pending state. On x86 Mac instances, the scrubbing workflow might take up to 50 minutes to complete. On Apple silicon Mac instances, the scrubbing workflow might take up to 110 minutes to complete. Additionally, on x86 Mac instances, if the device firmware needs to be updated, the scrubbing workflow might take up to 3 hours to complete.

You can't start the stopped Mac instance or launch a new Mac instance until after the scrubbing workflow completes, at which point the Dedicated Host enters the `available` state.

Metering and billing is paused when the Dedicated Host enters the `pending` state. You are not charged for the duration of the scrubbing workflow.

Release the Dedicated Host for your Mac instance

When you are finished with your Mac instance, you can release the Dedicated Host. Before you can release the Dedicated Host, you must stop or terminate the Mac instance. You cannot release the host until the allocation period exceeds the 24-hour minimum.

To release the Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state**, then choose either **Stop instance** or **Terminate instance**.
4. In the navigation pane, choose **Dedicated Hosts**.
5. Select the Dedicated Host and choose **Actions**, **Release host**.
6. When prompted for confirmation, choose **Release**.

Configure System Integrity Protection for Amazon EC2 Mac instances

You can configure System Integrity Protection (SIP) settings for x86 Mac instances and Apple silicon Mac instances. SIP is a critical macOS security feature that helps to prevent unauthorized code execution and system-level modifications. For more information, see About System Integrity Protection.

You can either enable or disable SIP completely, or you can selectively enable or disable specific SIP settings. It is recommended that you disable SIP only temporarily to perform necessary tasks, and then reenable it as soon as possible. Leaving SIP disabled could leave your instance vulnerable to malicious code.

SIP configuration is supported in all AWS Regions where Amazon EC2 Mac instances are supported.

Topics

Considerations

- The following Amazon EC2 Mac instance types and macOS versions are supported:
  - **Mac1 | Mac2 | Mac2-m1ultra** — macOS Ventura (version 13.0 or later)

- **Mac2-m2 | Mac2-m2pro** — macOS Ventura (version 13.2 or later)

> **Note**
>
> Beta and preview versions of macOS are not supported.

- You can specify a custom SIP configuration to selectively enable or disable individual SIP settings. If you implement a custom configuration, connect to the instance and verify the settings to ensure that your requirements are properly implemented and functioning as intended.

  SIP configurations might change with macOS updates. We recommend that you review custom SIP settings after any macOS version upgrade to ensure continued compatibility and proper functionality of your security configurations.
- For x86 Mac instances, SIP settings are applied at the instance level. Any root volume attached to the instance will automatically inherit the configured SIP settings.

  For Apple silicon Mac instances, SIP settings are applied at the volume level. Root volumes attached to the instance do not inherit the SIP settings. If you attach another root volume, you must reconfigure the SIP settings to the required state.
- It can take up to 90 mins for SIP configuration tasks to complete. The instance remains unreachable while the SIP configuration task in progress.
- SIP configurations do not transfer to snapshots or AMIs that you subsequently create from the instance.
- Apple silicon Mac instances must have only one bootable volume, and each attached volume can have only one additional admin user.

Default SIP configurations

The following table lists the default SIP configuration for x86 Mac instances and Apple silicon Mac instances.

	Apple silicon Mac instances	x86 Mac instances
Apple Internal	Enabled	Disabled

	Apple silicon Mac instances	x86 Mac instances
Filesystem Protections	Enabled	Disabled
Base System	Enabled	Enabled
Debugging Restrictions	Enabled	Enabled
Dtrace Restrictions	Enabled	Enabled
Kext Signing	Enabled	Enabled
Nvram Protections	Enabled	Enabled

Check your SIP configuration

We recommend that you check your SIP configuration before and after making changes to ensure that it is configured as expected.

To check the SIP configuration for an Amazon EC2 Mac instance

Connect to the instance using SSH, and then run the following command at the command line.

```
$ csrutil status
```

The following is example output.

```
System Integrity Protection status: enabled.

Configuration:
    Apple Internal: enabled
    Kext Signing: disabled
    Filesystem Protections: enabled
    Debugging Restrictions: enabled
```

```
    DTrace Restrictions: enabled
    NVRAM Protections: enabled
    BaseSystem Verification: disabled
```

Prerequisites for Apple silicon Mac instances

Before you can configure the SIP settings for Apple silicon Mac instances, you must set a password and enable the secure token for the Amazon EBS root volume administrative user (`ec2-user`).

> **Note**
>
> The password and secure token are set the first time you connect to an Apple silicon Mac instance using the GUI. If you previously connected to the instance using the GUI, or if you are using an x86 Mac instance, you **do not** need to perform these steps.

To set a password and enable the secure token for the EBS root volume administrative user

1. Connect to the instance using SSH.
2. Set the password for the `ec2-user` user.

   ```
   $ sudo /usr/bin/dscl . -passwd /Users/ec2-user
   ```

3. Enable the secure token for the `ec2-user` user. For `-oldPassword`, specify the same password from the previous step. For `-newPassword`, specify a different password. The following command assumes that you have your old and new passowords saved in `.txt` files.

   ```
   $ sysadminctl -oldPassword `cat old_password.txt` -newPassword `cat
    new_password.txt`
   ```

4. Verify that the secure token is enabled.

   ```
   $ sysadminctl -secureTokenStatus ec2-user
   ```

Configure SIP settings

When you configure the SIP settings for your instance, you can either enable or disable all SIP settings, or you can specify a custom configuration that selectively enables or disables specific SIP settings.

> **Note**
>
> If you implement a custom configuration, connect to the instance and verify the settings to ensure that your requirements are properly implemented and functioning as intended. SIP configurations might change with macOS updates. We recommend that you review custom SIP settings after any macOS version upgrade to ensure continued compatibility and proper functionality of your security configurations.

To configure the SIP settings for your instance, you must create a SIP configuration task. The SIP configuration task specifies the SIP settings for your instance.

When you create a SIP configuration for an Apple silicon Mac instance, you must specify the following credentials:

- **Internal disk administrative user**
  - Username — Only the default administrative user (`aws-managed-user`) is supported and it is used by default. You can't specify a different administrative user.
  - Password — If you did not change the default password for `aws-managed-user`, specify the default password, which is *blank*. Otherwise, specify your password.
- **Amazon EBS root volume administrative user**
  - Username — If you did not change the default administrative user, specify `ec2-user`. Otherwise, specify the username for your administrative user.
  - Password — You must always specify the password.

Use the following methods to create a SIP configuration task.

Console

To create a SIP configuration task using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, choose **Instances** and then select the Amazon EC2 Mac instance.
3. In the **Security** tab, choose **Modify Mac, Modify System Integrity Protection**.
4. To enable all SIP settings, select **Enable SIP**. To disable all SIP settings, clear **Enable SIP**.

5. To specify a custom configuration that selectively enables or disables specific SIP settings, select **Specify a custom SIP configuration**, and then select the SIP settings to enable, or clear the SIP settings to disable.
6. Specify the credentials for the root volume user and internal disk owner.
7. Choose **Create SIP modification task**.

AWS CLI

To create a SIP configuration task using the AWS CLI

Use the create-mac-system-integrity-protection-modification-task command.

Enable or disable all SIP settings

To completely enable or disable all SIP settings, use only the `--mac-system-integrity-protection-status` parameter.

The following example command enables all SIP settings.

```
aws ec2 create-mac-system-integrity-protection-modification-task \
--instance-id i-0abcdef9876543210 \
--mac-system-integrity-protection-status enabled \
--mac-credentials file://mac-credentials.json
```

Specify a custom SIP configuration

To specify a custom SIP configuration that selectively enables or disable specific SIP settings, specify the `--mac-system-integrity-protection-status` and `--mac-system-integrity-protection-configuration` parameters. In this case, use `mac-system-integrity-protection-status` to specify the overall SIP status, and use `mac-system-integrity-protection-configuration` to selectively enable or disable individual SIP settings.

The following example command creates a SIP configuration task to enable all SIP settings, except `NvramProtections` and `FilesystemProtections`.

```
aws ec2 create-mac-system-integrity-protection-modification-task \
--instance-id i-0abcdef9876543210 \
--mac-system-integrity-protection-status enabled \
```

```
--mac-system-integrity-protection-configuration
 "NvramProtections=disabled, FilesystemProtections=disabled" \
--mac-credentials file://mac-credentials.json
```

The following example command creates a SIP configuration task to disable all SIP settings, except `DtraceRestrictions`.

```
aws ec2 create-mac-system-integrity-protection-modification-task \
--instance-id i-0abcdef9876543210 \
--mac-system-integrity-protection-status disabled \
--mac-system-integrity-protection-configuration "DtraceRestrictions=enabled" \
--mac-credentials file://mac-credentials.json
```

Contents of the `mac-credentials.json` file

The following is the contents of the `mac-credentials.json` file referenced in the preceding examples.

```
{
  "internalDiskPassword":"internal-disk-admin_password",
  "rootVolumeUsername":"root-volume-admin_username",
  "rootVolumepassword":"root-volume-admin_password"
}
```

Check SIP configuration task status

Use one of the following methods to check the state of SIP configuration tasks.

Console

To view SIP configuration tasks using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, choose **Instances** and then select the Amazon EC2 Mac instance.
3. In the **Security** tab, scroll down to the **Mac modification tasks** section.

AWS CLI

To check the state of SIP configuration tasks using the AWS CLI

Use the describe-mac-modification-tasks command.

Find supported macOS versions for your Amazon EC2 Mac Dedicated Host

You can view the latest macOS versions supported by your Amazon EC2 Mac Dedicated Host. With this functionality, you can validate whether your Dedicated Host can support instance launches with your preferred macOS versions.

Each macOS version requires a minimum firmware version on the underlying Apple Mac to successfully boot. The Apple Mac firmware version can become outdated if an allocated Mac Dedicated Host has remained idle for an extended period of time or if it has a long running instance on it.

To ensure supportability for the latest macOS versions, you can stop or terminate instances on your allocated Mac Dedicated Host. This triggers the host scrubbing workflow and updates the firmware on the underlying Apple Mac to support the latest macOS versions. A Dedicated Host with a long running instance will automatically be updated when you stop or terminate a running instance.

For more information about the scrubbing workflow, see Stop or terminate your Amazon EC2 Mac instance.

For more information about launching Mac instances, see Launch a Mac instance using the AWS Management Console or the AWS CLI.

You can view information about the latest macOS versions supported on your allocated Dedicated Host using the Amazon EC2 console or the AWS CLI.

Console

To view Dedicated Host firmware information using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts details** page, under **Latest supported macOS versions**, you can see the latest macOS versions that the host can support.

AWS CLI

To view Dedicated Host firmware information using the AWS CLI

Use the [describe-mac-hosts](#) command, replacing `region` with the appropriate AWS Region.

```
$ aws ec2 describe-mac-hosts --region us-east-1
  {
      "MacHosts": [
          {
              "HostId": "h-07879acf49EXAMPLE",
              "MacOSLatestSupportedVersions": [
                  "14.3",
                  "13.6.4",
                  "12.7.3"
              ]
          }
      ]
  }
```

Subscribe to macOS AMI notifications

To be notified when new AMIs are released or when bridgeOS has been updated, subscribe for notifications using Amazon SNS.

For more information about EC2 macOS AMIs, see [Amazon EC2 macOS AMIs release notes](#).

To subscribe to macOS AMI notifications

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications that you are subscribing to were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. For the **Create subscription** dialog box, do the following:

    a. For **Topic ARN**, copy and paste one of the following Amazon Resource Names (ARNs):

    - **`arn:aws:sns:us-east-1:898855652048:amazon-ec2-macos-ami-updates`**
    - **`arn:aws:sns:us-east-1:898855652048:amazon-ec2-bridgeos-updates`**

    b. For **Protocol**, choose one of the following:

- **Email:**

  For **Endpoint**, type an email address that you can use to receive the notifications. After you create your subscription you'll receive a confirmation message with the subject line `AWS Notification - Subscription Confirmation`. Open the email and choose **Confirm subscription** to complete your subscription

- **SMS:**

  For **Endpoint**, type a phone number that you can use to receive the notifications.

- **AWS Lambda, Amazon SQS, Amazon Data Firehose** (*Notifications come in JSON format*):

  For **Endpoint**, enter the ARN for the Lambda function, SQS queue, or Firehose stream you can use to receive the notifications.

c. Choose **Create subscription**.

Whenever macOS AMIs are released, we send notifications to the subscribers of the `amazon-ec2-macos-ami-updates` topic. Whenever bridgeOS is updated, we send notifications to the subscribers of the `amazon-ec2-bridgeos-updates` topic. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

To unsubscribe from macOS AMI notifications

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Select the subscriptions and then choose **Actions**, **Delete subscriptions** When prompted for confirmation, choose **Delete**.

Retrieve macOS AMI IDs using AWS Systems Manager Parameter Store API

You must specify an AMI when you launch an instance. An AMI is specific to an AWS Region, operating system, and processor architecture. You can view all of the macOS AMIs in an AWS Region and retrieve the latest macOS AMI by querying the AWS Systems Manager Parameter Store API. Using these public parameters, you don't need to manually look up macOS AMI IDs. Public parameters are available for both x86 and ARM64 macOS AMIs, and can be integrated with your existing AWS CloudFormation templates.

Required permissions

To perform this action, the IAM principal must have permissions to call the `ssm:GetParameter` API action.

To view a list of all macOS AMIs in the current AWS Region using the AWS CLI

Use the following get-parameters-by-path command to view a list of all macOS AMIs in the current Region.

```
aws ssm get-parameters-by-path --path /aws/service/ec2-macos --recursive --query
 "Parameters[].Name"
```

To retrieve the AMI ID of the latest major macOS AMI using the AWS CLI

Use the following get-parameter command with the sub-parameter `image_id`. In the following example, replace `sonoma` with a macOS supported major version, `x86_64_mac` with the processor, and `region-code` with a supported AWS Region for which you want the latest macOS AMI ID.

```
aws ssm get-parameter --name /aws/service/ec2-macos/sonoma/x86_64_mac/latest/image_id
 --region region-code
```

For more information, see Calling AMI public parameters for macOS in the *AWS Systems Manager User Guide*.

Amazon EC2 macOS AMIs release notes

The following information provides details about the packages included by default in the EC2 macOS AMIs and summarizes the changes for each EC2 macOS AMI release.

For information about how to subscribe to macOS AMI notifications, see Subscribe to macOS AMI notifications.

Mac instances can run one of the following operating systems:

- macOS Mojave (version 10.14) (x86 Mac instances only)
- macOS Catalina (version 10.15) (x86 Mac instances only)

- macOS Big Sur (version 11) (x86 and M1 Mac instances)
- macOS Monterey (version 12) (x86 and M1 Mac instances)
- macOS Ventura (version 13) (all Mac instances, M2 and M2 Pro Mac instances support macOS Ventura version 13.2 or later)
- macOS Sonoma (version 14) (all Mac instances)
- macOS Sequoia (version 15) (all Mac instances)

Approve Local Network Privacy policies for macOS Sequoia

macOS Sequoia (version 15) has a new Local Network Privacy feature that impacts users of local IP-based services, including Amazon EC2 Instance Metadata Service (IMDS).

> **Important**
>
> To make sure that you have uninterrupted access to local IP-based services, use the following steps to approve the Local Network Privacy policies.

To approve Local Network Privacy policies

1. Connect to your instance's graphical user interface (GUI).
2. Follow the prompts on the screen to approve the Local Network Privacy policies.
3. After you have approved the policies, create an AMI of your EC2 Mac instance. For more information, see Create an Amazon EBS-backed AMI.

Any EC2 Mac instances that are launched from the newly created AMI will retain the Local Network Privacy permissions.

Default packages included in Amazon EC2 macOS AMIs

The following table describes packages that are included by default in the EC2 macOS AMIs.

Packages	Release notes
EC2 macOS Init	https://github.com/aws/ec2-macos-init/tags

Packages	Release notes
EC2 macOS Utils	https://github.com/aws/ec2-macos-utils/tags
Amazon SSM Agent	https://github.com/aws/amazon-ssm-agent/releases
AWS Command Line Interface (AWS CLI) version 2	https://raw.githubusercontent.com/aws/aws-cli/v2/CHANGELOG.rst
Command Line Tools for Xcode	https://developer.apple.com/documentation/xcode-release-notes
Homebrew	https://github.com/Homebrew/brew/releases
EC2 Instance Connect	https://github.com/aws/aws-ec2-instance-connect-config/releases
Safari	https://developer.apple.com/documentation/safari-release-notes

Amazon EC2 macOS AMI updates

The following table describes changes included in the EC2 macOS AMI releases. Note that some changes apply to all EC2 macOS AMIs, whereas others apply to only a subset of these AMIs.

EC2 macOS AMI updates

Release	Changes
2025.09.04	**All AMIs** • Updated `awscli` to 2.28.19 • Updated Homebrew to 4.6.7 **Release of macOS Ventura 13.7.8** • Security content of macOS Ventura 13.7.8

Release	Changes
	Release of macOS Sonoma 14.7.8 • Security content of macOS Sonoma 14.7.8 **Release of macOS Sequoia 15.6.1** • Security content of macOS Sequoia 15.6.1

2025.08.05	**All AMIs**
	• Updated `awscli` to 2.28.0
	• Updated Homebrew to 4.5.13
	
	Release of macOS Ventura 13.7.7
	• Security content of macOS Ventura 13.7.7
	• Updated Safari to 18.6
	    • Security content of Safari 18.6
	
	Release of macOS Sonoma 14.7.7
	• Security content of macOS Sonoma 14.7.7
	• Updated Safari to 18.6
	    • Security content of Safari 18.6
	
	Release of macOS Sequoia 15.6
	• Security content of macOS Sequoia 15.6
	• Updated AWS ENA Ethernet to 2.0.0

Release	Changes

2025.06.27	**All AMIs**
	
	• Updated `awscli` to 2.27.40
	• Updated Homebrew to 4.5.7
	• Migrated x86_64 images to AWS ENA Ethernet dext
	
	Release of macOS Ventura 13.7.6
	
	• Security content of macOS Ventura 13.7.6
	• Updated Safari to 18.5
	  • Security content of Safari 18.5
	
	Release of macOS Sonoma 14.7.6
	
	• Security content of macOS Sonoma 14.7.6
	• Updated Safari to 18.5
	  • Security content of Safari 18.5
	
	Release of macOS Sequoia 15.5
	
	• Security content of macOS Sequoia 15.5
	• Updated Command Line Tools to 16.4
	• Updated AWS ENA Ethernet to 1.0.9

Release	Changes

2025.05.21	**All AMIs**
	• Updated `awscli` to 2.27.7
	• Updated `ec2-macos-init` to 1.5.11
	• Updated `ec2-macos-utils` to 1.0.5
	• Updated Homebrew to 4.5.1
	
	Release of macOS Ventura 13.7.5
	• Security content of macOS Ventura 13.7.5
	• Updated Safari to 18.4
	  ◦ Security content of Safari 18.4
	
	Release of macOS Sonoma 14.7.5
	• Security content of macOS Sonoma 14.7.5
	• Updated Safari to 18.4
	  ◦ Security content of Safari 18.4
	
	Release of macOS Sequoia 15.4.1
	• Security content of macOS Sequoia 15.4.1
	• Updated Command Line Tools to 16.3

Release	Changes

2025.05.05	**All AMIs**
	• Updated `awscli` to 2.27.1
	• Updated `ec2-macos-init` to 1.5.11
	• Updated `ec2-macos-system-monitor` to 1.3.1
	• Updated `ec2-macos-utils` to 1.0.5
	• Updated Homebrew to 4.4.32
	
	Release of macOS Ventura 13.7.5
	• Security content of macOS Ventura 13.7.5
	• Updated Safari to 18.4
	  ◦ Security content of Safari 18.4
	
	Release of macOS Sonoma 14.7.5
	• Security content of macOS Sonoma 14.7.5
	• Updated Safari to 18.4
	  ◦ Security content of Safari 18.4
	
	Release of macOS Sequoia 15.4.1
	• Security content of macOS Sequoia 15.4.1

Release	Changes
2025.03.18	**All AMIs** • Updated `awscli` to 2.24.2 • Updated Homebrew to 4.4.20 **Release of macOS Sequoia 15.3.1** • Security content of macOS Sequoia 15.3.1 **Release of macOS Sonoma 14.7.4** • Security content of macOS Sonoma 14.7.4 • Updated Safari to 18.3 **Release of macOS Ventura 13.7.4** • Security content of macOS Ventura 13.7.4 • Updated Safari to 18.3

Release	Changes
2025.01.24	**All AMIs** • Updated `awscli` to 2.22.33 • Updated Homebrew to 4.4.15 **Release of macOS Sequoia 15.2** • Security content of macOS Sequoia 15.2 • Updated Command Line Tools to 16.2 **Release of macOS Sonoma 14.7.2** • Security content of macOS Sonoma 14.7.2 • Updated Safari to 18.2 • Updated Command Line Tools to 16.2 **Release of macOS Ventura 13.7.2** • Security content of macOS Ventura 13.7.2 • Updated Safari to 18.2

Release	Changes
2024.12.20	**All AMIs** • Updated Homebrew to 4.4.8 • Updated `aws-cli` to 2.22.5 • Updated `amazon-ssm-agent` to 3.3.987.0 **Release of macOS Sequoia 15.1.1** • Security content of macOS Sequoia 15.1.1 **Release of macOS Sonoma 14.7.1** • Security content of macOS Sonoma 14.7.1 • Updated Safari to 18.1.1 **Release of macOS Ventura 13.7.1** • Security content of macOS Ventura 13.7.1 • Updated Safari to 18.1.1

Release	Changes

2024.10.28	**All AMIs**
	
	• Updated Homebrew to 4.4.2
	• Updated `aws-cli` to 2.18.13
	• Updated `amazon-ssm-agent` to 3.3.987.0
	• Updated `ec2-macos-init` to 1.5.10
	• Updated `ec2-macos-utils` to 1.0.4
	
	Release of macOS Sequoia 15.0
	
	• Security content of macOS Sequoia 15
	
	Release of macOS Sonoma 14.7
	
	• Security content of macOS Sonoma 14.7.
	• Updated Command Line Tools to 16.0
	• Updated Safari to 18.0.1
	    • Security content of Safari 18
	
	Release of macOS Ventura 13.7
	
	• Security content of macOS Ventura 13.7
	• Updated Safari to 18.0.1
	    • Security content of Safari 18

<table>
<tr><th>Release</th><th>Changes</th></tr>
<tr><td>2024.08.20</td><td>All AMIs
Updated Homebrew to 4.3.14
Updated <code>aws-cli</code> to 2.17.29
Release of macOS Sonoma 14.6.1
No published CVE entries.
Release of macOS Ventura 13.6.9
No published CVE entries.
Updated Safari to 17.6

	• Updated Safari to 17.5
	    • Security content of Safari 17.5
	
	Release of macOS Monterey 12.7.5
	
	• Security content of macOS Monterey 12.7.5
	• Updated Safari to 17.5
	    • Security content of Safari 17.5

Release	Changes

2024.04.12	**All AMIs**
	
	• Updated Homebrew to 4.2.16-1
	• Updated `aws-cli` to 2.15.36
	
	Release of macOS Sonoma 14.4.1
	
	• Security content of macOS Sonoma 14.4.1
	
	Release of macOS Ventura 13.6.6
	
	• Security content of macOS Ventura 13.6.6
	• Updated Safari to 17.4.1
	  ◦ Security content of Safari 17.4.1
	
	For macOS Monterey
	
	• Updated Safari to 17.4.1
	  ◦ Security content of Safari 17.4.1

Amazon EBS-optimized instance types

Amazon EBS–optimized instances use an optimized configuration stack and provide additional, dedicated bandwidth for Amazon EBS I/O. This optimization provides the best performance for your EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

When attached to an EBS–optimized instance, General Purpose SSD (`gp2` and `gp3`) volumes are designed to deliver at least 90 percent of their provisioned IOPS performance 99 percent of the time in a given year, and Provisioned IOPS SSD (`io1` and `io2`) volumes are designed to deliver at least 90 percent of their provisioned IOPS performance 99.9 percent of the time in a given year. Throughput Optimized HDD (`st1`) and Cold HDD (`sc1`) deliver at least 90 percent of their expected throughput performance 99 percent of the time in a given year. Non-compliant periods are approximately uniformly distributed, targeting 99 percent of expected total throughput each hour. For more information, see [Amazon EBS volume types] in the *Amazon EBS User Guide*.

Some instance types are **EBS-optimized by default**, and there is no need to enable it and no effect if you attempt to disable it. Other instance types optionally **support EBS optimization** and you can enable it during or after launch for an additional hourly fee. Some instance types do not support EBS optimization.

For detailed instance type specifications and features, see the Amazon EC2 Instance Types Guide.

Considerations

- An instance's EBS performance is bounded by the instance type's performance limits, or the aggregated performance of its attached volumes, whichever is smaller. To achieve maximum EBS performance, an instance must have attached volumes that provide a combined performance equal to or greater than the maximum instance performance. For example, to achieve `80,000` IOPS for `r6i.16xlarge`, the instance must have at least 5 `gp3` volumes provisioned with `16,000` IOPS each (5 volumes x `16,000` IOPS = `80,000` IOPS). We recommend that you choose an instance type that provides more dedicated Amazon EBS throughput than your application needs; otherwise, the connection between Amazon EBS and Amazon EC2 can become a performance bottleneck.
- The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see Amazon EBS volume limits for Amazon EC2 instances.
- The maximum IOPS and throughput limits are interdependent. Depending on your I/O size, you might reach one limit before the other, which can affect overall performance. For optimal results, consider both limits when planning your workload.

EBS-optimized by default

The following instance types are EBS–optimized by default. There is no need to enable EBS optimization and no effect if you disable EBS optimization.

Instances

- General purpose
- Compute optimized
- Memory optimized

- Storage optimized
- Accelerated computing
- High-performance computing

General purpose

> **Note**
>
> M8g, M8gd, M8i, M8i-flex instance types support configurable bandwidth weightings. With these instance types, you can optimize an instance's bandwidth for either networking performance or Amazon EBS performance. The following table shows the default Amazon EBS bandwidth performance for these instance types. For more information, see EC2 instance bandwidth weighting configuration.

Instance size	Baseline bandwidth (Mbps)	Maximum bandwidth (Mbps)	Baseline throughput (MB/s, 128 KiB I/O)	Maximum throughput (MB/s, 128 KiB I/O)	Baseline IOPS (16 KiB I/O)	Maximum IOPS (16 KiB I/O)
a1.medium [1]	300	3500	37.50	437.50	2500	20000
a1.large [1]	525	3500	65.62	437.50	4000	20000
a1.xlarge [1]	800	3500	100.00	437.50	6000	20000
a1.2xlarge [1]	1750	3500	218.75	437.50	10000	20000
a1.4xlarge [2]	3500		437.5		20000	
a1.metal [2]	3500		437.5		20000	
m4.large [2]	450		56.25		3600	

Instance size	Baseline bandwidth (Mbps)	Maximum bandwidth (Mbps)	Baseline throughput (MB/s, 128 KiB I/O)	Maximum throughput (MB/s, 128 KiB I/O)	Baseline IOPS (16 KiB I/O)	Maximum IOPS (16 KiB I/O)
m4.xlarge [2]	750		93.75		6000

[1] These instances can sustain the maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

[2] These instances can sustain their stated performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

Compute optimized

> **Note**
>
> C8g, C8gd instance types support configurable bandwidth weightings. With these instance types, you can optimize an instance's bandwidth for either networking performance or Amazon EBS performance. The following table shows the default Amazon EBS bandwidth performance for these instance types. For more information, see [EC2 instance bandwidth weighting configuration](#).

Instance size	Baseline bandwidth (Mbps)	Maximum bandwidth (Mbps)	Baseline throughput (MB/s, 128 KiB I/O)	Maximum throughput (MB/s, 128 KiB I/O)	Baseline IOPS (16 KiB I/O)	Maximum IOPS (16 KiB I/O)

[1] These instances can sustain the maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

[2] These instances can sustain their stated performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

Memory optimized

> **Note**
>
> - R8g, R8gd, R8i, R8i-flex, X8g instance types support configurable bandwidth weightings. With these instance types, you can optimize an instance's bandwidth for either networking performance or Amazon EBS performance. The following table shows the default Amazon EBS bandwidth performance for these instance types. For more information, see EC2 instance bandwidth weighting configuration.
> - For maximum IOPS performance with U7i instances, we recommend that you use io2 BlockExpress volumes.

Instance size	Baseline bandwidth (Mbps)	Maximum bandwidth (Mbps)	Baseline throughput (MB/s, 128 KiB I/O)	Maximum throughput (MB/s, 128 KiB I/O)	Baseline IOPS (16 KiB I/O)	Maximum IOPS (16 KiB I/O)

[2] These instances can sustain their stated performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

EBS optimization supported

The following instance types support EBS optimization but EBS optimization is not enabled by default. You must enable EBS optimization, at an additional hourly fee, during or after launch to achieve the level of EBS performance described.

Instance size	Maximum bandwidth (Mbps)	Maximum throughput (MB/s, 128 KiB I/O)	Maximum IOPS (16 KiB I/O)
c1.xlarge	1000	125.0	8000
c3.xlarge	500	62.5	4000
c3.2xlarge	1000	125.0	8000
c3.4xlarge	2000	250.0	16000
i2.xlarge	500	62.5	4000
i2.2xlarge	1000	125.0	8000
i2.4xlarge	2000	250.0	16000
m1.large	500	62.5	4000
m1.xlarge	1000	125.0	8000
m2.2xlarge	500	62.5	4000
m2.4xlarge	1000	125.0	8000
m3.xlarge	500	62.5	4000
m3.2xlarge	1000	125.0	8000
r3.xlarge	500	62.5	4000
r3.2xlarge	1000	125.0	8000

Instance size	Maximum bandwidth (Mbps)	Maximum throughput (MB/s, 128 KiB I/O)	Maximum IOPS (16 KiB I/O)
r3.4xlarge	2000	250.0	16000

Note

The `i2.8xlarge`, `c3.8xlarge`, and `r3.8xlarge` instances do not have dedicated EBS bandwidth and therefore do not offer EBS optimization. On these instances, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

Get the maximum Amazon EBS optimized performance

An instance's EBS performance is bounded by the instance type's performance limits, or the aggregated performance of its attached volumes, whichever is smaller. To achieve maximum EBS performance, an instance must have attached volumes that provide a combined performance equal to or greater than the maximum instance performance. For example, to achieve `80,000` IOPS for `r6i.16xlarge`, the instance must have at least 5 gp3 volumes provisioned with `16,000` IOPS each (5 volumes x `16,000` IOPS = `80,000` IOPS). We recommend that you choose an instance type that provides more dedicated Amazon EBS throughput than your application needs; otherwise, the connection between Amazon EBS and Amazon EC2 can become a performance bottleneck.

Important

When using configurable bandwidth weightings, the EBS bandwidth limits for your instance might change. For instances with the `VPC-1` weighting configuration, which increases networking bandwidth, you might experience lower than expected IOPS for EBS volumes due to reaching the EBS bandwidth limit before the IOPS limit. This is particularly noticeable with larger I/O sizes. Always test your specific workload to ensure it meets your performance requirements with your selected bandwidth weighting. For more information, see EC2 instance bandwidth weighting configuration.

You can use the `EBSIOBalance%` and `EBSByteBalance%` metrics to help you determine whether your instances are sized correctly. You can view these metrics in the CloudWatch console and set an alarm that is triggered based on a threshold you specify. These metrics are expressed as a percentage. Instances with a consistently low balance percentage are candidates to size up. Instances where the balance percentage never drops below 100% are candidates for downsizing. For more information, see Monitor your instances using CloudWatch.

The high memory instances are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database, in the cloud. To maximize EBS performance, use high memory instances with an even number of `io1` or `io2` volumes with identical provisioned performance. For example, for IOPS heavy workloads, use four `io1` or `io2` volumes with 40,000 provisioned IOPS to get the maximum 160,000 instance IOPS. Similarly, for throughput heavy workloads, use six `io1` or `io2` volumes with 48,000 provisioned IOPS to get the maximum 4,750 MB/s throughput. For additional recommendations, see Storage Configuration for SAP HANA.

Considerations

- G4dn, I3en, Inf1, M5a, M5ad, R5a, R5ad, T3, T3a, and Z1d instances launched after February 26, 2020 provide the maximum EBS optimized performance. To get the maximum performance from an instance launched before February 26, 2020, stop and start it.
- C5, C5d, C5n, M5, M5d, M5n, M5dn, R5, R5d, R5n, R5dn, and P3dn instances launched after December 3, 2019 provide the maximum EBS optimized performance. To get the maximum performance from an instance launched before December 3, 2019, stop and start it.
- `u-6tb1.metal`, `u-9tb1.metal`, and `u-12tb1.metal` instances launched after March 12, 2020 provide the maximum EBS optimized performance. Instances of these types launched before March 12, 2020 might provide lower performance. To get the maximum performance from an instance launched before March 12, 2020, contact your account team to upgrade the instance at no additional cost.

Find EBS-optimized EC2 instance types

You can view the instances types that support EBS optimization in each Region.

Console

To find instance types that are EBS-optimized by default

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instance Types**.
3. Add the filter **EBS optimization support = default**.

4. (Optional) Click the **Preferences** icon and then turn on the relevant columns, such as **EBS Maximum IOPS** and **EBS Baseline IOPS**.
5. (Optional) Add filters to further scope to specific instance types of interest.

AWS CLI

To find instance types that are EBS-optimized by default

Use the following [describe-instance-types](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-instance-types.html) command.

```
aws ec2 describe-instance-types \
    --filters Name=ebs-info.ebs-optimized-support,Values=default  \
    --query 'InstanceTypes[].{InstanceType:InstanceType, \
        "MaxBandwidth(Mb/s)":EbsInfo.EbsOptimizedInfo.MaximumBandwidthInMbps,\
        MaxIOPS:EbsInfo.EbsOptimizedInfo.MaximumIops,\
        "MaxThroughput(MB/s)":EbsInfo.EbsOptimizedInfo.MaximumThroughputInMBps}' \
    --output=table
```

To find instance types that optionally support EBS optimization

Use the following [describe-instance-types](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-instance-types.html) command.

```
aws ec2 describe-instance-types \
    --filters Name=ebs-info.ebs-optimized-support,Values=supported \
    --query 'InstanceTypes[].{InstanceType:InstanceType, \
        "MaxBandwidth(Mb/s)":EbsInfo.EbsOptimizedInfo.MaximumBandwidthInMbps, \
        MaxIOPS:EbsInfo.EbsOptimizedInfo.MaximumIops, \
        "MaxThroughput(MB/s)":EbsInfo.EbsOptimizedInfo.MaximumThroughputInMBps}' \
    --output=table
```

The following is example output for `eu-west-1`.

```

```

PowerShell

To find instance types that are EBS-optimized by default

Use the Get-EC2InstanceType cmdlet.

```
Get-EC2InstanceType `
    -Filter @{Name="ebs-info.ebs-optimized-support"; Values="default"} | `
    Select InstanceType, `
        @{Name="MaxBandwidth(Mb/s)";
 Expression={($_.EbsInfo.EbsOptimizedInfo.MaximumBandwidthInMbps)}}, `
        @{Name="MaxIOPS"; Expression={($_.EbsInfo.EbsOptimizedInfo.MaximumIops)}}, `
        @{Name="MaxThroughput (MB/s)";
 Expression={($_.EbsInfo.EbsOptimizedInfo.MaximumThroughputInMBps)}}
```

To find instance types that optionally support EBS optimization

Use the Get-EC2InstanceType cmdlet.

```
Get-EC2InstanceType `
    -Filter @{Name="ebs-info.ebs-optimized-support"; Values="supported"} | `
    Select InstanceType, `
        @{Name="MaxBandwidth(Mb/s)";
 Expression={($_.EbsInfo.EbsOptimizedInfo.MaximumBandwidthInMbps)}}, `
        @{Name="MaxIOPS"; Expression={($_.EbsInfo.EbsOptimizedInfo.MaximumIops)}}, `
        @{Name="MaxThroughput (MB/s)";
 Expression={($_.EbsInfo.EbsOptimizedInfo.MaximumThroughputInMBps)}}
```

The following is example output for `eu-west-1`.

```
InstanceType MaxBandwidth(Mb/s) MaxIOPS MaxThroughput (MB/s)
------------ ------------------ ------- --------------------
m2.4xlarge                 1000    8000              125.000
i2.2xlarge                 1000    8000              125.000
c1.xlarge                  1000    8000              125.000

```

Enable EBS optimization for an Amazon EC2 instance

You can manually enable EBS optimization only for previous generation instances types that optionally support EBS optimization. If you enable EBS optimization for these instance types, there is additional hourly fee

Prerequisites

- Verify that the instance type requires that you enable EBS optimization. For more information, see EBS optimization supported.
- To you enable EBS optimization after launch, you must stop the instance.

> **Warning**
>
> When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

Console

To enable Amazon EBS optimization during launch

In the Launch instances wizard, select the required instance type. Expand the **Advanced details** section, then for **EBS-optimized instance**, select **Enable**.

If the selected instance type does not support Amazon EBS optimization, the drop-down is disabled. If the instance type is Amazon EBS-optimized by default, Enable is already selected.

To enable Amazon EBS optimization after launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and select the instance.
3. Stop the instance. Choose **Actions**, **Instance state**, **Stop instance**.
4. With the instance still selected, choose **Actions**, **Instance settings**, **Change instance type**.
5. Select **EBS-optimized** and then choose **Apply**.

   If the instance type is Amazon EBS-optimized by default, or if it does not support Amazon EBS optimization, the checkbox is disabled.
6. Restart the instance. Choose **Instance state**, **Start instance**.

AWS CLI

To enable Amazon EBS optimization during launch

Use the run-instances command with the `--ebs-optimized` option.

To enable Amazon EBS optimization after launch

1. If the instance is running, stop it by using the stop-instances command.

   ```
   aws ec2 stop-instances --instance-ids i-1234567890abcdef0
   ```

2. Enable EBS optimization by using the modify-instance-attribute command with the `--ebs-optimized` option.

   ```
   aws ec2 modify-instance-attribute \
       --instance-id i-1234567890abcdef0 \
       --ebs-optimized
   ```

PowerShell

To enable Amazon EBS optimization during launch

Use the New-EC2Instance cmdlet with the `-EbsOptimized` option.

To enable Amazon EBS optimization after launch

1. If the instance is running, stop it by using the Stop-EC2Instance cmdlet.

```
Stop-EC2Instance -InstanceId i-1234567890abcdef0
```

2. Enable EBS optimization by using the Edit-EC2InstanceAttribute cmdlet with the `-EbsOptimized` option.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -EbsOptimized $true
```

CPU options for Amazon EC2 instances

Many Amazon EC2 instances support simultaneous multithreading (SMT), which enables multiple threads to run concurrently on a single CPU core. Each thread is represented as a virtual CPU (vCPU) on the instance. An instance has a default number of CPU cores, which varies according to instance type. For example, an `m5.xlarge` instance type has two CPU cores and two threads per core by default—four vCPUs in total.

In most cases, there is an Amazon EC2 instance type that has a combination of memory and number of vCPUs to suit your workloads. However, to optimize your instance for specific workloads or business needs, you can specify the following CPU options during and after instance launch:

- **Number of CPU cores**: You can customize the number of CPU cores for the instance. You might do this to potentially optimize the licensing costs of your software with an instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core**: You can disable SMT by specifying a single thread per CPU core. You might do this for certain workloads, such as high performance computing (HPC) workloads.

Considerations

- You can't modify the number of threads per core for T2, C7a, M7a, R7a, and Apple silicon Mac instances, and instances based on the AWS Graviton processor.
- The number of instances that you can run is based on the default vCPUs for the instance types used. How we calculate the vCPUs consumed by an instance is not affected by changing its CPU options.

Pricing

There is no additional or reduced charge for specifying CPU options. You're charged the same as instances that are launched with the default CPU options.

Contents

Rules for specifying CPU options for an Amazon EC2 instance

To specify the CPU options for your instance, be aware of the following rules:

- You can't specify CPU options for bare metal instances.
- You can specify CPU options both during and after instance launch.
- To configure CPU options, you must specify both the number of CPU cores and threads per core in the request. For example requests, see Specify CPU options for an Amazon EC2 instance.
- The number of vCPUs for the instance is the number of CPU cores multiplied by the threads per core. To specify a custom number of vCPUs, you must specify a valid number of CPU cores and threads per core for the instance type. You cannot exceed the default number of vCPUs for the instance. For more information, see Supported CPU options for Amazon EC2 instance types.
- To disable simultaneous multithreading (SMT), also referred to as hyper-threading, specify one thread per core.
- In the console, when you change the instance type of an existing instance, Amazon EC2 applies the CPU option settings from the existing instance to the new instance, if possible. If the new

instance type doesn't support those settings, the CPU options are reset to **Use default CPU options**. This option uses the default number of vCPUs for the new instance type.

To update settings for the new instance, select **Specify CPU options** under **Advanced details** in the **Change instance type** view.

- The specified CPU options persist after you stop, start, or reboot an instance.

Supported CPU options for Amazon EC2 instance types

The following tables list the instance types that support specifying CPU options.

Contents

General purpose instances

Instance type	Default vCPUs	Default CPU cores	Default threads per core	Valid CPU cores	Valid threads per core
`m2.xlarge`	2	2	1	1, 2	1
`m2.2xlarge`	4	4	1	1, 2, 3, 4	1
`m2.4xlarge`	8	8	1	1, 2, 3, 4, 5, 6, 7, 8	1

Specify CPU options for an Amazon EC2 instance

You can specify CPU options during or after instance launch.

Tasks

- Disable simultaneous multithreading
- Specify a custom number of vCPUs at launch
- Specify a custom number of vCPUs in a launch template
- Change CPU options for your EC2 instance

Disable simultaneous multithreading

To disable simultaneous multithreading (SMT), also known as hyper-threading, specify 1 thread per core.

Console

To disable SMT during instance launch

1. Follow the Launch an EC2 instance using the launch instance wizard in the console procedure and configure your instance as needed.
2. Expand **Advanced details**, and select the **Specify CPU options** checkbox.
3. For **Core count**, choose the number of required CPU cores. In this example, to specify the default CPU core count for an `r5.4xlarge` instance, choose 8.
4. To disable SMT, for **Threads per core**, choose **1**.
5. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

AWS CLI

To disable SMT during instance launch

Use the run-instances AWS CLI command and specify a value of 1 for `ThreadsPerCore` for the `--cpu-options` parameter. For `CoreCount`, specify the number of CPU cores. In this example, to specify the default CPU core count for an `r7i.4xlarge` instance, specify a value of 8.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type r7i.4xlarge \
    --cpu-options "CoreCount=8,ThreadsPerCore=1" \
    --key-name my-key-pair
```

PowerShell

To disable SMT during instance launch

Use the New-EC2Instance command and specify a value of 1 for `ThreadsPerCore` for the `-CpuOptions` parameter. For `CoreCount`, specify the number of CPU cores. In this example, to specify the default CPU core count for an `r7i.4xlarge` instance, specify a value of 8.

```
New-EC2Instance `
    -ImageId 'ami-0abcdef1234567890' `
    -InstanceType 'r7i.4xlarge' `
    -CpuOptions @{CoreCount=8; ThreadsPerCore=1} `
```

```
    -KeyName 'my-key-pair'
```

> **Note**
>
> To disable SMT for an existing instance, follow the process shown in Change CPU options for your EC2 instance, and change the number of threads that run per core to 1.

Specify a custom number of vCPUs at launch

You can customize the number of CPU cores and threads per core when you launch an instance from the EC2 console or AWS CLI. The examples in this section use an `r5.4xlarge` instance type, which has the following default settings:

- CPU cores: 8
- Threads per core: 2

Instances launch with the maximum number of vCPUs available for the instance type by default. For this instance type, that's 16 total vCPUs (8 cores running 2 threads each). For more information about this instance type, see Memory optimized instances.

The following example launches an `r5.4xlarge` instance with 4 vCPUs.

Console

To specify a custom number of vCPUs during instance launch

1. Follow the Launch an EC2 instance using the launch instance wizard in the console procedure and configure your instance as needed.
2. Expand **Advanced details**, and select the **Specify CPU options** checkbox.
3. To get 4 vCPUs, specify 2 CPU cores and 2 threads per core, as follows:
   - For **Core count**, choose **2**.
   - For **Threads per core**, choose **2**.
4. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

AWS CLI

To specify a custom number of vCPUs during instance launch

Use the run-instances AWS CLI command and specify the number of CPU cores and number of threads in the `--cpu-options` parameter. You can specify 2 CPU cores and 2 threads per core to get 4 vCPUs.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type r7i.4xlarge \
    --cpu-options "CoreCount=2,ThreadsPerCore=2" \
    --key-name my-key-pair
```

Alternatively, specify 4 CPU cores and 1 thread per core (disable SMT) to get 4 vCPUs:

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type r7i.4xlarge \
    --cpu-options "CoreCount=4,ThreadsPerCore=1" \
    --key-name my-key-pair
```

PowerShell

To specify a custom number of vCPUs during instance launch

Use the New-EC2Instance command and specify the number of CPU cores and number of threads in the `-CpuOptions` parameter. You can specify 2 CPU cores and 2 threads per core to get 4 vCPUs.

```
New-EC2Instance `
    -ImageId 'ami-0abcdef1234567890' `
    -InstanceType 'r7i.4xlarge' `
    -CpuOptions @{CoreCount=2; ThreadsPerCore=2} `
    -KeyName 'my-key-pair'
```

Alternatively, specify 4 CPU cores and 1 thread per core (disable SMT) to get 4 vCPUs:

```
New-EC2Instance `
    -ImageId 'ami-0abcdef1234567890' `
    -InstanceType 'r7i.4xlarge' `
```

```
    -CpuOptions @{CoreCount=4; ThreadsPerCore=1} `
    -KeyName 'my-key-pair'
```

Specify a custom number of vCPUs in a launch template

You can customize the number of CPU cores and threads per core for the instance in a launch template. The examples in this section use an `r5.4xlarge` instance type, which has the following default settings:

- CPU cores: 8
- Threads per core: 2

Instances launch with the maximum number of vCPUs available for the instance type by default. For this instance type, that's 16 total vCPUs (8 cores running 2 threads each). For more information about this instance type, see Memory optimized instances.

The following example creates a launch template that specifies the configuration for an `r5.4xlarge` instance with 4 vCPUs.

Console

To specify a custom number of vCPUs in a launch template

1. Follow the Create a launch template by specifying parameters procedure and configure your launch template as needed.
2. Expand **Advanced details**, and select the **Specify CPU options** checkbox.
3. To get 4 vCPUs, specify 2 CPU cores and 2 threads per core, as follows:
   - For **Core count**, choose **2**.
   - For **Threads per core**, choose **2**.
4. In the **Summary** panel, review your instance configuration, and then choose **Create launch template**. For more information, see Store instance launch parameters in Amazon EC2 launch templates.

AWS CLI

To specify a custom number of vCPUs in a launch template

Use the create-launch-template AWS CLI command and specify the number of CPU cores and number of threads in the `CpuOptions` parameter. You can specify 2 CPU cores and 2 threads per core to get 4 vCPUs.

```
aws ec2 create-launch-template \
    --launch-template-name TemplateForCPUOptions \
    --version-description CPUOptionsVersion1 \
    --launch-template-data file://template-data.json
```

The following is an example JSON file that contains the launch template data, which includes the CPU options, for the instance configuration for this example.

```
{
    "NetworkInterfaces": [{
        "AssociatePublicIpAddress": true,
        "DeviceIndex": 0,
        "Ipv6AddressCount": 1,
        "SubnetId": "subnet-0abcdef1234567890"
    }],
    "ImageId": "ami-0abcdef1234567890",
    "InstanceType": "r5.4xlarge",
    "TagSpecifications": [{
        "ResourceType": "instance",
        "Tags": [{
            "Key":"Name",
            "Value":"webserver"
        }]
    }],
    "CpuOptions": {
        "CoreCount":2,
        "ThreadsPerCore":2
    }
}
```

Alternatively, specify 4 CPU cores and 1 thread per core (disable SMT) to get 4 vCPUs:

```
{
    "NetworkInterfaces": [{
        "AssociatePublicIpAddress": true,
        "DeviceIndex": 0,
        "Ipv6AddressCount": 1,
        "SubnetId": "subnet-0abcdef1234567890"
```

```
    }],
    "ImageId": "ami-0abcdef1234567890",
    "InstanceType": "r5.4xlarge",
    "TagSpecifications": [{
        "ResourceType": "instance",
        "Tags": [{
            "Key":"Name",
            "Value":"webserver"
        }]
    }],
    "CpuOptions": {
        "CoreCount":4,
        "ThreadsPerCore":1
    }
}
```

PowerShell

To specify a custom number of vCPUs in a launch template

Use the [New-EC2LaunchTemplate](https://docs.aws.amazon.com/powershell/latest/reference/items/New-EC2LaunchTemplate.html).

```
New-EC2LaunchTemplate `
    -LaunchTemplateName 'TemplateForCPUOptions' `
    -VersionDescription 'CPUOptionsVersion1' `
    -LaunchTemplateData (Get-Content -Path 'template-data.json' | ConvertFrom-Json)
```

Change CPU options for your EC2 instance

As your needs change over time, you might want to change the configuration of CPU options for an existing instance. Each thread that runs on your instance is known as a virtual CPU (vCPU). You can change the number of vCPUs that run for an existing instance in the Amazon EC2 console, AWS CLI, API, or SDKs. The instance state must be `Stopped` before you can make this change.

Console

To change the number of active vCPUs for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**, and select your instance.

3. If the instance is running, you must stop it before you proceed. Choose **Instance state**, **Stop instance**.
4. To change the vCPU configuration, choose **Actions**, **Instance settings**, **Change CPU options**.
5. Choose one of the following CPU options:

   - To reset your instance to the default number of vCPUs for its instance type, choose **Use default CPU options**. The default is to run all threads for all CPU cores.
   - To configure the number of vCPUs on your instance, choose **Specify CPU options**.
6. If you chose **Specify CPU options**, the **Active vCPUs** fields are displayed.

   a. Use the first selector to configure the number of threads for each CPU core. To disable simultaneous multithreading, choose 1.
   b. Use the second selector to configure the number of CPUs for your instance.

   The following fields update dynamically as you make changes to the CPU option selectors:

   - **Active vCPUs**: The number of CPU cores multiplied by the threads per core, based on the selections that you made. For example, if you selected 2 threads and 4 cores, that would equal 8 vCPUs.
   - **Total vCPUs**: The maximum number of vCPUs for the instance type. For example, for an `m6i.4xlarge` instance type, this is 16 vCPUs (8 cores running 2 threads each).
7. Choose **Change**.

AWS CLI

To change the number of active vCPUs for an instance

Use the modify-instance-cpu-options command and specify the number of CPU cores that run in the `--core-count` parameter, and the number of threads that run per core in the `--threads-per-core` parameter.

The following examples shows two possible configurations on an `m6i.4xlarge` instance type to run 8 vCPUs on the specified instance. The default for this instance type is 16 vCPUs (8 cores running 2 threads each).

Example 1: Run 4 CPU cores with 2 threads per core, for a total of 8 vCPU.

```
aws ec2 modify-instance-cpu-options \
    --instance-id 1234567890abcdef0 \
    --core-count=4 \
    --threads-per-core=2
```

Example 2: Disable simultaneous multi-threading by changing the number of threads that run per core to 1. The resulting configuration also runs a total of 8 vCPUs (8 CPU cores with 1 thread per core).

```
aws ec2 modify-instance-cpu-options \
    --instance-id 1234567890abcdef0 \
    --core-count=8 \
    --threads-per-core=1
```

PowerShell

To change the number of active vCPUs for an instance

Use the Edit-EC2InstanceCpuOption cmdlet and specify the number of CPU cores that run in the `-CoreCount` parameter, and the number of threads that run per core in the `ThreadsPerCore` parameter.

Example 1: Run 4 CPU cores with 2 threads per core, for a total of 8 vCPU.

```
Edit-EC2InstanceCpuOption `
    -InstanceId 'i-1234567890abcdef0' `
    -CoreCount 4 `
    -ThreadsPerCore 2
```

Example 2: Disable simultaneous multi-threading by changing the number of threads that run per core to 1. The resulting configuration also runs a total of 8 vCPUs (8 CPU cores with 1 thread per core).

```
Edit-EC2InstanceCpuOption `
    -InstanceId 'i-1234567890abcdef0' `
    -CoreCount 8 `
    -ThreadsPerCore 1
```

View CPU threads and cores for an Amazon EC2 instance

You can view the CPU options for an existing instance by describing the instance.

Console

To view the CPU options for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances** and select the instance.
3. On the **Details** tab, under **Host and placement group**, find **Number of vCPUs**.

AWS CLI

To view the CPU options for an instance

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[].Instances[].CpuOptions
```

The following is example output. The `CoreCount` field indicates the number of cores for the instance. The `ThreadsPerCore` field indicates the number of threads per core.

```
[
    {
        "CoreCount": 24,
        "ThreadsPerCore": 2
    },
]
```

PowerShell

To view the CPU options for an instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance `
```

```
    -InstanceId 'i-1234567890abcdef0').Instances.CpuOptions
```

The following is example output.

```
AmdSevSnp CoreCount ThreadsPerCore
--------- --------- --------------
          24        2
```

Alternatively, to view CPU information, you can connect to your instance and use one of the following system tools:

- Windows `Task Manager` on your Windows instance
- The **lscpu** command on your Linux instance

You can use AWS Config to record, assess, audit, and evaluate configuration changes for instances, including terminated instances. For more information, see Getting Started with AWS Config in the *AWS Config Developer Guide*.

AMD SEV-SNP for Amazon EC2 instances

AMD Secure Encrypted Virtualization-Secure Nested Paging (AMD SEV-SNP) is a CPU feature that provides the following properties:

- **Attestation** – AMD SEV-SNP enables you to retrieve a signed attestation report that contains a cryptographic measure that can be used to validate the instance's state and identity, and that it is running on genuine AMD hardware. For more information, see Attest an Amazon EC2 instance with AMD SEV-SNP.
- **Memory encryption** – Starting with AMD EPYC (Milan), AWS Graviton2, and Intel Xeon Scalable (Ice Lake) processors, instance memory is always encrypted. Instances that are enabled for AMD SEV-SNP use an instance-specific key for their memory encryption.

Contents

- Pricing
- Find EC2 instance types that support AMD SEV-SNP
- Enable AMD SEV-SNP for an EC2 instance
- Attest an Amazon EC2 instance with AMD SEV-SNP

Concepts and terminology

Before you begin using AMD SEV-SNP, ensure that you are familiar with the following concepts and terminology.

AMD SEV-SNP attestation report

The AMD SEV-SNP attestation report is a document that an instance can request from the CPU. The AMD SEV-SNP attestation report can be used to validate the state and identity of an instance, and to verify that it is running in a sanctioned AMD environment. The report includes a launch measurement, which is a cryptographic hash of the initial boot state of an instance, including its initial instance memory contents and initial state of the vCPUs. The AMD SEV-SNP attestation report is signed with a VLEK signature that chains back to an AMD root of trust.

VLEK

The Versioned Loaded Endorsement Key (VLEK) is a versioned signing key that is certified by AMD and used by the AMD CPU to sign the AMD SEV-SNP attestation reports. VLEK signatures can be validated using certificates provided by AMD.

OVMF binary

The Open Virtual Machine Firmware (OVMF) is the early-boot code that is used to provide a UEFI environment for the instance. The early-boot code is run before the code in the AMI is booted. The OVMF also finds and runs the boot loader provided in the AMI. For more information, see the OVMF repository.

Requirements

To use AMD SEV-SNP, you must do the following:

- Use one of the following supported instance types:
  - **General purpose**: `m6a.large` | `m6a.xlarge` | `m6a.2xlarge` | `m6a.4xlarge` | `m6a.8xlarge`

  - **Compute optimized**: `c6a.large` | `c6a.xlarge` | `c6a.2xlarge` | `c6a.4xlarge` | `c6a.8xlarge` | `c6a.12xlarge` | `c6a.16xlarge`
  - **Memory optimized**: `r6a.large` | `r6a.xlarge` | `r6a.2xlarge` | `r6a.4xlarge`
- Launch your instance in a supported AWS Region. Currently, only US East (Ohio) and Europe (Ireland) are supported.
- Use an AMI with `uefi` or `uefi-preferred` boot mode and an operating system that supports AMD SEV-SNP. For more information about AMD SEV-SNP support on your operating system, refer to the respective operating system's documentation. For AWS, AMD SEV-SNP is supported on AL2023, RHEL 9.3, SLES 15 SP4, and Ubuntu 23.04 and later.

Considerations

You can only enable AMD SEV-SNP when you launch an instance. When AMD SEV-SNP is enabled for your instance launch, the following rules apply.

- After it is enabled, AMD SEV-SNP can't be disabled. It remains enabled throughout the instance lifecycle.
- You can only change the instance type to another instance type that supports AMD SEV-SNP.
- Hibernation and Nitro Enclaves aren't supported.
- Dedicated Hosts aren't supported.
- If the underlying host for your instance is scheduled for maintenance, you'll receive a scheduled event notification 14 days before the event. You must manually stop or restart your instance to move it to a new host.

Pricing

When you launch an Amazon EC2 instance with AMD SEV-SNP enabled, you are charged an additional hourly usage fee that is equivalent to 10 percent of the On-Demand hourly rate of the selected instance type.

This AMD SEV-SNP usage fee is a separate charge to your Amazon EC2 instance usage. Reserved Instances, Savings Plans, and operating system usage don't impact this fee.

If you configure a Spot Instance to launch with AMD SEV-SNP enabled, you are charged an additional hourly usage fee that is equivalent to 10 percent of the On-Demand hourly rate of the selected instance type. If the allocation strategy uses price as an input, Spot Fleet does not include this additional fee; only the Spot price is used.

Find EC2 instance types that support AMD SEV-SNP

You can find instance types that support AMD SEV-SNP. The Amazon EC2 console does not display this information for an instance type.

AWS CLI

To find the instance types that support AMD SEV-SNP

Use the following describe-instance-types command.

```
aws ec2 describe-instance-types \
    --filters Name=processor-info.supported-features,Values=amd-sev-snp \
    --query 'InstanceTypes[*].[InstanceType]' \
    --output text | sort
```

The following is example output.

```
c6a.12xlarge
c6a.16xlarge
c6a.2xlarge
c6a.4xlarge
c6a.8xlarge
c6a.large
c6a.xlarge
m6a.2xlarge
m6a.4xlarge
m6a.8xlarge
m6a.large
m6a.xlarge
r6a.2xlarge
r6a.4xlarge
r6a.large
r6a.xlarge
```

PowerShell

To find the instance types that support AMD SEV-SNP

Use the Get-EC2InstanceType cmdlet.

```
(Get-EC2InstanceType `
    -Filter @{Name="processor-info.supported-features"; Values="amd-sev-
snp"}).InstanceType.Value | Sort-Object
```

The following is example output.

```
c6a.12xlarge
c6a.16xlarge
c6a.2xlarge
c6a.4xlarge
c6a.8xlarge
c6a.large
c6a.xlarge
m6a.2xlarge
m6a.4xlarge
m6a.8xlarge
m6a.large
m6a.xlarge
r6a.2xlarge
r6a.4xlarge
r6a.large
r6a.xlarge
```

Enable AMD SEV-SNP for an EC2 instance

You can launch an instance with AMD SEV-SNP enabled. You can't enable AMD SEV-SNP after launch.

Launch an instance with AMD SEV-SNP enabled

You can't enable AMD SEV-SNP using the Amazon EC2 console.

AWS CLI

To launch an instance with AMD SEV-SNP enabled

Use the run-instances command with the `--cpu-options` option. For additional requirements, see AMD SEV-SNP requirements.

```
--cpu-options AmdSevSnp=enabled
```

PowerShell

To launch an instance with AMD SEV-SNP enabled

Use the New-EC2Instance cmdlet with the `-CpuOption` parameter.

```
-CpuOption @{AmdSevSnp="enabled"}
```

Check if an EC2 instance is enabled for AMD SEV-SNP

You can find instances that are enabled for AMD SEV-SNP. The Amazon EC2 console does not display this information.

AWS CLI

To check whether AMD SEV-SNP is enabled for an instance

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[].Instances[].CpuOptions
```

The following is example output. If `AmdSevSnp` is not present in `CpuOptions`, then AMD SEV-SNP is disabled.

```
[
    {
        "AmdSevSnp": "enabled",
        "CoreCount": 1,
        "ThreadsPerCore": 2
    }
]
```

PowerShell

To check whether AMD SEV-SNP is enabled for an instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance `
    -InstanceId i-1234567890abcdef0).Instances.CpuOptions
```

The following is example output. If the value of `AmdSevSnp` is not present, then AMD SEV-SNP is disabled.

```
AmdSevSnp CoreCount ThreadsPerCore
--------- --------- --------------
enabled   1         2
```

AWS CloudTrail

In the AWS CloudTrail event for the instance launch request, the following property indicates that AMD SEV-SNP is enabled for the instance.

```
"cpuOptions": {"AmdSevSnp": "enabled"}
```

Attest an Amazon EC2 instance with AMD SEV-SNP

Attestation is a process that allows your instance to prove its state and identity. After you enable AMD SEV-SNP for your instance, you can request an AMD SEV-SNP attestation report from the underlying processor. The AMD SEV-SNP attestation report contains a cryptographic hash, called the launch measurement, of the initial guest memory contents and initial vCPU state. The attestation report is signed with a VLEK signature that chains back to an AMD root of trust. You can use the launch measurement included in the attestation report to validate that the instance is running in a genuine AMD environment and to validate the initial boot code that was used to launch the instance.

Prerequisite

Launch an instance that is enabled for AMD SEV-SNP. For more information, see Enable AMD SEV-SNP for an EC2 instance.

Steps

- Step 1: Get the attestation report
- Step 2: Validate the attestation report signature

Step 1: Get the attestation report

In this step, you install and build the `snpguest` utility, and then use it to request the AMD SEV-SNP attestation report and certificates.

1. Connect to your instance.
2. Run the following commands to build the `snpguest` utility from the snpguest repository.

```
$ git clone https://github.com/virtee/snpguest.git
$ cd snpguest
$ cargo build -r
$ cd target/release
```

3. Generate a request for the attestation report. The utility requests the attestation report from the host, and writes it to a binary file with the provided request data.

   The following example creates a random request string, and uses it as the request file (`request-file.txt`). When the command returns the attestation report it's stored in the file path that you specify (`report.bin`). In this case, the utility stores the report in the current directory.

```
$ ./snpguest report report.bin request-file.txt --random
```

4. Request the certificates from host memory, and store them as PEM files. The following example stores the files in the same directory as the `snpguest` utility. If certificates already exist in the specified directory, those certificates are overwritten.

```
$ ./snpguest certificates PEM ./
```

Step 2: Validate the attestation report signature

The attestation report is signed with a certificate, called the Versioned Loaded Endorsement Key (VLEK), which is issued by AMD for AWS. In this step, you can validate that the VLEK certificate is issued by AMD, and that the attestation report is signed by that VLEK certificate.

1. Download the VLEK root of trust certificates from the official AMD website to the current directory.

```
$ sudo curl --proto '=https' --tlsv1.2 -sSf https://kdsintf.amd.com/vlek/v1/Milan/
cert_chain -o ./cert_chain.pem
```

2. Use `openssl` to validate that the VLEK certificate is signed by the AMD root of trust certificates.

```
$ sudo openssl verify --CAfile ./cert_chain.pem vlek.pem
```

The following is example output.

```
vlek.pem: OK
```

3. Use the `snpguest` utility to validate that the attestation report is signed by the VLEK certificate.

```
$ ./snpguest verify attestation ./ report.bin
```

The following is exmaple output.

```
Reported TCB Boot Loader from certificate matches the attestation report.
Reported TCB TEE from certificate matches the attestation report.
Reported TCB SNP from certificate matches the attestation report.
Reported TCB Microcode from certificate matches the attestation report.
VEK signed the Attestation Report!
```

Processor state control for Amazon EC2 Linux instances

C-states control the sleep levels that a core can enter when it is idle. C-states are numbered starting with C0 (the shallowest state where the core is totally awake and executing instructions) and go to C6 (the deepest idle state where a core is powered off).

P-states control the desired performance (in CPU frequency) from a core. P-states are numbered starting from P0 (the highest performance setting where the core is allowed to use Intel Turbo Boost Technology to increase frequency if possible), and they go from P1 (the P-state that requests the maximum baseline frequency) to P15 (the lowest possible frequency).

> **Note**
>
> AWS Graviton processors have built-in power saving modes and operate at a fixed frequency. Therefore, they do not provide the ability for the operating system to control C-states and P-states.

C-states and P-states

The following instance types provide the ability for an operating system to control processor C-states and P-states:

- **General purpose**: `m4.10xlarge` | `m4.16xlarge`
- **Compute optimized**: `c4.8xlarge`
- **Memory optimized**: `r4.8xlarge` | `r4.16xlarge` | `x1.16xlarge` | `x1.32xlarge` | `x1e.8xlarge` | `x1e.16xlarge` | `x1e.32xlarge`
- **Storage optimized**: `d2.8xlarge` | `i3.8xlarge` | `i3.16xlarge` | `h1.8xlarge` | `h1.16xlarge`
- **Accelerated computing**: `f1.16xlarge` | `g3.16xlarge` | `p2.16xlarge` | `p3.16xlarge`
- **Bare metal**: All bare metal instances with Intel and AMD processors

C-states only

The following instance types provide the ability for an operating system to control processor C-states:

- **General purpose**: `m5.12xlarge` | `m5.24xlarge` | `m5d.12xlarge` | `m5d.24xlarge` | `m5n.12xlarge` | `m5n.24xlarge` | `m5dn.12xlarge` | `m5dn.24xlarge` | `m5zn.6xlarge` | `m5zn.12xlarge` | `m6a.24xlarge` | `m6a.48xlarge` | `m6i.16xlarge` | `m6i.32xlarge` | `m6id.16xlarge` | `m6id.32xlarge` | `m6idn.16xlarge` | `m6in.16xlarge` | `m6in.32xlarge` | `m7a.medium` | `m7a.large` | `m7a.xlarge` | `m7a.2xlarge` | `m7a.4xlarge` | `m7a.8xlarge` | `m7a.12xlarge` | `m7a.16xlarge` | `m7a.24xlarge` | `m7a.32xlarge` | `m7a.48xlarge` | `m7i.large` | `m7i.xlarge` | `m7i.2xlarge` | `m7i.4xlarge` | `m7i.8xlarge` | `m7i.12xlarge` | `m7i.16xlarge` | `m7i.24xlarge` | `m7i.48xlarge` | `m8i.large` | `m8i.xlarge` | `m8i.2xlarge` | `m8i.4xlarge` | `m8i.8xlarge` | `m8i.12xlarge` | `m8i.16xlarge` | `m8i.24xlarge` | `m8i.32xlarge` | `m8i.48xlarge` | `m8i.96xlarge`

- **Compute optimized**: c5.9xlarge | c5.12xlarge | c5.18xlarge | c5.24xlarge | c5a.24xlarge | c5ad.24xlarge | c5d.9xlarge | c5d.12xlarge | c5d.18xlarge | c5d.24xlarge | c5n.9xlarge | c5n.18xlarge | c6a.24xlarge | c6a.32xlarge | c6a.48xlarge | c6i.16xlarge | c6i.32xlarge | c6id.24xlarge | c6id.32xlarge | c6in.32xlarge | c7a.medium | c7a.large | c7a.xlarge | c7a.2xlarge | c7a.4xlarge | c7a.8xlarge | c7a.12xlarge | c7a.16xlarge | c7a.24xlarge | c7a.32xlarge | c7a.48xlarge | c7i.large | c7i.xlarge | c7i.2xlarge | c7i.4xlarge | c7i.8xlarge | c7i.12xlarge | c7i.16xlarge | c7i.24xlarge | c7i.48xlarge
- **Memory optimized**: r5.12xlarge | r5.24xlarge | r5b.12xlarge | r5d.12xlarge | r5d.24xlarge | r5n.12xlarge | r5n.24xlarge | r5dn.12xlarge | r5dn.24xlarge | r6a.24xlarge | r6a.48xlarge | r6i.16xlarge | r6i.32xlarge | r6id.16xlarge | r6id.32xlarge | r6in.16xlarge | r6in.32xlarge | r7a.medium | r7a.large | r7a.xlarge | r7a.2xlarge | r7a.4xlarge | r7a.8xlarge | r7a.12xlarge | r7a.16xlarge | r7a.24xlarge | r7a.32xlarge | r7a.48xlarge | r7i.large | r7i.xlarge | r7i.2xlarge | r7i.4xlarge | r7i.8xlarge | r7i.12xlarge | r7i.16xlarge | r7i.24xlarge | r7i.48xlarge | r7iz.large | r7iz.xlarge | r7iz.2xlarge | r7iz.4xlarge | r7iz.8xlarge | r7iz.12xlarge | r7iz.16xlarge | r7iz.32xlarge | r8i.large | r8i.xlarge | r8i.2xlarge | r8i.4xlarge | r8i.8xlarge | r8i.12xlarge | r8i.16xlarge | r8i.24xlarge | r8i.32xlarge | r8i.48xlarge | r8i.96xlarge | u-3tb1.56xlarge | u-6tb1.56xlarge | u-6tb1.112xlarge | u-9tb1.112xlarge | u-12tb1.112xlarge | u-18tb1.112xlarge | u-24tb1.112xlarge | u7i-6tb.112xlarge | u7i-8tb.112xlarge | u7i-12tb.224xlarge | u7in-16tb.224xlarge | u7in-24tb.224xlarge | u7in-32tb.224xlarge | u7inh-32tb.480xlarge | x2idn.32xlarge | x2iedn.16xlarge | x2iedn.32xlarge | x2iezn.12xlarge | z1d.6xlarge | z1d.12xlarge
- **Storage optimized**: d3en.12xlarge | dl1.24xlarge | i3en.12xlarge | i3en.24xlarge | i4i.16xlarge | i7i.large | i7i.xlarge | i7i.2xlarge | i7i.4xlarge | i7i.8xlarge | i7i.12xlarge | i7i.16xlarge | i7i.24xlarge | i7i.48xlarge | i7ie.large | i7ie.xlarge | i7ie.2xlarge | i7ie.3xlarge | i7ie.6xlarge | i7ie.12xlarge | i7ie.18xlarge | i7ie.24xlarge | i7ie.48xlarge | r5b.12xlarge | r5b.24xlarge
- **Accelerated computing**: dl1.24xlarge | f2.6xlarge | f2.12xlarge | f2.48xlarge | g5.24xlarge | g5.48xlarge | g6.24xlarge | g6.48xlarge | g6e.12xlarge | g6e.24xlarge | g6e.48xlarge | inf1.24xlarge | p3dn.24xlarge | p4d.24xlarge | p4de.24xlarge | p5.48xlarge | p5e.48xlarge | p5en.48xlarge | p6-b200.48xlarge |

`trn1.32xlarge` | `trn2.3xlarge` | `trn2.48xlarge` | `trn2a.3xlarge` | `trn2a.48xlarge` | `trn2n.3xlarge` | `trn2n.48xlarge` | `trn2p.48xlarge` | `trn2u.48xlarge` | `vt1.24xlarge`

You might want to change the C-state or P-state settings to increase processor performance consistency, reduce latency, or tune your instance for a specific workload. The default C-state and P-state settings provide maximum performance, which is optimal for most workloads. However, if your application would benefit from reduced latency at the cost of higher single- or dual-core frequencies, or from consistent performance at lower frequencies as opposed to bursty Turbo Boost frequencies, consider experimenting with the C-state or P-state settings that are available to these instances.

For information about different processor configurations and how to monitor the effects of your configuration for Amazon Linux, see Processor state control for Amazon EC2 Amazon Linux instance in the *Amazon Linux 2 User Guide*. These procedures were written for, and apply to Amazon Linux; however, they might also work for other Linux distributions with a Linux kernel of 3.9 or newer. For more information about other Linux distributions and processor state control, see your system-specific documentation.

Amazon EC2 managed instances

An *Amazon EC2 managed instance* is an EC2 instance that is provisioned and managed by a designated service provider, such as Amazon EKS through EKS Auto Mode. Managed instances provide a simplified way for running compute workloads on Amazon EC2 by allowing you to delegate operational control of the instance to a service provider.

Delegated control is the only change introduced for managed instances. The technical specifications and billing remain the same as non-managed EC2 instances. Because managed instances allow you to delegate control to the service provider, you can benefit from the service provider’s operational expertise and best practices. When an instance is managed, the service provider is responsible for tasks such as provisioning the instance, configuring software, scaling capacity, handling instance failures and replacements, and terminating the instance.

You can’t directly modify the settings of a managed instance or terminate it. The service and specific operations are determined by the agreement between you and the service provider. However, you can add, modify, or remove tags from your managed instances, allowing you to categorize them within your AWS environment.

Contents

Billing for managed instances

An Amazon EC2 managed instance incurs the same base charge as a non-managed Amazon EC2 instance, plus a separate fee for the service provider. This additional fee is charged by the service provider managing your instance and is billed separately. It covers the cost of services provided for operating and maintaining your managed instance.

All Amazon EC2 purchasing options are available for managed instances, including On-Demand Instances, Reserved Instances, Spot Instances, and Savings Plans. By sourcing your compute directly from EC2 and then providing it to your service provider, you benefit from any existing Reserved Instances or Savings Plans applied to your account, ensuring that you're using the most cost-effective compute capacity available.

For example, when using Amazon EKS Auto Mode, you pay the standard EC2 instance rate for the underlying instances, plus an additional charge from Amazon EKS for managing the instances on your behalf. If you then decide to sign up for a Savings Plans, the EC2 instance rate is reduced by the Savings Plans, while the additional charge from Amazon EKS remains unchanged.

Identify managed instances

Managed instances are identified by a **true** value in the **Managed** field. The service provider is identified in the **Operator** field (in the console) or `Principal` field (in the CLI).

Use the following procedures to identify managed instances.

Console

To identify a managed instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance you want to check.
4. On the **Details** tab (if you selected the checkbox) or in the summary area (if you selected the instance ID), find the **Managed** field.

- A value of **true** indicates a managed instance.
- A value of **false** indicates a non-managed instance.

5. If **Managed** is set to **true**, the **Operator** field displays a value identifying the service provider responsible for managing the instance. For example, a value of **eks.amazonaws.com** identifies Amazon EKS as the service provider.

AWS CLI

To identify a managed instance

Use the describe-instances command and specify the instance ID.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query Reservations[].Instances[].Operator
```

The following is example output. If `Managed` is `true`, the instance is a managed instance and a `Principal` is included. The principal is the service provider that manages the instance. For example, a value of `eks.amazonaws.com` identifies Amazon EKS as the service provider.

```
[
    {
        "Managed": true,
        "Principal": "eks.amazonaws.com"
    }
]
```

To find your managed instances

Use the describe-instances command and specify the `operator.managed` filter with a value of `true`. The `--query` option displays only the IDs of the managed instances.

```
aws ec2 describe-instances \
    --filters "Name=operator.managed,Values=true" \
    --query Reservations[*].Instances[].InstanceId
```

PowerShell

To identify a managed instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -InstanceId i-1234567890abcdef0).Instances.Operator
```

The following is example output.

```
Managed Principal
------- ---------
True    eks.amazonaws.com
```

To find your managed instances

Use the Get-EC2Instance cmdlet. This example displays only the IDs of the managed instances.

```
(Get-EC2Instance -Filter @{Name="operator.managed";
 Values="true"}).Instances.InstanceId
```

Get started with managed instances

For guidance on using managed instances, see Automate cluster infrastructure with EKS Auto Mode in the *Amazon EKS User Guide*.

Amazon EC2 billing and purchasing options

You can use the following options to optimize your costs for Amazon EC2:

- **On-Demand Instances** – Pay, by the second, for the instances that you launch.
- **Savings Plans** – Reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.
- **Reserved Instances** – Reduce your Amazon EC2 costs by making a commitment to a consistent instance configuration, including instance type and Region, for a term of 1 or 3 years.
- **Spot Instances** – Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.
- **Dedicated Hosts** – Pay for a physical host that is fully dedicated to running your instances, and bring your existing per-socket, per-core, or per-VM software licenses to reduce costs.
- **Dedicated Instances** – Pay, by the hour, for instances that run on single-tenant hardware.
- **Capacity Reservations** – Reserve capacity for your EC2 instances in a specific Availability Zone.

If you can't make a commitment to a specific instance configuration, but you can commit to a usage amount, purchase Savings Plans to reduce your On-Demand Instance costs. If you require a capacity reservation, purchase Reserved Instances or Capacity Reservations for a specific Availability Zone. Capacity Blocks can be used to reserve a cluster of GPU instances. Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if they can be interrupted. Dedicated Hosts or Dedicated Instances can help you address compliance requirements and reduce costs by using your existing server-bound software licenses.

For more information, see Amazon EC2 Pricing and Amazon EC2 managed instances.

Purchasing On-Demand Instances for Amazon EC2

With On-Demand Instances, you pay for compute capacity by the second with no long-term commitments. You have full control over the instance's lifecycle—you decide when to launch, stop, hibernate, start, reboot, or terminate it.

There is no long-term commitment required when you purchase On-Demand Instances. You pay only for the seconds that your On-Demand Instances are in the `running` state, with a 60-second minimum. The price per second for a running On-Demand Instance is fixed, and is listed on the Amazon EC2 Pricing, On-Demand Pricing page.

We recommend that you use On-Demand Instances for applications with short-term, irregular workloads that cannot be interrupted.

For significant savings over On-Demand Instances, use AWS Savings Plans, Spot Instances, or Reserved Instances for Amazon EC2 overview.

Contents

On-Demand Instance quotas

There are quotas for the number of running On-Demand Instances per AWS account per Region. On-Demand Instance quotas are managed in terms of the *number of virtual central processing units* *(vCPUs)* that your running On-Demand Instances are using, regardless of the instance type. Each quota type specifies the maximum number of vCPUs for one or more instance families.

Your account includes the following quotas for On-Demand Instances. Instances that are in the pending, stopping, stopped, and hibernated states do not count towards your On-Demand Instance quotas. Capacity Reservations count toward your On-Demand Instance quotas, even if they are unused.

Name	Default	Adjustable
Running On-Demand DL instances	0	Yes
Running On-Demand F instances	0	Yes
Running On-Demand G and VT instances	0	Yes
Running On-Demand HPC instances	0	Yes
Running On-Demand High Memory instances	0	Yes
Running On-Demand Inf instances	0	Yes
Running On-Demand P instances	0	Yes
Running On-Demand Standard (A, C, D, H, I, M, R, T, Z) instances	5	Yes
Running On-Demand Trn instances	0	Yes
Running On-Demand X instances	0	Yes

For information about the different instance families, generations, and sizes, see the Amazon EC2 Instance Types Guide.

You can launch any combination of instance types that meet your changing application needs, as long as the number of vCPUs does not exceed your account quota. For example, with a Standard instance quota of 256 vCPUs, you could launch 32 `m5.2xlarge` instances (32 x 8 vCPUs) or 16 `c5.4xlarge` instances (16 x 16 vCPUs). For more information, see EC2 On-Demand Instance limits.

Tasks

- Monitor On-Demand Instance quotas and usage
- Request a quota increase

Monitor On-Demand Instance quotas and usage

You can view and manage your On-Demand Instance quotas for each Region using the following methods.

To view your current quotas using the Service Quotas console

1. Open the Service Quotas console at https://console.aws.amazon.com/servicequotas/home/services/ec2/quotas/.
2. From the navigation bar, select a Region.
3. In the filter field, enter **`On-Demand`**.
4. The **Applied quota value** column displays the maximum number of vCPUs for each On-Demand Instance quota type for your account.

To view your current quotas using the AWS Trusted Advisor console

Open Service limits page in the AWS Trusted Advisor console.

To configure CloudWatch alarms

With Amazon CloudWatch metrics integration, you can monitor your EC2 usage against your quotas. You can also configure alarms to warn about approaching quotas. For more information, see Service Quotas and Amazon CloudWatch alarms in the *Service Quotas User Guide*.

Request a quota increase

Even though Amazon EC2 automatically increases your On-Demand Instance quotas based on your usage, you can request a quota increase if necessary. For example, if you intend to launch more instances than your current quota allows, you can request a quota increase by using the Service Quotas console described in Amazon EC2 service quotas.

Query the prices of On-Demand Instances

You can use the Price List Service API or the AWS Price List API to query the prices of On-Demand Instances. For more information, see Using the AWS Price List API in the *AWS Billing User Guide*.

Reserved Instances for Amazon EC2 overview

> **Important**
>
> We recommend Savings Plans over Reserved Instances. Saving Plans are the easiest and most flexible way to save money on your AWS compute costs and offer lower prices (up to 72% off On-Demand pricing), just like Reserved Instances. However, Savings Plans are different to Reserved Instances. With Reserved Instances, you make a commitment to a specific instance configuration, whereas with Savings Plans, you have the flexibility to use the instance configurations that best meet your needs. To use Savings Plans, you make a commitment to a consistent usage amount, measured in USD per hour. For more information, see the AWS Savings Plans User Guide.

Reserved Instances provide you with significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. Reserved Instances are not physical instances, but rather a billing discount applied to the use of On-Demand Instances in your account. These On-Demand Instances must match certain attributes, such as instance type and Region, in order to benefit from the billing discount.

Reserved Instances topics

- Reserved Instance example scenario

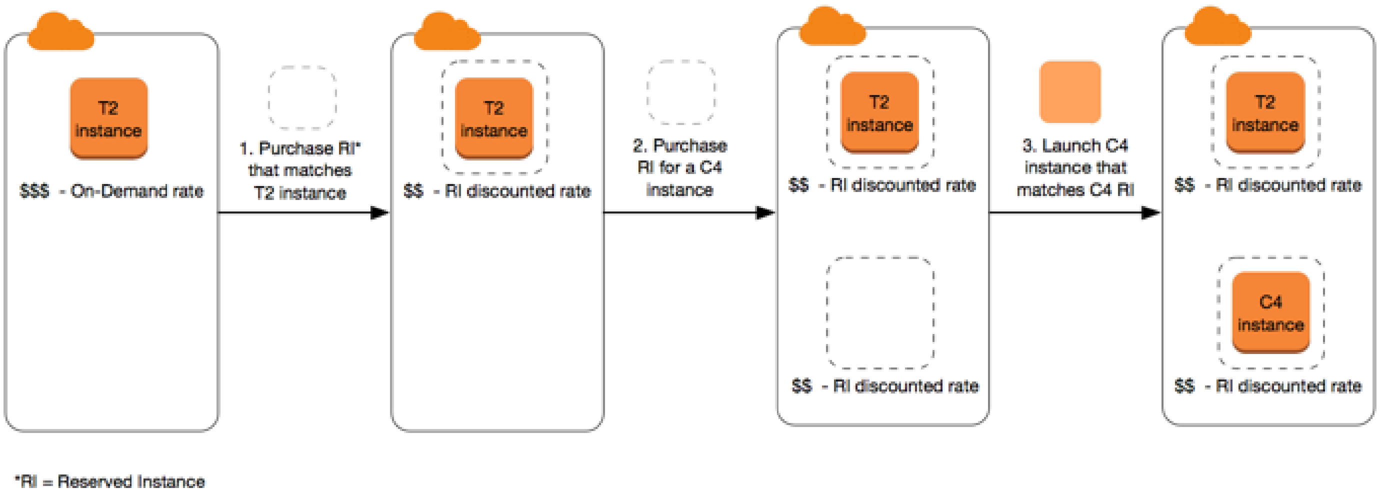
- Use your Reserved Instances
- How billing works with Reserved Instances
- Buy Reserved Instances for Amazon EC2
- Sell Reserved Instances for Amazon EC2 in the Reserved Instance Marketplace
- Modify Reserved Instances
- Exchange Convertible Reserved Instances
- Reserved Instance quotas

Reserved Instance example scenario

The following diagram shows a basic scenario of purchasing and using Reserved Instances.



In this scenario, you have a running On-Demand Instance (T2) in your account, for which you're currently paying On-Demand rates. You purchase a Reserved Instance that matches the attributes of your running instance, and the billing benefit is immediately applied. Next, you purchase a Reserved Instance for a C4 instance. You do not have any running instances in your account that match the attributes of this Reserved Instance. In the final step, you launch an instance that matches the attributes of the C4 Reserved Instance, and the billing benefit is immediately applied.

Key variables that determine Reserved Instance pricing

The Reserved Instance pricing is determined by the following key variables.

Instance attributes

A Reserved Instance has four instance attributes that determine its price.

- **Instance type**: For example, `m4.large`. This is composed of the instance family (for example, `m4`) and the instance size (for example, `large`).
- **Region**: The Region in which the Reserved Instance is purchased.
- **Tenancy**: Whether your instance runs on shared (default) or single-tenant (dedicated) hardware. For more information, see Amazon EC2 Dedicated Instances.
- **Platform**: The operating system; for example, Windows or Linux/Unix. For more information, see Choosing a platform.

Term commitment

You can purchase a Reserved Instance for a one-year or three-year commitment, with the three-year commitment offering a bigger discount.

- **One-year**: A year is defined as 31536000 seconds (365 days).
- **Three-year**: Three years is defined as 94608000 seconds (1095 days).

Reserved Instances do not renew automatically; when they expire, you can continue using the EC2 instance without interruption, but you are charged On-Demand rates. In the above example, when the Reserved Instances that cover the T2 and C4 instances expire, you go back to paying the On-Demand rates until you terminate the instances or purchase new Reserved Instances that match the instance attributes.

> **Important**
>
> After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to modify, exchange, or sell your Reserved Instance if your needs change.

Payment options

The following payment options are available for Reserved Instances:

- **All Upfront**: Full payment is made at the start of the term, with no other costs or additional hourly charges incurred for the remainder of the term, regardless of hours used.
- **Partial Upfront**: A portion of the cost must be paid upfront and the remaining hours in the term are billed at a discounted hourly rate, regardless of whether the Reserved Instance is being used.
- **No Upfront**: You are billed a discounted hourly rate for every hour within the term, regardless of whether the Reserved Instance is being used. No upfront payment is required.

  > **Note**
  >
  > No Upfront Reserved Instances are based on a contractual obligation to pay monthly for the entire term of the reservation. For this reason, a successful billing history is required before you can purchase No Upfront Reserved Instances.

Generally speaking, you can save more money making a higher upfront payment for Reserved Instances. You can also find Reserved Instances offered by third-party sellers at lower prices and shorter term lengths on the Reserved Instance Marketplace. For more information, see Sell Reserved Instances for Amazon EC2 in the Reserved Instance Marketplace.

Offering class

If your computing needs change, you might be able to modify or exchange your Reserved Instance, depending on the offering class.

- **Standard**: These provide the most significant discount, but can only be modified. Standard Reserved Instances can't be exchanged.
- **Convertible**: These provide a lower discount than Standard Reserved Instances, but can be exchanged for another Convertible Reserved Instance with different instance attributes. Convertible Reserved Instances can also be modified.

For more information, see Types of Reserved Instances (offering classes).

> **Important**
>
> After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to modify, exchange, or sell your Reserved Instance if your needs change.

For more information, see the Amazon EC2 Reserved Instances Pricing page.

Regional and zonal Reserved Instances (scope)

When you purchase a Reserved Instance, you determine the scope of the Reserved Instance. The scope is either regional or zonal.

- **Regional**: When you purchase a Reserved Instance for a Region, it's referred to as a *regional* Reserved Instance.
- **Zonal**: When you purchase a Reserved Instance for a specific Availability Zone, it's referred to as a *zonal* Reserved Instance.

The scope does not affect the price. You pay the same price for a regional or zonal Reserved Instance. For more information about Reserved Instance pricing, see Key variables that determine Reserved Instance pricing and Amazon EC2 Reserved Instances Pricing.

For more information about how to specify the scope of a Reserved Instance, see RI Attributes, specifically the **Availability Zone** bullet.

Differences between regional and zonal Reserved Instances

The following table highlights some key differences between regional Reserved Instances and zonal Reserved Instances:

	Regional Reserved Instances	**Zonal Reserved Instances**
Ability to reserve capacity	A regional Reserved Instance does *not* reserve capacity.	A zonal Reserved Instance reserves capacity in the specified Availability Zone.
Availability Zone flexibility	The Reserved Instance discount applies to instance usage in any Availability Zone in the specified Region.	No Availability Zone flexibility—the Reserved Instance discount applies to instance usage in the specified Availability Zone only.
Instance size flexibility	The Reserved Instance discount applies to instance usage within the instance family, regardless of size. Only supported on Amazon Linux/Unix Reserved Instances with default tenancy. For more information, see Instance size flexibility determined by normalization factor.	No instance size flexibility—the Reserved Instance discount applies to instance usage for the specified instance type and size only.

	Regional Reserved Instances	Zonal Reserved Instances
Queuing a purchase	You can queue purchases for regional Reserved Instances.	You can't queue purchases for zonal Reserved Instances.

For more information and examples, see How Reserved Instance discounts are applied.

Types of Reserved Instances (offering classes)

The offering class of a Reserved Instance is either Standard or Convertible. A Standard Reserved Instance provides a more significant discount than a Convertible Reserved Instance, but you can't exchange a Standard Reserved Instance. You can exchange Convertible Reserved Instances. You can modify Standard and Convertible Reserved Instances.

The configuration of a Reserved Instance comprises a single instance type, platform, scope, and tenancy over a term. If your computing needs change, you might be able to modify or exchange your Reserved Instance.

Differences between Standard and Convertible Reserved Instances

The following are the differences between Standard and Convertible Reserved Instances.

	Standard Reserved Instance	Convertible Reserved Instance
Modify Reserved Instances	Some attributes can be modified. For more informati on, see Modify Reserved Instances.	Some attributes can be modified. For more informati on, see Modify Reserved Instances.
Exchange Reserved Instances	Can't be exchanged.	Can be exchanged during the term for another Convertib le Reserved Instance with new attributes, including instance family, instance type, platform, scope, or tenancy. For more informati

	Standard Reserved Instance	Convertible Reserved Instance
		on, see Exchange Convertible Reserved Instances.
Sell in the Reserved Instance Marketplace	Can be sold in the Reserved Instance Marketplace.	Can't be sold in the Reserved Instance Marketplace.
Buy in the Reserved Instance Marketplace	Can be bought in the Reserved Instance Marketpla ce.	Can't be bought in the Reserved Instance Marketpla ce.

How Reserved Instance discounts are applied

Reserved Instances are not physical instances, but rather a billing discount that is applied to the running On-Demand Instances in your account. The On-Demand Instances must match certain specifications of the Reserved Instances in order to benefit from the billing discount.

If you purchase a Reserved Instance and you already have a running On-Demand Instance that matches the specifications of the Reserved Instance, the billing discount is applied immediately and automatically. You do not have to restart your instances. If you do not have an eligible running On-Demand Instance, launch an On-Demand Instance with the same specifications as your Reserved Instance. For more information, see Use your Reserved Instances.

The offering class (Standard or Convertible) of the Reserved Instance does not affect how the billing discount is applied.

Topics

- How zonal Reserved Instances are applied
- How regional Reserved Instances are applied
- Instance size flexibility
- Examples of applying Reserved Instances

How zonal Reserved Instances are applied

A Reserved Instance that is purchased to reserve capacity in a specific Availability Zone is called a zonal Reserved Instance.

- The Reserved Instance discount applies to matching instance usage in that Availability Zone.
- The attributes (tenancy, platform, Availability Zone, instance type, and instance size) of the running instances must match that of the Reserved Instances.

For example, if you purchase two `c4.xlarge` default tenancy Linux/Unix Standard Reserved Instances for Availability Zone us-east-1a, then up to two `c4.xlarge` default tenancy Linux/Unix instances running in the Availability Zone us-east-1a can benefit from the Reserved Instance discount.

How regional Reserved Instances are applied

A Reserved Instance that is purchased for a Region is called a regional Reserved Instance, and provides Availability Zone and instance size flexibility.

- The Reserved Instance discount applies to instance usage in any Availability Zone in that Region.
- The Reserved Instance discount applies to instance usage within the instance family, regardless of size—this is known as instance size flexibility.

Instance size flexibility

With instance size flexibility, the Reserved Instance discount applies to instance usage for instances that have the same family. The Reserved Instance is applied from the smallest to the largest instance size within the instance family based on the normalization factor. For an example of how the Reserved Instance discount is applied, see Scenario 2: Reserved Instances in a single account using the normalization factor.

Limitations

- **Supported:** Instance size flexibility is only supported for Regional Reserved Instances.
- **Not supported:** Instance size flexibility is *not supported* for the following Reserved Instances:
  - Reserved Instances that are purchased for a specific Availability Zone (zonal Reserved Instances)
  - Reserved Instances for G4ad, G4dn, G5, G5g, G6, G6e, G6f, Gr6, Gr6f, hpc7a, P5, Inf1, Inf2, u7i-6tb, and u7i-8tb instances
  - Reserved Instances for Windows Server, Windows Server with SQL Standard, Windows Server with SQL Server Enterprise, Windows Server with SQL Server Web, RHEL, and SUSE Linux Enterprise Server

- Reserved Instances with dedicated tenancy

Instance size flexibility determined by normalization factor

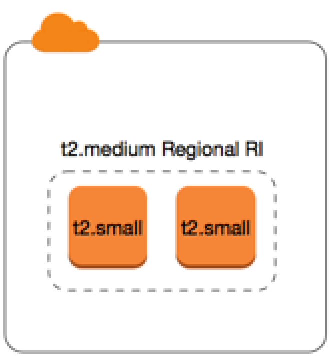
Instance size flexibility is determined by the normalization factor of the instance size. The discount applies either fully or partially to running instances of the same instance family, depending on the instance size of the reservation, in any Availability Zone in the Region. The only attributes that must be matched are the instance family, tenancy, and platform.

The following table lists the different sizes within an instance family, and the corresponding normalization factor. This scale is used to apply the discounted rate of Reserved Instances to the normalized usage of the instance family.

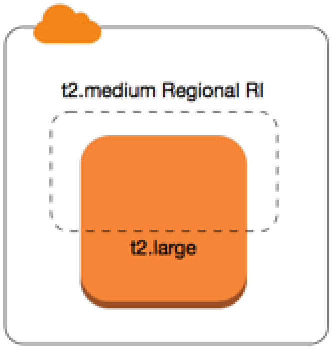
Instance size	Normalization factor
nano	0.25
micro	0.5
small	1
medium	2
large	4
xlarge	8
2xlarge	16
3xlarge	24
4xlarge	32
6xlarge	48
8xlarge	64
9xlarge	72
10xlarge	80

Instance size	Normalization factor
12xlarge	96
16xlarge	128
18xlarge	144
24xlarge	192
32xlarge	256
48xlarge	384
56xlarge	448
112xlarge	896

For example, a `t2.medium` instance has a normalization factor of 2. If you purchase a `t2.medium` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia) and you have two running `t2.small` instances in your account in that Region, the billing benefit is applied in full to both instances.



Or, if you have one `t2.large` instance running in your account in the US East (N. Virginia) Region, the billing benefit is applied to 50% of the usage of the instance.



The normalization factor is also applied when modifying Reserved Instances. For more information, see Modify Reserved Instances.

Normalization factor for bare metal instances

Instance size flexibility also applies to bare metal instances within the instance family. If you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on bare metal instances, you can benefit from the Reserved Instance savings within the same instance family. The opposite is also true: if you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on instances in the same family as a bare metal instance, you can benefit from the Reserved Instance savings on the bare metal instance.

The `metal` instance size does not have a single normalization factor. A bare metal instance has the same normalization factor as the equivalent virtualized instance size within the same instance family. For example, an `i3.metal` instance has the same normalization factor as an `i3.16xlarge` instance.

<table>
<tr><th>Instance size</th><th>Normalization factor</th></tr>
<tr><td>a1.metal</td><td>32</td></tr>
<tr><td>m5zn.metal | x2iezn.metal z1d.metal</td><td>96</td></tr>
<tr><td>c6g.metal | c6gd.metal | i3.metal | m6g.metal | m6gd.metal | r6g.metal | r6gd.metal | x2gd.metal</td><td>128</td></tr>
<tr><td>c5n.metal</td><td>144</td></tr>
</table>

Instance size	Normalization factor
c5.metal | c5d.metal | i3en.metal | m5.metal | m5d.metal | m5dn.metal | m5n.metal | r5.metal | r5b.metal | r5d.metal | r5dn.metal | r5n.metal	192
c6i.metal | c6id.metal | m6i.metal | m6id.metal | r6d.metal | r6id.metal	256
u-18tb1.metal | u-24tb1.metal	448
u-6tb1.metal | u-9tb1.metal | u-12tb1.metal	896

For example, an `i3.metal` instance has a normalization factor of 128. If you purchase an `i3.metal` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia), the billing benefit can apply as follows:

- If you have one running `i3.16xlarge` in your account in that Region, the billing benefit is applied in full to the `i3.16xlarge` instance (`i3.16xlarge` normalization factor = 128).
- Or, if you have two running `i3.8xlarge` instances in your account in that Region, the billing benefit is applied in full to both `i3.8xlarge` instances (`i3.8xlarge` normalization factor = 64).
- Or, if you have four running `i3.4xlarge` instances in your account in that Region, the billing benefit is applied in full to all four `i3.4xlarge` instances (`i3.4xlarge` normalization factor = 32).

The opposite is also true. For example, if you purchase two `i3.8xlarge` default tenancy Amazon Linux/Unix Reserved Instances in the US East (N. Virginia), and you have one running `i3.metal` instance in that Region, the billing benefit is applied in full to the `i3.metal` instance.

Examples of applying Reserved Instances

The following scenarios cover the ways in which Reserved Instances are applied.

- Scenario 1: Reserved Instances in a single account
- Scenario 2: Reserved Instances in a single account using the normalization factor
- Scenario 3: Regional Reserved Instances in linked accounts

- [Scenario 4: Zonal Reserved Instances in a linked account]

Scenario 1: Reserved Instances in a single account

You are running the following On-Demand Instances in account A:

- 4 x `m3.large` Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x `m4.xlarge` Amazon Linux, default tenancy instances in Availability Zone us-east-1b
- 1 x `c4.xlarge` Amazon Linux, default tenancy instances in Availability Zone us-east-1c

You purchase the following Reserved Instances in account A:

- 4 x `m3.large` Linux, default tenancy Reserved Instances in Availability Zone us-east-1a (capacity is reserved)
- 4 x `m4.large` Amazon Linux, default tenancy Reserved Instances in Region us-east-1
- 1 x `c4.large` Amazon Linux, default tenancy Reserved Instances in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The discount and capacity reservation of the four `m3.large` zonal Reserved Instances is used by the four `m3.large` instances because the attributes (instance size, Region, platform, tenancy) between them match.
- The `m4.large` regional Reserved Instances provide Availability Zone and instance size flexibility, because they are regional Amazon Linux Reserved Instances with default tenancy.

  An `m4.large` is equivalent to 4 normalized units/hour.

  You've purchased four `m4.large` regional Reserved Instances, and in total, they are equal to 16 normalized units/hour (4x4). Account A has two `m4.xlarge` instances running, which is equivalent to 16 normalized units/hour (2x8). In this case, the four `m4.large` regional Reserved Instances provide the full billing benefit to the usage of the two `m4.xlarge` instances.
- The `c4.large` regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy, and applies to the `c4.xlarge` instance. A `c4.large` instance is equivalent to 4 normalized units/hour and a `c4.xlarge` is equivalent to 8 normalized units/hour.

In this case, the `c4.large` regional Reserved Instance provides partial benefit to `c4.xlarge` usage. This is because the `c4.large` Reserved Instance is equivalent to 4 normalized units/hour of usage, but the `c4.xlarge` instance requires 8 normalized units/hour. Therefore, the `c4.large` Reserved Instance billing discount applies to 50% of `c4.xlarge` usage. The remaining `c4.xlarge` usage is charged at the On-Demand rate.

Scenario 2: Reserved Instances in a single account using the normalization factor

You are running the following On-Demand Instances in account A:

- 2 x `m3.xlarge` Amazon Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x `m3.large` Amazon Linux, default tenancy instances in Availability Zone us-east-1b

You purchase the following Reserved Instance in account A:

- 1 x `m3.2xlarge` Amazon Linux, default tenancy Reserved Instance in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The `m3.2xlarge` regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy. It applies first to the `m3.large` instances and then to the `m3.xlarge` instances, because it applies from the smallest to the largest instance size within the instance family based on the normalization factor.

  An `m3.large` instance is equivalent to 4 normalized units/hour.

  An `m3.xlarge` instance is equivalent to 8 normalized units/hour.

  An `m3.2xlarge` instance is equivalent to 16 normalized units/hour.

  The benefit is applied as follows:

  The `m3.2xlarge` regional Reserved Instance provides full benefit to 2 x `m3.large` usage, because together these instances account for 8 normalized units/hour. This leaves 8 normalized units/hour to apply to the `m3.xlarge` instances.

With the remaining 8 normalized units/hour, the `m3.2xlarge` regional Reserved Instance provides full benefit to 1 x `m3.xlarge` usage, because each `m3.xlarge` instance is equivalent to 8 normalized units/hour. The remaining `m3.xlarge` usage is charged at the On-Demand rate.

Scenario 3: Regional Reserved Instances in linked accounts

Reserved Instances are first applied to usage within the purchasing account, followed by qualifying usage in any other account in the organization. For more information, see Reserved Instances and consolidated billing. For regional Reserved Instances that offer instance size flexibility, the benefit is applied from the smallest to the largest instance size within the instance family.

You're running the following On-Demand Instances in account A (the purchasing account):

- 2 x `m4.xlarge` Linux, default tenancy instances in Availability Zone us-east-1a
- 1 x `m4.2xlarge` Linux, default tenancy instances in Availability Zone us-east-1b
- 2 x `c4.xlarge` Linux, default tenancy instances in Availability Zone us-east-1a
- 1 x `c4.2xlarge` Linux, default tenancy instances in Availability Zone us-east-1b

Another customer is running the following On-Demand Instances in account B—a linked account:

- 2 x `m4.xlarge` Linux, default tenancy instances in Availability Zone us-east-1a

You purchase the following regional Reserved Instances in account A:

- 4 x `m4.xlarge` Linux, default tenancy Reserved Instances in Region us-east-1
- 2 x `c4.xlarge` Linux, default tenancy Reserved Instances in Region us-east-1

The regional Reserved Instance benefits are applied in the following way:

- The discount of the four `m4.xlarge` Reserved Instances is used by the two `m4.xlarge` instances and the single `m4.2xlarge` instance in account A (purchasing account). All three instances match the attributes (instance family, Region, platform, tenancy). The discount is applied to instances in the purchasing account (account A) first, even though account B (linked account) has two `m4.xlarge` that also match the Reserved Instances. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.

- The discount of the two `c4.xlarge` Reserved Instances applies to the two `c4.xlarge` instances, because they are a smaller instance size than the `c4.2xlarge` instance. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.

Scenario 4: Zonal Reserved Instances in a linked account

In general, Reserved Instances that are owned by an account are applied first to usage in that account. However, if there are qualifying, unused Reserved Instances for a specific Availability Zone (zonal Reserved Instances) in other accounts in the organization, they are applied to the account before regional Reserved Instances owned by the account. This is done to ensure maximum Reserved Instance utilization and a lower bill. For billing purposes, all the accounts in the organization are treated as one account. The following example might help explain this.

You're running the following On-Demand Instance in account A (the purchasing account):

- 1 x `m4.xlarge` Linux, default tenancy instance in Availability Zone us-east-1a

A customer is running the following On-Demand Instance in linked account B:

- 1 x `m4.xlarge` Linux, default tenancy instance in Availability Zone us-east-1b

You purchase the following regional Reserved Instances in account A:

- 1 x `m4.xlarge` Linux, default tenancy Reserved Instance in Region us-east-1

A customer also purchases the following zonal Reserved Instances in linked account C:

- 1 x `m4.xlarge` Linux, default tenancy Reserved Instances in Availability Zone us-east-1a

The Reserved Instance benefits are applied in the following way:

- The discount of the `m4.xlarge` zonal Reserved Instance owned by account C is applied to the `m4.xlarge` usage in account A.
- The discount of the `m4.xlarge` regional Reserved Instance owned by account A is applied to the `m4.xlarge` usage in account B.

- If the regional Reserved Instance owned by account A was first applied to the usage in account A, the zonal Reserved Instance owned by account C remains unused and usage in account B is charged at On-Demand rates.

For more information, see Understanding your reservations in the AWS Cost and Usage Report.

> **Note**
>
> Zonal Reserved Instances reserve capacity only for the owning account and cannot be shared with other AWS accounts. If you need to share capacity with other AWS accounts, use Reserve compute capacity with EC2 On-Demand Capacity Reservations.

Use your Reserved Instances

Reserved Instances are automatically applied to running On-Demand Instances provided that the specifications match. If you have no running On-Demand Instances that match the specifications of your Reserved Instance, the Reserved Instance is unused until you launch an instance with the required specifications.

If you're launching an On-Demand Instance to take advantage of the billing benefit of a Reserved Instance, ensure that you specify the following information when you configure your On-Demand Instance:

Platform

You must specify an Amazon Machine Image (AMI) that matches the platform (product description) of your Reserved Instance. For example, if you specified `Linux/UNIX` for your Reserved Instance, you can launch an instance from an Amazon Linux AMI or an Ubuntu AMI.

Instance type

If you purchased a zonal Reserved Instance, you must specify the same instance type as your Reserved Instance; for example, `t3.large`. For more information, see How zonal Reserved Instances are applied.

If you purchased a regional Reserved Instance, you must specify an instance type from the same instance family as the instance type of your Reserved Instance. For example, if you specified `t3.xlarge` for your Reserved Instance, you must launch your instance from the T3 family, but you can specify any size, for example, `t3.medium`. For more information, see How regional Reserved Instances are applied.

Availability Zone

If you purchased a zonal Reserved Instance for a specific Availability Zone, you must launch the instance into the same Availability Zone.

If you purchased a regional Reserved Instance, you can launch the instance into any Availability Zone in the Region that you specified for the Reserved Instance.

Tenancy

The tenancy (`dedicated` or `shared`) of the instance must match the tenancy of your Reserved Instance. For more information, see Amazon EC2 Dedicated Instances.

For examples of how Reserved Instances are applied to your running On-Demand Instances, see How Reserved Instance discounts are applied. For more information, see Why aren't my Amazon EC2 Reserved Instances applying to my AWS billing in the way that I expected?

You can use various methods to launch the On-Demand Instances that use your Reserved Instance discount. For information about the different launch methods, see Launch an Amazon EC2 instance. You can also use Amazon EC2 Auto Scaling to launch an instance. For more information, see the Amazon EC2 Auto Scaling User Guide.

How billing works with Reserved Instances

All Reserved Instances provide you with a discount compared to On-Demand pricing. With Reserved Instances, you pay for the entire term regardless of actual use. You can choose to pay for your Reserved Instance upfront, partially upfront, or monthly, depending on the payment option specified for the Reserved Instance.

When Reserved Instances expire, you are charged On-Demand rates for EC2 instance usage. You can queue a Reserved Instance for purchase up to three years in advance. This can help you ensure that you have uninterrupted coverage. For more information, see Queue your purchase.

The AWS Free Tier is available for new AWS accounts. If you are using the AWS Free Tier to run Amazon EC2 instances, and you purchase a Reserved Instance, you are charged the standard pricing. For information, see AWS Free Tier.

Usage billing

Reserved Instances are billed for every clock-hour during the term that you select, regardless of whether an instance is running. Each clock-hour starts on the hour (zero minutes and zero seconds past the hour) of a standard 24-hour clock. For example, 1:00:00 to 1:59:59 is one clock-hour. For more information about instance states, see Amazon EC2 instance state changes.

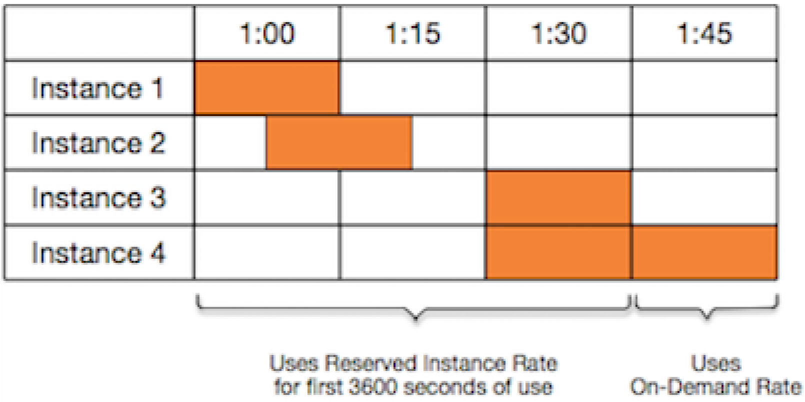
A Reserved Instance billing benefit can be applied to a running instance on a per-second basis. Per-second billing is available for instances using an open-source Linux distribution, such as Amazon Linux and Ubuntu. Per-hour billing is used for commercial Linux distributions, such as Red Hat Enterprise Linux and SUSE Linux Enterprise Server.

A Reserved Instance billing benefit can apply to a maximum of 3600 seconds (one hour) of instance usage per clock-hour. You can run multiple instances concurrently, but can only receive the benefit of the Reserved Instance discount for a total of 3600 seconds per clock-hour; instance usage that exceeds 3600 seconds in a clock-hour is billed at the On-Demand rate.

For example, if you purchase one `m4.xlarge` Reserved Instance and run four `m4.xlarge` instances concurrently for one hour, one instance is charged at one hour of Reserved Instance usage and the other three instances are charged at three hours of On-Demand usage.

However, if you purchase one `m4.xlarge` Reserved Instance and run four `m4.xlarge` instances for 15 minutes (900 seconds) each within the same hour, the total running time for the instances is one hour, which results in one hour of Reserved Instance usage and 0 hours of On-Demand usage.

If multiple eligible instances are running concurrently, the Reserved Instance billing benefit is applied to all the instances at the same time up to a maximum of 3600 seconds in a clock-hour; thereafter, On-Demand rates apply.



Cost Explorer on the Billing and Cost Management console enables you to analyze the savings against running On-Demand Instances. The Reserved Instances FAQ includes an example of a list value calculation.

If you close your AWS account, On-Demand billing for your resources stops. However, if you have any Reserved Instances in your account, you continue to receive a bill for these until they expire.

Viewing your bill

You can find out about the charges and fees to your account by viewing the AWS Billing and Cost Management console.

- The **Dashboard** displays a spend summary for your account.
- On the **Bills** page, under **Details** expand the **Elastic Compute Cloud** section and the Region to get billing information about your Reserved Instances.

You can view the charges online, or you can download a CSV file.

You can also track your Reserved Instance utilization using the AWS Cost and Usage Report. For more information, see Understanding your reservations.

Reserved Instances and consolidated billing

The pricing benefits of Reserved Instances are shared when the purchasing account is part of a set of accounts billed under one consolidated billing payer account. The instance usage across all member accounts is aggregated in the payer account every month. This is typically useful for companies in which there are different functional teams or groups; then, the normal Reserved Instance logic is applied to calculate the bill. For more information, see Consolidated billing for AWS Organizations.

If you close the account that purchased the Reserved Instance, the payer account is charged for the Reserved Instance until the Reserved Instance expires. After the closed account is permanently deleted in 90 days, the member accounts no longer benefit from the Reserved Instance billing discount.

> **Note**
>
> Zonal Reserved Instances reserve capacity only for the owning account and cannot be shared with other AWS accounts. If you need to share capacity with other AWS accounts, use Reserve compute capacity with EC2 On-Demand Capacity Reservations.

Reserved Instance discount pricing tiers

If your account qualifies for a discount pricing tier, it automatically receives discounts on upfront and instance usage fees for Reserved Instance purchases that you make within that tier level from that point on. To qualify for a discount, the list value of your Reserved Instances in the Region must be $500,000 USD or more.

The following rules apply:

- Pricing tiers and related discounts apply only to purchases of Amazon EC2 Standard Reserved Instances.
- Pricing tiers do not apply to Reserved Instances for Windows with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tiers do not apply to Reserved Instances for Linux with SQL Server of any kind.
- Pricing tier discounts only apply to purchases made from AWS. They do not apply to purchases of third-party Reserved Instances.
- Discount pricing tiers are currently not applicable to Convertible Reserved Instance purchases.

Topics

Calculate Reserved Instance pricing discounts

You can determine the pricing tier for your account by calculating the list value for all of your Reserved Instances in a Region. Multiply the hourly recurring price for each reservation by the total number of hours for the term and add the undiscounted upfront price (also known as the fixed price) at the time of purchase. Because the list value is based on undiscounted (public) pricing, it is not affected if you qualify for a volume discount or if the price drops after you buy your Reserved Instances.

```
List value = fixed price + (undiscounted recurring hourly price * hours in term)
```

For example, for a 1-year Partial Upfront `t2.small` Reserved Instance, assume the upfront price is $60.00 and the hourly rate is $0.007. This provides a list value of $121.32.

```
121.32 = 60.00 + (0.007 * 8760)
```

To view the fixed price values for Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**.
3. To display the **Upfront price** column, choose settings ( ) in the top-right corner, turn on **Upfront price**, and choose **Confirm**.

To view the fixed price values for Reserved Instances using the command line

- describe-reserved-instances (AWS CLI)
- Get-EC2ReservedInstance (AWS Tools for Windows PowerShell)

Buy with a discount tier

When you buy Reserved Instances, Amazon EC2 automatically applies any discounts to the part of your purchase that falls within a discount pricing tier. You don't need to do anything differently, and you can buy Reserved Instances using any of the Amazon EC2 tools. For more information, see Buy Reserved Instances for Amazon EC2.

After the list value of your active Reserved Instances in a Region crosses into a discount pricing tier, any future purchase of Reserved Instances in that Region are charged at a discounted rate. If a single purchase of Reserved Instances in a Region takes you over the threshold of a discount tier, then the portion of the purchase that is above the price threshold is charged at the discounted rate. For more information about the temporary Reserved Instance IDs that are created during the purchase process, see Crossing pricing tiers.

If your list value falls below the price point for that discount pricing tier—for example, if some of your Reserved Instances expire—future purchases of Reserved Instances in the Region are not discounted. However, you continue to get the discount applied against any Reserved Instances that were originally purchased within the discount pricing tier.

When you buy Reserved Instances, one of four possible scenarios occurs:

- **No discount**—Your purchase within a Region is still below the discount threshold.
- **Partial discount**—Your purchase within a Region crosses the threshold of the first discount tier. No discount is applied to one or more reservations and the discounted rate is applied to the remaining reservations.
- **Full discount—**Your entire purchase within a Region falls within one discount tier and is discounted appropriately.
- **Two discount rates**—Your purchase within a Region crosses from a lower discount tier to a higher discount tier. You are charged two different rates: one or more reservations at the lower discounted rate, and the remaining reservations at the higher discounted rate.

Crossing pricing tiers

If your purchase crosses into a discounted pricing tier, you see multiple entries for that purchase: one for that part of the purchase charged at the regular price, and another for that part of the purchase charged at the applicable discounted rate.

The Reserved Instance service generates several Reserved Instance IDs because your purchase crossed from an undiscounted tier, or from one discounted tier to another. There is an ID for each set of reservations in a tier. Consequently, the ID returned by your purchase CLI command or API action is different from the actual ID of the new Reserved Instances.

Consolidated billing for pricing tiers

A consolidated billing account aggregates the list value of member accounts within a Region. When the list value of all active Reserved Instances for the consolidated billing account reaches a discount pricing tier, any Reserved Instances purchased after this point by any member of the consolidated billing account are charged at the discounted rate (as long as the list value for that consolidated account stays above the discount pricing tier threshold). For more information, see Reserved Instances and consolidated billing.

Buy Reserved Instances for Amazon EC2

To buy a Reserved Instance for Amazon EC2, you can use the Amazon EC2 console, a command line tool, or an SDK to search for Reserved Instance offerings from AWS and third-party sellers, adjusting your search parameters until you find the exact match that you're looking for.

When you search for Reserved Instances to buy, you receive a quote on the cost of the returned offerings. When you proceed with the purchase, AWS automatically places a limit price on the purchase price. The total cost of your Reserved Instances won't exceed the amount that you were quoted.

If the price rises or changes for any reason, the purchase is not completed. When you are purchasing a third-party seller’s Reserved Instance from the Amazon EC2 Reserved Instance Marketplace, if there are offerings similar to your choice but at a lower upfront price, AWS sells you the offerings at the lower upfront price.

Before you confirm your purchase, review the details of the Reserved Instance that you plan to buy, and make sure that all the parameters are accurate. After you purchase a Reserved Instance (either from a third-party seller in the Reserved Instance Marketplace or from AWS), you cannot cancel your purchase. You can queue a purchase for a future date, and cancel the queued purchase before its scheduled time.

To purchase and modify Reserved Instances, ensure that your user has the appropriate permissions, such as the ability to describe Availability Zones. For information, see the section called “Work with Reserved Instances” (API) or the section called “Work with Reserved Instances” (console).

Tasks

- Choosing a platform
- Queue your purchase
- Buy Standard Reserved Instances

- Buy Convertible Reserved Instances
- Buy from the Reserved Instance Marketplace
- Cancel a queued purchase
- Renew a Reserved Instance

Choosing a platform

Amazon EC2 supports the following platforms for Reserved Instances:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
- SUSE Linux
- Red Hat Enterprise Linux
- Red Hat Enterprise Linux with HA
- Windows
- Windows with SQL Server Standard
- Windows with SQL Server Web
- Windows with SQL Server Enterprise

Considerations

- If you bring your existing subscription (BYOS) for **Red Hat Enterprise Linux**, **SUSE Linux**, or **Ubuntu Pro**, you must choose an offering for the **Linux/Unix** platform.
- Reserved Instances are not supported on instances running **macOS** or Ubuntu Pro (EC2 subscription-included, i.e., not BYOS). For saving with On-Demand instance pricing, we recommend that you use macOS and Ubuntu Pro (EC2 subscription-included) instances with Savings Plans. For more information, see Savings Plans User Guide.

To ensure that an instance runs in a specific Reserved Instance, the platform of the Reserved Instance must match the platform of the AMI used to launch the instance. For Linux AMIs, it is important to check whether the AMI platform uses the general value **Linux/UNIX** or a more specific value like **SUSE Linux**.

Console

To check the AMI platform

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select the AMI.
4. On the **Details** tab, note the value of **Platform details**.

AWS CLI

To check the AMI platform

Use the describe-images command and check the value of `PlatformDetails`.

```
aws ec2 describe-images \
    --image-id ami-0abcdef1234567890 \
    --query Images[*].PlatformDetails
```

The following is example output.

```
[
    "Linux/UNIX"
]
```

PowerShell

To check the AMI platform

Use the Get-EC2Image cmdlet and check the value of `PlatformDetails`.

```
Get-EC2Image `
    -ImageId ami-0abcdef1234567890 | `
    Select PlatformDetails
```

The following is example output.

```
PlatformDetails
---------------
Linux/UNIX
```

Queue your purchase

By default, when you purchase a Reserved Instance, the purchase is made immediately. Alternatively, you can queue your purchases for a future date and time. For example, you can queue a purchase for around the time that an existing Reserved Instance expires. This can help you ensure that you have uninterrupted coverage.

You can queue purchases for regional Reserved Instances, but not zonal Reserved Instances or Reserved Instances from other sellers. You can queue a purchase up to three years in advance. On the scheduled date and time, the purchase is made using the default payment method. After the payment is successful, the billing benefit is applied.

You can set a date for your queued purchases in the Amazon EC2 console, and the purchase is queued until 00:00 UTC on this date. To specify a different time for the queued purchase, use an AWS SDK or command line tool.

You can view your queued purchases in the Amazon EC2 console. The status of a queued purchase is **queued**. You can cancel a queued purchase any time before its scheduled time. For details, see Cancel a queued purchase.

Buy Standard Reserved Instances

You can buy Standard Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Standard Reserved Instance.

After the purchase is complete, if you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not need to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the exact criteria that you specified for your Reserved Instance. For more information, see Use your Reserved Instances.

For examples of how Reserved Instances are applied to your running instances, see How Reserved Instance discounts are applied.

Console

To buy Standard Reserved Instances

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Standard** to display Standard Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

   To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.
5. Select other configurations as needed, and then choose **Search**.
6. For each Reserved Instance that you want to purchase, enter the desired quantity, and choose **Add to cart**.

   To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd party** in the **Seller** column in the search results. The **Term** column displays non-standard terms. For more information, see Buy from the Reserved Instance Marketplace.
7. To see a summary of the Reserved Instances that you selected, choose **View cart**.
8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order all**.

   If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.
10. Choose **Close**.

    The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from `Payment-pending` to `Active`. When the Reserved Instance is `Active`, it is ready to use.

    If the status goes to `Retired`, AWS might not have received your payment.

AWS CLI

To buy a Standard Reserved Instance

1. Find available Reserved Instances using the describe-reserved-instances-offerings command. Specify `standard` for the `--offering-class` option to return only Standard Reserved Instances. You can apply additional criteria to narrow your results. For example, use the following command to purchase a regional `t2.large` Reserved Instance with a default tenancy for `Linux/UNIX` for a 1-year term only.

```
aws ec2 describe-reserved-instances-offerings \
    --instance-type t2.large \
    --offering-class standard \
    --product-description "Linux/UNIX" \
    --instance-tenancy default \
    --filters Name=duration,Values=31536000 \
              Name=scope,Values=Region
```

   To find Reserved Instances on the Reserved Instance Marketplace only, use the `marketplace` filter and do not specify a duration in the request, as the term might be shorter than a 1– or 3-year term.

```
aws ec2 describe-reserved-instances-offerings \
    --instance-type t2.large \
    --offering-class standard \
    --product-description "Linux/UNIX" \
    --instance-tenancy default \
    --filters Name=marketplace,Values=true
```

   When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
"ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
```

2. Use the purchase-reserved-instances-offering command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```
aws ec2 purchase-reserved-instances-offering \
    --reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2 \
```

```
    --instance-count 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following option to the previous call.

```
--purchase-time "2020-12-01T00:00:00Z"
```

3. Use the describe-reserved-instances command to get the status of your Reserved Instance.

```
aws ec2 describe-reserved-instances \
    --reserved-instances-ids b847fa93-e282-4f55-b59a-1342fec06327 \
    --query ReservedInstances[].State
```

PowerShell

To buy a Standard Reserved Instance

1. Find available Reserved Instances using the Get-EC2ReservedInstancesOffering cmdlet. Specify `standard` for the `-OfferingClass` parameter to return only Standard Reserved Instances. You can apply additional criteria to narrow your results. For example, use the following command to purchase a regional `t2.large` Reserved Instance with a default tenancy for `Linux/UNIX` for a 1-year term only.

```
Get-EC2ReservedInstancesOffering `
    -InstanceType "t2.large" `
    -OfferingClass "standard" `
    -ProductDescription "Linux/UNIX" `
    -InstanceTenancy "default" `
    -Filters @{Name="duration"; Values="31536000"} `
             @{Name="scope"; Values="Region"
```

To find Reserved Instances on the Reserved Instance Marketplace only, use the `marketplace` filter and do not specify a duration in the request, as the term might be shorter than a 1– or 3-year term.

```
Get-EC2ReservedInstancesOffering `
    -InstanceType t2.large `
    -OfferingClass "standard" `
    -ProductDescription "Linux/UNIX" `
```

```
    -InstanceTenancy default `
    -Filters @{Name="marketplace"; Values="true"}
```

When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
bec624df-a8cc-4aad-a72f-4f8abc34caf2
```

2. Use the New-EC2ReservedInstance cmdlet to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```
New-EC2ReservedInstance `
    -ReservedInstancesOfferingId "bec624df-a8cc-4aad-a72f-4f8abc34caf2" `
    -InstanceCount 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
-PurchaseTime "2020-12-01T00:00:00Z"
```

3. Use the Get-EC2ReservedInstance cmdlet to get the status of your Reserved Instance.

```
Get-EC2ReservedInstance `
    -ReservedInstancesId b847fa93-e282-4f55-b59a-1342fec06327 | `
    Select State
```

Buy Convertible Reserved Instances

You can buy Convertible Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Convertible Reserved Instance.

If you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see Use your Reserved Instances.

For examples of how Reserved Instances are applied to your running instances, see How Reserved Instance discounts are applied.

Console

To buy Convertible Reserved Instances

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Convertible** to display Convertible Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

   To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.
5. Select other configurations as needed and choose **Search**.
6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to cart**.
7. To see a summary of your selection, choose **View cart**.
8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order all**.

   If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.
10. Choose **Close**.

    The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from `Payment-pending` to `Active`. When the Reserved Instance is `Active`, it is ready to use.

    If the status goes to `Retired`, AWS might not have received your payment.

AWS CLI

To buy a Convertible Reserved Instance

1. Find available Reserved Instances using the describe-reserved-instances-offerings command. Specify `convertible` for the `--offering-class` option to return only Convertible Reserved Instances. You can apply additional criteria to narrow your results. For example, use the following command to purchase a regional `t2.large` Reserved Instance with a default tenancy for `Linux/UNIX`.

   ```
   aws ec2 describe-reserved-instances-offerings \
       --instance-type t2.large \
       --offering-class convertible \
       --product-description "Linux/UNIX" \
       --instance-tenancy default \
       --filters Name=scope,Values=Region
   ```

   When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

   ```
   "ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
   ```

2. Use the purchase-reserved-instances-offering command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

   ```
   aws ec2 purchase-reserved-instances-offering \
       --reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2 \
       --instance-count 1
   ```

   By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following option to the previous call.

   ```
   --purchase-time "2020-12-01T00:00:00Z"
   ```

3. Use the describe-reserved-instances command to get the status of your Reserved Instance.

   ```
   aws ec2 describe-reserved-instances \
       --reserved-instances-ids b847fa93-e282-4f55-b59a-1342fec06327 \
   ```

```
    --query ReservedInstances[].State
```

PowerShell

To buy a Convertible Reserved Instance

1. Find available Reserved Instances using the Get-EC2ReservedInstancesOffering cmdlet. Specify `convertible` for the `-OfferingClass` parameter to return only Convertible Reserved Instances. You can apply additional criteria to narrow your results. For example, use the following command to purchase a regional `t2.large` Reserved Instance with a default tenancy for `Linux/UNIX`.

```
Get-EC2ReservedInstancesOffering `
    -InstanceType "t2.large" `
    -OfferingClass "convertible" `
    -ProductDescription "Linux/UNIX" `
    -InstanceTenancy "default" `
    -Filters @{Name="scope"; Values="Region"
```

   When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
bec624df-a8cc-4aad-a72f-4f8abc34caf2
```

2. Use the New-EC2ReservedInstance cmdlet to buy your Reserved Instance. You must specify the Reserved Instance offering ID that you obtained the previous step and you must specify the number of instances for the reservation.

```
New-EC2ReservedInstance `
    -ReservedInstancesOfferingId "bec624df-a8cc-4aad-a72f-4f8abc34caf2" `
    -InstanceCount 1
```

   By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
-PurchaseTime "2020-12-01T00:00:00Z"
```

3. Use the Get-EC2ReservedInstance cmdlet to get the status of your Reserved Instance.

```
Get-EC2ReservedInstance `
    -ReservedInstancesId b847fa93-e282-4f55-b59a-1342fec06327 | `
    Select State
```

Buy from the Reserved Instance Marketplace

You can purchase Reserved Instances from third-party sellers who own Reserved Instances that they no longer need from the Reserved Instance Marketplace. You can do this using the Amazon EC2 console or a command line tool. The process is similar to purchasing Reserved Instances from AWS. For more information, see Buy Standard Reserved Instances.

There are a few differences between Reserved Instances purchased in the Reserved Instance Marketplace and Reserved Instances purchased directly from AWS:

- **Term** – Reserved Instances that you purchase from third-party sellers have less than a full standard term remaining. Full standard terms from AWS run for one year or three years.
- **Upfront price** – Third-party Reserved Instances can be sold at different upfront prices. The usage or recurring fees remain the same as the fees set when the Reserved Instances were originally purchased from AWS.
- **Types of Reserved Instances** – Only Amazon EC2 Standard Reserved Instances can be purchased from the Reserved Instance Marketplace. Convertible Reserved Instances, Amazon RDS, and Amazon ElastiCache Reserved Instances are not available for purchase on the Reserved Instance Marketplace.

Basic information about you is shared with the seller, for example, your ZIP code and country information.

This information enables sellers to calculate any necessary transaction taxes that they have to remit to the government (such as sales tax or value-added tax) and is provided as a disbursement report. In rare circumstances, AWS might have to provide the seller with your email address, so that they can contact you regarding questions related to the sale (for example, tax questions).

For similar reasons, AWS shares the legal entity name of the seller on the buyer's purchase invoice. If you need additional information about the seller for tax or related reasons, contact Support.

Cancel a queued purchase

You can queue a purchase up to three years in advance. You can cancel a queued purchase any time before its scheduled time.

Console

To cancel a queued purchase

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**.
3. Select one or more Reserved Instances.
4. Choose **Actions**, **Delete queued Reserved Instances**.
5. When prompted for confirmation, choose **Delete**, and then **Close**.

AWS CLI

To cancel a queued purchase

Use the delete-queued-reserved-instances command.

```
aws ec2 delete-queued-reserved-instances \
    --reserved-instances-ids b847fa93-e282-4f55-b59a-1342fec06327
```

PowerShell

To cancel a queued purchase

Use the Remove-EC2QueuedReservedInstance cmdlet.

```
Remove-EC2QueuedReservedInstance `
    -ReservedInstancesId b847fa93-e282-4f55-b59a-1342fec06327
```

Renew a Reserved Instance

You can renew a Reserved Instance before it is scheduled to expire. Renewing a Reserved Instance queues the purchase of a Reserved Instance with the same configuration until the current Reserved Instance expires.

You must renew a Reserved Instance using the Amazon EC2 console.

To renew a Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance to renew.
4. Choose **Actions**, **Renew Reserved Instances**.
5. To complete the order, choose **Order all**, and then **Close**.

Sell Reserved Instances for Amazon EC2 in the Reserved Instance Marketplace

The Amazon EC2 Reserved Instance Marketplace is a platform that facilitates the sale of unused Standard Reserved Instances from AWS customers and third-party sellers. These Reserved Instances can vary in term lengths and pricing options. You might want to sell your Reserved Instances when you no longer need them, such as when you move your instances to a new AWS Region, change to a different instance type, finish projects before the Reserved Instance term expires, your business needs change, or you have excess capacity.

As soon as you list your Reserved Instances in the Reserved Instance Marketplace, they are available for potential buyers to find. All Reserved Instances are grouped according to the duration of the term remaining and the hourly price.

To fulfill a buyer's request to purchase a third-party seller’s Reserved Instance via the Reserved Instance Marketplace, AWS first sells the Reserved Instance with the lowest upfront price in the specified grouping. Then, AWS sells the Reserved Instance with the next lowest price, until the buyer's entire order is fulfilled. AWS then processes the transactions and transfers ownership of the Reserved Instances to the buyer.

You own your Reserved Instance until it's sold. After the sale, you've given up the capacity reservation and the discounted recurring fees. If you continue to use your instance, AWS charges you the On-Demand price starting from the time that your Reserved Instance was sold.

If you want to sell your unused Reserved Instances on the Reserved Instance Marketplace, you must meet certain eligibility criteria.

For information about buying Reserved Instances on the Reserved Instance Marketplace, see Buy from the Reserved Instance Marketplace.

Contents

Restrictions and limitations

Before you can sell your unused reservations, you must register as a seller in the Reserved Instance Marketplace. For information, see Register as a seller.

The following limitations and restrictions apply when selling Reserved Instances:

- Only Amazon EC2 Standard regional and zonal Reserved Instances can be sold in the Reserved Instance Marketplace.
- Amazon EC2 Convertible Reserved Instances can't be sold in the Reserved Instance Marketplace.
- Reserved Instances for other AWS services, such as Amazon RDS and Amazon ElastiCache, cannot be sold in the Reserved Instance Marketplace.
- There must be at least one month remaining in the term of the Standard Reserved Instance.
- You can't sell a Standard Reserved Instance in a Region that is disabled by default.
- The minimum price allowed in the Reserved Instance Marketplace is $0.00.
- You can sell No Upfront, Partial Upfront, or All Upfront Reserved Instances in the Reserved Instance Marketplace as long as they have been active in your account for at least 30 days. Additionally, if there is an upfront payment on a Reserved Instance, it can only be sold after AWS has received the upfront payment.
- You can't sell a Reserved Instance in the Reserved Instance Marketplace if you purchased it using a volume discount.

- You cannot modify your listing in the Reserved Instance Marketplace directly. However, you can change your listing by first canceling it and then creating another listing with new parameters. For information, see Price your Reserved Instances. You can also modify your Reserved Instances before listing them. For information, see Modify Reserved Instances.
- AWS charges a service fee of 12 percent of the total upfront price of each Standard Reserved Instance you sell in the Reserved Instance Marketplace. The upfront price is the price the seller is charging for the Standard Reserved Instance.
- When you register as a seller, the bank you specify must have a US address. For more information, see Additional seller requirements for paid products in the *AWS Marketplace Seller Guide*.
- Amazon Web Services India Private Limited (AWS India) customers can't sell Reserved Instances in the Reserved Instance Marketplace even if they have a US bank account. For more information, see What are the differences between AWS accounts and AWS India accounts?

Register as a seller

> **Note**
>
> Only the AWS account root user can register an account as a seller.

To sell in the Reserved Instance Marketplace, you must first register as a seller. During registration, you provide the following information:

- **Bank information**—AWS must have your bank information in order to disburse funds collected when you sell your reservations. The bank you specify must have a US address. For more information, see Bank account for disbursement.
- **Tax information**—All sellers are required to complete a tax information interview to determine any necessary tax reporting obligations. For more information, see Tax information.

After AWS receives your completed seller registration, you receive an email confirming your registration and informing you that you can get started selling in the Reserved Instance Marketplace.

Bank account for disbursement

AWS must have your bank information in order to disburse funds collected when you sell your Reserved Instance. The bank you specify must have a US address. For more information, see Additional seller requirements for paid products in the *AWS Marketplace Seller Guide*.

To register a default bank account for disbursements

1. Open the Reserved Instance Marketplace Seller Registration page and sign in using your AWS credentials.
2. On the **Manage Bank Account** page, provide the following information about the bank through to receive payment:
   - Bank account holder name
   - Routing number
   - Account number
   - Bank account type

   > **Note**
   >
   > If you are using a corporate bank account, you are prompted to send the information about the bank account via fax (1-206-765-3424).

After registration, the bank account provided is set as the default, pending verification with the bank. It can take up to two weeks to verify a new bank account, during which time you can't receive disbursements. For an established account, it usually takes about two days for disbursements to complete.

To change the default bank account for disbursement

1. On the Reserved Instance Marketplace Seller Registration page, sign in with the account that you used when you registered.
2. On the **Manage Bank Account** page, add a new bank account or modify the default bank account as needed.

Tax information

Your sale of Reserved Instances might be subject to a transaction-based tax, such as sales tax or value-added tax. You should check with your business's tax, legal, finance, or accounting department to determine if transaction-based taxes are applicable. You are responsible for collecting and sending the transaction-based taxes to the appropriate tax authority.

As part of the seller registration process, you must complete a tax interview in the Seller Registration Portal. The interview collects your tax information and populates an IRS form W-9, W-8BEN, or W-8BEN-E, which is used to determine any necessary tax reporting obligations.

The tax information you enter as part of the tax interview might differ depending on whether you operate as an individual or business, and whether you or your business are a US or non-US person or entity. As you fill out the tax interview, keep in mind the following:

- Information provided by AWS, including the information in this topic, does not constitute tax, legal, or other professional advice. To find out how the IRS reporting requirements might affect your business, or if you have other questions, contact your tax, legal, or other professional advisor.
- To fulfill the IRS reporting requirements as efficiently as possible, answer all questions and enter all information requested during the interview.
- Check your answers. Avoid misspellings or entering incorrect tax identification numbers. They can result in an invalidated tax form.

Based on your tax interview responses and IRS reporting thresholds, Amazon might file Form 1099-K. Amazon mails a copy of your Form 1099-K on or before January 31 in the year following the year that your tax account reaches the threshold levels. For example, if your account reaches the threshold in 2018, your Form 1099-K is mailed on or before January 31, 2019.

For more information about IRS requirements and Form 1099-K, see Form 1099-K FAQs on the IRS website.

Price your Reserved Instances

When setting the price for your Reserved Instances, consider the following:

- **Upfront price** – The upfront price is the only price that you can specify for the Reserved Instance that you're selling. The upfront price is the one-time price that the buyer pays when they purchase each Reserved Instance.

Because the value of Reserved Instances decreases over time, by default, AWS can set prices to decrease in equal increments month over month. However, you can set different upfront prices based on when your reservation sells. For example, if your Reserved Instance has nine months of its term remaining, you can specify the amount that you would accept if a customer were to purchase that Reserved Instance with nine months remaining. You could set another price with five months remaining, and yet another price with one month remaining.

The minimum allowed price in the Reserved Instance Marketplace is $0.00.

- **Limits –** The following limits for selling Reserved Instances apply to the *lifetime* of your AWS account. They are not annual limits and they can't be increased.
  - **You can sell up to $50,000 in Reserved Instances**.
  - **You can sell up to 5,000 Reserved Instances**.
- **Can't modify –** You cannot modify your listing directly. However, you can change your listing by first canceling it and then creating another listing with new parameters.
- **Can cancel –** You can cancel your listing at any time, as long as it's in the `active` state. You cannot cancel the listing if it's already matched or being processed for a sale. If some of the instances in your listing are matched and you cancel the listing, only the remaining unmatched instances are removed from the listing.

List your Reserved Instances

As a registered seller, you can choose to sell one or more of your Reserved Instances. You can choose to sell all of them in one listing or in portions. In addition, you can list Reserved Instances with any configuration of instance type, platform, and scope.

The console determines a suggested price. It checks for offerings that match your Reserved Instance and matches the one with the lowest price. Otherwise, it calculates a suggested price based on the cost of the Reserved Instance for its remaining time. If the calculated value is less than $1.01, the suggested price is $1.01.

If you cancel your listing and a portion of that listing has already been sold, the cancellation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

Console

To list a Reserved Instance in the Reserved Instance Marketplace

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instances to list, and choose **Actions**, **Sell Reserved Instances**.
4. On the **Configure Your Reserved Instance Listing** page, set the number of instances to sell and the upfront price for the remaining term in the relevant columns. See how the value of your reservation changes over the remainder of the term by selecting the arrow next to the **Months Remaining** column.
5. If you are an advanced user and you want to customize the pricing, you can enter different values for the subsequent months. To return to the default linear price drop, choose **Reset**.
6. Choose **Continue** when you are finished configuring your listing.
7. Confirm the details of your listing, on the **Confirm Your Reserved Instance Listing** page and if you're satisfied, choose **List Reserved Instance**.

To view your listings in the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance that you've listed and choose the **My Listings** tab near the bottom of the page.

AWS CLI

To manage Reserved Instances in the Reserved Instance Marketplace

1. Get a list of your Reserved Instances by using the describe-reserved-instances command. Note that ID of the Reserved Instance that you want to list.
2. Use the create-reserved-instances-listing command. You must specify the ID of the Reserved Instance, the number of instances, and the pricing schedule.
3. To view your listing, use the describe-reserved-instances-listings command.
4. To cancel your listing, use the cancel-reserved-instances-listing command.

PowerShell

To manage Reserved Instances in the Reserved Instance Marketplace

1. Get a list of your Reserved Instances by using the Get-EC2ReservedInstance cmdlet. Note that ID of the Reserved Instance that you want to list.
2. Use the New-EC2ReservedInstancesListing cmdlet. You must specify the ID of the Reserved Instance, the number of instances, and the pricing schedule.
3. To view your listing, use the Get-EC2ReservedInstancesListing cmdlet.
4. To cancel your listing, use the Stop-EC2ReservedInstancesListing cmdlet.

Reserved Instance listing states

Listing State on the **My Listings** tab of the Reserved Instances page displays the current status of your listings:

The information displayed by **Listing State** is about the status of your listing in the Reserved Instance Marketplace. It is different from the status information that is displayed by the **State** column in the **Reserved Instances** page. This **State** information is about your reservation.

- **active**—The listing is available for purchase.
- **canceled**—The listing is canceled and isn't available for purchase in the Reserved Instance Marketplace.
- **closed**—The Reserved Instance is not listed. A Reserved Instance might be `closed` because the sale of the listing was completed.

Lifecycle of a listing

When all the instances in your listing are matched and sold, the **My Listings** tab shows that the **Total instance count** matches the count listed under **Sold**. Also, there are no **Available** instances left for your listing, and its **Status** is `closed`.

When only a portion of your listing is sold, AWS retires the Reserved Instances in the listing and creates the number of Reserved Instances equal to the Reserved Instances remaining in the count. So, the listing ID and the listing that it represents, which now has fewer reservations for sale, is still active.

Any future sales of Reserved Instances in this listing are processed this way. When all the Reserved Instances in the listing are sold, AWS marks the listing as `closed`.

For example, you create a listing *Reserved Instances listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample* with a listing count of 5.

The **My Listings** tab in the **Reserved Instance** console page displays the listing this way:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total reservation count = 5
- Sold = 0
- Available = 5
- Status = active

A buyer purchases two of the reservations, which leaves a count of three reservations still available for sale. Because of this partial sale, AWS creates a new reservation with a count of three to represent the remaining reservations that are still for sale.

This is how your listing looks in the **My Listings** tab:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total reservation count = 5
- Sold = 2
- Available = 3
- Status = active

If you cancel your listing and a portion of that listing has already sold, the cancelation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

After your Reserved Instance is sold

When your Reserved Instance is sold, AWS sends you an email notification. Each day that there is any kind of activity, you receive one email notification capturing all the activities of the day. Activities can include when you create or sell a listing, or when AWS sends funds to your account.

Console

To track the status of a Reserved Instance listing

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation page, choose **Reserved Instances**.
3. On the **My Listings** tab, find the value of **Listing State**. The tab also contains information about the term, listing price, and a breakdown of how many instances in the listing are available, pending, sold, and canceled.

AWS CLI

To track the status of a Reserved Instance listing

Use the describe-reserved-instances-listings command with the appropriate filter to obtain information about your listings.

```
aws ec2 describe-reserved-instances-listings
```

PowerShell

To track the status of a Reserved Instance listing

Use the Get-EC2ReservedInstancesListing cmdlet.

```
Get-EC2ReservedInstancesListing
```

Getting paid

As soon as AWS receives funds from the buyer, a message is sent to the registered owner account email for the sold Reserved Instance.

AWS sends an Automated Clearing House (ACH) wire transfer to your specified bank account. Typically, this transfer occurs between one to three days after your Reserved Instance has been sold. Disbursements take place once a day. You will receive an email with a disbursement report after the funds are released. Keep in mind that you can't receive disbursements until AWS receives verification from your bank. This can take up to two weeks.

The Reserved Instance that you sold continues to appear when you describe your Reserved Instances.

You receive a cash disbursement for your Reserved Instances through a wire transfer directly into your bank account. AWS charges a service fee of 12 percent of the total upfront price of each Reserved Instance you sell in the Reserved Instance Marketplace.

Information shared with the buyer

When you sell in the Reserved Instance Marketplace, AWS shares your company's legal name on the buyer's statement in accordance with US regulations. In addition, if the buyer calls Support because the buyer needs to contact you for an invoice or for some other tax-related reason, AWS might need to provide the buyer with your email address so that the buyer can contact you directly.

For similar reasons, the buyer's ZIP code and country information are provided to the seller in the disbursement report. As a seller, you might need this information to accompany any necessary transaction taxes that you remit to the government (such as sales tax and value-added tax).

AWS cannot offer tax advice, but if your tax specialist determines that you need specific additional information, contact Support.

Modify Reserved Instances

When your needs change, you can modify your Standard or Convertible Reserved Instances and continue to benefit from the billing benefit. You can modify attributes such as the Availability Zone, instance size (within the same instance family and generation), and scope of your Reserved Instance.

> **Note**
>
> You can also exchange a Convertible Reserved Instance for another Convertible Reserved Instance with a different configuration. For more information, see Exchange Convertible Reserved Instances.

You can modify all or a subset of your Reserved Instances. You can separate your original Reserved Instances into two or more new Reserved Instances. For example, if you have a reservation for 10 instances in `us-east-1a` and decide to move 5 instances to `us-east-1b`, the modification request results in two new reservations: one for 5 instances in `us-east-1a` and the other for 5 instances in `us-east-1b`.

You can also *merge* two or more Reserved Instances into a single Reserved Instance. For example, if you have four `t2.small` Reserved Instances of one instance each, you can merge them to create one `t2.large` Reserved Instance. For more information, see [Support for modifying instance sizes](#).

After modification, the benefit of the Reserved Instances is applied only to instances that match the new parameters. For example, if you change the Availability Zone of a reservation, the capacity reservation and pricing benefits are automatically applied to instance usage in the new Availability Zone. Instances that no longer match the new parameters are charged at the On-Demand rate, unless your account has other applicable reservations.

If your modification request succeeds:

- The modified reservation becomes effective immediately and the pricing benefit is applied to the new instances beginning at the hour of the modification request. For example, if you successfully modify your reservations at 9:15PM, the pricing benefit transfers to your new instance at 9:00PM. You can get the effective date of the modified Reserved Instances by using the describe-reserved-instances command.
- The original reservation is retired. Its end date is the start date of the new reservation, and the end date of the new reservation is the same as the end date of the original Reserved Instance. If you modify a three-year reservation that had 16 months left in its term, the resulting modified reservation is a 16-month reservation with the same end date as the original one.
- The modified reservation lists a $0 fixed price and not the fixed price of the original reservation.
- The fixed price of the modified reservation does not affect the discount pricing tier calculations applied to your account, which are based on the fixed price of the original reservation.

If your modification request fails, your Reserved Instances maintain their original configuration, and are immediately available for another modification request.

There is no fee for modification, and you do not receive any new bills or invoices.

You can modify your reservations as frequently as you like, but you cannot change or cancel a pending modification request after you submit it. After the modification has completed successfully, you can submit another modification request to roll back any changes you made, if needed.

Contents

- Submit modification requests
- Troubleshoot modification requests

Requirements and restrictions for modification

You can modify these attributes as follows.

Modifiable attribute	Supported platforms	Limitations and considerations
Change **Availability Zones** within the same Region	Linux and Windows	-
Change the **scope** from Availability Zone to Region and vice versa	Linux and Windows	A zonal Reserved Instance is scoped to an Availability Zone and reserves capacity in that Availability Zone. If you change the scope from Availability Zone to Region (in other words, from zonal to regional), you lose the capacity reservation benefit. A regional Reserved Instance is scoped to a Region. Your Reserved Instance discount can apply to instances running in any Availability Zone in that Region. Furthermore, the Reserved Instance discount applies to instance usage across all sizes in the selected instance family. If you change the scope from Region to Availability Zone (in other

Modifiable attribute	Supported platforms	Limitations and considera tions
		words, from regional to zonal), you lose Availability Zone flexibility and instance size flexibility (if applicable). For more information, see [How Reserved Instance discounts are applied].
Change the **instance size** within the same instance family and generation	Linux/UNIX only Instance size flexibility is not available for Reserved Instances on the other platforms, which include Linux with SQL Server Standard, Linux with SQL Server Web, Linux with SQL Server Enterprise, Red Hat Enterprise Linux, SUSE Linux, Windows, Windows with SQL Standard, Windows with SQL Server Enterprise, and Windows with SQL Server Web.	The reservation must use default tenancy. Some instance families are not supported, because there are no other sizes available. For more information, see [Support for modifying instance sizes]

Requirements

Amazon EC2 processes your modification request if there is sufficient capacity for your new configuration (if applicable), and if the following conditions are met:

- The Reserved Instance cannot be modified before or at the same time that you purchase it
- The Reserved Instance must be active
- There cannot be a pending modification request

- The Reserved Instance is not listed in the Reserved Instance Marketplace
- There must be a match between the instance size footprint of the original reservation and the new configuration. For more information, see Support for modifying instance sizes.
- The original Reserved Instances are all Standard Reserved Instances or all Convertible Reserved Instances, not some of each type
- The original Reserved Instances must expire within the same hour, if they are Standard Reserved Instances
- For modifying instance size, the Reserved Instance must support instance size flexibility. For the list of Reserved Instances that don't support instance size flexibility, see Instance size flexibility.

Support for modifying instance sizes

You can modify the instance size of a Reserved Instance if the following requirements are met.

Requirements

- The platform is Linux/UNIX.
- You must select another instance size in the same instance family (indicated by a letter, for example, T) and generation (indicated by a number, for example, 2).

  For example, you can modify a Reserved Instance from `t2.small` to `t2.large` because they're both in the same T2 family and generation. But you can't modify a Reserved Instance from T2 to M2 or from T2 to T3, because in both these examples, the target instance family and generation are not the same as the original Reserved Instance.
- You can modify the instance size of a Reserved Instance only if it supports instance size flexibility. For the list of Reserved Instances that don't support instance size flexibility, see Instance size flexibility.
- You can't modify the instance size of Reserved Instances for `t1.micro` instances, because `t1.micro` has only one size.
- The original and new Reserved Instance must have the same instance size footprint.

Contents

Instance size footprint

Each Reserved Instance has an *instance size footprint*, which is determined by the normalization factor of the instance size and the number of instances in the reservation. When you modify the instance sizes in an Reserved Instance, the footprint of the new configuration must match that of the original configuration, otherwise the modification request is not processed.

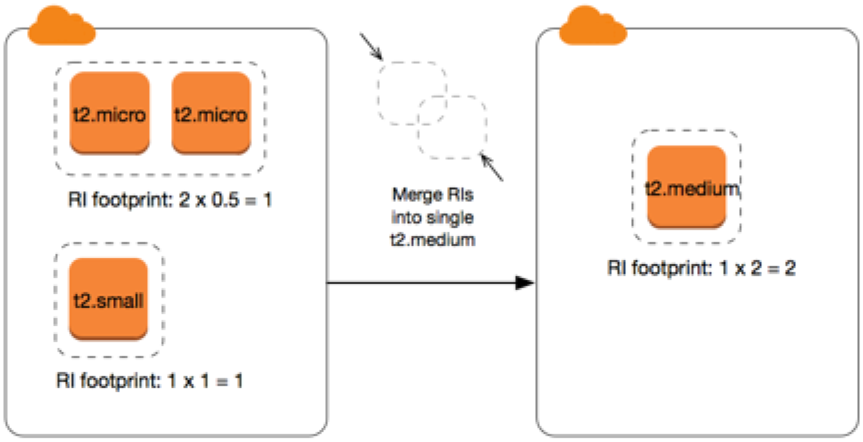
To calculate the instance size footprint of a Reserved Instance, multiply the number of instances by the normalization factor. In the Amazon EC2 console, the normalization factor is measured in units. The following table describes the normalization factor for the instance sizes in an instance family. For example, `t2.medium` has a normalization factor of 2, so a reservation for four `t2.medium` instances has a footprint of 8 units.

Instance size	Normalization factor
nano	0.25
micro	0.5
small	1
medium	2
large	4
xlarge	8
2xlarge	16
3xlarge	24
4xlarge	32
6xlarge	48
8xlarge	64
9xlarge	72
10xlarge	80

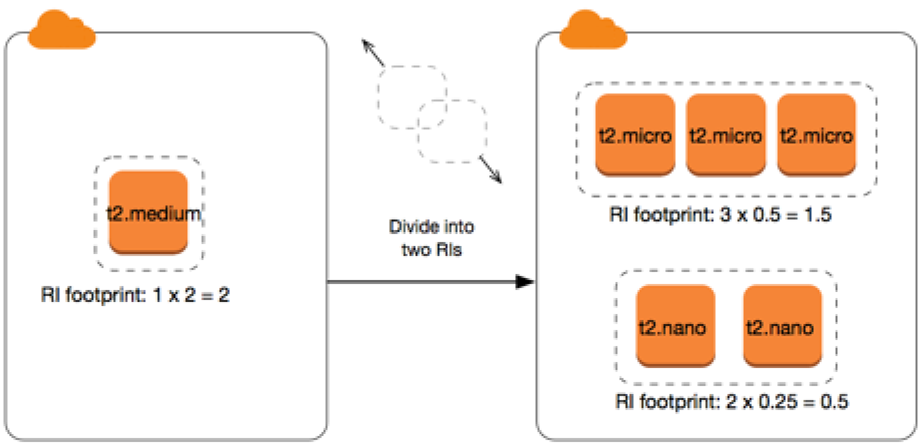
Instance size	Normalization factor
12xlarge	96
16xlarge	128
18xlarge	144
24xlarge	192
32xlarge	256
48xlarge	384
56xlarge	448
112xlarge	896

You can allocate your reservations into different instance sizes across the same instance family as long as the instance size footprint of your reservation remains the same. For example, you can divide a reservation for one `t2.large` (1 @ 4 units) instance into four `t2.small` (4 @ 1 unit) instances. Similarly, you can combine a reservation for four `t2.small` instances into one `t2.large` instance. However, you cannot change your reservation for two `t2.small` instances into one `t2.large` instance because the footprint of the new reservation (4 units) is larger than the footprint of the original reservation (2 units).

In the following example, you have a reservation with two `t2.micro` instances (1 unit) and a reservation with one `t2.small` instance (1 unit). If you merge both of these reservations to a single reservation with one `t2.medium` instance (2 units), the footprint of the new reservation equals the footprint of the combined reservations.



You can also modify a reservation to divide it into two or more reservations. In the following example, you have a reservation with a `t2.medium` instance (2 units). You can divide the reservation into two reservations, one with two `t2.nano` instances (.5 units) and the other with three `t2.micro` instances (1.5 units).



Normalization factors for bare metal instances

You can modify a reservation with `metal` instances using other sizes within the same instance family. Similarly, you can modify a reservation with instances other than bare metal instances using the `metal` size within the same instance family. Generally, a bare metal instance is the same size as the largest available instance size within the same instance family. For example, an `i3.metal` instance is the same size as an `i3.16xlarge` instance, so they have the same normalization factor.

The following table describes the normalization factor for the bare metal instance sizes in the instance families that have bare metal instances. The normalization factor for `metal` instances depends on the instance family, unlike the other instance sizes.

Instance size	Normalization factor
a1.metal	32
m5zn.metal | x2iezn.metal z1d.metal	96
c6g.metal | c6gd.metal | i3.metal | m6g.metal | m6gd.metal | r6g.metal | r6gd.metal | x2gd.metal	128
c5n.metal	144
c5.metal | c5d.metal | i3en.metal | m5.metal | m5d.metal | m5dn.metal | m5n.metal | r5.metal | r5b.metal | r5d.metal | r5dn.metal | r5n.metal	192
c6i.metal | c6id.metal | m6i.metal | m6id.metal | r6d.metal | r6id.metal	256
u-18tb1.metal | u-24tb1.metal	448
u-6tb1.metal | u-9tb1.metal | u-12tb1.metal	896

For example, an `i3.metal` instance has a normalization factor of 128. If you purchase an `i3.metal` default tenancy Amazon Linux/Unix Reserved Instance, you can divide the reservation as follows:

- An `i3.16xlarge` is the same size as an `i3.metal` instance, so its normalization factor is 128 (128/1). The reservation for one `i3.metal` instance can be modified into one `i3.16xlarge` instance.
- An `i3.8xlarge` is half the size of an `i3.metal` instance, so its normalization factor is 64 (128/2). The reservation for one `i3.metal` instance can be divided into two `i3.8xlarge` instances.
- An `i3.4xlarge` is a quarter the size of an `i3.metal` instance, so its normalization factor is 32 (128/4). The reservation for one `i3.metal` instance can be divided into four `i3.4xlarge` instances.

Submit modification requests

Before you modify your Reserved Instances, ensure that you have read the applicable restrictions. Before you modify the instance size, calculate the total instance size footprint of the original reservations that you want to modify and ensure that it matches the total instance size footprint of your new configurations.

Console

To modify your Reserved Instances

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the **Reserved Instances** page, select one or more Reserved Instances to modify, and choose **Actions**, **Modify Reserved Instances**.

   If your Reserved Instances are not in the active state or cannot be modified, **Modify Reserved Instances** is disabled.
3. The first entry in the modification table displays attributes of the selected Reserved Instances, and at least one target configuration beneath it. The **Units** column displays the total instance size footprint. Choose **Add** for each new configuration to add. Modify the attributes as needed for each configuration.
   - **Scope**: Choose whether the configuration applies to an Availability Zone or to the whole Region.
   - **Availability Zone**: Choose the required Availability Zone. Not applicable for regional Reserved Instances.
   - **Instance type**: Select the required instance type. The combined configurations must equal the instance size footprint of your original configurations.
   - **Count**: Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose **Add**, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.
4. Choose **Continue**.
5. To confirm your modification choices when you finish specifying your target configurations, choose **Submit modifications**.

6. You can determine the status of your modification request by looking at the **State** column in the Reserved Instances screen. The following are the possible states.

   - **active *(pending modification)*** — Transition state for original Reserved Instances
   - **retired *(pending modification)*** — Transition state for original Reserved Instances while new Reserved Instances are being created
   - **retired** — Reserved Instances successfully modified and replaced
   - **active** — One of the following:
     - New Reserved Instances created from a successful modification request
     - Original Reserved Instances after a failed modification request

AWS CLI

To modify your Reserved Instances

Use the modify-reserved-instances command. You can provide the configuration details in a JSON file.

```
aws ec2 modify-reserved-instances \
    --reserved-instances-ids b847fa93-e282-4f55-b59a-1342f5bd7c02 \
    --target-configurations file://configuration.json
```

To get the status of your modification request

Use the describe-reserved-instances-modifications command. The status is `processing`, `fulfilled`, or `failed`.

```
aws ec2 describe-reserved-instances-modifications \
    --reserved-instances-modification-ids rimod-d3ed4335-b1d3-4de6-ab31-0f13aaf46687
 \
    --query ReservedInstancesModifications[].Status
```

PowerShell

To modify your Reserved Instances

Use the Edit-EC2ReservedInstance cmdlet. You can provide the configuration details in an object of type `Amazon.EC2.Model.ReservedInstancesConfiguration`.

```
Edit-EC2ReservedInstance `
    -ReservedInstancesId b847fa93-e282-4f55-b59a-1342f5bd7c02 `
    -TargetConfiguration $configuration
```

To get the status of your modification request

Use the Get-EC2ReservedInstancesModification cmdlet. The status is `processing`, `fulfilled`, or `failed`.

```
Get-EC2ReservedInstancesModification `
    -ReservedInstancesModificationId rimod-d3ed4335-b1d3-4de6-ab31-0f13aaf46687 | `
    Select Status
```

Troubleshoot modification requests

If the target configuration settings that you requested were unique, you receive a message that your request is being processed. At this point, Amazon EC2 has only determined that the parameters of your modification request are valid. Your modification request can still fail during processing due to unavailable capacity.

In some situations, you might get a message indicating incomplete or failed modification requests instead of a confirmation. Use the information in such messages as a starting point for resubmitting another modification request. Ensure that you have read the applicable restrictions before submitting the request.

Not all selected Reserved Instances can be processed for modification

Amazon EC2 identifies and lists the Reserved Instances that cannot be modified. If you receive a message like this, go to the **Reserved Instances** page in the Amazon EC2 console and check the information for the Reserved Instances.

Error in processing your modification request

You submitted one or more Reserved Instances for modification and none of your requests can be processed. Depending on the number of reservations you are modifying, you can get different versions of the message.

Amazon EC2 displays the reasons why your request cannot be processed. For example, you might have specified the same target configuration—a combination of Availability Zone and platform

—for one or more subsets of the Reserved Instances you are modifying. Try submitting the modification requests again, but ensure that the instance details of the reservations match, and that the target configurations for all subsets being modified are unique.

Exchange Convertible Reserved Instances

You can exchange one or more Convertible Reserved Instances for another Convertible Reserved Instance with a different configuration, including instance family, operating system, and tenancy. There are no limits to how many times you perform an exchange, as long as the new Convertible Reserved Instance is of an equal or higher value than the Convertible Reserved Instances that you are exchanging.

When you exchange your Convertible Reserved Instance, the number of instances for your current reservation is exchanged for a number of instances that cover the equal or higher value of the configuration of the new Convertible Reserved Instance. Amazon EC2 calculates the number of Reserved Instances that you can receive as a result of the exchange.

You can't exchange Standard Reserved Instances, but you can modify them. For more information, see Modify Reserved Instances .

Contents

Requirements for exchanging Convertible Reserved Instances

If the following conditions are met, Amazon EC2 processes your exchange request. Your Convertible Reserved Instance must be:

- Active
- Not pending a previous exchange request
- Have at least 24 hours remaining before it expires

The following rules apply:

- Convertible Reserved Instances can only be exchanged for other Convertible Reserved Instances currently offered by AWS.
- Convertible Reserved Instances are associated with a specific Region, which is fixed for the duration of the reservation's term. You cannot exchange a Convertible Reserved Instance for a Convertible Reserved Instance in a different Region.
- You can exchange one or more Convertible Reserved Instances at a time for one Convertible Reserved Instance only.
- To exchange a portion of a Convertible Reserved Instance, you can modify it into two or more reservations, and then exchange one or more of the reservations for a new Convertible Reserved Instance. For more information, see Exchange a portion of a Convertible Reserved Instance. For more information about modifying your Reserved Instances, see Modify Reserved Instances.
- All Upfront Convertible Reserved Instances can be exchanged for Partial Upfront Convertible Reserved Instances, and vice versa.

> **Note**
>
> If the total upfront payment required for the exchange (true-up cost) is less than $0.00, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that true-up cost is $0.00 or more.

> **Note**
>
> If the total value (upfront price + hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- To benefit from better pricing, you can exchange a No Upfront Convertible Reserved Instance for an All Upfront or Partial Upfront Convertible Reserved Instance.
- You cannot exchange All Upfront and Partial Upfront Convertible Reserved Instances for No Upfront Convertible Reserved Instances.
- You can exchange a No Upfront Convertible Reserved Instance for another No Upfront Convertible Reserved Instance only if the new Convertible Reserved Instance's hourly price is the same or higher than the exchanged Convertible Reserved Instance's hourly price.

> **Note**
>
> If the total value (hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- If you exchange multiple Convertible Reserved Instances that have different expiration dates, the expiration date for the new Convertible Reserved Instance is the date that's furthest in the future.
- If you exchange a single Convertible Reserved Instance, it must have the same term (1-year or 3-years) as the new Convertible Reserved Instance. If you merge multiple Convertible Reserved Instances with different term lengths, the new Convertible Reserved Instance has a 3-year term. For more information, see Merge Convertible Reserved Instances.
- When Amazon EC2 exchanges a Convertible Reserved Instance, it retires the associated reservation, and transfers the end date to the new reservation. After the exchange, Amazon EC2 sets both the end date for the old reservation and the start date for the new reservation equal to the date of the exchange. For example, if you exchange a three-year reservation that had 16 months left in its term, the new reservation is a 16-month reservation with the same end date as the reservation from the Convertible Reserved Instance that you exchanged.

Calculate Convertible Reserved Instances exchanges

Exchanging Convertible Reserved Instances is free. However, you might be required to pay a true-up cost, which is a prorated upfront cost of the difference between the Convertible Reserved Instances that you had and the new Convertible Reserved Instances that you receive from the exchange.

Each Convertible Reserved Instance has a list value. This list value is compared to the list value of the Convertible Reserved Instances that you want in order to determine how many instance reservations you can receive from the exchange.

For example: You have 1 x $35-list value Convertible Reserved Instance that you want to exchange for a new instance type with a list value of $10.

```
$35/$10 = 3.5
```

You can exchange your Convertible Reserved Instance for three $10 Convertible Reserved Instances. It's not possible to purchase half reservations; therefore you must purchase an additional Convertible Reserved Instance to cover the remainder:

```
3.5 = 3 whole Convertible Reserved Instances + 1 additional Convertible Reserved
 Instance
```

The fourth Convertible Reserved Instance has the same end date as the other three. If you are exchanging Partial or All Upfront Convertible Reserved Instances, you pay the true-up cost for the fourth reservation. If the remaining upfront cost of your Convertible Reserved Instances is $500, and the new reservation would normally cost $600 on a prorated basis, you are charged $100.

```
$600 prorated upfront cost of new reservations - $500 remaining upfront cost of old
 reservations = $100 difference
```

Merge Convertible Reserved Instances

If you merge two or more Convertible Reserved Instances, the term of the new Convertible Reserved Instance must be the same as the old Convertible Reserved Instances, or the highest of the Convertible Reserved Instances. The expiration date for the new Convertible Reserved Instance is the expiration date that's furthest in the future.

For example, you have the following Convertible Reserved Instances in your account:

Reserved Instance ID	Term	Expiration date
aaaa1111	1-year	2018-12-31
bbbb2222	1-year	2018-07-31
cccc3333	3-year	2018-06-30
dddd4444	3-year	2019-12-31

- You can merge aaaa1111 and bbbb2222 and exchange them for a 1-year Convertible Reserved Instance. You cannot exchange them for a 3-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-12-31.
- You can merge bbbb2222 and cccc3333 and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-07-31.
- You can merge cccc3333 and dddd4444 and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2019-12-31.

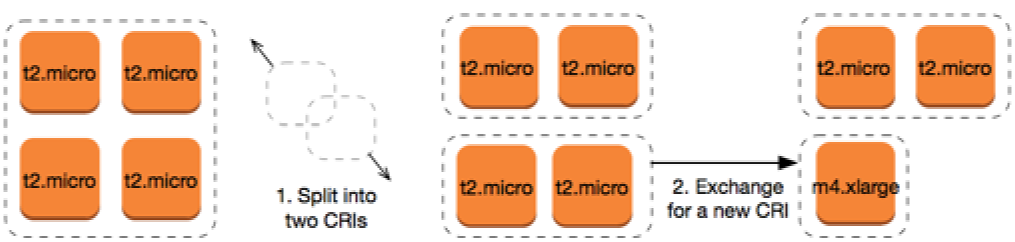
Exchange a portion of a Convertible Reserved Instance

You can use the modification process to split your Convertible Reserved Instance into smaller reservations, and then exchange one or more of the new reservations for a new Convertible Reserved Instance. The following examples demonstrate how you can do this.

Example Example: Convertible Reserved Instance with multiple instances

In this example, you have a `t2.micro` Convertible Reserved Instance with four instances in the reservation. To exchange two `t2.micro` instances for an `m4.xlarge` instance:

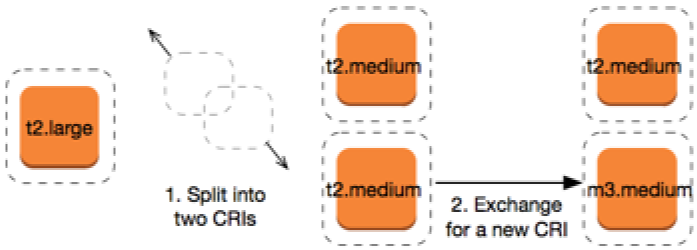
1. Modify the `t2.micro` Convertible Reserved Instance by splitting it into two `t2.micro` Convertible Reserved Instances with two instances each.
2. Exchange one of the new `t2.micro` Convertible Reserved Instances for an `m4.xlarge` Convertible Reserved Instance.



Example Example: Convertible Reserved Instance with a single instance

In this example, you have a `t2.large` Convertible Reserved Instance. To change it to a smaller `t2.medium` instance and a `m3.medium` instance:

1. Modify the `t2.large` Convertible Reserved Instance by splitting it into two `t2.medium` Convertible Reserved Instances. A single `t2.large` instance has the same instance size footprint as two `t2.medium` instances.
2. Exchange one of the new `t2.medium` Convertible Reserved Instances for an `m3.medium` Convertible Reserved Instance.



For more information, see Support for modifying instance sizes and Submit exchange requests.

Submit exchange requests

You can exchange your Convertible Reserved Instances. Reserved Instances that are exchanged are retired.

Console

To exchange Convertible Reserved Instances

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Reserved Instances**, select the Convertible Reserved Instances to exchange, and choose **Actions**, **Exchange Reserved Instance**.
3. Select the attributes of the desired configuration, and choose **Find offering**.
4. Select a new Convertible Reserved Instance. At the bottom of the screen, you can view the number of Reserved Instances that you receive for the exchange, and any additional costs.
5. When you have selected a Convertible Reserved Instance that meets your needs, choose **Review**.
6. Choose **Exchange**, and then **Close**.

AWS CLI

To exchange a Convertible Reserved Instance

1. Find a new Convertible Reserved Instance that meets your needs by using the describe-reserved-instances-offerings command.
2. Get a quote for the exchange by using the get-reserved-instances-exchange-quote command. This includes the number of Reserved Instances you get from the exchange, and the true-up cost for the exchange:
3. Perform the exchange by using the accept-reserved-instances-exchange-quote command.

PowerShell

To exchange a Convertible Reserved Instance

1. Find a new Convertible Reserved Instance that meets your needs by using the Get-EC2ReservedInstancesOffering cmdlet.
2. Get a quote for the exchange by using the GetEC2-ReservedInstancesExchangeQuote cmdlet. This includes the number of Reserved Instances you get from the exchange, and the true-up cost for the exchange:
3. Perform the exchange by using the Approve-EC2ReservedInstancesExchangeQuote cmdlet

Reserved Instance quotas

You can purchase new Reserved Instances each month. The number of new Reserved Instances that you can purchase each month is determined by your monthly quota, as follows:

Quota description	Default quota
New regional Reserved Instances	20 per Region per month
New zonal Reserved Instances	20 per Availability Zone per month

For example, in a Region with three Availability Zones, the default quota is 80 new Reserved Instances per month, calculated as follows:

- 20 regional Reserved Instances for the Region

- Plus 60 zonal Reserved Instances (20 for each of the three Availability Zones)

Instances in the `running` state count toward your quota. Instances that are in the `pending`, `stopping`, `stopped`, and `hibernated` states do not count towards your quota.

View the number of Reserved Instances you have purchased

The number of Reserved Instances that you purchase is indicated by the **Instance count** field (console) or the `InstanceCount` parameter (AWS CLI). When you purchase new Reserved Instances, the quota is measured against the total instance count. For example, if you purchase a single Reserved Instance configuration with an instance count of 10, the purchase counts towards your quota as 10, not 1.

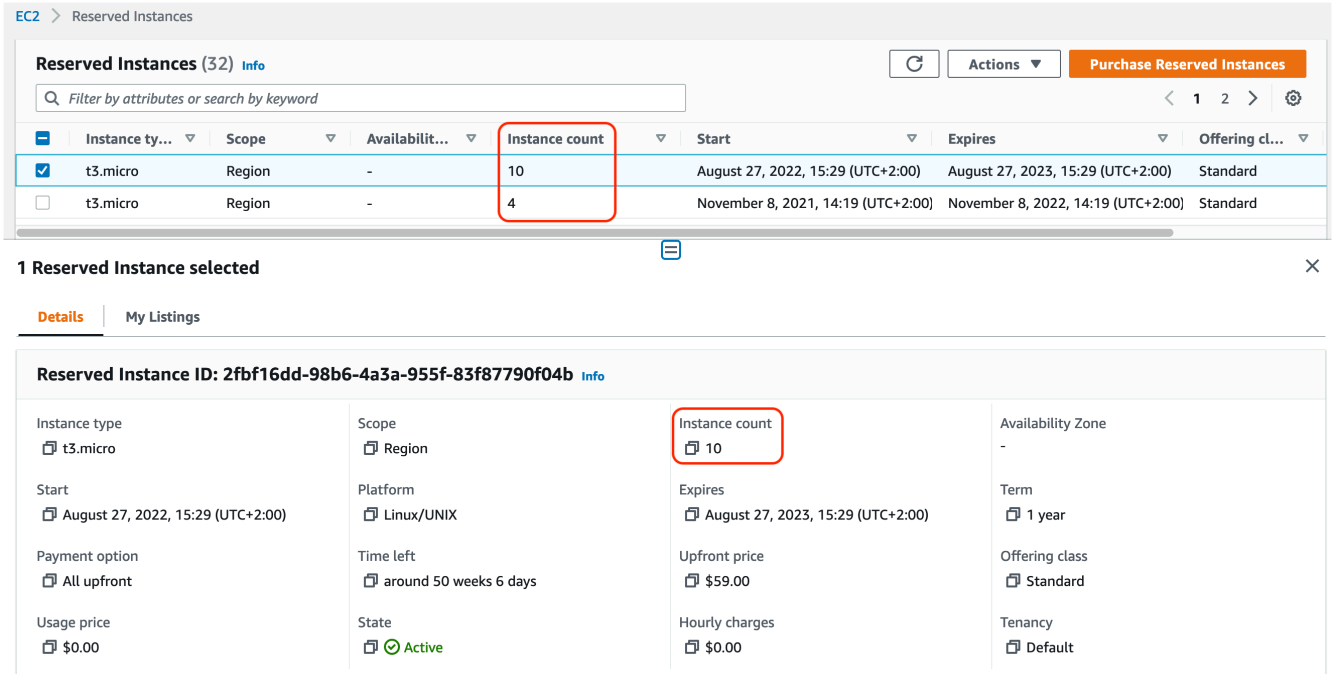
You can view how many Reserved Instances you have purchased by using the Amazon EC2 or the AWS CLI.

Console

To view the number of Reserved Instances you have purchased

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Reserved Instances**.
3. Select a Reserved Instance configuration from the table, and check the **Instance count** field.

   In the following screenshot, the selected line represents a single Reserved Instance configuration for a `t3.micro` instance type. The **Instance count** column in the table view and the **Instance count** field in the detail view (outlined in the screenshot) indicate that there are 10 Reserved Instances for this configuration.



AWS CLI

To view the number of Reserved Instances you have purchased

Use the describe-reserved-instances command and specify the ID of the Reserved Instance configuration.

```
aws ec2 describe-reserved-instances \
    --reserved-instances-ids a1b2c3d4-5678-90ab-cdef-EXAMPLE11111 \
    --output table
```

The following is example output. The `InstanceCount` field indicates that there are 10 Reserved Instances for this configuration.

```

```

Considerations

A regional Reserved Instance applies a discount to a running On-Demand Instance. The default On-Demand Instance limit is 20. You cannot exceed your running On-Demand Instance limit by purchasing regional Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 regional Reserved Instances, the 20 regional Reserved Instances are used to apply a discount to the 20 running On-Demand Instances. If you purchase more regional Reserved Instances, you will not be able to launch more instances because you have reached your On-Demand Instance limit.

Before purchasing regional Reserved Instances, make sure your On-Demand Instance limit matches or exceeds the number of regional Reserved Instances you intend to own. If required, make sure you request an increase to your On-Demand Instance limit *before* purchasing more regional Reserved Instances.

A zonal Reserved Instance—a Reserved Instance that is purchased for a specific Availability Zone —provides a capacity reservation as well as a discount. You *can exceed* your running On-Demand Instance limit by purchasing zonal Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 zonal Reserved Instances, you can launch a further 20 On-Demand Instances that match the specifications of your zonal Reserved Instances, giving you a total of 40 running instances.

View your Reserved Instance quotas and request a quota increase

The Amazon EC2 console provides quota information. You can also request an increase in your quotas. For more information, see View your current quotas and Request an increase.

Spot Instances

A Spot Instance is an instance that uses spare EC2 capacity that is available for less than the On-Demand price. Because Spot Instances enable you to request unused EC2 instances at steep discounts, you can lower your Amazon EC2 costs significantly. The hourly price for a Spot Instance is called a Spot price. The Spot price of each instance type in each Availability Zone is set by Amazon EC2, and is adjusted gradually based on the long-term supply of and demand for Spot Instances. Your Spot Instance runs whenever capacity is available.

Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if your applications can be interrupted. For example, Spot Instances are well-suited for data analysis, batch jobs, background processing, and optional tasks. For more information, see Amazon EC2 Spot Instances.

For a comparison of the different purchasing options for EC2 instances, see Amazon EC2 billing and purchasing options.

Concepts

Before you get started with Spot Instances, you should be familiar with the following concepts:

- *Spot capacity pool* – A set of unused EC2 instances with the same instance type (for example, `m5.large`) and Availability Zone.
- *Spot price* – The current price of a Spot Instance per hour.
- *Spot Instance request* – Requests a Spot Instance. When capacity is available, Amazon EC2 fulfills your request. A Spot Instance request is either *one-time* or *persistent*. Amazon EC2 automatically resubmits a persistent Spot Instance request after the Spot Instance associated with the request is interrupted.
- *EC2 instance rebalance recommendation* – Amazon EC2 emits an instance rebalance recommendation signal to notify you that a Spot Instance is at an elevated risk of interruption. This signal provides an opportunity to proactively rebalance your workloads across existing or new Spot Instances without having to wait for the two-minute Spot Instance interruption notice.
- *Spot Instance interruption* – Amazon EC2 terminates, stops, or hibernates your Spot Instance when Amazon EC2 needs the capacity back. Amazon EC2 provides a Spot Instance interruption notice, which gives the instance a two-minute warning before it is interrupted.

Differences between Spot Instances and On-Demand Instances

The following table lists the key differences between Spot Instances and On-Demand Instances.

	Spot Instances	On-Demand Instances

	Spot Instances	On-Demand Instances
Launch time	Can only be launched immediately if the Spot Instance request is active and capacity is available.	Can only be launched immediately if you make a manual launch request and capacity is available.
Available capacity	If capacity is not available, the Spot Instance request continues to automatically make the launch request until capacity becomes available.	If capacity is not available when you make a launch request, you get an insufficient capacity error (ICE).
Hourly price	The hourly price for Spot Instances varies based on long-term supply and demand.	The hourly price for On-Demand Instances is static.
Rebalance recommendation	The signal that Amazon EC2 emits for a running Spot Instance when the instance is at an elevated risk of interruption.	You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).
Instance interruption	You can stop and start an Amazon EBS-backed Spot Instance. In addition, Amazon EC2 can interrupt an individual Spot Instance if capacity is no longer available.	You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).

Pricing and savings

You pay the Spot price for Spot Instances, which is set by Amazon EC2 and adjusted gradually based on the long-term supply of and demand for Spot Instances. Your Spot Instances run until you terminate them, capacity is no longer available, or your Amazon EC2 Auto Scaling group terminates them during scale in.

If you or Amazon EC2 interrupts a running Spot Instance, you are charged for the seconds used or the full hour, or you receive no charge, depending on the operating system used and who interrupted the Spot Instance. For more information, see Billing for interrupted Spot Instances.

Spot Instances are not covered by Savings Plans. If you have a Savings Plans, it does not provide additional savings on top of the savings that you already get from using Spot Instances. Furthermore, your spend on Spot Instances does not apply the commitments in your Compute Savings Plans.

View prices

To view the current (updated every five minutes) lowest Spot price per AWS Region and instance type, see the Amazon EC2 Spot Instances Pricing page.

To view the Spot price history for the past three months, use the Amazon EC2 console or the describe-spot-price-history command. For more information, see View Spot Instance pricing history.

We independently map Availability Zones to codes for each AWS account. Therefore, you can get different results for the same Availability Zone code (for example, `us-west-2a`) between different accounts.

View savings

You can view the savings made from using Spot Instances for a single Spot Fleet or for all Spot Instances. You can view the savings made in the last hour or the last three days, and you can view the average cost per vCPU hour and per memory (GiB) hour. Savings are estimated and may differ from actual savings because they do not include the billing adjustments for your usage. For more information about viewing savings information, see Savings from purchasing Spot Instances.

View billing

Your bill provides details about your service usage. For more information, see Viewing your bill in the *AWS Billing User Guide*.

Best practices for Amazon EC2 Spot

Amazon EC2 provides access to spare EC2 compute capacity in the AWS Cloud through Spot Instances at savings of up to 90% compared to On-Demand prices. The only difference between On-Demand Instances and Spot Instances is that Spot Instances can be interrupted by Amazon EC2, with two minutes of notice, if Amazon EC2 needs to reclaim the capacity. To ensure the best experience with Spot Instances, it's important to understand and apply best practices for their use.

Spot Instances are recommended for stateless, fault-tolerant, flexible applications. For example, Spot Instances work well for big data, containerized workloads, CI/CD, stateless web servers, high performance computing (HPC), and rendering workloads.

While running, Spot Instances are exactly the same as On-Demand Instances. However, Spot does not guarantee that you can keep your running instances long enough to finish your workloads. Spot also does not guarantee that you can get immediate availability of the instances that you are looking for, or that you can always get the aggregate capacity that you requested. Moreover, Spot Instance interruptions and capacity can change over time because Spot Instance availability varies based on supply and demand, and past performance isn't a guarantee of future results.

Spot Instances are not suitable for workloads that are inflexible, stateful, fault-intolerant, or tightly coupled between instance nodes. We do not recommend Spot Instances for workloads that are intolerant of occasional periods when the entire target capacity is not completely available. While following Spot best practices to be flexible about instance types and Availability Zones provides the best chance for high availability, there are no guarantees that capacity will be available, because surges in demand for On-Demand Instances can disrupt workloads on Spot Instances.

We strongly discourage using Spot Instances for these workloads or attempting to fail over to On-Demand Instances to handle interruptions or periods of unavailability. Failing over to On-Demand Instances can inadvertently drive interruptions for your other Spot Instances. In addition if Spot Instances for a combination of instance type and Availability Zone get interrupted, it might become difficult for you to get On-Demand Instances with that same combination.

Regardless of whether you're an experienced Spot user or new to Spot Instances, if you are currently experiencing issues with Spot Instance interruptions or availability, we recommend that you follow these best practices to have the best experience using the Spot service.

Spot best practices

- Prepare individual instances for interruptions
- Be flexible about instance types and Availability Zones
- Use attribute-based instance type selection
- Use Spot placement scores to identify optimal Regions and Availability Zones
- Use EC2 Auto Scaling groups or EC2 Fleet to manage your aggregate capacity
- Use the price and capacity optimized allocation strategy
- Use integrated AWS services to manage your Spot Instances
- Which is the best Spot request method to use?

Prepare individual instances for interruptions

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of EC2 instance rebalance recommendations and Spot Instance interruption notices.

An EC2 Instance rebalance recommendation is a signal that notifies you when a Spot Instance is at an elevated risk of interruption. The signal gives you the opportunity to proactively manage the Spot Instance in advance of the two-minute Spot Instance interruption notice. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption. We've made it easy for you to use this signal by using the Capacity Rebalancing feature in Auto Scaling groups and EC2 Fleet.

A Spot Instance interruption notice is a warning that is issued two minutes before Amazon EC2 interrupts a Spot Instance. If your workload is "time-flexible," you can configure your Spot Instances to be stopped or hibernated, instead of being terminated, when they are interrupted. Amazon EC2 automatically stops or hibernates your Spot Instances on interruption, and automatically resumes the instances when we have available capacity.

We recommend that you create a rule in Amazon EventBridge that captures the rebalance recommendations and interruption notifications, and then triggers a checkpoint for the progress of your workload or gracefully handles the interruption. For more information, see Monitor rebalance recommendation signals. For a detailed example that walks you through how to create and use event rules, see Taking Advantage of Amazon EC2 Spot Instance Interruption Notices.

For more information, see EC2 instance rebalance recommendations and Spot Instance interruptions.

Be flexible about instance types and Availability Zones

A Spot capacity pool is a set of unused EC2 instances with the same instance type (for example, `m5.large`) and Availability Zone (for example, us-east-1a). You should be flexible about which instance types you request and in which Availability Zones you can deploy your workload. This gives Spot a better chance to find and allocate your required amount of compute capacity. For example, don't just ask for `c5.large` if you'd be willing to use larges from the c4, m5, and m4 families.

Depending on your specific needs, you can evaluate which instance types you can be flexible across to fulfill your compute requirements. If a workload can be vertically scaled, you should include larger instance types (more vCPUs and memory) in your requests. If you can only scale horizontally, you should include older generation instance types because they are less in demand from On-Demand customers.

A good rule of thumb is to be flexible across at least 10 instance types for each workload. In addition, make sure that all Availability Zones are configured for use in your VPC and selected for your workload.

Use attribute-based instance type selection

With attribute-based instance type selection, you can specify instance attributes—such as vCPUs, memory, and storage—for the workload you want to run. EC2 Auto Scaling or EC2 Fleet will then automatically identify and launch instances that match your specified attributes. This removes the effort required to manually select specific instance types, which requires an in-depth understanding of each instance type's offering.

Moreover, attribute-based instance type selection enables you to automatically use newly released instance types as they become available. This ensures seamless access to an increasingly broad range of Spot Instance capacity.

Attribute-based instance type selection is ideal for workloads and frameworks that can be flexible about the instance types they run on, such as High Performance Computing (HPC) and big data workloads.

For more information, see Create mixed instances group using attribute-based instance type selection in the *Amazon EC2 Auto Scaling User Guide* and Specify attributes for instance type selection for EC2 Fleet or Spot Fleet in this guide.

Use Spot placement scores to identify optimal Regions and Availability Zones

Spot Instances are unused EC2 capacity, and this capacity fluctuates based on EC2 supply and demand. As a result, you might not always get the exact Spot capacity that you require in a specific location at a specific time. To mitigate this unpredictability, you can use the Spot placement score feature. This feature provides recommendations for Regions or Availability Zones that are more likely to have sufficient capacity to meet your Spot capacity needs without requiring you to launch Spot Instances in those locations first.

Spot placement score is best used for workloads that can be flexible about the instance types and the Region or Availability Zone they can use. All you need to do is specify the Spot capacity that you need, your instance type requirements, and whether you want a recommendations for Regions or Availability Zones. In return, you receive a score ranging from 1 to 10 for each Region or Availability Zone, indicating the likelihood of successfully provisioning your requested Spot capacity in that location. A score of 10 indicates that your Spot request is highly likely to succeed.

It's important to note that a Spot placement score is a point-in-time recommendation, because capacity can vary over time. It does not guarantee available capacity or predict the risk of interruption.

You can use the Spot placement score feature in the Amazon EC2 console, AWS CLI, or an SDK. For more information, see Spot placement score.

Use EC2 Auto Scaling groups or EC2 Fleet to manage your aggregate capacity

Spot enables you to think in terms of aggregate capacity—in units that include vCPUs, memory, storage, or network throughput—rather than thinking in terms of individual instances. Auto Scaling groups and EC2 Fleet enable you to launch and maintain a target capacity, and to automatically request resources to replace any that are disrupted or manually terminated. When you configure an Auto Scaling group or an EC2 Fleet, you need only specify the instance types and target capacity based on your application needs. For more information, see Auto Scaling groups in the *Amazon EC2 Auto Scaling User Guide* and Create an EC2 Fleet in this user guide.

Use the price and capacity optimized allocation strategy

Allocation strategies in Auto Scaling groups help you to provision your target capacity without the need to manually look for the Spot capacity pools with spare capacity. We recommend using the `price-capacity-optimized` strategy because this strategy automatically provisions instances from the most-available Spot capacity pools that also have the lowest possible price. You can also take advantage of the `price-capacity-optimized` allocation strategy in EC2 Fleet. Because your Spot Instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances are reclaimed. For more information, see Allocation strategies for multiple instance types in the *Amazon EC2 Auto Scaling User Guide* and When workloads have a high cost of interruption in this user guide.

Use integrated AWS services to manage your Spot Instances

Other AWS services integrate with Spot to reduce overall compute costs without the need to manage the individual instances or fleets. We recommend that you consider the following solutions for your applicable workloads: Amazon EMR, Amazon Elastic Container Service, AWS Batch, Amazon Elastic Kubernetes Service, Amazon SageMaker AI, AWS Elastic Beanstalk, and Amazon GameLift Servers. To learn more about Spot best practices with these services, see the Amazon EC2 Spot Instances Workshops Website.

Which is the best Spot request method to use?

Use the following table to determine which API to use when requesting Spot Instances.

API	When to use?	Use case	Should I use this API?
[CreateAutoScalingGroup]()	• You need multiple instances with either a single configuration or a mixed configuration. • You want to automate the lifecycle management through a configurable API.	Create an Auto Scaling group that manages the lifecycle of your instances while maintaining the desired number of instances. Supports horizontal scaling (adding more instances) between specified minimum and maximum limits.	Yes
[CreateFleet]()	• You need multiple instances with either a single configuration or a mixed configuration. • You want to self-manage your instance lifecycle. • If you don't need auto scaling, we recommend that you use an	Create a fleet of both On-Demand Instances and Spot Instances in a single request, with multiple launch specifications that vary by instance type, AMI, Availability Zone, or subnet. The Spot Instance allocation strategy defaults to `lowest-price` per unit, but you can change it to `price-capacity-`	Yes – in `instant` mode if you don't need auto scaling

API	When to use?	Use case	Should I use this API?
	`instant` type fleet.	`optimized` , `capacity-optimized` , or `diversified` .	
RunInstances	• You're already using the RunInstances API to launch On-Demand Instances, and you simply want to change to launching Spot Instances by changing a single parameter. • You do not need multiple instances with different instance types.	Launch a specified number of instances using an AMI and one instance type.	No – because RunInstances does not allow mixed instance types in a single request

API	When to use?	Use case	Should I use this API?
RequestSpotFleet	• We strongly discourage using the RequestSpotFleet API because it is a legacy API with no planned investment. • If you want to manage your instance lifecycle, use the CreateFleet API. • If you don't want to manage your instance lifecycle, use the CreateAutoScalingGroup API.	DO NOT USE. RequestSpotFleet is legacy API with no planned investment.	No
RequestSpotInstances	• We strongly discourage using the RequestSpotInstances API because it is a legacy API with no planned investment.	DO NOT USE. RequestSpotInstances is legacy API with no planned investment.	No

How Spot Instances work

To launch a Spot Instance, either you create a *Spot Instance request*, or Amazon EC2 creates a Spot Instance request on your behalf. The Spot Instance launches when the Spot Instance request is fulfilled.

You can launch a Spot Instance using several different services. For more information, see Getting Started with Amazon EC2 Spot Instances. In this user guide, we describe the following ways to launch a Spot Instance using EC2:

- You can create a Spot Instance request by using the launch instance wizard in the Amazon EC2 console or the run-instances command. For more information, see Manage your Spot Instances.
- You can create an EC2 Fleet, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the EC2 Fleet. For more information, see Create an EC2 Fleet.
- You can create a Spot Fleet request, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the Spot Fleet request. For more information, see Create a Spot Fleet.

Your Spot Instance launches if there is available capacity. Your Spot Instance runs until you stop or terminate it, or until Amazon EC2 interrupts it (known as a *Spot Instance interruption*). Amazon EC2 can stop, terminate, or hibernate a Spot Instance when it interrupts it.

When you use Spot Instances, you must be prepared for interruptions. Amazon EC2 can interrupt your Spot Instance when the demand for Spot Instances rises or when the supply of Spot Instances decreases. When Amazon EC2 interrupts a Spot Instance, it provides a Spot Instance interruption notice, which gives the instance a two-minute warning before Amazon EC2 interrupts it. You can't enable termination protection for Spot Instances. For more information, see Spot Instance interruptions.

Contents

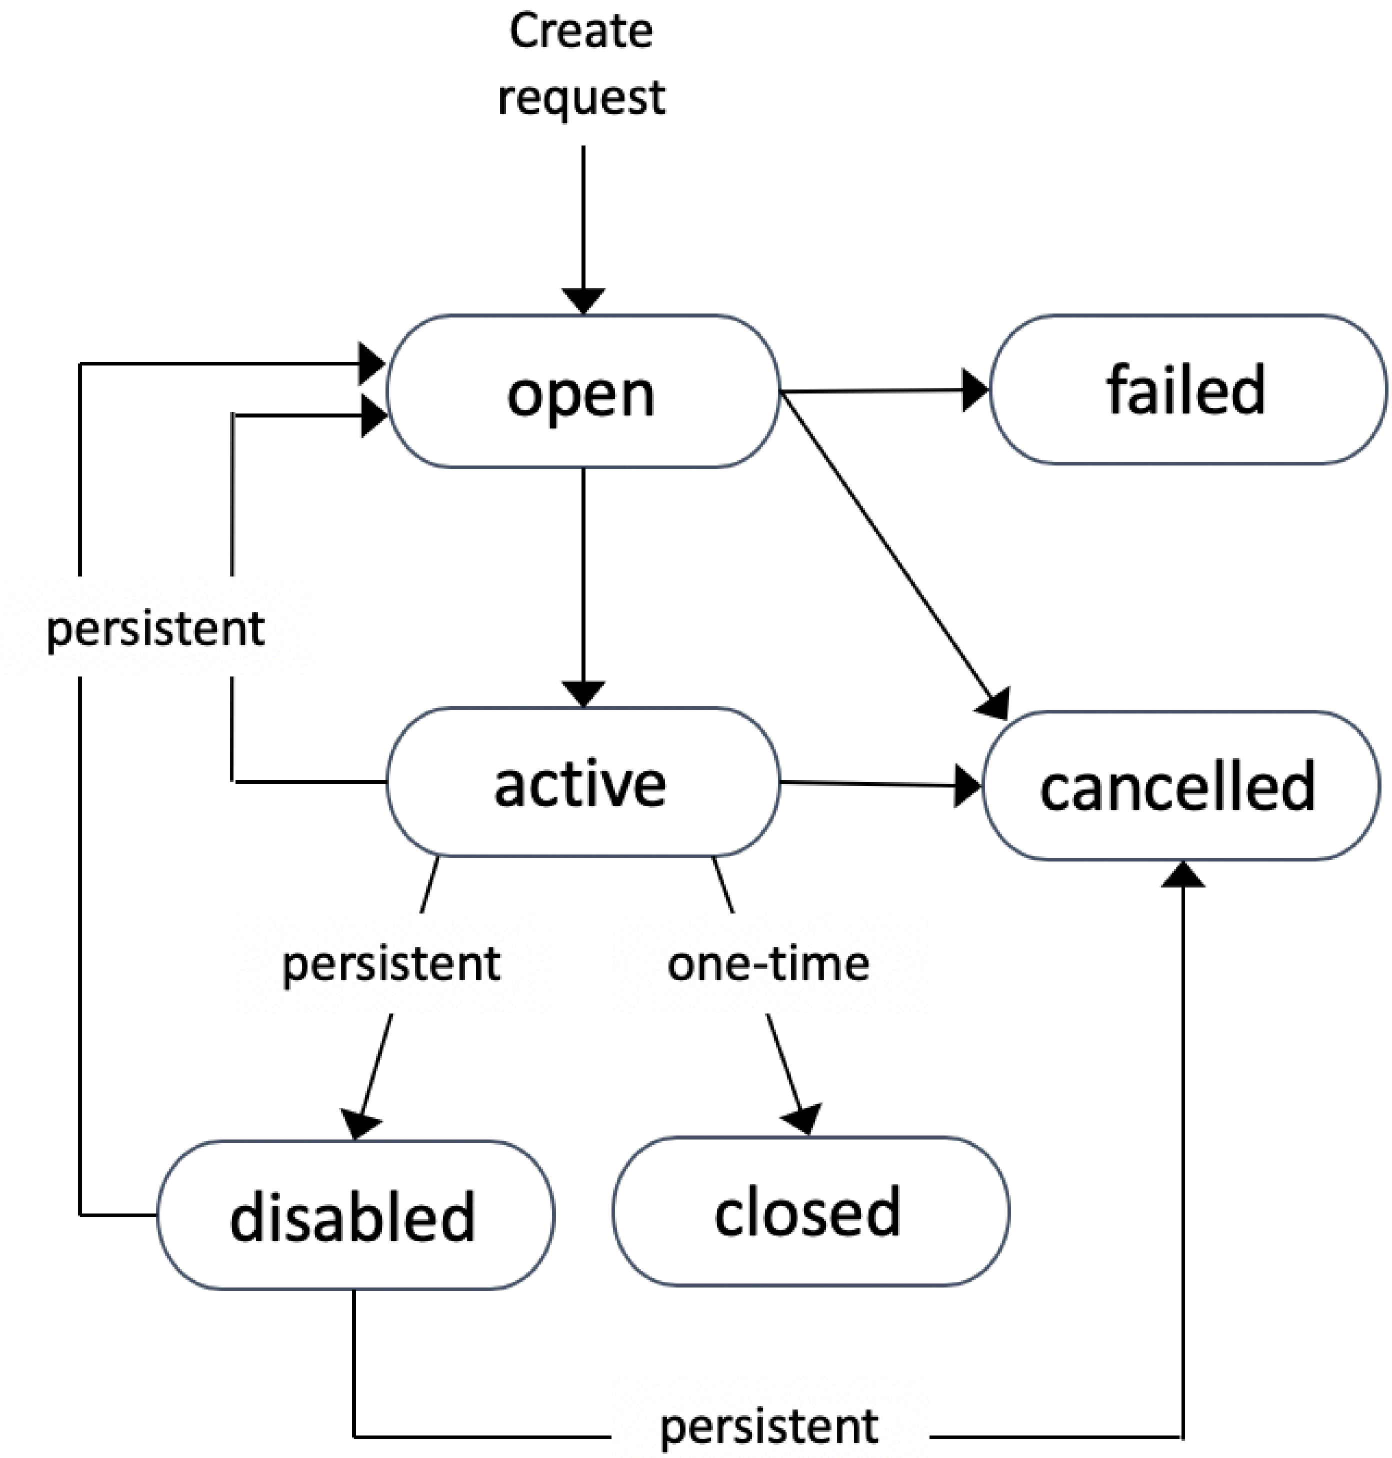
- [Launch on single-tenant hardware]

Spot Instance request states

A Spot Instance request can be in one of the following states:

- `open` – The request is waiting to be fulfilled.
- `active` – The request is fulfilled and has an associated Spot Instance.
- `failed` – The request has one or more bad parameters.
- `closed` – The Spot Instance was interrupted or terminated.
- `disabled` – You stopped the Spot Instance.
- `cancelled` – You canceled the request, or the request expired.

The following illustration represents the transitions between the request states. Notice that the transitions depend on the request type (one-time or persistent).



A one-time Spot Instance request remains active until Amazon EC2 launches the Spot Instance, the request expires, or you cancel the request. If capacity is not available, your Spot Instance is terminated and the Spot Instance request is closed.

A persistent Spot Instance request remains active until it expires or you cancel it, even if the request is fulfilled. If capacity is not available, your Spot Instance is interrupted. After your instance is interrupted, when capacity becomes available again, the Spot Instance is started if stopped or resumed if hibernated. You can stop a Spot Instance and start it again if capacity is available. If the Spot Instance is terminated (irrespective of whether the Spot Instance is in a stopped or running state), the Spot Instance request is opened again and Amazon EC2 launches a new Spot Instance. For more information, see Stop a Spot Instance, Start a Spot Instance, and Terminate a Spot Instance.

You can track the status of your Spot Instance requests, as well as the status of the Spot Instances launched, through the status. For more information, see Get the status of a Spot Instance request.

Launch Spot Instances in a launch group

Specify a launch group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances only if it can launch them all. In addition, if the Spot service must terminate one of the instances in a launch group, it must terminate them all. However, if you terminate one or more of the instances in a launch group, Amazon EC2 does not terminate the remaining instances in the launch group.

Although this option can be useful, adding this constraint can decrease the chances that your Spot Instance request is fulfilled and increase the chances that your Spot Instances are terminated. For example, your launch group includes instances in multiple Availability Zones. If capacity in one of these Availability Zones decreases and is no longer available, then Amazon EC2 terminates all instances for the launch group.

If you create another successful Spot Instance request that specifies the same (existing) launch group as an earlier successful request, then the new instances are added to the launch group. Subsequently, if an instance in this launch group is terminated, all instances in the launch group are terminated, which includes instances launched by the first and second requests.

Launch Spot Instances in an Availability Zone group

Specify an Availability Zone group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances in the same Availability Zone. Amazon EC2 need not interrupt all instances in an Availability Zone group at the same time. If Amazon EC2 must interrupt one of the instances in an Availability Zone group, the others remain running.

Although this option can be useful, adding this constraint can lower the chances that your Spot Instance request is fulfilled.

If you specify an Availability Zone group but don't specify an Availability Zone in the Spot Instance request, the result depends on the network you specified.

Default VPC

Amazon EC2 uses the Availability Zone for the specified subnet. If you don't specify a subnet, it selects an Availability Zone and its default subnet, but not necessarily the lowest-priced zone. If you deleted the default subnet for an Availability Zone, then you must specify a different subnet.

Nondefault VPC

Amazon EC2 uses the Availability Zone for the specified subnet.

Launch Spot Instances in a VPC

You specify a subnet for your Spot Instances the same way that you specify a subnet for your On-Demand Instances.

- [Default VPC] If you want your Spot Instance launched in a specific low-priced Availability Zone, you must specify the corresponding subnet in your Spot Instance request. If you do not specify a subnet, Amazon EC2 selects one for you, and the Availability Zone for this subnet might not have the lowest Spot price.
- [Nondefault VPC] You must specify the subnet for your Spot Instance.

Launch burstable performance instances

The T instance types are burstable performance instances. If you launch your Spot Instances using a burstable performance instance type, and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in Standard mode to avoid paying higher costs. If you launch burstable performance Spot Instances in Unlimited mode and burst CPU immediately, you'll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn't have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see When to use unlimited mode versus fixed CPU.

T2 instances, when configured in Standard mode, get launch credits. T2 instances are the only burstable performance instances that get launch credits. Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not permitted. If you require sustained CPU, you can earn credits (by idling over some period), use Unlimited mode for T2 Spot Instances, or use an instance type with dedicated CPU.

Launch on single-tenant hardware

You can run a Spot Instance on single-tenant hardware. Dedicated Spot Instances are physically isolated from instances that belong to other AWS accounts. For more information, see Amazon EC2 Dedicated Instances and the Amazon EC2 Dedicated Instances.

To run a Dedicated Spot Instance, do one of the following:

- Specify a tenancy of `dedicated` when you create the Spot Instance request. For more information, see Manage your Spot Instances.
- Request a Spot Instance in a VPC with an instance tenancy of `dedicated`. For more information, see Launch Dedicated Instances into a VPC with default tenancy. You can't request a Spot Instance with a tenancy of `default` if you request it in a VPC with an instance tenancy of `dedicated`.

All instance families support Dedicated Spot Instances except T instances. For each supported instance family, only the largest instance size or metal size supports Dedicated Spot Instances.

View Spot Instance pricing history

Spot Instance prices are set by Amazon EC2 and adjust gradually based on long-term trends in supply and demand for Spot Instance capacity.

When your Spot request is fulfilled, your Spot Instances launch at the current Spot price, not exceeding the On-Demand price. You can view the Spot price history for the last 90 days, filtering by instance type, operating system, and Availability Zone.

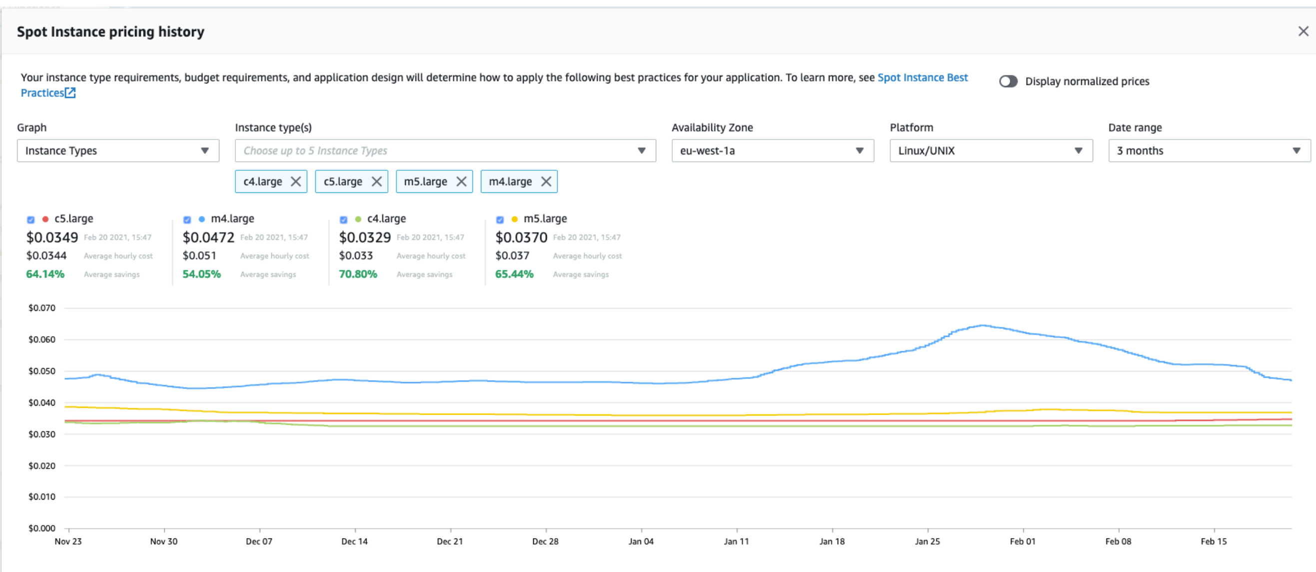
For the *current* Spot Instance prices, see Amazon EC2 Spot Instances Pricing.

Console

To view the Spot price history

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Pricing history**.
4. For **Graph**, choose to compare the price history by **Availability Zones** or by **Instance Types**.
   - If you choose **Availability Zones**, then choose the **Instance type**, operating system (**Platform**), and **Date range** for which to view the price history.
   - If you choose **Instance Types**, then choose up to five **Instance type(s)**, the **Availability Zone**, operating system (**Platform**), and **Date range** for which to view the price history.

   The following screenshot shows a price comparison for different instance types.

5. Hover (move your pointer) over the graph to display the prices at specific times in the selected date range. The prices are displayed in the information blocks above the graph. The price displayed in the top row shows the price on a specific date. The price displayed in the second row shows the average price over the selected date range.
6. To display the price per vCPU, toggle on **Display normalized prices**. To display the price for the instance type, toggle off **Display normalized prices**.

AWS CLI

To view the Spot price history

Use the following describe-spot-price-history command.

```
aws ec2 describe-spot-price-history \
    --instance-types c6i.xlarge \
    --product-descriptions "Linux/UNIX" \
    --start-time 2025-04-01T00:00:00 \
    --end-time 2025-04-02T00:00:0
```

PowerShell

To view the Spot price history

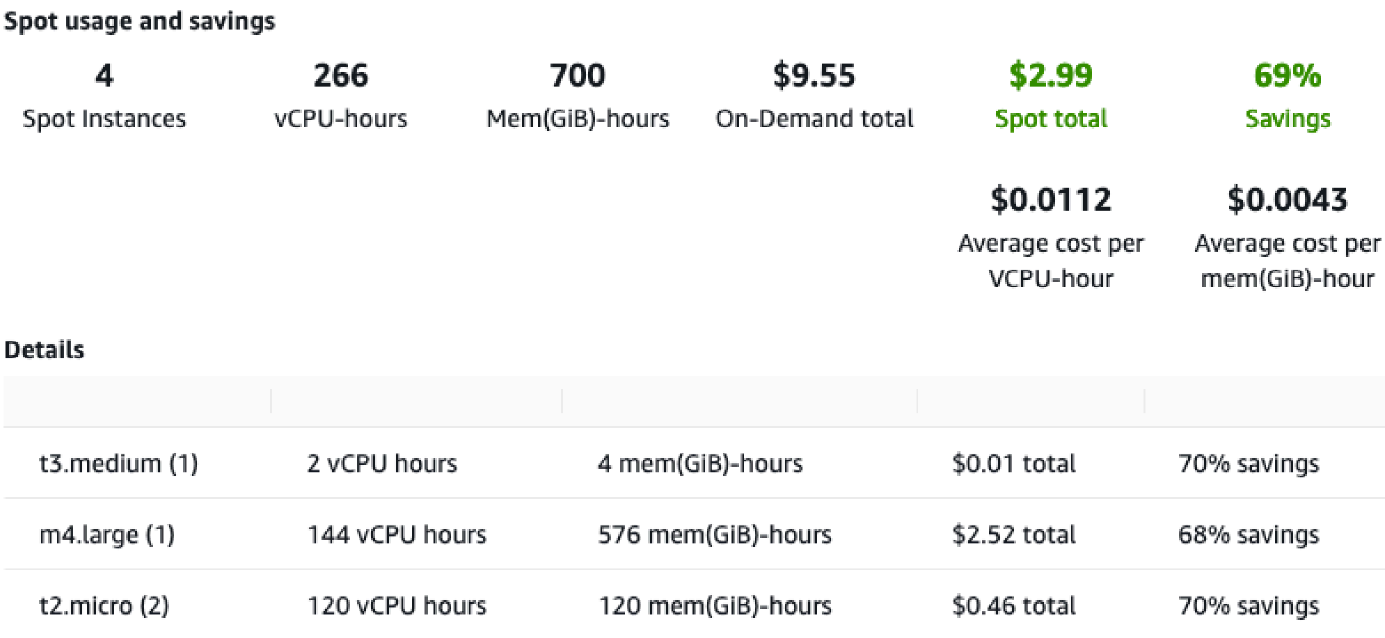
Use the Get-EC2SpotPriceHistory cmdlet.

```
Get-EC2SpotPriceHistory `
    -InstanceType c6i.xlarge `
    -ProductDescription "Linux/UNIX" `
    -UtcStartTime 2025-04-01T00:00:00 `
    -UtcEndTime 2025-04-02T00:00:0
```

Savings from purchasing Spot Instances

You can view the usage and savings information for Spot Instances at the per-fleet level, or for all running Spot Instances. At the per-fleet level, the usage and savings information includes all instances launched and terminated by the fleet. You can view this information from the last hour or the last three days.

The following screenshot from the **Savings** section shows the Spot usage and savings information for a Spot Fleet.



You can view the following usage and savings information:

- **Spot Instances** – The number of Spot Instances launched and terminated by the Spot Fleet. When viewing the savings summary, the number represents all your running Spot Instances.
- **vCPU-hours** – The number of vCPU hours used across all the Spot Instances for the selected time frame.
- **Mem(GiB)-hours** – The number of GiB hours used across all the Spot Instances for the selected time frame.
- **On-Demand total** – The total amount you would've paid for the selected time frame had you launched these instances as On-Demand Instances.
- **Spot total** – The total amount to pay for the selected time frame.
- **Savings** – The percentage that you are saving by not paying the On-Demand price.
- **Average cost per vCPU-hour** – The average hourly cost of using the vCPUs across all the Spot Instances for the selected time frame, calculated as follows: **Average cost per vCPU-hour** = **Spot total / vCPU-hours**.
- **Average cost per mem(GiB)-hour** – The average hourly cost of using the GiBs across all the Spot Instances for the selected time frame, calculated as follows: **Average cost per mem(GiB)-hour** = **Spot total / Mem(GiB)-hours**.

- **Details** table – The different instance types (the number of instances per instance type is in parentheses) that comprise the Spot Fleet. When viewing the savings summary, these comprise all your running Spot Instances.

Savings information can only be viewed using the Amazon EC2 console.

To view the savings information for a Spot Fleet

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation pane, choose **Spot Requests**.
3. Select the ID of a Spot Fleet request and scroll to the **Savings** section.

   Alternatively, select the checkbox next to the Spot Fleet request ID and choose the **Savings** tab.
4. By default, the page displays usage and savings information for the last three days. You can choose **last hour** or the **last three days**. For Spot Fleets that were launched less than an hour ago, the page shows the estimated savings for the hour.

To view the savings information for all running Spot Instances

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation pane, choose **Spot Requests**.
3. Choose **Savings summary**.

Create a Spot Instance request

To use Spot Instances, you create a Spot Instance request that includes the desired number of instances, the instance type, and the Availability Zone. If capacity is available, Amazon EC2 fulfills your request immediately. Otherwise, Amazon EC2 waits until your request can be fulfilled or until you cancel the request.

You can use the launch instance wizard in the Amazon EC2 console or the run-instances command to request a Spot Instance in the same way that you can launch an On-Demand Instance. This method is only recommended for the following reasons:

- You're already using the launch instance wizard or run-instances command to launch On-Demand Instances, and you simply want to change to launching Spot Instances by changing a single parameter.
- You do not need multiple instances with different instance types.

This method is generally not recommended for launching Spot Instances because you can't specify multiple instance types, and you can't launch Spot Instances and On-Demand Instances in the same request. For the preferred methods for launching Spot Instances, which include launching a *fleet* that includes Spot Instances and On-Demand Instances with multiple instance types, see Which is the best Spot request method to use?

If you request multiple Spot Instances at one time, Amazon EC2 creates separate Spot Instance requests so that you can track the status of each request separately. For more information about tracking Spot Instance requests, see Get the status of a Spot Instance request.

Console

To create a Spot Instance request

Steps 1–9 are the same steps you'd use to launch an On-Demand Instance. At Step 10, you configure the Spot Instance request.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, select a Region.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. (Optional) Under **Name and tags**, you can name your instance, and tag the Spot Instance request, the instance, the volumes, and the elastic graphics. For information about tags, see Tag your Amazon EC2 resources.

    a. For **Name**, enter a descriptive name for your instance.

       The instance name is a tag, where the key is **Name**, and the value is the name that you specify. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.

    b. To tag the Spot Instance request, the instance, the volumes, and the elastic graphics, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

5. Under **Application and OS Images (Amazon Machine Image)**, choose the operating system (OS) for your instance, and then select an AMI. For more information, see Application and OS Images (Amazon Machine Image).
6. Under **Instance type**, select the instance type that meets your requirements for the hardware configuration and size of your instance. For more information, see Instance type.
7. Under **Key pair (login)**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see Amazon EC2 key pairs and Amazon EC2 instances.

   > **Important**
   >
   > If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

8. Under **Network settings**, use the default settings, or choose **Edit** to configure the network settings as necessary.

   Security groups form part of the network settings, and define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance.

   For more information, see Network settings.
9. The AMI you selected includes one or more volumes of storage, including the root device volume. Under **Configure storage**, you can specify additional volumes to attach to the instance by choosing **Add new volume**. For more information, see Configure storage.
10. Under **Advanced details**, configure the Spot Instance request as follows:

    a. Under **Purchasing option**, select the **Request Spot Instances** checkbox.

    b. You can either keep the default configuration for the Spot Instance request, or choose **Customize** (at the right) to specify custom settings for your Spot Instance request.

       When you choose **Customize**, the following fields appear.

       i. **Maximum price**: You can request Spot Instances at the Spot price, capped at the On-Demand price, or you can specify the maximum amount you're willing to pay.

> **Warning**
>
> If you specify a maximum price, your instances will be interrupted more frequently than if you choose **No maximum price**.
>
> If you specify a maximum price, it must be more than USD $0.001. Specifying a value below USD $0.001 will result in a failed launch.

- **No maximum price**: Your Spot Instance will launch at the current Spot price. The price will never exceed the On-Demand price. (Recommended)
- **Set your maximum price (per instance/hour)**: You can specify the maximum amount you're willing pay.
  - If you specify a maximum price that is less than the current Spot price, your Spot Instance will not launch.
  - If you specify a maximum price that is more than the current Spot price, your Spot Instance will launch and be charged at the current Spot price. After your Spot Instance is running, if the Spot price rises above your maximum price, Amazon EC2 interrupts your Spot Instance.
  - Regardless of the maximum price you specify, you will always be charged the current Spot price.

To review Spot price trends, see View Spot Instance pricing history.

ii. **Request type**: The Spot Instance request type that you choose determines what happens if your Spot Instance is interrupted.

- **One-time**: Amazon EC2 places a one-time request for your Spot Instance. If your Spot Instance is interrupted, the request is not resubmitted.
- **Persistent request**: Amazon EC2 places a persistent request for your Spot Instance. If your Spot Instance is interrupted, the request is resubmitted to replenish the interrupted Spot Instance.

If you do not specify a value, the default is a one-time request.

iii. **Valid to**: The expiration date of a *persistent* Spot Instance request.

This field is not supported for one-time requests. A *one-time* request remains active until all the instances in the request launch or you cancel the request.

- **No request expiry date**: The request remains active until you cancel it.
- **Set your request expiry date**: The persistent request remains active until the date that you specify, or until you cancel it.

iv. **Interruption behavior**: The behavior that you choose determines what happens when a Spot Instance is interrupted.

- For persistent requests, valid values are **Stop** and **Hibernate**. When an instance is stopped, charges for EBS volume storage apply.

> **Note**
>
> Spot Instances now use the same hibernation functionality as On-Demand Instances. To enable hibernation, you can either choose **Hibernate** here, or you can choose **Enable** from the **Stop - Hibernate behavior** field, which appears lower down in the launch instance wizard. For the hibernation prerequisites, see Prerequisites for EC2 instance hibernation.

- For one-time requests, only **Terminate** is valid.

If you do not specify a value, the default is **Terminate**, which is not valid for a persistent Spot Instance request. If you keep the default and try to launch a persistent Spot Instance request, you'll get an error.

For more information, see Behavior of Spot Instance interruptions.

11. On the **Summary** panel, for **Number of instances**, enter the number of instances to launch.

> **Note**
>
> Amazon EC2 creates a separate request for each Spot Instance.

12. On the **Summary** panel, review the details of your instance, and make any necessary changes. After you submit your Spot Instance request, you can't change the parameters

of the request. You can navigate directly to a section in the launch instance wizard by choosing its link in the **Summary** panel. For more information, see Summary.

13. When you're ready to launch your instance, choose **Launch instance**.

    If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.

AWS CLI

To create a Spot Instance request using run-instances

Use the run-instances command and specify the Spot Instance options in the `--instance-market-options` parameter as follows.

```
--instance-market-options file://spot-options.json
```

The following is the data structure to specify in the JSON file. You can also specify `ValidUntil` and `InstanceInterruptionBehavior`. If you do not specify a field in the data structure, the default value is used.

The following example creates a `persistent` request.

```
{
  "MarketType": "spot",
  "SpotOptions": {
    "SpotInstanceType": "persistent"
  }
}
```

To create a Spot Instance request using request-spot-instances

> **Note**
>
> We strongly discourage using the request-spot-instances command to request a Spot Instance because it is a legacy API with no planned investment. For more information, see Which is the best Spot request method to use?

Use the request-spot-instances command to create a one-time request.

```
aws ec2 request-spot-instances \
    --instance-count 5 \
    --type "one-time" \
    --launch-specification file://specification.json
```

Use the request-spot-instances command to create a persistent request.

```
aws ec2 request-spot-instances \
    --instance-count 5 \
    --type "persistent" \
    --launch-specification file://specification.json
```

For example launch specification files to use with these commands, see Spot Instance request example launch specifications. If you download a launch specification file from the Spot Requests console, you must use the request-spot-fleet command instead (the Spot Requests console specifies a Spot Instance request using a Spot Fleet).

PowerShell

To create a Spot Instance request

Use the New-EC2Instance cmdlet and specify the Spot Instance options using the `-InstanceMarketOption` parameter.

```
-InstanceMarketOptions $marketOptions
```

Create the data structure for the Spot Instance options as follows.

```
$spotOptions = New-Object Amazon.EC2.Model.SpotMarketOptions
$spotOptions.SpotInstanceType="persistent"
$marketOptions = New-Object Amazon.EC2.Model.InstanceMarketOptionsRequest
$marketOptions.MarketType = "spot"
$marketOptions.SpotOptions = $spotOptions
```

Spot Instance request example launch specifications

The following examples show launch configurations that you can use with the request-spot-instances command to create a Spot Instance request. For more information, see Manage your Spot Instances.

> **Important**
>
> We strongly discourage using the request-spot-instances command to request a Spot Instance because it is a legacy API with no planned investment. For more information, see Which is the best Spot request method to use?

Examples

- Example 1: Launch Spot Instances
- Example 2: Launch Spot Instances in the specified Availability Zone
- Example 3: Launch Spot Instances in the specified subnet
- Example 4: Launch a Dedicated Spot Instance

Example 1: Launch Spot Instances

The following example does not include an Availability Zone or subnet. Amazon EC2 selects an Availability Zone for you. Amazon EC2 launches the instances in the default subnet of the selected Availability Zone.

```
{
  "ImageId": "ami-0abcdef1234567890",
  "KeyName": "my-key-pair",
  "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],
  "InstanceType": "m5.medium",
  "IamInstanceProfile": {
      "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
  }
}
```

Example 2: Launch Spot Instances in the specified Availability Zone

The following example includes an Availability Zone. Amazon EC2 launches the instances in the default subnet of the specified Availability Zone.

```
{
  "ImageId": "ami-0abcdef1234567890",
  "KeyName": "my-key-pair",
  "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],
```

```
  "InstanceType": "m5.medium",
  "Placement": {
    "AvailabilityZone": "us-west-2a"
  },
  "IamInstanceProfile": {
      "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
  }
}
```

Example 3: Launch Spot Instances in the specified subnet

The following example includes a subnet. Amazon EC2 launches the instances in the specified subnet. If the VPC is a nondefault VPC, the instance does not receive a public IPv4 address by default.

```
{
  "ImageId": "ami-0abcdef1234567890",
  "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],
  "InstanceType": "m5.medium",
  "SubnetId": "subnet-1a2b3c4d",
  "IamInstanceProfile": {
      "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
  }
}
```

To assign a public IPv4 address to an instance in a nondefault VPC, specify the `AssociatePublicIpAddress` field as shown in the following example. When you specify a network interface, you must include the subnet ID and security group ID using the network interface, rather than using the `SubnetId` and `SecurityGroupIds` fields shown in the previous code block.

```
{
  "ImageId": "ami-0abcdef1234567890",
  "KeyName": "my-key-pair",
  "InstanceType": "m5.medium",
  "NetworkInterfaces": [
    {
      "DeviceIndex": 0,
      "SubnetId": "subnet-1a2b3c4d5e6f7g8h9",
      "Groups": [ "sg-1a2b3c4d5e6f7g8h9" ],
      "AssociatePublicIpAddress": true
```

```
    }
  ],
  "IamInstanceProfile": {
      "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
  }
}
```

Example 4: Launch a Dedicated Spot Instance

The following example requests Spot Instance with a tenancy of `dedicated`. A Dedicated Spot Instance must be launched in a VPC.

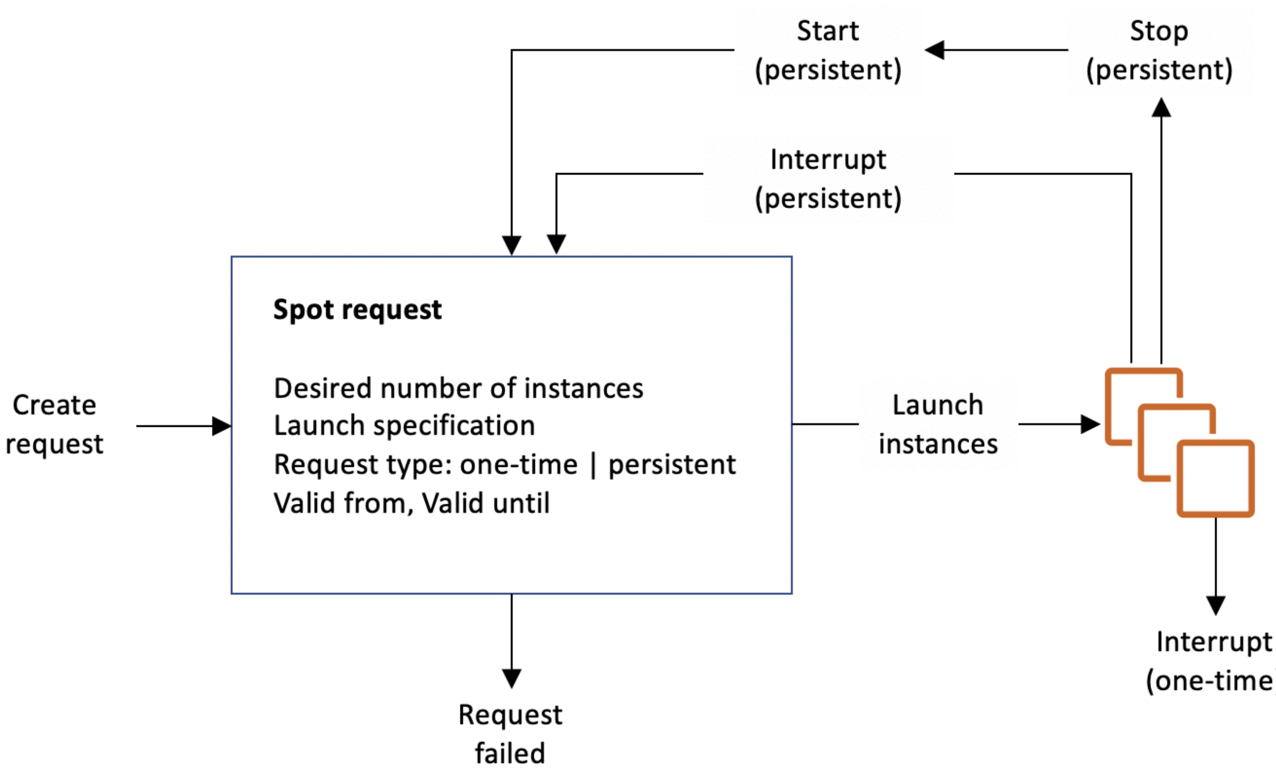
```
{
  "ImageId": "ami-0abcdef1234567890",
  "KeyName": "my-key-pair",
  "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],
  "InstanceType": "c5.8xlarge",
  "SubnetId": "subnet-1a2b3c4d5e6f7g8h9",
  "Placement": {
    "Tenancy": "dedicated"
  }
}
```

Get the status of a Spot Instance request

To help you track your Spot Instance requests and plan your use of Spot Instances, use the request status provided by Amazon EC2. For example, the request status can provide the reason why your Spot request isn't fulfilled yet, or list the constraints that are preventing the fulfillment of your Spot request.

At each step of the process—also called the Spot request *lifecycle*—specific events determine successive request states.

The following illustration shows how Spot Instance requests work. Notice that the request type (one-time or persistent) determines whether the request is opened again when Amazon EC2 interrupts a Spot Instance or if you stop a Spot Instance. If the request is persistent, the request is opened again after your Spot Instance is interrupted. If the request is persistent and you stop your Spot Instance, the request only opens after you start your Spot Instance.



Contents

Get request status information

You can get status information for your Spot Instance request.

Console

To get request status information

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests** and select the Spot request.
3. To check the status, on the **Description** tab, check the **Status** field.

AWS CLI

To get request status information

Use the following describe-spot-instance-requests command.

```
aws ec2 describe-spot-instance-requests --spot-instance-request-
ids sir-0e54a519c9EXAMPLE
```

PowerShell

To get request status information

Use the Get-EC2SpotInstanceRequest cmdlet.

```
Get-EC2SpotInstanceRequest -SpotInstanceRequestId sir-0e54a519c9EXAMPLE
```

Spot request status codes

Spot request status information is composed of a status code, the update time, and a status message. Together, these help you determine the disposition of your Spot request.

The following are the Spot request status codes:

`az-group-constraint`

Amazon EC2 cannot launch all the instances you requested in the same Availability Zone.

`bad-parameters`

One or more parameters for your Spot request are not valid (for example, the AMI you specified does not exist). The status message indicates which parameter is not valid.

`canceled-before-fulfillment`

The user canceled the Spot request before it was fulfilled.

`capacity-not-available`

There is not enough capacity available for the instances that you requested.

`constraint-not-fulfillable`

The Spot request can't be fulfilled because one or more constraints are not valid (for example, the Availability Zone does not exist). The status message indicates which constraint is not valid.

`fulfilled`

The Spot request is `active`, and Amazon EC2 is launching your Spot Instances.

`instance-stopped-by-price`

Your instance was stopped because the Spot price exceeded your maximum price.

`instance-stopped-by-user`

Your instance was stopped because a user stopped the instance or ran the shutdown command from the instance.

`instance-stopped-no-capacity`

Your instance was stopped due to EC2 capacity management needs.

`instance-terminated-by-price`

Your instance was terminated because the Spot price exceeded your maximum price. If your request is persistent, the process restarts, so your request is pending evaluation.

`instance-terminated-by-schedule`

Your Spot Instance was terminated at the end of its scheduled duration.

`instance-terminated-by-service`

Your instance was terminated from a stopped state.

`instance-terminated-by-user` or `spot-instance-terminated-by-user`

You terminated a Spot Instance that had been fulfilled, so the request state is `closed` (unless it's a persistent request) and the instance state is `terminated`.

`instance-terminated-launch-group-constraint`

One or more of the instances in your launch group was terminated, so the launch group constraint is no longer fulfilled.

`instance-terminated-no-capacity`

Your instance was terminated due to standard capacity management processes.

`launch-group-constraint`

Amazon EC2 cannot launch all the instances that you requested at the same time. All instances in a launch group are started and terminated together.

`limit-exceeded`

The limit on the number of EBS volumes or total volume storage was exceeded. For more information, see Quotas for Amazon EBS in the *Amazon EBS User Guide*.

`marked-for-stop`

The Spot Instance is marked for stopping.

`marked-for-termination`

The Spot Instance is marked for termination.

`not-scheduled-yet`

The Spot request is not evaluated until the scheduled date.

`pending-evaluation`

After you make a Spot Instance request, it goes into the `pending-evaluation` state while the system evaluates the parameters of your request.

`pending-fulfillment`

Amazon EC2 is trying to provision your Spot Instances.

`placement-group-constraint`

The Spot request can't be fulfilled yet because a Spot Instance can't be added to the placement group at this time.

`price-too-low`

The request can't be fulfilled yet because your maximum price is below the Spot price. In this case, no instance is launched and your request remains `open`.

`request-canceled-and-instance-running`

You canceled the Spot request while the Spot Instances are still running. The request is `cancelled`, but the instances remain `running`.

`schedule-expired`

The Spot request expired because it was not fulfilled before the specified date.

`system-error`

There was an unexpected system error. If this is a recurring issue, please contact AWS Support for assistance.

EC2 Spot Instance Request Fulfillment event

When a Spot Instance request is fulfilled, Amazon EC2 sends an EC2 Spot Instance Request Fulfillment event to Amazon EventBridge. You can create a rule to take an action whenever this event occurs, such as invoking a Lambda function or notifying an Amazon SNS topic.

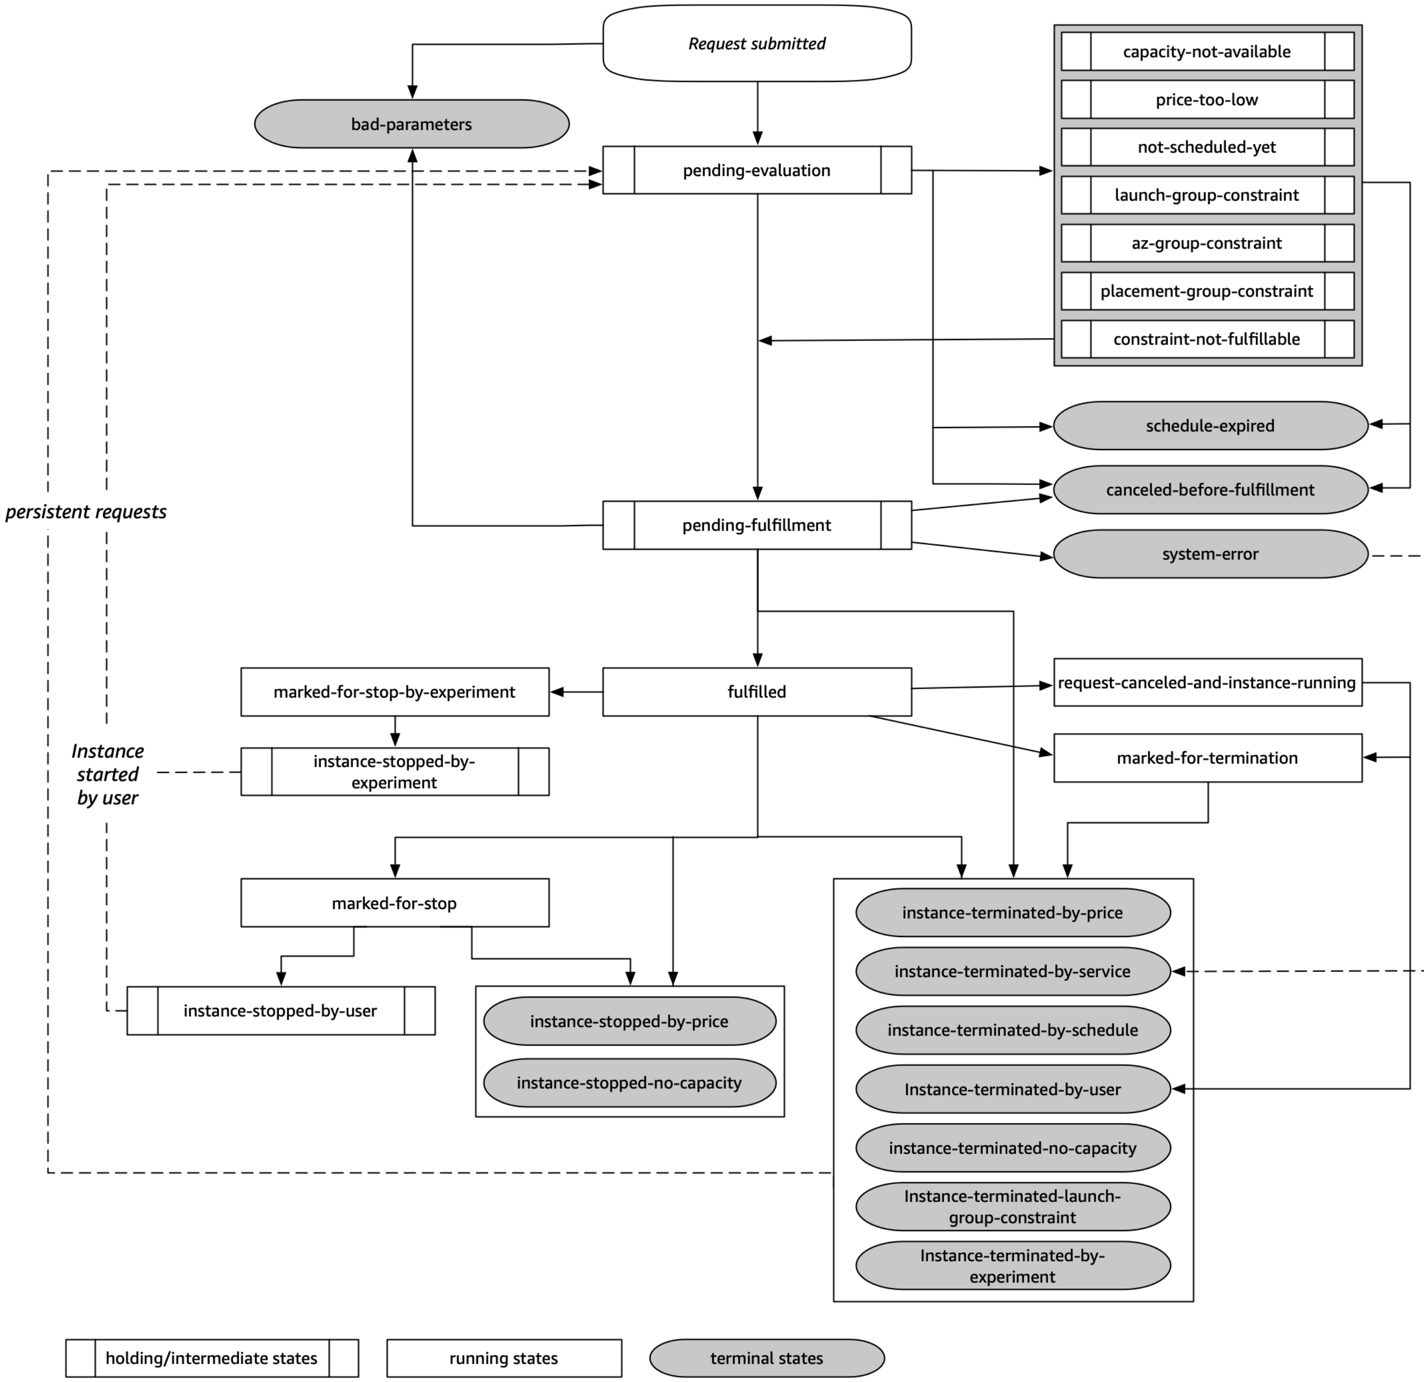
The following is example data for this event.

```
{
    "version": "0",
    "id": "01234567-1234-0123-1234-012345678901",
    "detail-type": "EC2 Spot Instance Request Fulfillment",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-2",
    "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"],
    "detail": {
        "spot-instance-request-id": "sir-0e54a519c9EXAMPLE",
        "instance-id": "i-1234567890abcdef0"
    }
}
```

For more information, see the [Amazon EventBridge User Guide].

State changes for a Spot request

The following diagram shows you the paths that your Spot request can follow throughout its lifecycle, from submission to termination. Each step is depicted as a node, and the status code for each node describes the status of the Spot request and Spot Instance.



Pending evaluation

As soon as you create a Spot Instance request, it goes into the `pending-evaluation` state unless one or more request parameters are not valid (`bad-parameters`).

Status code	Request state	Instance state
`pending-evaluation`	`open`	Not applicable
`bad-parameters`	`closed`	Not applicable

Holding

If one or more request constraints are valid but can't be met yet, or if there is not enough capacity, the request goes into a holding state waiting for the constraints to be met. The request options affect the likelihood of the request being fulfilled. For example, if there is no capacity, your request stays in a holding state until there is available capacity. If you specify an Availability Zone group, the request stays in a holding state until the Availability Zone constraint is met.

In the event of an outage of one of the Availability Zones, there is a chance that the spare EC2 capacity available for Spot Instance requests in other Availability Zones can be affected.

Status code	Request state	Instance state
`capacity-not-available`	`open`	Not applicable
`price-too-low`	`open`	Not applicable
`not-scheduled-yet`	`open`	Not applicable
`launch-group-constraint`	`open`	Not applicable
`az-group-constraint`	`open`	Not applicable
`placement-group-constraint`	`open`	Not applicable
`constraint-not-fulfillable`	`open`	Not applicable

Pending evaluation/fulfillment-terminal

Your Spot Instance request can go to a `terminal` state if you create a request that is valid only during a specific time period and this time period expires before your request reaches the pending fulfillment phase. It might also happen if you cancel the request, or if a system error occurs.

Status code	Request state	Instance state
`schedule-expired`	`cancelled`	Not applicable
`canceled-before-fulfillment` [1]	`cancelled`	Not applicable
`bad-parameters`	`failed`	Not applicable
`system-error`	`closed`	Not applicable

[1] If you cancel the request.

Pending fulfillment

When the constraints you specified (if any) are met, your Spot request goes into the `pending-fulfillment` state.

At this point, Amazon EC2 is getting ready to provision the instances that you requested. If the process stops at this point, it is likely to be because it was canceled by the user before a Spot Instance was launched. It might also be because an unexpected system error occurred.

Status code	Request state	Instance state
`pending-fulfillment`	`open`	Not applicable

Fulfilled

When all the specifications for your Spot Instances are met, your Spot request is fulfilled. Amazon EC2 launches the Spot Instances, which can take a few minutes. If a Spot Instance is hibernated or stopped when interrupted, it remains in this state until the request can be fulfilled again or the request is canceled.

Status code	Request state	Instance state
`fulfilled`	`active`	`pending` → `running`
`fulfilled`	`active`	`stopped` → `running`

If you stop a Spot Instance, your Spot request goes into the `marked-for-stop` or `instance-stopped-by-user` state until the Spot Instance can be started again or the request is cancelled.

Status code	Request state	Instance state
`marked-for-stop`	`active`	`stopping`
`instance-stopped-by-user` [1]	`disabled` or `cancelled` [2]	`stopped`

[1] A Spot Instance goes into the `instance-stopped-by-user` state if you stop the instance or run the shutdown command from the instance. After you've stopped the instance, you can start it again. On restart, the Spot Instance request returns to the `pending-evaluation` state and then Amazon EC2 launches a new Spot Instance when the constraints are met.

[2] The Spot request state is `disabled` if you stop the Spot Instance but do not cancel the request. The request state is `cancelled` if your Spot Instance is stopped and the request expires.

Fulfilled-terminal

Your Spot Instances continue to run as long as there is available capacity for your instance type, and you don't terminate the instance. If Amazon EC2 must terminate your Spot Instances, the Spot request goes into a terminal state. A request also goes into the terminal state if you cancel the Spot request or terminate the Spot Instances.

Status code	Request state	Instance state
request-canceled-and-instance-running	cancelled	running
marked-for-stop	active	running
marked-for-termination	active	running
instance-stopped-by-price	disabled	stopped
instance-stopped-by-user	disabled	stopped
instance-stopped-no-capacity	disabled	stopped
instance-terminated-by-price	closed (one-time), open (persistent)	terminated
instance-terminated-by-schedule	closed	terminated
instance-terminated-by-service	cancelled	terminated
instance-terminated-by-user	closed or cancelled [1]	terminated
instance-terminated-no-capacity	closed (one-time), open (persistent)	running †
instance-terminated-no-capacity	closed (one-time), open (persistent)	terminated

Status code	Request state	Instance state
`instance-terminated-launch-group-constraint`	`closed` (one-time), `open` (persistent)	`terminated`

[1] The request state is `closed` if you terminate the instance but do not cancel the request. The request state is `cancelled` if you terminate the instance and cancel the request. Even if you terminate a Spot Instance before you cancel its request, there might be a delay before Amazon EC2 detects that your Spot Instance was terminated. In this case, the request state can either be `closed` or `cancelled`.

† When Amazon EC2 interrupts a Spot Instance if it needs the capacity back *and* the instance is configured to *terminate* on interruption, the status is immediately set to `instance-terminated-no-capacity` (it is not set to `marked-for-termination`). However, the instance remains in the `running` state for 2 minutes to reflect the 2-minute period when the instance receives the Spot Instance interruption notice. After 2 minutes, the instance state is set to `terminated`.

Interruption experiments

You can use AWS Fault Injection Service to initiate a Spot Instance interruption so that you can test how the applications on your Spot Instances respond. If AWS FIS stops a Spot Instance, your Spot request enters the `marked-for-stop-by-experiment` state and then the `instance-stopped-by-experiment` state. If AWS FIS terminates a Spot Instance, your Spot request enters the `instance-terminated-by-experiment` state. For more information, see the section called “Initiate an interruption”.

Status code	Request state	Instance state
`marked-for-stop-by-experiment`	`active`	`running`
`instance-stopped-by-experiment`	`disabled`	`stopped`
`instance-terminated-by-experiment`	`closed`	`terminated`

Persistent requests

When your Spot Instances are terminated (either by you or Amazon EC2), if the Spot request is a persistent request, it returns to the `pending-evaluation` state and then Amazon EC2 can launch a new Spot Instance when the constraints are met.

Tag Spot Instance requests

To help categorize and manage your Spot Instance requests, you can tag them with custom metadata. You can assign a tag to a Spot Instance request when you create it, or afterward. You can assign tags using the Amazon EC2 console or a command line tool.

When you tag a Spot Instance request, the instances and volumes that are launched by the Spot Instance request are not automatically tagged. You need to explicitly tag the instances and volumes launched by the Spot Instance request. You can assign a tag to a Spot Instance and volumes during launch, or afterward.

For more information about how tags work, see Tag your Amazon EC2 resources.

Contents

Prerequisites

Grant the user the permission to tag resources. For more information about IAM policies and example policies, see Example: Tag resources.

The IAM policy you create is determined by which method you use for creating a Spot Instance request.

- If you use the launch instance wizard or `run-instances` to request Spot Instances, see To grant a user the permission to tag resources when using the launch instance wizard or run-instances.
- If you use the `request-spot-instances` command to request Spot Instances, see To grant a user the permission to tag resources when using request-spot-instances.

To grant a user the permission to tag resources when using the launch instance wizard or run-instances

Create a IAM policy that includes the following:

- The `ec2:RunInstances` action. This grants the user permission to launch an instance.
- For `Resource`, specify `spot-instances-request`. This allows users to create Spot Instance requests, which request Spot Instances.
- The `ec2:CreateTags` action. This grants the user permission to create tags.
- For `Resource`, specify `*`. This allows users to tag all resources that are created during instance launch.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowLaunchInstances",
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances"
            ],
            "Resource": [
                "arn:aws:ec2:us-east-1::image/*",
                "arn:aws:ec2:us-east-1:*:subnet/*",
                "arn:aws:ec2:us-east-1:*:network-interface/*",
                "arn:aws:ec2:us-east-1:*:security-group/*",
                "arn:aws:ec2:us-east-1:*:key-pair/*",
                "arn:aws:ec2:us-east-1:*:volume/*",
                "arn:aws:ec2:us-east-1:*:instance/*",
                "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
            ]
        },
        {
            "Sid": "TagSpotInstanceRequests",
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
```

```
    ]
}
```

When you use the RunInstances action to create Spot Instance requests and tag the Spot Instance requests on create, you need to be aware of how Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement it is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

Therefore, for the `spot-instances-request` resource, the following rules apply to the IAM policy:

- If you use RunInstances to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don’t need to explicitly allow the `spot-instances-request` resource; the call will succeed.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the `spot-instances-request` resource in the RunInstances allow statement, otherwise the call will fail.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the `spot-instances-request` resource or include a `*` wildcard in the CreateTags allow statement, otherwise the call will fail.

For example IAM policies, including policies that are not supported for Spot Instance requests, see Work with Spot Instances.

To grant a user the permission to tag resources when using request-spot-instances

Create a IAM policy that includes the following:

- The `ec2:RequestSpotInstances` action. This grants the user permission to create a Spot Instance request.
- The `ec2:CreateTags` action. This grants the user permission to create tags.

- For `Resource`, specify `spot-instances-request`. This allows users to tag only the Spot Instance request.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "TagSpotInstanceRequest",
            "Effect": "Allow",
            "Action": [
                "ec2:RequestSpotInstances",
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws:ec2:us-east-1:111122223333:spot-instances-
request/*"
        }
    ]
}
```

Tag a new Spot Instance request

In the AWS CLI and PowerShell examples, configure the Spot Instance request as follows:

- For `ResourceType`, specify `spot-instances-request`. If you specify another value, the Spot Instance request will fail.
- For `Tags`, specify the key-value pair. You can specify more than one key-value pair.

Console

To tag a new Spot Instance request

1. Follow the Manage your Spot Instances procedure.
2. To add a tag, on the **Add Tags** page, choose **Add Tag**, and enter the key and value for the tag. Choose **Add another tag** for each additional tag.

For each tag, you can tag the Spot Instance request, the Spot Instances, and the volumes with the same tag. To tag all three, ensure that **Instances**, **Volumes**, and **Spot Instance Requests** are selected. To tag only one or two, ensure that the resources you want to tag are selected, and the other resources are cleared.

3. Complete the required fields to create a Spot Instance request, and then choose **Launch**. For more information, see Manage your Spot Instances.

AWS CLI

To tag a new Spot Instance request

Use the request-spot-instances command with the `--tag-specification` option.

The tag specification adds two tags to the Spot Instance request: `Environment=Production` and `Cost-Center=123`.

```
aws ec2 request-spot-instances \
    --instance-count 5 \
    --type "one-time" \
    --launch-specification file://specification.json \
    --tag-specification 'ResourceType=spot-instances-
request,Tags=[{Key=Environment,Value=Production},{Key=Cost-Center,Value=123}]'
```

PowerShell

To tag a new Spot Instance request

Use the Request-EC2SpotInstance cmdlet with the `-TagSpecification` parameter.

```
-TagSpecification $tagspec
```

The tag specification is defined as follows. It adds two tags to the Spot Instance request: `Environment=Production` and `Cost-Center=123`.

```
$tag1 = @{Key="Environment"; Value="Production"}
$tag2 = @{Key="Cost-Center"; Value="123"}
$tagspec = New-Object Amazon.EC2.Model.TagSpecification
$tagspec.ResourceType = "spot-instances-request"
$tagspec.Tags = @($tag1,$tag2)
```

Tag an existing Spot Instance request

Console

To tag an existing Spot Instance request

After you have created a Spot Instance request, you can add tags to the Spot Instance request using the console.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Instance request.
4. Choose the **Tags** tab and choose **Create Tag**.

To tag an existing Spot Instance using the console

After your Spot Instance request has launched your Spot Instance, you can add tags to the instance using the console. For more information, see Add tags using the console.

AWS CLI

To tag an existing Spot Instance request or Spot Instance

Use the create-tags command to tag existing resources. In the following example, the existing Spot Instance request and the Spot Instance are tagged with `purpose=test`.

```
aws ec2 create-tags \
    --resources sir-0e54a519c9EXAMPLE i-1234567890abcdef0 \
    --tags Key=purpose,Value=test
```

PowerShell

To tag an existing Spot Instance request or Spot Instance

Use the New-EC2Tag cmdlet. The following example adds the tag `purpose=test` to the existing Spot Instance request and the Spot Instance.

```
New-EC2Tag `
    -Resource sir-0e54a519c9EXAMPLE, i-1234567890abcdef0 `
    -Tag @{Key="purpose"; Value="test"}
```

View Spot Instance request tags

Console

To view Spot Instance request tags

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Instance request and choose the **Tags** tab.

AWS CLI

To describe Spot Instance request tags

Use the describe-spot-instance-requests command to view the configuration of the specified Spot Instance request, which includes any tags that were specified for the request.

```
aws ec2 describe-spot-instance-requests \
    --spot-instance-request-ids sir-0e54a519c9EXAMPLE \
    --query "SpotInstanceRequests[*].Tags"
```

The following is example output.

```
[
    [
        {
            "Key": "Environment",
            "Value": "Production"
        },
        {
            "Key": "Department",
            "Value": "101"
        }
    ]
]
```

PowerShell

To describe Spot Instance request tags

Use the Get-EC2SpotInstanceRequest cmdlet.

```
(Get-EC2SpotInstanceRequest `
    -SpotInstanceRequestId sir-0e54a519c9EXAMPLE).Tags
```

The following is example output.

```
Key         Value
---         -----
Environment Production
Department  101
```

Cancel a Spot Instance request

If you no longer want your Spot Instance request, you can cancel it. You can only cancel Spot Instance requests that are `open`, `active`, or `disabled`.

- Your Spot Instance request is `open` when your request has not yet been fulfilled and no instances have been launched.
- Your Spot Instance request is `active` when your request has been fulfilled and Spot Instances have launched as a result.
- Your Spot Instance request is `disabled` when you stop your Spot Instance.

If your Spot Instance request is `active` and has an associated running Spot Instance, canceling the request does not terminate the instance. For more information about terminating a Spot Instance, see Terminate a Spot Instance.

Console

To cancel a Spot Instance request

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Select the Spot Instance request.
4. Choose **Actions**, **Cancel request**.
5. (Optional) If you are finished with the associated Spot Instances, you can terminate them. In the **Cancel Spot request** dialog box, select **Terminate instances**, and then choose **Confirm**.

AWS CLI

To cancel a Spot Instance request

Use the following cancel-spot-instance-requests command.

```
aws ec2 cancel-spot-instance-requests --spot-instance-request-
ids sir-0e54a519c9EXAMPLE
```

PowerShell

To cancel a Spot Instance request

Use the Stop-EC2SpotInstanceRequest cmdlet.

```
Stop-EC2SpotInstanceRequest -SpotInstanceRequestId sir-0e54a519c9EXAMPLE
```

Manage your Spot Instances

Amazon EC2 launches a Spot Instance when capacity is available. A Spot Instance runs until it is interrupted or you terminate it yourself.

Contents

Find your Spot Instances

A Spot Instance appears in the **Instances** page in the console, along with On-Demand Instances. Use the following procedure to find your Spot Instances.

Console

To find your Spot Instances

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Instances**.
3. To find all Spot Instances, in the search pane, choose **Instance lifecycle=spot**.
4. To verify that an instance is a Spot Instance, select the instance, choose the **Details** tab, and check the value of **Lifecycle**. The value for a Spot Instance is `spot` and the value for an On-Demand Instance is `normal`.

AWS CLI

To find your Spot Instances

Use the following describe-instances command.

```
aws ec2 describe-instances --filters "Name=instance-lifecycle,Values=spot"
```

To determine whether an instance is a Spot Instance

Use the following describe-instances command.

```
aws ec2 describe-instances \
    --instance-ids i-1234567890abcdef0 \
    --query "Reservations[*].Instances[*].InstanceLifecycle" \
    --output text
```

If the output is `spot`, the instance is a Spot Instance. If there is no output, the instance is an On-Demand Instance.

PowerShell

To find your Spot Instances

Use the Get-EC2Instance cmdlet.

```
Get-EC2Instance -Filter @{Name="instance-lifecycle"; Values="spot"}
```

To determine whether an instance is a Spot Instance

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -InstanceId i-1234567890abcdef0).Instances.InstanceLifecycle
```

If the output is `Spot`, the instance is a Spot Instance. If there is no output, the instance is an On-Demand Instance.

Find instances launched by a specific request

Use the following procedure to find the Spot Instances launched from a specific Spot Instance or Spot Fleet request.

Console

To find the Spot Instances for a request

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**. The list contains both Spot Instance requests and Spot Fleet requests.
3. If a Spot Instance request is fulfilled, **Capacity** is the ID of the Spot Instance. For a Spot Fleet, **Capacity** indicates how much of the requested capacity has been fulfilled. To view the IDs of the instances in a Spot Fleet, choose the expand arrow, or select the fleet and choose **Instances**.
4. For a Spot Fleet, **Capacity** indicates how much of the requested capacity is fulfilled. To view the IDs of the instances in a Spot Fleet, choose the fleet ID to open its details page and locate the **Instances** pane.

AWS CLI

To find the Spot Instances for a request

Use the following describe-spot-instance-requests command.

```
aws ec2 describe-spot-instance-requests \
    --spot-instance-request-ids sir-0e54a519c9EXAMPLE \
    --query "SpotInstanceRequests[*].{ID:InstanceId}"
```

The following is example output:

```
[
    {
        "ID": "i-1234567890abcdef0"
```

```
    },
    {
        "ID": "i-0598c7d356eba48d7"
    }
]
```

PowerShell

To find the Spot Instances for a request

Use the Get-EC2SpotInstanceRequest cmdlet.

```
(Get-EC2SpotInstanceRequest -SpotInstanceRequestId sir-0e54a519c9EXAMPLE).InstanceId
```

Stop a Spot Instance

If you don't need your Spot Instances now, but you want to restart them later without losing the data persisted in the Amazon EBS volume, you can stop them. The steps for stopping a Spot Instance are similar to the steps for stopping an On-Demand Instance.

> **Note**
>
> While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type.
> We don't charge usage for a stopped Spot Instance, or data transfer fees, but we do charge for the storage for any Amazon EBS volumes.

Limitations

- You can only stop a Spot Instance if the Spot Instance was launched from a `persistent` Spot Instance request.
- You can't stop a Spot Instance if the associated Spot Instance request is cancelled. When the Spot Instance request is cancelled, you can only terminate the Spot Instance.
- You can't stop a Spot Instance if it is part of a fleet or launch group, or Availability Zone group.

Console

To stop a Spot Instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the Spot Instance. If you didn't save the instance ID of the Spot Instance, see the section called "Find your Spot Instances".
4. Choose **Instance state**, **Stop instance**.
5. When prompted for confirmation, choose **Stop**.

AWS CLI

To stop a Spot Instance

Use the stop-instances command to manually stop your Spot Instances.

```
aws ec2 stop-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To stop a Spot Instance

Use the Stop-EC2Instance cmdlet.

```
Stop-EC2Instance -InstanceId i-1234567890abcdef0
```

Start a Spot Instance

You can start a Spot Instance that you previously stopped.

Prerequisites

You can only start a Spot Instance if:

- You manually stopped the Spot Instance.
- The Spot Instance is an EBS-backed instance.
- Spot Instance capacity is available.

- The Spot price is lower than your maximum price.

Limitations

- You can't start a Spot Instance if it is part of fleet or launch group, or Availability Zone group.

The steps for starting a Spot Instance are similar to the steps for starting an On-Demand Instance.

Console

To start a Spot Instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the Spot Instance. If you didn't save the instance ID of the Spot Instance, see the section called “Find your Spot Instances”.
4. Choose **Instance state**, **Start instance**.

AWS CLI

To start a Spot Instance

Use the start-instances command to manually start your Spot Instances.

```
aws ec2 start-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To start a Spot Instance

Use the Start-EC2Instance cmdlet.

```
Start-EC2Instance -InstanceId i-1234567890abcdef0
```

Terminate a Spot Instance

If you terminate a running or stopped Spot Instance that was launched by a persistent Spot Instance request, the Spot Instance request transitions to the open state so that a new Spot

Instance can be launched. To ensure that no new Spot Instance is launched, you must first cancel the Spot Instance request.

If you cancel an `active` Spot Instance request that has a running Spot Instance, the running Spot Instance is not automatically terminated; you must manually terminate the Spot Instance.

If you cancel a `disabled` Spot Instance request that has a stopped Spot Instance, the stopped Spot Instance is automatically terminated by the Amazon EC2 Spot service. There might be a short lag between when you cancel the Spot Instance request and when the Spot service terminates the Spot Instance.

For more information, see Cancel a Spot Instance request.

Console

To manually terminate a Spot Instance

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose **Instances**.
4. Select the Spot Instance. If you didn't save the instance ID of the Spot Instance, see the section called "Find your Spot Instances".
5. Choose **Instance state**, **Terminate (delete) instance**.
6. Choose **Terminate (delete)** when prompted for confirmation.

AWS CLI

To manually terminate a Spot Instance

Use the terminate-instances command to manually terminate your Spot Instances.

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0 i-0598c7d356eba48d7
```

PowerShell

To manually terminate a Spot Instance

Use the Remove-EC2Instance cmdlet.

```
Remove-EC2Instance -InstanceId i-1234567890abcdef0
```

Spot Instance interruptions

You can launch Spot Instances on spare EC2 capacity for steep discounts in exchange for returning them when Amazon EC2 needs the capacity back. When Amazon EC2 reclaims a Spot Instance, we call this event a *Spot Instance interruption*.

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted. The following are the possible reasons that Amazon EC2 might interrupt your Spot Instances:

Capacity

Amazon EC2 can interrupt your Spot Instance when it needs it back. EC2 reclaims your instance mainly to repurpose capacity, but it can also occur for other reasons such as host maintenance or hardware decommission.

Price

The Spot price is higher than your maximum price.

You can specify the maximum price in your Spot request. However, if you specify a maximum price, your instances will be interrupted more frequently than if you do not specify it.

Constraints

If your Spot request includes a constraint such as a launch group or an Availability Zone group, the Spot Instances are terminated as a group when the constraint can no longer be met.

When Amazon EC2 interrupts a Spot Instance, it either terminates, stops, or hibernates the instance, depending on the interruption behavior that you specified when you created the Spot request.

Contents

Behavior of Spot Instance interruptions

When you create a Spot request, you can specify the interruption behavior. The following are the possible interruption behaviors:

- Stop
- Hibernate
- Terminate

The default behavior is that Amazon EC2 terminates Spot Instances when they are interrupted.

Stop interrupted Spot Instances

You can specify that Amazon EC2 stops your Spot Instances when they are interrupted. The Spot Instance request type must be `persistent`. You can't specify a launch group in the Spot Instance request. For EC2 Fleet or Spot Fleet, the request type must be `maintain`.

Considerations

- Only Amazon EC2 can restart an interrupted stopped Spot Instance.
- For a Spot Instance launched by a `persistent` Spot Instance request: Amazon EC2 restarts the stopped instance when capacity is available in the same Availability Zone and for the same instance type as the stopped instance (the same launch specification must be used).
- While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type. If you detach or delete an EBS volume, it is not attached when the Spot Instance is started. If you detach the root volume and Amazon EC2 attempts to start the Spot Instance, the instance will fail to start and Amazon EC2 will terminate the stopped instance.
- You can terminate a Spot Instance while it is stopped.

- If you cancel a Spot Instance request, an EC2 Fleet, or a Spot Fleet, Amazon EC2 terminates any associated Spot Instances that are stopped.
- While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved. With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account. For more information about how you're charged when a Spot Instance is interrupted, see Billing for interrupted Spot Instances.
- Make sure that you are familiar with the implications of stopping an instance. For information about what happens when an instance is stopped, see Differences between instance states.

Hibernate interrupted Spot Instances

You can specify that Amazon EC2 hibernates your Spot Instances when they are interrupted. For more information, see Hibernate your Amazon EC2 instance.

Amazon EC2 now offers the same hibernation experience for Spot Instances as is currently available for On-Demand Instances. It offers more extensive support, where the following is now supported for Spot Instance hibernation:

- More supported AMIs
- More supported instance families
- User-initiated hibernation

Terminate interrupted Spot Instances

When Amazon EC2 interrupts a Spot Instance, it terminates the instance by default, unless you specify a different interruption behavior, such as stop or hibernate. For more information, see Terminate Amazon EC2 instances.

Prepare for Spot Instance interruptions

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted. Therefore, you must ensure that your application is prepared for a Spot Instance interruption.

We recommend that you follow these best practices so that you're prepared for a Spot Instance interruption.

- Create your Spot request using an Auto Scaling group. If your Spot Instances are interrupted, the Auto Scaling group will automatically launch replacement instances. For more information, see Auto Scaling groups with multiple instance types and purchase options in the *Amazon EC2 Auto Scaling User Guide*.
- Ensure that your instance is ready to go as soon as the request is fulfilled by using an Amazon Machine Image (AMI) that contains the required software configuration. You can also use user data to run commands at startup.
- Data on instance store volumes is lost when the instance is stopped or terminated. Back up any important data on instance store volumes to a more persistent storage, such as Amazon S3, Amazon EBS, or Amazon DynamoDB.
- Store important data regularly in a place that isn't affected if the Spot Instance terminates. For example, you can use Amazon S3, Amazon EBS, or DynamoDB.
- Divide the work into small tasks (using a Grid, Hadoop, or queue-based architecture) or use checkpoints so that you can save your work frequently.
- Amazon EC2 emits a rebalance recommendation signal to the Spot Instance when the instance is at an elevated risk of interruption. You can rely on the rebalance recommendation to proactively manage Spot Instance interruptions without having to wait for the two-minute Spot Instance interruption notice. For more information, see EC2 instance rebalance recommendations.
- Use the two-minute Spot Instance interruption notices to monitor the status of your Spot Instances. For more information, see Spot Instance interruption notices.
- While we make every effort to provide these warnings as soon as possible, it is possible that your Spot Instance is interrupted before the warnings can be made available. Test your application to ensure that it handles an unexpected instance interruption gracefully, even if you are monitoring for rebalance recommendation signals and interruption notices. You can do this by running the application using an On-Demand Instance and then terminating the On-Demand Instance yourself.
- Run a controlled fault injection experiment with AWS Fault Injection Service to test how your application responds when your Spot Instance is interrupted. For more information, see the Tutorial: Test Spot Instance interruptions using AWS FIS in the *AWS Fault Injection Service User Guide*.

Initiate a Spot Instance interruption

You can select a Spot Instance request or a Spot Fleet request in the Amazon EC2 console and initiate a Spot Instance interruption so that you can test how the applications on your Spot

Instances handle being interrupted. When you initiate a Spot Instance interruption, Amazon EC2 notifies you that your Spot Instance will be interrupted in two minutes, and then, after two minutes, the instance is interrupted.

The underlying service that performs the Spot Instance interruption is AWS Fault Injection Service (AWS FIS). For information about AWS FIS, see AWS Fault Injection Service.

> **Note**
>
> Interruption behaviors are `terminate`, `stop`, and `hibernate`. If you set the interruption behavior to `hibernate`, when you initiate a Spot Instance interruption, the hibernation process will begin immediately.

Initiating a Spot Instance interruption is supported in all AWS Regions except Asia Pacific (Jakarta), Asia Pacific (Osaka), China (Beijing), China (Ningxia), and Middle East (UAE).

Contents

Initiate a Spot Instance interruption

You can use the EC2 console to quickly initiate a Spot Instance interruption. When you select a Spot Instance request, you can initiate the interruption of one Spot Instance. When you select a Spot Fleet request, you can initiate the interruption of multiple Spot Instances at once.

For more advanced experiments to test Spot Instance interruptions, you can create your own experiments using the AWS FIS console.

To initiate the interruption of one Spot Instance in a Spot Instance request using the EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation pane, choose **Spot Requests**.
3. Select a Spot Instance request, and then choose **Actions**, **Initiate interruption**. You can't select multiple Spot Instance requests to initiate an interruption.

4. In the **Initiate Spot Instance interruption** dialog box, under **Service access**, either use the default role, or choose an existing role. To choose an existing role, choose **Use an existing service role**, and then, for **IAM role**, select the role to use.
5. When you're ready to initiate the Spot Instance interruption, choose **Initiate interruption.**

To initiate the interruption of one or more Spot Instances in a Spot Fleet request using the EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation pane, choose **Spot Requests**.
3. Select a Spot Fleet request, and then choose **Actions**, **Initiate interruption**. You can't select multiple Spot Fleet requests to initiate an interruption.
4. In the **Specify number of Spot Instances** dialog box, for **Number of instances to interrupt**, enter the number of Spot Instances to interrupt, and then choose **Confirm**.

   > **Note**
   >
   > The number can't exceed the number of Spot Instances in the fleet or your quota for the number of Spot Instances that AWS FIS can interrupt per experiment.

5. In the **Initiate Spot Instance interruption** dialog box, under **Service access**, either use the default role, or choose an existing role. To choose an existing role, choose **Use an existing service role**, and then, for **IAM role**, select the role to use.
6. When you're ready to initiate the Spot Instance interruption, choose **Initiate interruption.**

To create more advanced experiments to test Spot Instance interruptions using the AWS FIS console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation pane, choose **Spot Requests**.
3. Choose **Actions**, **Create advanced experiments**.

   The AWS FIS console opens. For more information, see Tutorial: Test Spot Instance interruptions using AWS FIS in the *AWS Fault Injection Service User Guide*.

Verify the Spot Instance interruption

After you initiate the interruption, the following occurs:

- The Spot Instance receives an instance rebalance recommendation.
- A Spot Instance interruption notice is issued two minutes before AWS FIS interrupts your instance.
- After two minutes, the Spot Instance is interrupted.
- A Spot Instance that was stopped by AWS FIS remains stopped until you restart it.

To verify that the instance was interrupted after you initiated the interruption

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation pane, open **Spot Requests** and **Instances** in separate browser tabs or windows.
3. For **Spot Requests**, select the Spot Instance request or Spot Fleet request. The initial status is `fulfilled`. After the instance is interrupted, the status changes as follows, depending on the interruption behavior:
   - `terminate` – The status changes to `instance-terminated-by-experiment`.
   - `stop` – The status changes to `marked-for-stop-by-experiment` and then `instance-stopped-by-experiment`.
4. For **Instances**, select the Spot Instance. The initial status is `Running`. Two minutes after you receive the Spot Instance interruption notice, the status changes as follows, depending on the interruption behavior:
   - `stop` – The status changes to `Stopping` and then `Stopped`.
   - `terminate` – The status changes to `Shutting-down` and then `Terminated`.

Quotas

Your AWS account has the following default quota for the number of Spot Instances that AWS FIS can interrupt per experiment.

Name	Default	Adjustable	Description
		Yes	

Name	Default	Adjustable	Description
Target SpotInstances for aws:ec2:send-spot-instance-interruptions	Each supported Region: 5		The maximum number of Spot Instances that aws:ec2:send-spot-instance-interruptions can target when you identify targets using tags, per experiment.

You can request a quota increase. For more information, see Requesting a quota increase in the *Service Quotas User Guide*.

To view all the quotas for AWS FIS, open the Service Quotas console. In the navigation pane, choose **AWS services** and select **AWS Fault Injection Service**. You can also view all the quotas for AWS Fault Injection Service in the *AWS Fault Injection Service User Guide*.

Spot Instance interruption notices

A *Spot Instance interruption notice* is a warning that is issued two minutes before Amazon EC2 stops or terminates your Spot Instance. If you specify hibernation as the interruption behavior, you receive an interruption notice, but you do not receive a two-minute warning because the hibernation process begins immediately.

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of Spot Instance interruption notices. We recommend that you check for these interruption notices every 5 seconds.

The interruption notices are made available as an EventBridge event and as items in the instance metadata on the Spot Instance. Interruption notices are emitted on a best effort basis.

EC2 Spot Instance Interruption Warning event

When Amazon EC2 is going to interrupt your Spot Instance, it emits an event two minutes prior to the actual interruption (except for hibernation, which gets the interruption notice, but not two minutes in advance, because hibernation begins immediately). This event can be detected by Amazon EventBridge. For more information about EventBridge events, see the Amazon

EventBridge User Guide. For a detailed example that walks you through how to create and use event rules, see Taking Advantage of Amazon EC2 Spot Instance Interruption Notices.

The following is an example of the event for Spot Instance interruption. The possible values for `instance-action` are `hibernate`, `stop`, or `terminate`.

```
{
    "version": "0",
    "id": "12345678-1234-1234-1234-123456789012",
    "detail-type": "EC2 Spot Instance Interruption Warning",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-2",
    "resources": ["arn:aws:ec2:us-east-2a:instance/i-1234567890abcdef0"],
    "detail": {
        "instance-id": "i-1234567890abcdef0",
        "instance-action": "action"
    }
}
```

> **Note**
>
> The ARN format of the Spot Instance interruption event is `arn:aws:ec2:`*`availability-zone`*`:instance/`*`instance-id`*. This format differs from the EC2 resource ARN format.

instance-action

The `instance-action` item specifies the action and the approximate time, in UTC, when the action will occur.

If your Spot Instance is marked to be stopped or terminated by Amazon EC2, the `instance-action` item is present in your instance metadata. Otherwise, it is not present. You can retrieve the `instance-action` using Instance Metadata Service Version 2 (IMDSv2) as follows.

Linux

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
```

```
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/
meta-data/spot/instance-action
```

Windows

```
[string]$token = Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} `
    -Method PUT -Uri http://169.254.169.254/latest/meta-data/spot/instance-action
```

The following example output indicates the time at which this instance will be stopped.

```
{"action": "stop", "time": "2017-09-18T08:22:00Z"}
```

The following example output indicates the time at which this instance will be terminated.

```
{"action": "terminate", "time": "2017-09-18T08:22:00Z"}
```

If Amazon EC2 is not preparing to stop or terminate the instance, or if you terminated the instance yourself, `instance-action` is not present in the instance metadata and you receive an HTTP 404 error when you try to retrieve it.

termination-time

The `termination-time` item specifies the approximate time in UTC when the instance will receive the shutdown signal.

> **Note**
>
> This item is maintained for backward compatibility; you should use `instance-action` instead.

If your Spot Instance is marked for termination by Amazon EC2 (either due to a Spot Instance interruption where the interruption behavior is set to `terminate`, or due to the cancellation of a persistent Spot Instance request), the `termination-time` item is present in your instance metadata. Otherwise, it is not present. You can retrieve the `termination-time` using IMDSv2 as follows.

Linux

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"`
if curl -H "X-aws-ec2-metadata-token: $TOKEN" -s http://169.254.169.254/latest/meta-data/spot/termination-time | grep -q .*T.*Z; then echo termination_scheduled; fi
```

Windows

```
[string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/meta-data/spot/termination-time
```

The following is example output.

```
2015-01-05T18:02:00Z
```

If Amazon EC2 is not preparing to terminate the instance (either because there is no Spot Instance interruption or because your interruption behavior is set to `stop` or `hibernate`), or if you terminated the Spot Instance yourself, the `termination-time` item is either not present in the instance metadata (so you receive an HTTP 404 error) or contains a value that is not a time value.

If Amazon EC2 fails to terminate the instance, the request status is set to `fulfilled`. The `termination-time` value remains in the instance metadata with the original approximate time, which is now in the past.

Find interrupted Spot Instances

When you describe your EC2 instances, the results include your Spot Instances. The instance lifecycle of a Spot Instance is `spot`. The instance state of a Spot Instance is either `stopped` or `terminated`, depending on the interruption behavior that you configured. For a hibernated Spot Instance, the instance state is `stopped`.

For additional details about the reason for the interruption, check the Spot request status code. For more information, see the section called “Get the status of a Spot Instance request”.

Console

To find an interrupted Spot Instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Apply the following filter: **Instance lifecycle=spot**.
4. Apply the **Instance state=stopped** or **Instance state=terminated** filter depending on the interruption behavior that you configured.
5. For each Spot Instance, on the **Details** tab, under **Instance details**, find **State transition message**. The following codes indicate that the Spot Instance was interrupted.
   - `Server.SpotInstanceShutdown`
   - `Server.SpotInstanceTermination`

AWS CLI

To find interrupted Spot Instances

Use the describe-instances command with the `--filters` option. To list only the instance IDs in the output, include the `--query` option.

If the interruption behavior is to terminate the Spot Instances, use the following example:

```
aws ec2 describe-instances \
    --filters Name=instance-lifecycle,Values=spot \
              Name=instance-state-name,Values=terminated \
              Name=state-reason-code,Values=Server.SpotInstanceTermination \
    --query "Reservations[*].Instances[*].InstanceId"
```

If the interruption behavior is to stop the Spot Instances, use the following example:

```
aws ec2 describe-instances \
    --filters Name=instance-lifecycle,Values=spot \
              Name=instance-state-name,Values=stopped \
              Name=state-reason-code,Values=Server.SpotInstanceShutdown \
    --query "Reservations[*].Instances[*].InstanceId"
```

PowerShell

To find interrupted Spot Instances

Use the Get-EC2Instance cmdlet.

If the interruption behavior is to terminate the Spot Instances, use the following example:

```
(Get-EC2Instance `
    -Filter @{Key="instance-lifecycle"; Values="spot"} `
            @{Key="instance-state-name"; Values="terminated"} `
            @{Key="state-reason-code";
 Values="Server.SpotInstanceTermination"}).Instances.InstanceId
```

If the interruption behavior is to stop the Spot Instances, use the following example:

```
(Get-EC2Instance `
    -Filter @{Key="instance-lifecycle"; Values="spot"} `
            @{Key="instance-state-name"; Values="stopped"} `
            @{Key="state-reason-code";
 Values="Server.SpotInstanceTermination"}).Instances.InstanceId
```

Determine whether Amazon EC2 terminated a Spot Instance

A Spot Instance runs until Amazon EC2 terminates it in response to a Spot Instance interruption, or until you terminate it yourself. For more information, see the section called “Interruption behavior”.

After a Spot Instance is terminated, you can use AWS CloudTrail to see whether Amazon EC2 terminated it. If the CloudTrail log includes a `BidEvictedEvent`, this indicates that Amazon EC2 terminated the Spot Instance. If instead you see a `TerminateInstances` event, this indicates that a user terminated the Spot Instance.

Alternatively, if you want to receive notification that Amazon EC2 is going to interrupt your Spot Instance, use Amazon EventBridge to respond to the EC2 Spot Instance Interruption Warning event.

To view BidEvictedEvent events in CloudTrail

1. Open the CloudTrail console at https://console.aws.amazon.com/cloudtrail/.
2. In the navigation pane, choose **Event history**.

3. From the list of filters, choose **Event name**, and then in the filter field to the right, enter **BidEvictedEvent**.
4. (Optional) Select a time range.
5. If the list is not empty, choose **BidEvictedEvent** from the resulting entry to open its details page. You can find information about the Spot Instance in the **Event record** pane, including the ID of the Spot Instance. The following is an example of the event record.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "accountId": "123456789012",
        "invokedBy": "ec2.amazonaws.com"
    },
    "eventTime": "2016-08-16T22:30:00Z",
    "eventSource": "ec2.amazonaws.com",
    "userAgent": "ec2.amazonaws.com",
    "sourceIPAddress": "ec2.amazonaws.com",
    "eventName": "BidEvictedEvent",
    "awsRegion": "us-east-2",
    "eventID": "d27a6096-807b-4bd0-8c20-a33a83375054",
    "eventType": "AwsServiceEvent",
    "recipientAccountId": "123456789012",
    "RequestParameters": null,
    "ResponseElements": null,
    "serviceEventDetails": {
        "instanceIdSet": [
          "i-1eb2ac8eEXAMPLE"
        ]
    }
}
```

6. If you did not find an entry for the `BidEvictedEvent` event, enter **TerminateInstances** as the event name. For more information about the event record for `TerminateInstances`, see the section called "Amazon EC2 API event examples".

Billing for interrupted Spot Instances

When a Spot Instance is interrupted, you're charged for instance and EBS volume usage, and you might incur other charges, as follows.

Instance usage

Who interrupts the Spot Instance	Operating system	Interrupted in the first hour	Interrupted in any hour after the first hour
If **you** stop or terminate the Spot Instance	Windows and Linux (excluding SUSE)	Charged for the seconds used	Charged for the seconds used
	SUSE	Charged for the full hour even if you used a partial hour	Charged for the full hours used, and charged a full hour for the interrupted partial hour
If the **Amazon EC2** interrupts the Spot Instance	Windows and Linux (excluding SUSE)	No charge	Charged for the seconds used
	SUSE	No charge	Charged for the full hours used, but no charge for the inter rupted partial hour

EBS volume usage

While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved.

With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account.

EC2 instance rebalance recommendations

An EC2 instance *rebalance recommendation* is a signal that notifies you when a Spot Instance is at elevated risk of interruption. The signal can arrive sooner than the two-minute Spot Instance interruption notice, giving you the opportunity to proactively manage the Spot Instance. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption.

It is not always possible for Amazon EC2 to send the rebalance recommendation signal before the two-minute Spot Instance interruption notice. Therefore, the rebalance recommendation signal can arrive along with the two-minute interruption notice.

Rebalance recommendations are made available as a EventBridge event and as an item in the instance metadata on the Spot Instance. Events are emitted on a best effort basis.

> **Note**
>
> Rebalance recommendations are only supported for Spot Instances that are launched after November 5, 2020 00:00 UTC.

Contents

Rebalance actions you can take

These are some of the possible rebalancing actions that you can take:

Graceful shutdown

When you receive the rebalance recommendation signal for a Spot Instance, you can start your instance shutdown procedures, which might include ensuring that processes are completed before stopping them. For example, you can upload system or application logs to Amazon Simple Storage Service (Amazon S3), you can shut down Amazon SQS workers, or you can complete deregistration from the Domain Name System (DNS). You can also save your work in external storage and resume it at a later time.

Prevent new work from being scheduled

When you receive the rebalance recommendation signal for a Spot Instance, you can prevent new work from being scheduled on the instance, while continuing to use the instance until the scheduled work is completed.

Proactively launch new replacement instances

You can configure Auto Scaling groups, EC2 Fleet, or Spot Fleet to automatically launch replacement Spot Instances when a rebalance recommendation signal is emitted. For more information, see Use Capacity Rebalancing to handle Amazon EC2 Spot interruptions in the *Amazon EC2 Auto Scaling User Guide*, and Use Capacity Rebalancing in EC2 Fleet and Spot Fleet to replace at-risk Spot Instances in this user guide.

Monitor rebalance recommendation signals

You can monitor the rebalance recommendation signal so that, when it is emitted, you can take the actions that are specified in the preceding section. The rebalance recommendation signal is made available as an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events) and as instance metadata on the Spot Instance.

Monitor rebalance recommendation signals:

- Use Amazon EventBridge
- Use instance metadata

Use Amazon EventBridge

When the rebalance recommendation signal is emitted for a Spot Instance, the event for the signal is sent to Amazon EventBridge. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes a target (or targets) specified in the rule.

The following is an example event for the rebalance recommendation signal.

```
{
    "version": "0",
    "id": "12345678-1234-1234-1234-123456789012",
    "detail-type": "EC2 Instance Rebalance Recommendation",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-2",
    "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"],
    "detail": {
        "instance-id": "i-1234567890abcdef0"
    }
```

```
}
```

The following fields form the event pattern that is defined in the rule:

`"detail-type": "EC2 Instance Rebalance Recommendation"`

Identifies that the event is a rebalance recommendation event

`"source": "aws.ec2"`

Identifies that the event is from Amazon EC2

Create an EventBridge rule

You can write an EventBridge rule and automate what actions to take when the event pattern matches the rule.

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time Amazon EC2 emits a rebalance recommendation signal. The signal is emitted as an `EC2 Instance Rebalance Recommendation` event, which triggers the action defined by the rule.

Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule for a rebalance recommendation event

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose **Create rule**.
3. For **Define rule detail**, do the following:

   a. Enter a **Name** for the rule, and, optionally, a description.

      A rule can't have the same name as another rule in the same Region and on the same event bus.

   b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.

   c. For **Rule type**, choose **Rule with an event pattern**.

   d. Choose **Next**.

4. For **Build event pattern**, do the following:

   a. For **Event source**, choose **AWS events or EventBridge partner events**.

   b. For **Event pattern**, for this example you'll specify the following event pattern to match the `EC2 Instance Rebalance Recommendation` event, and then choose **Save**.

```
{
 "source": ["aws.ec2"],
 "detail-type": ["EC2 Instance Rebalance Recommendation"]
}
```

   To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

      i. To use a template to create the event pattern, do the following:

         A. Choose **Event pattern form**.

         B. For **Event source**, choose **AWS services**.

         C. For **AWS Service**, choose **EC2 Spot Fleet**.

         D. For **Event type**, choose **EC2 Instance Rebalance Recommendation**.

         E. To customize the template, choose **Edit pattern** and make your changes to match the example event pattern.

      ii. (Alternative) To specify a custom event pattern, do the following:

         A. Choose **Custom pattern (JSON editor)**.

         B. In the **Event pattern** box, add the event pattern for this example.

   c. Choose **Next**.

5. For **Select target(s)**, do the following:

   a. For **Target types**, choose **AWS service**.

   b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.

   c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person (A2P) messaging] in the *Amazon Simple Notification Service Developer Guide*.

   d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see Creating Amazon EventBridge rules that react to events (step 16) in the *Amazon EventBridge User Guide*.

   e. Choose **Next**.

6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.

7. For **Review and create**, do the following:

   a. Review the details of the rule and modify them as necessary.

   b. Choose **Create rule**.

For more information, see Amazon EventBridge rules and Amazon EventBridge event patterns in the *Amazon EventBridge User Guide*

Use instance metadata

The instance metadata category `events/recommendations/rebalance` provides the approximate time, in UTC, when the rebalance recommendation signal was emitted for a Spot Instance.

We recommend that you check for rebalance recommendation signals every 5 seconds so that you don't miss an opportunity to act on the rebalance recommendation.

If a Spot Instance receives a rebalance recommendation, the time that the signal was emitted is present in the instance metadata. You can retrieve the time that the signal was emitted as follows.

IMDSv2

Linux

Run the following command from your Linux instance.

IMDSv2

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
    && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/events/recommendations/rebalance
```

Windows

Run the following cmdlet from your Windows instance

```
[string]$token = Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} `
    -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod `
    -Headers @{"X-aws-ec2-metadata-token" = $token} `
    -Method GET -Uri http://169.254.169.254/latest/meta-data/events/recommendations/
rebalance
```

IMDSv1

Linux

Run the following command from your Linux instance.

```
curl http://169.254.169.254/latest/meta-data/events/recommendations/rebalance
```

Windows

Run the following cmdlet from your Windows instance.

```
Invoke-RestMethod -Uri http://169.254.169.254/latest/meta-data/events/
recommendations/rebalance
```

The following is example output, which indicates the time, in UTC, that the rebalance recommendation signal was emitted for the Spot Instance.

```
{"noticeTime": "2020-10-27T08:22:00Z"}
```

If the signal has not been emitted for the instance, `events/recommendations/rebalance` is not present and you receive an HTTP 404 error when you try to retrieve it.

Services that use the rebalance recommendation signal

Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet use the rebalance recommendation signal to make it easy for you to maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance receives the two-minute Spot Instance interruption notice. You can have these services monitor and respond proactively to changes affecting the availability of your Spot Instances. For more information, see the following:

- Use Capacity Rebalancing to handle Amazon EC2 Spot interruptions in the *Amazon EC2 Auto Scaling User Guide*
- Use Capacity Rebalancing in EC2 Fleet and Spot Fleet to replace at-risk Spot Instances in the EC2 Fleet and Spot Fleet topic in this user guide

Spot placement score

The Spot placement score feature can recommend an AWS Region or Availability Zone based on your Spot capacity requirements. Spot capacity fluctuates, and you can't be sure that you'll always get the capacity that you need. A Spot placement score indicates how likely it is that a Spot request will succeed in a Region or Availability Zone.

> **Note**
>
> A Spot placement score does not provide any guarantees in terms of available capacity or risk of interruption. A Spot placement score serves only as a recommendation.

Use cases

You can use the Spot placement score feature for the following:

- To relocate and scale Spot compute capacity in a different Region, as needed, in response to increased capacity needs or decreased available capacity in the current Region.
- To identify the most optimal Availability Zone in which to run single-Availability Zone workloads.
- To simulate future Spot capacity needs so that you can pick an optimal Region for the expansion of your Spot-based workloads.
- To find an optimal combination of instance types to fulfill your Spot capacity needs.

Contents

- How Spot placement score works
- Required permissions for Spot placement score
- Calculate the Spot placement score

Limitations

- **Target capacity limit** – Your Spot placement score target capacity limit is based on your recent Spot usage, while accounting for potential usage growth. If you have no recent Spot usage, we provide you with a low default limit aligned with your Spot request limit.
- **Request configurations limit** – We can limit the number of new request configurations within a 24-hour period if we detect patterns not associated with the intended use of the Spot placement score feature. If you reach the limit, you can retry the request configurations that you've already used, but you can't specify new request configurations until the next 24-hour period.
- **Minimum number of instance types** – If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types. Instance types are considered different if they have a different name. For example, m5.8xlarge, m5a.8xlarge, and m5.12xlarge are all considered different.

Costs

There is no additional charge for using the Spot placement score feature.

How Spot placement score works

When you use the Spot placement score feature, you first specify your compute requirements for your Spot Instances, and then Amazon EC2 returns the top 10 Regions or Availability Zones where your Spot request is likely to succeed. Each Region or Availability Zone is scored on a scale from 1 to 10, with 10 indicating that your Spot request is highly likely to succeed, and 1 indicating that your Spot request is not likely to succeed.

To use the Spot placement score feature, follow these steps:

- Step 1: Specify your Spot requirements
- Step 2: Filter the Spot placement score response
- Step 3: Review the recommendations
- Step 4: Use the recommendations

Step 1: Specify your Spot requirements

First, you specify your desired target Spot capacity and your compute requirements, as follows:

1. **Specify the target Spot capacity, and optionally the target capacity unit.**

   You can specify your desired target Spot capacity in terms of the number of instances or vCPUs, or in terms of the amount of memory in MiB. To specify the target capacity in number of vCPUs or amount of memory, you must specify the target capacity unit as `vcpu` or `memory-mib`. Otherwise, it defaults to number of instances.

   By specifying your target capacity in terms of the number of vCPUs or the amount of memory, you can use these units when counting the total capacity. For example, if you want to use a mix of instances of different sizes, you can specify the target capacity as a total number of vCPUs. The Spot placement score feature then considers each instance type in the request by its number of vCPUs, and counts the total number of vCPUs rather than the total number of instances when totaling up the target capacity.

   For example, say you specify a total target capacity of 30 vCPUs, and your instance type list consists of c5.xlarge (4 vCPUs), m5.2xlarge (8 vCPUs), and r5.large (2 vCPUs). To achieve a total of 30 vCPUs, you could get a mix of 2 c5.xlarge (2*4 vCPUs), 2 m5.2xlarge (2*8 vCPUs), and 3 r5.large (3*2 vCPUs).

2. **Specify instance types or instance attributes.**

   You can either specify the instance types to use, or you can specify the instance attributes that you need for your compute requirements, and then let Amazon EC2 identify the instance types that have those attributes. This is known as attribute-based instance type selection.

   You can't specify both instance types and instance attributes in the same Spot placement score request.

   If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types.

For examples of different ways to specify your Spot requirements, see Example configurations.

Step 2: Filter the Spot placement score response

Amazon EC2 calculates the Spot placement score for each Region or Availability Zone, and returns either the top 10 Regions or the top 10 Availability Zones where your Spot request is likely to succeed. The default is to return a list of scored Regions. If you plan to launch all of your Spot capacity into a single Availability Zone, then it's useful to request a list of scored Availability Zones.

You can specify a Region filter to narrow down the Regions that will be returned in the response.

You can combine the Region filter and a request for scored Availability Zones. In this way, the scored Availability Zones are confined to the Regions for which you've filtered. To find the highest-scored Availability Zone in a Region, specify only that Region, and the response will return a scored list of all of the Availability Zones in that Region.

Step 3: Review the recommendations

The Spot placement score for each Region or Availability Zone is calculated based on the target capacity, the composition of the instance types, the historical and current Spot usage trends, and the time of the request. Because Spot capacity is constantly fluctuating, the same Spot placement score request can yield different scores when calculated at different times.

Regions and Availability Zones are scored on a scale from 1 to 10. A score of 10 indicates that your Spot request is highly likely—but not guaranteed—to succeed. A score of 1 indicates that your Spot request is not likely to succeed at all. The same score might be returned for different Regions or Availability Zones.

If low scores are returned, you can edit your compute requirements and recalculate the score. You can also request Spot placement score recommendations for the same compute requirements at different times of the day.

Step 4: Use the recommendations

A Spot placement score is only relevant if your Spot request has exactly the same configuration as the Spot placement score configuration (target capacity, target capacity unit, and instance types or instance attributes), and is configured to use the `capacity-optimized` allocation strategy. Otherwise, the likelihood of getting available Spot capacity will not align with the score.

While a Spot placement score serves as a guideline, and no score guarantees that your Spot request will be fully or partially fulfilled, you can use the following information to get the best results:

- **Use the same configuration** – The Spot placement score is relevant only if the Spot request configuration (target capacity, target capacity unit, and instance types or instance attributes) in your Auto Scaling group, EC2 Fleet, or Spot Fleet is the same as what you entered to get the Spot placement score.

  If you used attribute-based instance type selection in your Spot placement score request, you can use attribute-based instance type selection to configure your Auto Scaling group, EC2 Fleet, or Spot Fleet. For more information, see Create mixed instances group using attribute-based instance type selection and Specify attributes for instance type selection for EC2 Fleet or Spot Fleet.

  > **Note**
  >
  > If you specified your target capacity in terms of the number of vCPUs or the amount of memory, and you specified instance types in your Spot placement score configuration, note that you can’t currently create this configuration in your Auto Scaling group, EC2 Fleet, or Spot Fleet. Instead, you must manually set the instance weighting by using the `WeightedCapacity` parameter.

- **Use the `capacity-optimized` allocation strategy** – Any score assumes that your fleet request will be configured to use all Availability Zones (for requesting capacity across Regions) or a single Availability Zone (if requesting capacity in one Availability Zone) and the `capacity-optimized` Spot allocation strategy for your request for Spot capacity to succeed. If you use other allocation strategies, such as `lowest-price`, the likelihood of getting available Spot capacity will not align with the score.
- **Act on a score immediately** – The Spot placement score recommendation reflects the available Spot capacity at the time of the request, and the same configuration can yield different scores when calculated at different times due to Spot capacity fluctuations. While a score of 10 means that your Spot capacity request is highly likely—but not guaranteed—to succeed, for best results we recommend that you act on a score immediately. We also recommend that you get a fresh score each time you attempt a capacity request.

Required permissions for Spot placement score

By default, IAM identities (users, roles, or groups) don't have permission to use the section called “Spot placement score”. To allow IAM identities to use Spot placement score, you must create an

IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action. You then attach the policy to the IAM identities that require this permission.

The following is an example IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:GetSpotPlacementScores",
            "Resource": "*"
        }
    ]
}
```

For information about editing an IAM policy, see Editing IAM policies in the *IAM User Guide*.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the *AWS IAM Identity Center User Guide*.
- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.
- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

Calculate the Spot placement score

You can calculate a Spot placement score based on target capacity and compute requirements. For more information, see the section called “How Spot placement score works”.

Required permissions

Ensure that you have the required permissions. For more information, see the section called “Required permissions”.

Options

- Calculate using instance attributes
- Calculate using instance types
- Calculate using the AWS CLI

Looking for an automated solution? Instead of following the manual steps in this user guide, you can build a Spot placement score tracker dashboard that automatically captures and stores the scores in Amazon CloudWatch. For more information, see Guidance for Building a Spot Placement Score Tracker Dashboard on AWS.

Calculate using instance attributes

To calculate a Spot placement score by specifying instance attributes

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Choose the down arrow next to **Request Spot Instances** and choose **Calculate Spot Placement Score**.
4. Choose **Enter requirements**.
5. For **Target capacity**, enter your desired capacity in terms of the number of **instances** or **vCPUs**, or the amount of **memory (MiB)**.
6. For **Instance type requirements**, to specify your compute requirements and let Amazon EC2 identify the optimal instance types with these requirements, choose **Specify instance attributes that match your compute requirements**.
7. For **vCPUs**, enter the desired minimum and maximum number of vCPUs. To specify no limit, select **No minimum**, **No maximum**, or both.

8. For **Memory (GiB)**, enter the desired minimum and maximum amount of memory. To specify no limit, select **No minimum**, **No maximum**, or both.
9. For **CPU architecture**, select the required instance architecture.
10. (Optional) For **Additional instance attributes**, you can optionally specify one or more attributes to express your compute requirements in more detail. Each additional attribute adds a further constraint to your request. You can omit the additional attributes; when omitted, the default values are used. For a description of each attribute and their default values, see get-spot-placement-scores.
11. (Optional) To view the instance types with your specified attributes, expand **Preview matching instance types**. To exclude instance types from being used in the placement evaluation, select the instances and then choose **Exclude selected instance types**.
12. Choose **Load placement scores**, and review the results.
13. (Optional) To display the Spot placement score for specific Regions, for **Regions to evaluate**, select the Regions to evaluate, and then choose **Calculate placement scores**.
14. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the **Provide placement scores per Availability Zone** checkbox. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.
15. (Optional) To edit your compute requirements and get a new placement score, choose **Edit**, make the necessary adjustments, and then choose **Calculate placement scores**.

Calculate using instance types

To calculate a Spot placement score by specifying instance types

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Choose the down arrow next to **Request Spot Instances** and choose **Calculate Spot Placement Score**.
4. Choose **Enter requirements**.
5. For **Target capacity**, enter your desired capacity in terms of the number of **instances** or **vCPUs**, or the amount of **memory (MiB)**.
6. For **Instance type requirements**, to specify the instance types to use, choose **Manually select instance types**.

7. Choose **Select instance types**, select the instance types to use, and then choose **Select**. To quickly find instance types, you can use the filter bar to filter the instance types by different properties.
8. Choose **Load placement scores**, and review the results.
9. (Optional) To display the Spot placement score for specific Regions, for **Regions to evaluate**, select the Regions to evaluate, and then choose **Calculate placement scores**.
10. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the **Provide placement scores per Availability Zone** checkbox. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.
11. (Optional) To edit the list of instance types and get a new placement score, choose **Edit**, make the necessary adjustments, and then choose **Calculate placement scores**.

Calculate using the AWS CLI

To calculate the Spot placement score

1. (Optional) To generate all of the possible parameters that can be specified for the Spot placement score configuration, use the get-spot-placement-scores command and the `--generate-cli-skeleton` parameter.

```
aws ec2 get-spot-placement-scores \
    --region us-east-1 \
    --generate-cli-skeleton
```

The following is example output.

```
{
    "InstanceTypes": [
        ""
    ],
    "TargetCapacity": 0,
    "TargetCapacityUnitType": "vcpu",
    "SingleAvailabilityZone": true,
    "RegionNames": [
        ""
    ],
    "InstanceRequirementsWithMetadata": {
```

```
        "ArchitectureTypes": [
            "x86_64_mac"
        ],
        "VirtualizationTypes": [
            "hvm"
        ],
        "InstanceRequirements": {
            "VCpuCount": {
                "Min": 0,
                "Max": 0
            },
            "MemoryMiB": {
                "Min": 0,
                "Max": 0
            },
            "CpuManufacturers": [
                "amd"
            ],
            "MemoryGiBPerVCpu": {
                "Min": 0.0,
                "Max": 0.0
            },
            "ExcludedInstanceTypes": [
                ""
            ],
            "InstanceGenerations": [
                "previous"
            ],
            "SpotMaxPricePercentageOverLowestPrice": 0,
            "OnDemandMaxPricePercentageOverLowestPrice": 0,
            "BareMetal": "excluded",
            "BurstablePerformance": "excluded",
            "RequireHibernateSupport": true,
            "NetworkInterfaceCount": {
                "Min": 0,
                "Max": 0
            },
            "LocalStorage": "included",
            "LocalStorageTypes": [
                "hdd"
            ],
            "TotalLocalStorageGB": {
                "Min": 0.0,
                "Max": 0.0
```

```
            },
            "BaselineEbsBandwidthMbps": {
                "Min": 0,
                "Max": 0
            },
            "AcceleratorTypes": [
                "fpga"
            ],
            "AcceleratorCount": {
                "Min": 0,
                "Max": 0
            },
            "AcceleratorManufacturers": [
                "amd"
            ],
            "AcceleratorNames": [
                "vu9p"
            ],
            "AcceleratorTotalMemoryMiB": {
                "Min": 0,
                "Max": 0
            }
        }
    },
    "DryRun": true,
    "MaxResults": 0,
    "NextToken": ""
}
```

2. Create a JSON configuration file using the output from the previous step, and configure it as follows:

    a. For `TargetCapacity`, enter your desired Spot capacity in terms of the number of instances or vCPUs, or the amount of memory (MiB).

    b. For `TargetCapacityUnitType`, enter the unit for the target capacity. If you omit this parameter, it defaults to `units`.

       Valid values: `units` (which translates to number of instances) | `vcpu` | `memory-mib`

    c. For `SingleAvailabilityZone`, specify `true` for a response that returns a list of scored Availability Zones. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone. If you omit this parameter, it defaults to `false`, and the response returns a list of scored Regions.

d. (Optional) For `RegionNames`, specify the Regions to use as a filter. You must specify the Region code, for example, `us-east-1`.

   With a Region filter, the response returns only the Regions that you specify. If you specified `true` for `SingleAvailabilityZone`, the response returns only the Availability Zones in the specified Regions.

e. You can include either `InstanceTypes` or `InstanceRequirements`, but not both in the same configuration.

   Specify one of the following in your JSON configuration:

   - To specify a list of instance types, specify the instance types in the `InstanceTypes` parameter. Specify at least three different instance types. If you specify only one or two instance types, Spot placement score returns a low score. For the list of instance types, see Amazon EC2 Instance Types.
   - To specify the instance attributes so that Amazon EC2 will identify the instance types that match those attributes, specify the attributes that are located in the `InstanceRequirements` structure.

     You must provide values for `VCpuCount`, `MemoryMiB`, and `CpuManufacturers`. You can omit the other attributes; when omitted, the default values are used. For a description of each attribute and their default values, see get-spot-placement-scores.

   For example configurations, see Example configurations.

3. To get the Spot placement score for the requirements that you specified in the JSON file, use the get-spot-placement-scores command, and specify the name and path to your JSON file by using the `--cli-input-json` parameter.

```
aws ec2 get-spot-placement-scores \
    --region us-east-1 \
    --cli-input-json file://file_name.json
```

Example output if `SingleAvailabilityZone` is set to `false` or omitted (if omitted, it defaults to `false`) – a scored list of Regions is returned.

```
"SpotPlacementScores": [
    {
```

```
        "Region": "us-east-1",
        "Score": 7
    },
    {
        "Region": "us-west-1",
        "Score": 5
    },
   ...
```

Example output if `SingleAvailabilityZone` is set to `true` – a scored list of Availability Zones is returned.

```
"SpotPlacementScores": [
    {
        "Region": "us-east-1",
        "AvailabilityZoneId": "use1-az1",
        "Score": 8
    },
    {
        "Region": "us-east-1",
        "AvailabilityZoneId": "usw2-az3",
        "Score": 6
    },
   ...
```

Example configurations

When using the AWS CLI, you can use the following example configurations.

Example configurations

- Example: Specify instance types and target capacity
- Example: Specify instance types, and target capacity in terms of memory
- Example: Specify attributes for attribute-based instance type selection
- Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones

Example: Specify instance types and target capacity

The following example configuration specifies three different instance types and a target Spot capacity of 500 Spot Instances.

```
{
    "InstanceTypes": [
        "m5.4xlarge",
        "r5.2xlarge",
        "m4.4xlarge"
    ],
    "TargetCapacity": 500
}
```

Example: Specify instance types, and target capacity in terms of memory

The following example configuration specifies three different instance types and a target Spot capacity of 500,000 MiB of memory, where the number of Spot Instances to launch must provide a total of 500,000 MiB of memory.

```
{
    "InstanceTypes": [
        "m5.4xlarge",
        "r5.2xlarge",
        "m4.4xlarge"
    ],
    "TargetCapacity": 500000,
    "TargetCapacityUnitType": "memory-mib"
}
```

Example: Specify attributes for attribute-based instance type selection

The following example configuration is configured for attribute-based instance type selection, and is followed by a text explanation of the example configuration.

```
{
    "TargetCapacity": 5000,
    "TargetCapacityUnitType": "vcpu",
    "InstanceRequirementsWithMetadata": {
        "ArchitectureTypes": ["arm64"],
        "VirtualizationTypes": ["hvm"],
```

```
        "InstanceRequirements": {
            "VCpuCount": {
                "Min": 1,
                "Max": 12
            },
            "MemoryMiB": {
                "Min": 512
            }
        }
    }
}
```

InstanceRequirementsWithMetadata

To use attribute-based instance type selection, you must include the `InstanceRequirementsWithMetadata` structure in your configuration, and specify the desired attributes for the Spot Instances.

In the preceding example, the following required instance attributes are specified:

- `ArchitectureTypes` – The architecture type of the instance types must be `arm64`.
- `VirtualizationTypes` – The virtualization type of the instance types must be `hvm`.
- `VCpuCount` – The instance types must have a minimum of 1 and a maximum of 12 vCPUs.
- `MemoryMiB` – The instance types must have a minimum of 512 MiB of memory. By omitting the `Max` parameter, you are indicating that there is no maximum limit.

Note that there are several other optional attributes that you can specify. For the list of attributes, see get-spot-placement-scores.

TargetCapacityUnitType

The `TargetCapacityUnitType` parameter specifies the unit for the target capacity. In the example, the target capacity is `5000` and the target capacity unit type is `vcpu`, which together specify a desired target capacity of 5000 vCPUs, where the number of Spot Instances to launch must provide a total of 5000 vCPUs.

Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones

The following example configuration is configured for attribute-based instance type selection. By specifying `"SingleAvailabilityZone": true`, the response will return a list of scored Availability Zones.

```
{
    "TargetCapacity": 1000,
    "TargetCapacityUnitType": "vcpu",
    "SingleAvailabilityZone": true,
    "InstanceRequirementsWithMetadata": {
        "ArchitectureTypes": ["arm64"],
        "VirtualizationTypes": ["hvm"],
        "InstanceRequirements": {
            "VCpuCount": {
                "Min": 1,
                "Max": 12
            },
            "MemoryMiB": {
                "Min": 512
            }
        }
    }
}
```

Track your Spot Instance costs using the Spot Instance data feed

To help you understand the charges for your Spot Instances, Amazon EC2 provides a data feed that describes your Spot Instance usage and pricing. This data feed is sent to an Amazon S3 bucket that you specify when you subscribe to the data feed.

Data feed files arrive in your bucket typically once an hour. If you don't have a Spot Instance running during a certain hour, you don't receive a data feed file for that hour.

Each hour of Spot Instance usage is typically covered in a single data file. These files are compressed (gzip) before they are delivered to your bucket. Amazon EC2 can write multiple files for a given hour of usage where files are large (for example, when file contents for the hour exceed 50 MB before compression).

> **Note**
>
> You can create only one Spot Instance data feed per AWS account.

Spot Instance data feed is supported in all AWS Regions except China (Beijing), China (Ningxia), AWS GovCloud (US), and the Regions that are disabled by default.

Contents

Data feed file name and format

The Spot Instance data feed file name uses the following format (with the date and hour in UTC):

```
bucket-name.s3.amazonaws.com/optional-prefix/aws-account-id.YYYY-MM-DD-HH.n.unique-
id.gz
```

For example, if your bucket name is **`amzn-s3-demo-bucket`** and your prefix is **`my-prefix`**, your file names are similar to the following:

```
amzn-s3-demo-bucket.s3.amazonaws.com/my-
prefix/111122223333.2023-12-09-07.001.b959dbc6.gz
```

For more information about bucket names, see Bucket naming rules in the *Amazon S3 User Guide*.

The Spot Instance data feed files are tab-delimited. Each line in the data file corresponds to one instance hour and contains the fields listed in the following table.

Field	Description
`Timestamp`	The timestamp used to determine the price charged for this instance usage.

Field	Description
`UsageType`	The type of usage and instance type being charged for. For `m1.small` Spot Instances, this field is set to `SpotUsage` . For all other instance types, this field is set to `SpotUsage:` {*instance-type*}. For example, `SpotUsage:c1.medium` .
`Operation`	The product being charged for. For Linux Spot Instances, this field is set to `RunInstances` . For Windows Spot Instances, this field is set to `RunInstances:0002` . Spot usage is grouped according to Availability Zone.
`InstanceID`	The ID of the Spot Instance that generated this instance usage.
`MyBidID`	The ID for the Spot Instance request that generated this instance usage.
`MyMaxPrice`	The maximum price specified for this Spot request.
`MarketPrice`	The Spot price at the time specified in the `Timestamp` field.
`Charge`	The price charged for this instance usage.
`Version`	The data feed version. The possible version is 1.0.

Amazon S3 bucket requirements

When you subscribe to the data feed, you must specify an Amazon S3 bucket to store the data feed files.

Before you choose an Amazon S3 bucket for the data feed, consider the following:

- You must have `FULL_CONTROL` permission to the bucket. If you're the bucket owner, you have this permission by default. Otherwise, the bucket owner must grant your AWS account this permission.

- When you subscribe to a data feed, these permissions are used to update the bucket ACL to give the AWS data feed account `FULL_CONTROL` permission. The AWS data feed account writes data feed files to the bucket. If your account doesn't have the required permissions, the data feed files cannot be written to the bucket. For more information, see Logs sent to Amazon S3 in the *Amazon CloudWatch Logs User Guide*.

  If you update the ACL and remove the permissions for the AWS data feed account, the data feed files cannot be written to the bucket. You must resubscribe to the data feed to receive the data feed files.
- Each data feed file has its own ACL (separate from the ACL for the bucket). The bucket owner has `FULL_CONTROL` permission to the data files. The AWS data feed account has read and write permissions.
- If you delete your data feed subscription, Amazon EC2 doesn't remove the read and write permissions for the AWS data feed account on either the bucket or the data files. You must remove these permissions yourself.
- If you encrypt your Amazon S3 bucket using server-side encryption with a AWS KMS key stored in AWS Key Management Service (SSE-KMS), you must use a customer managed key. For more information, see Amazon S3 bucket server-side encryption in the *Amazon CloudWatch Logs User Guide*.

Subscribe to your Spot Instance data feed

You can subscribe to your Spot Instance data feed at any time. You can't complete this task using the Amazon EC2 console.

If you get an error that the bucket does not have enough permissions, see the following article for troubleshooting information: Troubleshoot the data feed for Spot Instances.

AWS CLI

To subscribe to your data feed

Use the create-spot-datafeed-subscription command.

To specify a bucket with a prefix, use the following example:

```
aws ec2 create-spot-datafeed-subscription \
    --bucket amzn-s3-demo-bucket \
    --prefix my-prefix
```

To specify a bucket without a prefix, use the following example:

```
aws ec2 create-spot-datafeed-subscription \
    --bucket amzn-s3-demo-bucket
```

PowerShell

To subscribe to your data feed

Use the New-EC2SpotDatafeedSubscription cmdlet.

To specify a bucket with a prefix, use the following example:

```
New-EC2SpotDatafeedSubscription `
    -Bucket amzn-s3-demo-bucket `
    -Prefix my-prefix
```

To specify a bucket without a prefix, use the following example:

```
New-EC2SpotDatafeedSubscription `
    -Bucket amzn-s3-demo-bucket
```

View the data in your data feed

In the AWS Management Console, open AWS CloudShell. Use the following s3 sync command to get the .gz files from the S3 bucket for your data feed and store them in the folder that you specify.

```
aws s3 sync s3://amzn-s3-demo-bucket ./data-feed
```

To display the contents of a .gz file, change to the folder where you stored the contents of the S3 bucket.

```
cd data-feed
```

Use the **ls** command to view the names of the files. Use the **zcat** command with the name of the file to display the contents of the compressed file. The following is an example command.

```
zcat  111122223333.2023-12-09-07.001.b959dbc6.gz
```

The following is example output.

```
#Version: 1.0
#Fields: Timestamp UsageType Operation InstanceID MyBidID MyMaxPrice MarketPrice Charge
 Version
2023-12-09 07:13:47 UTC USE2-SpotUsage:c7a.medium       RunInstances:SV050
 i-0c3e0c0b046e050df     sir-pwq6nmfp    0.0510000000 USD        0.0142000000 USD
  0.0142000000 USD        1
```

Delete your Spot Instance data feed

When you are finished with the Spot Instance data feed, you can delete it.

AWS CLI

To delete your data feed

Use the delete-spot-datafeed-subscription command.

```
aws ec2 delete-spot-datafeed-subscription
```

PowerShell

To delete your data feed

Use the Remove-EC2SpotDatafeedSubscription cmdlet.

```
Remove-EC2SpotDatafeedSubscription
```

Service-linked role for Spot Instance requests

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information, see Service-linked roles in the *IAM User Guide*.

Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2Spot** to launch and manage Spot Instances on your behalf.

Permissions granted by AWSServiceRoleForEC2Spot

Amazon EC2 uses **AWSServiceRoleForEC2Spot** to complete the following actions:

- `ec2:DescribeInstances` – Describe Spot Instances
- `ec2:StopInstances` – Stop Spot Instances
- `ec2:StartInstances` – Start Spot Instances

Create the service-linked role

Under most circumstances, you don't need to manually create a service-linked role. Amazon EC2 creates the **AWSServiceRoleForEC2Spot** service-linked role the first time you request a Spot Instance using the console.

If you had an active Spot Instance request before October 2017, when Amazon EC2 began supporting this service-linked role, Amazon EC2 created the **AWSServiceRoleForEC2Spot** role in your AWS account. For more information, see A New Role Appeared in My Account in the *IAM User Guide*.

If you use the AWS CLI or an API to request a Spot Instance, you must first ensure that this role exists.

To create AWSServiceRoleForEC2Spot using the console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. On the **Select type of trusted entity** page, choose **EC2**, **EC2 - Spot Instances**, **Next: Permissions**.
5. On the next page, choose **Next:Review**.
6. On the **Review** page, choose **Create role**.

To create AWSServiceRoleForEC2Spot using the AWS CLI

Use the create-service-linked-role command as follows.

```
aws iam create-service-linked-role --aws-service-name spot.amazonaws.com
```

If you no longer need to use Spot Instances, we recommend that you delete the **AWSServiceRoleForEC2Spot** role. After this role is deleted from your account, Amazon EC2 will create the role again if you request Spot Instances.

Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots

If you specify an encrypted AMI or an encrypted Amazon EBS snapshot for your Spot Instances and you use a customer managed key for encryption, you must grant the **AWSServiceRoleForEC2Spot** role permission to use the customer managed key so that Amazon EC2 can launch Spot Instances on your behalf. To do this, you must add a grant to the customer managed key, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see Using Grants and Using Key Policies in AWS KMS in the *AWS Key Management Service Developer Guide*.

To grant the AWSServiceRoleForEC2Spot role permissions to use the customer managed key

- Use the create-grant command to add a grant to the customer managed key and to specify the principal (the **AWSServiceRoleForEC2Spot** service-linked role) that is given permission to perform the operations that the grant permits. The customer managed key is specified by the `key-id` parameter and the ARN of the customer managed key. The principal is specified by the `grantee-principal` parameter and the ARN of the **AWSServiceRoleForEC2Spot** service-linked role.

```
aws kms create-grant \
    --region us-east-1 \
    --key-id arn:aws:kms:us-
east-1:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
    --grantee-principal arn:aws:iam::111122223333:role/aws-service-role/
spot.amazonaws.com/AWSServiceRoleForEC2Spot \
    --operations "Decrypt" "Encrypt" "GenerateDataKey"
 "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom"
 "ReEncryptTo"
```

Spot Instance quotas

There are quotas for the number of running Spot Instances and pending Spot Instance requests per AWS account per Region. After a pending Spot Instance request is fulfilled, the request no longer counts towards the quota because the running instance is counted towards the quota.

Spot Instance quotas are managed in terms of the *number of virtual central processing units (vCPUs)* that your running Spot Instances are either using or will use pending the fulfillment of open Spot Instance requests. If you terminate your Spot Instances but do not cancel the Spot Instance requests, the requests count against your Spot Instance vCPU quota until Amazon EC2 detects the Spot Instance terminations and closes the requests.

We provide the following quota types for Spot Instances.

Name	Default	Adjustable
All DL Spot Instance Requests	0	Yes
All F Spot Instance Requests	0	Yes
All G and VT Spot Instance Requests	0	Yes
All Inf Spot Instance Requests	0	Yes
All P4, P3 and P2 Spot Instance Requests	0	Yes
All P5 Spot Instance Requests	0	Yes
All Standard (A, C, D, H, I, M, R, T, Z) Spot Instance Requests	5	Yes
All Trn Spot Instance Requests	0	Yes
All X Spot Instance Requests	0	Yes

Even though Amazon EC2 automatically adjusts your Spot Instance quotas based on your usage, you can request a quota increase if necessary. For example, if you intend to launch more Spot Instances than your current quota allows, you can request a quota increase. You can also request a quota increase if you submit a Spot Instance request and you receive the error `Max spot instance count exceeded`. To request a quota increase, use the Service Quotas console described in Amazon EC2 service quotas.

You can launch any combination of instance types that meet your changing application needs. For example, with an All Standard Spot Instance Requests quota of 256 vCPUs, you could request 32 `m5.2xlarge` Spot Instances (32 x 8 vCPUs) or 16 `c5.4xlarge` Spot Instances (16 x 16 vCPUs).

With Amazon CloudWatch metrics integration, you can monitor EC2 usage against your quotas. You can also configure alarms to warn about approaching quotas. For more information, see Service Quotas and Amazon CloudWatch alarms in the *Service Quotas User Guide*.

Amazon EC2 Dedicated Hosts

An Amazon EC2 Dedicated Host is a physical server that is fully dedicated for your use. You can optionally choose to share the instance capacity with other AWS accounts. For more information, see Cross-account Amazon EC2 Dedicated Host sharing.

Dedicated Hosts provide visibility and control over instance placement and they support host affinity. This means that you can launch and run instances on specific hosts, and you can ensure that instances run only on specific hosts. For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.

Dedicated Hosts provide comprehensive Bring Your Own License (BYOL) support. They allow you to use your existing per-socket, per-core, or per-VM software licenses, including Windows Server, SQL Server, SUSE Linux Enterprise Server, Red Hat Enterprise Linux, or other software licenses that are bound to VMs, sockets, or physical cores, subject to your license terms.

If you require your instances to run on dedicated hardware, but you do not need visibility or control over instance placement, and you do not need to use per-socket or per-core software licenses, you can consider using Dedicated Instances instead. Dedicated Instances and Dedicated Hosts can both be used to launch Amazon EC2 instances onto dedicated physical servers. There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some key differences between them. The following table highlights some of the key differences between Dedicated Instances and Dedicated Hosts:

	Dedicated Host	**Dedicated Instance**
Dedicated physical server	Physical server with instance capacity fully dedicated to your use.	Physical server that's dedicated to a single customer account.
Instance capacity sharing	Can share instance capacity with other accounts.	Not supported
Billing	Per-host billing	Per-instance billing

	Dedicated Host	Dedicated Instance
Visibility of sockets, cores, and host ID	Provides visibility of the number of sockets and physical cores	No visibility
Host and instance affinity	Allows you to consistently deploy your instances to the same physical server over time	Not supported
Targeted instance placement	Provides additional visibility and control over how instances are placed on a physical server	Not supported
Automatic instance recovery	Supported. For more information, see Amazon EC2 Dedicated Host recovery.	Supported
Bring Your Own License (BYOL)	Supported	Partial support *
Capacity Reservations	Not supported	Supported

* Microsoft SQL Server with License Mobility through Software Assurance, and Windows Virtual Desktop Access (VDA) licenses can be used with Dedicated Instance.

For more information about Dedicated Instances, see Amazon EC2 Dedicated Instances.

Dedicated Hosts restrictions

Before you allocate Dedicated Hosts, take note of the following limitations and restrictions:

- To run RHEL and SUSE Linux on Dedicated Hosts, you must bring your own AMIs. You can't use the RHEL and SUSE Linux AMIs that are offered by AWS or that are available on AWS Marketplace with Dedicated Hosts. For more information about how to create your own AMI, see Bring your own software licenses to Amazon EC2 Dedicated Hosts.

This restriction does not apply to hosts allocated for high memory instances (`u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, and `u-24tb1.metal`). RHEL and SUSE Linux AMIs that are offered by AWS or that are available on AWS Marketplace can be used with these hosts.

- There is a limit on the number of running Dedicated Hosts per instance family per AWS account per Region. Quotas apply to running instances only. If your instance is pending, stopping, or stopped, it does not count towards your quota. To view the quotas for your account, or to request a quota increase, use the [Service Quotas console](#).
- Auto Scaling groups are supported when using a launch template that specifies a host resource group. For more information, see [Create a launch template using advanced settings](#) in the *Amazon EC2 Auto Scaling User Guide*.
- Amazon RDS instances are not supported.
- The AWS Free Usage tier is not available for Dedicated Hosts.
- Instance placement control refers to managing instance launches onto Dedicated Hosts. You can't launch Dedicated Hosts into placement groups.
- If you allocate a host for a virtualized instance type, you can't modify the instance type to a `.metal` instance type after the host is allocated. For example, if you allocate a host for the `m5.large` instance type, you can't modify the instance type to `m5.metal`.

  Similarly, if you allocate a host for a `.metal` instance type, you can't modify the instance type to a virtualized instance type after the host is allocated. For example, if you allocate a host for the `m5.metal` instance type, you can't modify the instance type to `m5.large`.

Contents

- Modify supported instance types for an existing Amazon EC2 Dedicated Host

Amazon EC2 Dedicated Host pricing and billing

The price for a Dedicated Host varies by payment option.

Payment Options

- On-Demand Dedicated Hosts
- Dedicated Host Reservations
- Savings Plans
- Pricing for Windows Server on Dedicated Hosts

On-Demand Dedicated Hosts

On-Demand billing is automatically activated when you allocate a Dedicated Host to your account.

The On-Demand price for a Dedicated Host varies by instance family and Region. You pay per second (with a minimum of 60 seconds) for active Dedicated Host, regardless of the quantity or the size of instances that you choose to launch on it. For more information about On-Demand pricing, see Amazon EC2 Dedicated Hosts On-Demand Pricing.

You can release an On-Demand Dedicated Host at any time to stop accruing charges for it. For information about releasing a Dedicated Host, see Release an Amazon EC2 Dedicated Host.

Dedicated Host Reservations

Dedicated Host Reservations provide a billing discount compared to running On-Demand Dedicated Hosts. Reservations are available in three payment options:

- **No Upfront**—No Upfront Reservations provide you with a discount on your Dedicated Host usage over a term and do not require an upfront payment. Available in one-year and three-year terms. Only some instance families support the three-year term for No Upfront Reservations.
- **Partial Upfront**—A portion of the reservation must be paid upfront and the remaining hours in the term are billed at a discounted rate. Available in one-year and three-year terms.
- **All Upfront**—Provides the lowest effective price. Available in one-year and three-year terms and covers the entire cost of the term upfront, with no additional future charges.

You must have active Dedicated Hosts in your account before you can purchase reservations. Each reservation can cover one or more hosts that support the same instance family in a single Availability Zone. Reservations are applied to the instance family on the host, not the instance size. If you have three Dedicated Hosts with different instances sizes (`m4.xlarge`, `m4.medium`, and `m4.large`) you can associate a single `m4` reservation with all those Dedicated Hosts. The instance family and Availability Zone of the reservation must match that of the Dedicated Hosts you want to associate it with.

When a reservation is associated with a Dedicated Host, the Dedicated Host can't be released until the reservation's term is over.

For more information about reservation pricing, see [Amazon EC2 Dedicated Hosts Pricing].

Savings Plans

Savings Plans are a flexible pricing model that offers significant savings over On-Demand Instances. With Savings Plans, you make a commitment to a consistent amount of usage, in USD per hour, for a term of one or three years. This provides you with the flexibility to use the Dedicated Hosts that best meet your needs and continue to save money, instead of making a commitment to a specific Dedicated Host. For more information, see the [AWS Savings Plans User Guide].

Note

Savings Plans are not supported with `u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, and `u-24tb1.metal` Dedicated Hosts.

Pricing for Windows Server on Dedicated Hosts

Subject to Microsoft licensing terms, you can bring your existing Windows Server and SQL Server licenses to Dedicated Hosts. There is no additional charge for software usage if you choose to bring your own licenses.

In addition, you can also use Windows Server AMIs provided by Amazon to run the latest versions of Windows Server on Dedicated Hosts. This is common for scenarios where you have existing SQL Server licenses eligible to run on Dedicated Hosts, but need Windows Server to run the SQL Server workload. Windows Server AMIs provided by Amazon are supported on current generation instance types only. For more information, see Amazon EC2 Dedicated Hosts Pricing.

Amazon EC2 Dedicated Host instance capacity configurations

Dedicated Hosts support different configurations (physical cores, sockets, and VCPUs) that allow you to run instances of different families and sizes.

When you allocate a Dedicated Host in your account, you can choose a configuration that supports either a **single instance type**, or **multiple instance types** within the same instance family. The number of instances that you can run on a host depends on the configuration you choose.

Contents

Single instance type support

You can allocate a Dedicated Host that supports only one instance type. With this configuration, every instance that you launch on the Dedicated Host must be of the same instance type, which you specify when you allocate the host.

For example, you can allocate a host that supports only the `m5.4xlarge` instance type. In this case, you can run only `m5.4xlarge` instances on that host.

The number of instances that you can launch onto the host depends on the number of physical cores provided by the host, and the number of cores consumed by the specified instance type. For example, if you allocate a host for `m5.4xlarge` instances, the host provides 48 physical cores, and each `m5.4xlarge` instance consumes 8 physical cores. This means that you can launch up to 6 instances on that host (*48 physical cores / 8 cores per instance = 6 instances*).

Multiple instance type support

You can allocate a Dedicated Host that supports multiple instance types within the same instance family. This allows you to run different instance types on the same host, as long as they're in the same instance family and the host has sufficient instance capacity.

For example, you can allocate a host that supports different instance types within the R5 instance family. In this case, you can launch certain combinations of R5 instance types, such as `r5.large`, `r5.xlarge`, `r5.2xlarge`, and `r5.4xlarge`, on that host, within the host's physical core capacity.

The following instance families support Dedicated Hosts with multiple instance type support:

- **General purpose:** A1 | M5 | M5n | M6i | M7i | T3
- **Compute optimized:** C5 | C5n | C6i | C7i
- **Memory optimized:** R5 | R5n | R6i | R7i

The number of instances you can run on the host depends on the number of physical cores provided by the host, and the number of cores consumed by each instance type that you run on the host. For example, if you allocate an R5 host, which provides 48 physical cores, and you run two `r5.2xlarge` instances (*4 cores x 2 instances*) and three `r5.4xlarge` instances (*8 cores x 3 instances*), those instances consume a total of 32 cores, and you might be able to run certain combinations of R5 instances as long as they are within the remaining 16 cores.

However, for each instance family, there is a limit on the number of instances that can be run for each instance type. For example, an R5 Dedicated Host supports a maximum of 2 `r5.8xlarge` instances, which uses 32 of the physical cores. In this case, additional R5 instances of smaller types can then be used to fill the host to core capacity. For the supported number of instance types for each instance family, see the [Dedicated Hosts Configuration Table](#).

The following table shows example instance type combinations:

Instance family	Example instance type combinations
R5	• Example 1: 4 x `r5.4xlarge` + 4 x `r5.2xlarge` • Example 2: 1 x `r5.12xlarge` + 1 x `r5.4xlarge` + 1 x `r5.2xlarge` + 5 x `r5.xlarge` + 2 x `r5.large`
C5	• Example 1: 1 x `c5.9xlarge` + 2 x `c5.4xlarge` + 1 x `c5.xlarge` • Example 2: 4 x `c5.4xlarge` + 1 x `c5.xlarge` + 2 x `c5.large`
M5	• Example 1: 4 x `m5.4xlarge` + 4 x `m5.2xlarge` • Example 2: 1 x `m5.12xlarge` + 1 x `m5.4xlarge` + 1 x `m5.2xlarge` + 5 x `m5.xlarge` + 2 x `m5.large`

Considerations

Keep the following in mind when working with Dedicated Hosts that support multiple instance types:

- Using multiple instance types on the same host is possible only within the same instance family.
- When mixing instance types, to maximize host utilization, we recommend launching larger instance types first followed by smaller instance types.
  - Depending on the combination and launch order of the instance types on a Dedicated Host, it may not be physically possible to maximize the utilization of the host. When mixing instance types on a host, some capacity might be available on the host but not usable. For example, you might see 16 vCPUs available on an r5n host but may not be able to launch a 4xlarge instance on the host even though r5n.4xlarge runs on 16 vCPUs.

> **Note**
>
> If you enable an A1 Dedicated Host for multiple instance types, you can launch only a mix of `a1.xlarge` and `a1.2xlarge` instances on that host. If you launch an `a1.medium` or `a1.large` instance on that host, you will be restricted to launching only more of that same instance type on the host. A single `a1.4xlarge` instance consumes all capacity on the host. If you require a host for either `a1.medium` or `a1.large` instances, we recommend that you allocate separate hosts for those instance types.

Burstable T3 instances on Amazon EC2 Dedicated Hosts

Dedicated Hosts support burstable performance T3 instances. T3 instances provide a cost-efficient way of using your eligible BYOL license software on dedicated hardware. The smaller vCPU footprint of T3 instances enables you to consolidate your workloads on fewer hosts and maximize your per-core license utilization.

T3 Dedicated Hosts are best suited for running BYOL software with low to moderate CPU utilization. This includes eligible per-socket, per-core, or per-VM software licenses, such as Windows Server, Windows Desktop, SQL Server, SUSE Enterprise Linux Server, Red Hat Enterprise Linux, and Oracle Database. Examples of workloads suited for T3 Dedicated Hosts are small and medium databases, virtual desktops, development and test environments, code repositories, and product prototypes. T3 Dedicated Hosts are not recommended for workloads with sustained high CPU utilization or for workloads that experience correlated CPU bursts simultaneously.

T3 instances on Dedicated Hosts use the same credit model as T3 instances on shared tenancy hardware. However, they support the `standard` credit mode only; they do not support the `unlimited` credit mode. In `standard` mode, T3 instances on Dedicated Hosts *earn*, *spend*, and *accrue* credits in the same way as burstable instances on shared tenancy hardware. They provide a baseline CPU performance with the ability to burst above the baseline level. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. When the accrued credits are depleted, CPU utilization is lowered to the baseline level. For more information about `standard` mode, see How standard burstable performance instances work.

T3 Dedicated Hosts support all of the features offered by Amazon EC2 Dedicated Hosts, including multiple instance sizes on a single host, Host resource groups, and BYOL.

Supported T3 instance sizes and configurations

T3 Dedicated Hosts run general purpose burstable T3 instances that share CPU resources of the host by providing a baseline CPU performance and the ability to burst to a higher level when needed. This enables T3 Dedicated Hosts, which have 48 cores, to support up to a maximum of 192 instances per host. In order to efficiently utilize the host's resources and to provide the best instance performance, the Amazon EC2 instance placement algorithm automatically calculates the supported number of instances and instance size combinations that can be launched on the host.

T3 Dedicated Hosts support multiple instance types on the same host. All T3 instance sizes are supported on Dedicated Hosts. You can run different combinations of T3 instances up to the CPU limit of the host.

The following table lists the supported instance types, summarizes the performance of each instance type, and indicates the maximum number of instances of each size that can be launched.

Insta type	vCPUs	Memory (GiB)	Baseline CPU utilization per vCPU	Network burst bandwidth (Gbps)	Amazon EBS burst bandwidth (Mbps)	Max number of instances per Dedicated Host
t3.na	2	0.5	5%	5	Up to 2,085	192
t3.m	2	1	10%	5	Up to 2,085	192
t3.sr	2	2	20%	5	Up to 2,085	192
t3.m	2	4	20%	5	Up to 2,085	192
t3.la	2	8	30%	5	2,780	96
t3.xl	4	16	40%	5	2,780	48
t3.2x e	8	32	40%	5	2,780	24

Monitor CPU utilization for T3 Dedicated Hosts

You can use the `DedicatedHostCPUUtilization` Amazon CloudWatch metric to monitor the vCPU utilization of a Dedicated Host. The metric is available in the `EC2` namespace and `Per-Host-Metrics` dimension. For more information, see [Dedicated Host metrics](#).

Bring your own software licenses to Amazon EC2 Dedicated Hosts

Dedicated Hosts allow you to use your existing per-socket, per-core, or per-VM software licenses. When you bring your own license, you are responsible for managing your own licenses. However, Amazon EC2 has features that help you maintain license compliance, such as instance affinity and targeted placement.

These are the general steps to follow in order to bring your own volume licensed machine image into Amazon EC2.

1. Verify that the license terms controlling the use of your machine images allow usage in a virtualized cloud environment. For more information about Microsoft Licensing, see Amazon Web Services and Microsoft Licensing.
2. After you have verified that your machine image can be used within Amazon EC2, import it using VM Import/Export. For information about how to import your machine image, see the VM Import/Export User Guide.
3. After you import your machine image, you can launch instances from it onto active Dedicated Hosts in your account.
4. When you run these instances, depending on the operating system, you might be required to activate these instances against your own KMS server (for example, Windows Server or Windows SQL Server). You can't activate your imported Windows AMI against the Amazon Windows KMS server.

> **Note**
>
> To track how your images are used in AWS, enable host recording in AWS Config. You can use AWS Config to record configuration changes to a Dedicated Host and use the output as a data source for license reporting. For more information, see Track Amazon EC2 Dedicated Host configuration changes using AWS Config.

Amazon EC2 Dedicated Host auto-placement and host affinity

Placement control for Dedicated Hosts happens on both the instance level and host level.

Auto-placement

Auto-placement is configured at the host level. It allows you to manage whether instances that you launch are launched onto a specific host, or onto any available host that has matching configurations.

When auto-placement is **disabled** for a Dedicated Host, it accepts only host tenancy instance launches that specify its unique host ID. This is the default setting for new Dedicated Hosts.

When auto-placement is **enabled** for a Dedicated Host, it accepts any untargeted, host tenancy instance launches that match its instance type configuration.

When launching an instance, you need to configure its tenancy. Launching an instance onto a Dedicated Host without providing a specific `HostId` enables it to launch on any Dedicated Host that has auto-placement *enabled* and that matches its instance type.

Host affinity

Host affinity is configured at the instance level. It establishes a launch relationship between an instance and a Dedicated Host.

When affinity is set to `Host`, an instance launched onto a specific host always restarts on the same host if stopped. This applies to both targeted and untargeted launches.

When affinity is set to `Default`, and you stop and restart the instance, it can be restarted on any available host. However, it tries to launch back onto the last Dedicated Host on which it ran (on a best-effort basis).

Allocate an Amazon EC2 Dedicated Host for use in your account

To begin using a Dedicated Host, you must first allocate it in your account. After you allocate the Dedicated Host, the Dedicated Host capacity is made available in your account immediately and you can start launching instances onto the Dedicated Host.

When you allocate a Dedicated Host in your account, you can choose a configuration that supports either a **single instance type**, or **multiple instance types** within the same instance family. The number of instances that you can run on the host depends on the configuration you choose. For more information see Amazon EC2 Dedicated Host instance capacity configurations.

Console

To allocate a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts** and then choose **Allocate Dedicated Host**.
3. For **Instance family**, choose the instance family for the Dedicated Host.
4. Specify whether the Dedicated Host supports multiple instance sizes within the selected instance family, or a specific instance type only. Do one of the following.
   - To configure the Dedicated Host to support multiple instance types in the selected instance family, for **Support multiple instance types**, choose **Enable**. Enabling this allows you to launch different instance sizes from the same instance family onto the Dedicated Host. For example, if you choose the `m5` instance family and choose this option, you can launch `m5.xlarge` and `m5.4xlarge` instances onto the Dedicated Host.
   - To configure the Dedicated Host to support a single instance type within the selected instance family, clear **Support multiple instance types**, and then for **Instance type**, choose the instance type to support. This allows you to launch a single instance type on the Dedicated Host. For example, if you choose this option and specify `m5.4xlarge` as the supported instance type, you can launch only `m5.4xlarge` instances onto the Dedicated Host.
5. For **Availability Zone**, choose the Availability Zone in which to allocate the Dedicated Host.
6. To allow the Dedicated Host to accept untargeted instance launches that match its instance type, for **Instance auto-placement**, choose **Enable**. For more information about auto-placement, see Amazon EC2 Dedicated Host auto-placement and host affinity.
7. To enable host recovery for the Dedicated Host, for **Host recovery**, choose **Enable**. For more information, see Amazon EC2 Dedicated Host recovery.
8. For **Quantity**, enter the number of Dedicated Hosts to allocate.
9. (Optional) Choose **Add new tag** and enter a tag key and a tag value.
10. Choose **Allocate**.

AWS CLI

To allocate a Dedicated Host

Use the allocate-hosts command. The following example allocates a Dedicated Host that supports multiple instance types from the m5 instance family in the us-east-1a Availability Zone. It also enables host recovery and disables auto-placement.

```
aws ec2 allocate-hosts \
    --instance-family "m5" \
    --availability-zone "us-east-1a" \
    --auto-placement "off" \
    --host-recovery "on" \
    --quantity 1
```

The following example allocates a Dedicated Host that supports *untargeted* instance launches in the specified Availability Zone, enables host recovery, and enables auto-placement.

```
aws ec2 allocate-hosts \
    --instance-type "m5.large" \
    --availability-zone "eu-west-1a" \
    --auto-placement "on" \
    --host-recovery "on" \
    --quantity 1
```

PowerShell

To allocate a Dedicated Host

Use the New-EC2Host cmdlet. The following example allocates a Dedicated Host that supports multiple instance types from the m5 instance family in the us-east-1a Availability Zone. The host also has host recovery enabled and auto-placement disabled.

```
New-EC2Host `
    -InstanceFamily m5 `
    -AvailabilityZone us-east-1a `
    -AutoPlacement Off `
    -HostRecovery On `
    -Quantity 1
```

The following example allocates a Dedicated Host that supports *untargeted* instance launches in the specified Availability Zone and enables host recovery.

```
New-EC2Host `
    -InstanceType m5.large `
```

```
    -AvailabilityZone eu-west-1a `
    -AutoPlacement On `
    -HostRecovery On `
    -Quantity 1
```

Launch Amazon EC2 instances on an Amazon EC2 Dedicated Host

After you have allocated a Dedicated Host, you can launch instances onto it. You can't launch instances with `host` tenancy if you do not have active Dedicated Hosts with enough available capacity for the instance type that you are launching.

Considerations

- SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.
- For Dedicated Hosts that support multiple instance sizes, we recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.
- Before you launch your instances, take note of the limitations. For more information, see [Dedicated Hosts restrictions](#).

Console

To launch an instance onto a specific Dedicated Host from the Dedicated Hosts page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, select a host and choose **Actions**, **Launch Instance(s) onto host**.
4. In the **Application and OS Images** section, select an AMI from the list.
5. In the **Instance type** section, select the instance type to launch.

> **Note**
>
> If the Dedicated Host supports a single instance type only, the supported instance type is selected by default and can't be changed.
> If the Dedicated Host supports multiple instance types, you must select an instance type within the supported instance family based on the available instance capacity

of the Dedicated Host. We recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.

6. In the **Key pair** section, select the key pair to associate with the instance.
7. In the **Advanced details** section, for **Tenancy affinity**, choose one of the following:

   - **Off** — Host affinity disabled. The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
   - A Dedicated Host ID — Host affinity enabled. If stopped, the instance always restarts on this specified host if it has capacity. If the host does not have capacity, the instance can't be restarted; you must estabilish affinity with a different host.

   For more information about Affinity, see Amazon EC2 Dedicated Host auto-placement and host affinity.

   > **Note**
   >
   > The **Tenancy** and **Host** options are pre-configured based on the host that you selected.

8. Configure the remaining instance options as needed. For more information, see Reference for Amazon EC2 instance configuration parameters.
9. Choose **Launch instance**.

To launch an instance onto a Dedicated Host using the Launch Instance wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, **Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.
4. In the **Instance type** section, select the instance type to launch.
5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, do the following:

   a. For **Tenancy**, select **Dedicated Host**.

   b. For **Target host by**, select **Host ID**.

c. For **Target host ID**, select the host onto which to launch the instance.

d. For **Tenancy affinity**, choose one of the following:

- **Off** — Host affinity disabled. The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
- A Dedicated Host ID — Host affinity enabled. If stopped, the instance always restarts on this specified host if it has capacity. If the host does not have capacity, the instance can't be restarted; you must estabilish affinity with a different host.

For more information about Affinity, see Amazon EC2 Dedicated Host auto-placement and host affinity.

7. Configure the remaining instance options as needed. For more information, see Reference for Amazon EC2 instance configuration parameters.
8. Choose **Launch instance**.

AWS CLI

To launch an instance onto a Dedicated Host

Use the run-instances command and specify the instance affinity, tenancy, and host in the `--placement` option.

```
--placement Affinity=Host,Tenancy=dedicated,HostId=h-07879acf49EXAMPLE
```

PowerShell

To launch an instance onto a Dedicated Host

Use the New-EC2Instance cmdlet and specify the instance affinity, tenancy, and host in the `-Placement` parameter.

```
-Placement_Affinity Host `
-Placement_Tenancy dedicated `
-Placement_HostId h-07879acf49EXAMPLE
```

Launch Amazon EC2 instances into a host resource group

Dedicated Hosts are also integrated with AWS License Manager. With License Manager, you can create a host resource group, which is a collection of Dedicated Hosts that are managed as a single entity. When creating a host resource group, you specify the host management preferences, such as auto-allocate and auto-release, for the Dedicated Hosts. This allows you to launch instances onto Dedicated Hosts without manually allocating and managing those hosts. For more information, see [Host Resource Groups] in the *AWS License Manager User Guide*.

When you launch an instance into a host resource group that has a Dedicated Host with available instance capacity, Amazon EC2 launches the instance onto that host. If the host resource group does not have a host with available instance capacity, Amazon EC2 automatically allocates a new host in the host resource group, and then launches the instance onto that host. For more information, see [Host Resource Groups] in the *AWS License Manager User Guide*.

Requirements and limits

- You must associate a core- or socket-based license configuration with the AMI.
- You can't use SQL Server, SUSE, or RHEL AMIs provided by Amazon EC2 with Dedicated Hosts.
- You can't target a specific host by choosing a host ID, and you can't enable instance affinity when launching an instance into a host resource group.

Console

To launch an instance into a host resource group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, **Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.
4. In the **Instance type** section, select the instance type to launch.
5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, do the following:

    a. For **Tenancy**, select **Dedicated Host**.

    b. For **Target host by**, select **Host resource group**.

    c. For **Tenancy host resource group**, select the host resource group into which to launch the instance.

d. For **Tenancy affinity**, do one of the following:

- Select **Off** — The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
- Select the Dedicated Host ID — If stopped, the instance always restarts on this specific host.

For more information about Affinity, see Amazon EC2 Dedicated Host auto-placement and host affinity.

7. Configure the remaining instance options as needed. For more information, see Reference for Amazon EC2 instance configuration parameters.
8. Choose **Launch instance**.

AWS CLI

To launch an instance into a host resource group

Use the run-instances command. In the `--placement` option, omit the tenancy and specify the ARN of the host resource group.

```
--placement HostResourceGroupArn=arn:aws:resource-groups:us-
east-2:123456789012:group/my-resource-group
```

PowerShell

To launch an instance into a host resource group

Use the New-EC2Instance cmdlet. In the `-Placement` parameter, omit the tenancy and specify the ARN of the host resource group.

```
-Placement_HostResourceGroupArn arn:aws:resource-groups:us-
east-2:123456789012:group/my-resource-group
```

Modify the auto-placement setting for an existing Amazon EC2 Dedicated Host

You can modify the auto-placement settings of a Dedicated Host after you have allocated it to your AWS account.

Console

To modify the auto-placement of a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select a host and choose **Actions**, **Modify host**.
4. For **Instance auto-placement**, choose **Enable** to enable auto-placement, or clear **Enable** to disable auto-placement. For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.
5. Choose **Save**.

AWS CLI

To modify the auto-placement of a Dedicated Host

Use the modify-hosts command.

```
aws ec2 modify-hosts \
    --auto-placement on \
    --host-ids h-012a3456b7890cdef
```

PowerShell

To modify the auto-placement of a Dedicated Host

Use the Edit-EC2Host cmdlet.

```
Edit-EC2Host `
    -AutoPlacement 1 `
    -HostId h-012a3456b7890cdef
```

Modify supported instance types for an existing Amazon EC2 Dedicated Host

You can modify a Dedicated Host to change the instance types that it supports. If it currently supports a single instance type, you can modify it to support multiple instance types within that instance family. Similarly, if it currently supports multiple instance types, you can modify it to support a specific instance type only.

To modify a Dedicated Host to support multiple instance types, you must first stop all running instances on the host. The modification takes approximately 10 minutes to complete. The Dedicated Host transitions to the `pending` state while the modification is in progress. You can't start stopped instances or launch new instances on the Dedicated Host while it is in the `pending` state.

To modify a Dedicated Host that supports multiple instance types to support only a single instance type, the host must either have no running instances, or the running instances must be of the instance type that you want the host to support. For example, to modify a host that supports multiple instance types in the `m5` instance family to support only `m5.large` instances, the Dedicated Host must either have no running instances, or it must have only `m5.large` instances running on it.

If you allocate a host for a virtualized instance type, you can't modify the instance type to a `.metal` instance type after the host is allocated. For example, if you allocate a host for the `m5.large` instance type, you can't modify the instance type to `m5.metal`. Similarly, if you allocate a host for a `.metal` instance type, you can't modify the instance type to a virtualized instance type after the host is allocated. For example, if you allocate a host for the `m5.metal` instance type, you can't modify the instance type to `m5.large`.

Console

To modify the supported instance types for a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the Navigation pane, choose **Dedicated Host**.
3. Select the Dedicated Host to modify and choose **Actions**, **Modify host**.
4. Do one of the following, depending on the current configuration of the Dedicated Host:

    - If the Dedicated Host currently supports a specific instance type, **Support multiple instance types** is not enabled, and **Instance type** lists the supported instance type. To modify the host to support multiple types in the current instance family, for **Support multiple instance types**, choose **Enable**.

      You must first stop all instances running on the host before modifying it to support multiple instance types.
    - If the Dedicated Host currently supports multiple instance types in an instance family, **Enabled** is selected for **Support multiple instance types**. To modify the host to support

a specific instance type, for **Support multiple instance types**, clear **Enable**, and then for **Instance type**, select the specific instance type to support.

You can't change the instance family supported by the Dedicated Host.

5. Choose **Save**.

AWS CLI

To modify the supported instance types for a Dedicated Host

Use the modify-hosts command.

The following example modifies a Dedicated Host to support multiple instance types within the `m5` instance family.

```
aws ec2 modify-hosts \
    --instance-family m5 \
    --host-ids h-012a3456b7890cdef
```

The following example modifies a Dedicated Host to support `m5.xlarge` instances only.

```
aws ec2 modify-hosts \
    --instance-type m5.xlarge \
    --instance-family --host-ids h-012a3456b7890cdef
```

PowerShell

To modify the supported instance types for a Dedicated Host

Use the Edit-EC2Host cmdlet.

The following example modifies a Dedicated Host to support multiple instance types within the `m5` instance family.

```
Edit-EC2Host `
    -InstanceFamily m5 `
    -HostId h-012a3456b7890cdef
```

The following example modifies a Dedicated Host to support `m5.xlarge` instances only.

```
Edit-EC2Host `
    -InstanceType m5.xlarge `
    -HostId h-012a3456b7890cdef
```

Modify Amazon EC2 Dedicated Host tenancy and affinity for an Amazon EC2 instance

You can change the tenancy of an instance after you have launched it. You can also modify the affinity for your instance to target a specific host or allow it to launch on any available dedicated host with matching attributes in your account. To modify either instance tenancy or affinity, the instance must be in the `stopped` state.

The operating system details of your instance—and whether SQL Server is installed—affect what conversions are supported. For more information about the tenancy conversion paths available to your instance, see Tenancy conversion in the *License Manager User Guide*.

> **Note**
>
> For T3 instances, you must launch the instance on a Dedicated Host to use a tenancy of `host`. For T3 instances, you can't change the tenancy from `host` to `dedicated` or `default`. Attempting to make one of these unsupported tenancy changes results in an `InvalidRequest` error code.

Console

To modify instance tenancy or affinity

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Instances**, and select the instance to modify.
3. Choose **Instance state**, **Stop**.
4. With the instance selected, choose **Actions**, **Instance settings**, **Modify instance placement**.
5. On the **Modify instance placement** page, configure the following:

   - **Tenancy**—Choose one of the following:
     - Run a dedicated hardware instance—Launches the instance as a Dedicated Instance. For more information, see Amazon EC2 Dedicated Instances.

- Launch the instance on a Dedicated Host—Launches the instance onto a Dedicated Host with configurable affinity.
- **Affinity**—Choose one of the following:
  - This instance can run on any one of my hosts—The instance launches onto any available Dedicated Host in your account that supports its instance type.
  - This instance can only run on the selected host—The instance is only able to run on the Dedicated Host selected for **Target Host**.
- **Target Host**—Select the Dedicated Host that the instance must run on. If no target host is listed, you might not have available, compatible Dedicated Hosts in your account.

For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.

6. Choose **Save**.

AWS CLI

To modify instance tenancy or affinity

Use the modify-instance-placement command. The following example changes the specified instance's affinity from `default` to `host`, and specifies the Dedicated Host that the instance has affinity with.

```
aws ec2 modify-instance-placement \
    --instance-id i-1234567890abcdef0 \
    --affinity host \
    --tenancy host \
    --host-id h-012a3456b7890cdef
```

PowerShell

To modify instance tenancy or affinity

Use the Edit-EC2InstancePlacement cmdlet. The following example changes the specified instance's affinity from `default` to `host`, and specifies the Dedicated Host that the instance has affinity with.

```
Edit-EC2InstancePlacement `
    -InstanceId i-1234567890abcdef0 `
```

```
    -Affinity host `
    -Tenancy host `
    -HostId h-012a3456b7890cdef
```

Release an Amazon EC2 Dedicated Host

If you no longer need Dedicated Host, you can stop the instances running on the host, direct them to launch on a different host, and then *release* the host.

Any running instances on the Dedicated Host must be stopped before you can release the host. These instances can be migrated to other Dedicated Hosts in your account so that you can continue to use them. These steps apply only to On-Demand Dedicated Hosts.

Console

To release a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select the Dedicated Host to release.
4. Choose **Actions**, **Release host**.
5. To confirm, choose **Release**.

AWS CLI

To release a Dedicated Host

Use the release-hosts command.

```
aws ec2 release-hosts --host-ids h-012a3456b7890cdef
```

PowerShell

To release a Dedicated Host

Use the Remove-EC2Host cmdlet.

```
Remove-EC2Host -HostId h-012a3456b7890cdef
```

After you release a Dedicated Host, you can't reuse the same host or host ID again, and you are no longer charged On-Demand billing rates for it. The state of the Dedicated Host is changed to `released`, and you are not able to launch any instances onto that host.

> **Note**
>
> If you have recently released Dedicated Hosts, it can take some time for them to stop counting towards your limit. During this time, you might experience `LimitExceeded` errors when trying to allocate new Dedicated Hosts. If this is the case, try allocating new hosts again after a few minutes.

The instances that were stopped are still available for use and are listed on the **Instances** page. They retain their `host` tenancy setting.

Migrate to Nitro-based Amazon EC2 Dedicated Hosts

The Nitro System is a collection of hardware and software components built by AWS that enable high performance, high availability, and high security. Nitro-based Dedicated Hosts offer improved price performance compared to Xen-based Dedicated Hosts. If you have any Xen-based Dedicated Hosts in your account, we recommend that you migrate your workloads to Nitro-based Dedicated Hosts. For more information, see AWS Nitro System.

To migrate from a Xen-based Dedicated Host to a Nitro-based Dedicated Host, you need to migrate the Xen-based instances on your Dedicated Host to Nitro-based instance types, allocate a new Nitro-based Dedicated Host, and then move your migrated Nitro-based instances to your new Nitro-based Dedicated Host.

This topic provides detailed steps for migrating from Xen-based Dedicated Hosts to Nitro-based Dedicated Hosts.

Migration steps

- Step 1: Identify your Xen-based Dedicated Hosts
- Step 2: Migrate Xen-based instances to Nitro-based instance types
- Step 3: Allocate a Nitro-based Dedicated Host
- Step 4: Move migrated instances to new Nitro-based Dedicated Host
- Step 5: Release unused Xen-based Dedicated Host

Step 1: Identify your Xen-based Dedicated Hosts

The following Dedicated Hosts are Xen-based and are eligible to be migrated to Nitro-based Dedicated Hosts.

- **General purpose:** M3 | M4
- **Compute optimized:** C3 | C4
- **Memory optimized:** R3 | R4 | X1 | X1e
- **Storage optimized:** D2 | H1 | I2 | I3
- **Accelerated computing:** F1 | G3 | P2 | P3

To check if you have Xen-based Dedicated Hosts in your account

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, choose **Dedicated Hosts**.
3. In the **Search field**, use the **Instance family** filter to search for the Xen-based Dedicated Hosts above. For example, *Instance family = m3*.

Step 2: Migrate Xen-based instances to Nitro-based instance types

Instances that run on Xen-based Dedicated Hosts are also Xen-based. You must migrate these instances to Nitro-based instance types before you can move them to Nitro-based Dedicated Hosts.

> **Important**
>
> Before you begin migrating your instances, we recommend that you back up your data. For more information, see Create multi-volume Amazon EBS snapshots from an Amazon EC2 instance.

To find instances running on your Xen-based Dedicated Hosts

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, choose **Dedicated Hosts**.
3. Select the Xen-based host you intend to migrate and then select the **Running instances** tab. The tab lists all of the instances running of the selected host.

To migrate **Linux instances**, see Amazon EC2 instance type changes.

To migrate **Windows instances**, see Migrate an EC2 Windows instance to a Nitro-based instance type.

> **Note**
>
> Ensure that you migrate your instances to an instance type that matches the Nitro-based Dedicated Host that you intend to migrate to. For example, if you intend to migrate to a M7i Dedicated Host, ensure that you migrate your instances to an M7i instance type.

Step 3: Allocate a Nitro-based Dedicated Host

To find supported Nitro-based Dedicated Hosts

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, select **Instance Types**.
3. Apply the following filters:
   - *Hypervisor = nitro*
   - *Dedicated Host support = true*

After you've found a suitable Nitro-based instance type, allocate a new Dedicated Host.

Step 4: Move migrated instances to new Nitro-based Dedicated Host

After you have allocated the Nitro-based Dedicated Host and it reaches the `available` state, you can move the instances that you previously migrated to Nitro-based instance types to the new Dedicated Host.

To move your instances to your new Nitro-based Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, **Instances**.
3. Select the instance that you migrated and choose **Actions**, **Instance settings**, **Modify instance placement**.
4. For **Target dedicated host**, select the new Nitro-based Dedicated Host, and then choose **Save**.

5. Restart the instance. Select the instance and choose **Instance state**, **Start instance**.

Step 5: Release unused Xen-based Dedicated Host

After you have migrated your workloads from the Xen-based Dedicated Host to the new Nitro-based Dedicated Host, you can release the Xen-based Dedicated Host if you no longer need it.

Purchase Dedicated Host Reservations for Dedicated Host billing discounts

Dedicated Host Reservations provide you with a discount of up to 70 percent compared to On-Demand Dedicated Host pricing. You must have active Dedicated Hosts allocated in your account before you can purchase Dedicated Host Reservations. For more information, see Dedicated Host Reservations.

Console

To purchase reservations

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Dedicated Hosts**, **Dedicated Host Reservations**, **Purchase Dedicated Host Reservation**.
3. On the **Find offerings** screen, do the following:
   a. For **Instance family**, select the instance family of the Dedicated Host for which to purchase the Dedicated Host Reservation.
   b. For **Payment option**, select and configure your preferred payment option.
4. Choose **Next**.
5. Select the Dedicated Hosts with which to associate the Dedicated Host Reservation, and then choose **Next**.
6. (*Optional*) Assign tags to the Dedicated Host Reservation.
7. Review your order and choose **Purchase**.

AWS CLI

To purchase reservations

1. Use the describe-host-reservation-offerings command to list the available offerings that match your needs. The following example lists the offerings that support instances in the `m4` instance family and have a one-year term.

   The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.

   ```
   aws ec2 describe-host-reservation-offerings \
       --filter Name=instance-family,Values=m4 \
       --max-duration 31536000
   ```

   The command returns a list of offerings that match your criteria. Note the ID of the offering to purchase.

2. Use the purchase-host-reservation command to purchase the offering and provide the `offeringId` noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account, and it applies a tag with a key of `purpose` and a value of `production`.

   ```
   aws ec2 purchase-host-reservation \
       --offering-id hro-03f707bf363b6b324 \
       --host-id-set h-013abcd2a00cbd123 \
       --tag-specifications 'ResourceType=host-
   reservation,Tags={Key=purpose,Value=production}'
   ```

PowerShell

To purchase reservations

1. Use the Get-EC2HostReservationOffering cmdlet to list the available offerings that match your needs. The following examples list the offerings that support instances in the `m5` instance family and have a one-year term.

   The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.

```
$filter = @{Name="instance-family"; Values="m5"}
Get-EC2HostReservationOffering `
    -Filter $filter `
    -MaxDuration 31536000
```

The command returns a list of offerings that match your criteria. Note the ID of the offering to purchase.

2. Use the New-EC2HostReservation cmdlet to purchase the offering and provide the offering ID noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account.

```
New-EC2HostReservation `
    -OfferingId hro-03f707bf363b6b324 `
    -HostIdSet h-013abcd2a00cbd123
```

Cross-account Amazon EC2 Dedicated Host sharing

Dedicated Host sharing enables Dedicated Host owners to share their Dedicated Hosts with other AWS accounts or within an AWS organization. This enables you to create and manage Dedicated Hosts centrally, and share the Dedicated Host across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Dedicated Host (*owner*) shares it with other AWS accounts (*consumers*). Consumers can launch instances onto Dedicated Hosts that are shared with them in the same way that they would launch instances onto Dedicated Hosts that they allocate in their own account. The owner is responsible for managing the Dedicated Host and the instances that they launch onto it. Owners can't modify instances that consumers launch onto shared Dedicated Hosts. Consumers are responsible for managing the instances that they launch onto Dedicated Hosts shared with them. Consumers can't view or modify instances owned by other consumers or by the Dedicated Host owner, and they can't modify Dedicated Hosts that are shared with them.

A Dedicated Host owner can share a Dedicated Host with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization

- Its entire AWS organization

Contents

Prerequisites for sharing Dedicated Hosts

- To share a Dedicated Host, you must own it in your AWS account. You can't share a Dedicated Host that has been shared with you.
- To share a Dedicated Host with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see Enable Sharing with AWS Organizations in the *AWS RAM User Guide*.

Limitations for sharing Dedicated Hosts

You can't share Dedicated Hosts that have been allocated for the following instance types: `u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, and `u-24tb1.metal`.

Related services

AWS Resource Access Manager

Dedicated Host sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS

Organizations. With AWS RAM, you share resources that you own by creating a *resource share*. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the AWS RAM User Guide.

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone `us-east-1a` for your AWS account might not have the same location as `us-east-1a` for another AWS account.

To identify the location of your Dedicated Hosts relative to your accounts, you must use the *Availability Zone ID* (AZ ID). The Availability Zone ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, `use1-az1` is an Availability Zone ID for the `us-east-1` Region and it is the same location in every AWS account.

To view the Availability Zone IDs for the Availability Zones in your account

1. Open the AWS RAM console at https://console.aws.amazon.com/ram/home.
2. The Availability Zone IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

Shared Dedicated Host permissions

Permissions for owners

Owners are responsible for managing their shared Dedicated Hosts and the instances that they launch onto them. Owners can view all instances running on the shared Dedicated Host, including those launched by consumers. However, owners can't take any action on running instances that were launched by consumers.

Permissions for consumers

Consumers are responsible for managing the instances that they launch onto a shared Dedicated Host. Consumers can't modify the shared Dedicated Host in any way, and they can't view or modify instances that were launched by other consumers or the Dedicated Host owner.

Billing and metering

There are no additional charges for sharing Dedicated Hosts.

Owners are billed for Dedicated Hosts that they share. Consumers are not billed for instances that they launch onto shared Dedicated Hosts.

Dedicated Host Reservations continue to provide billing discounts for shared Dedicated Hosts. Only Dedicated Host owners can purchase Dedicated Host Reservations for shared Dedicated Hosts that they own.

Dedicated Host limits

Shared Dedicated Hosts count towards the owner's Dedicated Hosts limits only. Consumer's Dedicated Hosts limits are not affected by Dedicated Hosts that have been shared with them. Similarly, instances that consumers launch onto shared Dedicated Hosts do not count towards their instance limits.

Host recovery and Dedicated Host sharing

Host recovery recovers instances launched by the Dedicated Host owner and the consumers with whom it has been shared. The replacement Dedicated Host is allocated to the owner's account. It is added to the same resource shares as the original Dedicated Host, and it is shared with the same consumers.

For more information, see [Amazon EC2 Dedicated Host recovery](#).

Share an Amazon EC2 Dedicated Host across AWS accounts

When an owner shares a Dedicated Host, it enables consumers to launch instances on the host. Consumers can launch as many instances onto the shared host as its available capacity allows.

> **Important**
>
> Note that you are responsible for ensuring that you have appropriate license rights to share any BYOL licenses on your Dedicated Hosts.

If you share a Dedicated Host with auto-placement enabled, keep the following in mind as it could lead to unintended Dedicated Host usage:

- If consumers launch instances with Dedicated Host tenancy and they do not have capacity on a Dedicated Host that they own in their account, the instance is automatically launched onto the shared Dedicated Host.

To share a Dedicated Host, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. You can add the Dedicated Host to an existing resource, or you can add it to a new resource share.

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are automatically granted access to the shared Dedicated Host. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared Dedicated Host after accepting the invitation.

> **Note**
>
> After you share a Dedicated Host, it could take a few minutes for consumers to have access to it.

Console

To share a Dedicated Host that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose the Dedicated Host to share and choose **Actions**, **Share host**.
4. Select the resource share to which to add the Dedicated Host and choose **Share host**.

   It could take a few minutes for consumers to get access to the shared host.

To share a Dedicated Host that you own using the AWS RAM console

See [Create a resource share](#) in the *AWS RAM User Guide*.

AWS CLI

To share a Dedicated Host that you own

Use the create-resource-share command.

```
aws ram create-resource-share \
    --name my-resource-share \
    --resource-arns arn:aws:ec2:us-east-2:123456789012:dedicated-
host/h-07879acf49EXAMPLE
```

PowerShell

To share a Dedicated Host that you own

Use the New-RAMResourceShare cmdlet.

```
New-RAMResourceShare `
    -Name my-resource-share `
    -ResourceArn arn:aws:ec2:us-east-2:123456789012:dedicated-
host/h-07879acf49EXAMPLE
```

Unshare a Dedicated Host that is shared with other AWS accounts

The Dedicated Host owner can unshare a shared Dedicated Host at any time. When you unshare a shared Dedicated Host, the following rules apply:

- Consumers with whom the Dedicated Host was shared can no longer launch new instances onto it.
- Instances owned by consumers that were running on the Dedicated Host at the time of unsharing continue to run but are scheduled for retirement. Consumers receive retirement notifications for the instances and they have two weeks to take action on the notifications. However, if the Dedicated Host is reshared with the consumer within the retirement notice period, the instance retirements are cancelled.

To unshare a shared Dedicated Host that you own, you must remove it from the resource share.

Console

To unshare a shared Dedicated Host that you own

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.

3. Choose the Dedicated Host to unshare and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Dedicated Host has been added. Select the resource share from which to remove the Dedicated Host and choose **Remove host from resource share**.

To unshare a shared Dedicated Host that you own using the AWS RAM console

See Update a resource share in the *AWS RAM User Guide*.

AWS CLI

To unshare a shared Dedicated Host that you own

Use the disassociate-resource-share command.

```
aws ram disassociate-resource-share \
    --resource-share-arn arn:aws:ram:us-east-2:123456789012:resource-share/7ab63972-
b505-7e2a-420d-6f5d3EXAMPLE \
 --resource-arns arn:aws:ec2:us-east-2:123456789012:dedicated-
host/h-07879acf49EXAMPLE
```

PowerShell

To unshare a shared Dedicated Host that you own

Use the Disconnect-RAMResourceShare cmdlet.

```
Disconnect-RAMResourceShare `
    -ResourceShareArn "arn:aws:ram:us-east-2:123456789012:resource-share/7ab63972-
b505-7e2a-420d-6f5d3EXAMPLE" `
    -ResourceArn "arn:aws:ec2:us-east-2:123456789012:dedicated-
host/h-07879acf49EXAMPLE"
```

View shared Amazon EC2 Dedicated Hosts in your AWS account

You can view Dedicated Host that you are sharing with other accounts, and Dedicated Hosts that are shared with you. If you own the Dedicated Host, you can see all of the instances running on the host, including instances launched by consumers. If the Dedicated Host is shared with you, you can see only the instances that you launched onto the shared host, and not those launched by other consumers.

Owners and consumers can identify shared Dedicated Hosts using one of the following methods.

Console

To identify a shared Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**. The screen lists Dedicated Hosts that you own and Dedicated Hosts that are shared with you.
3. The **Owner** column shows the AWS account ID of the Dedicated Host owner.
4. To view the instances running on the hosts, select the **Instances** tab.

AWS CLI

To identify a shared Dedicated Host

Use the describe-hosts command. The command returns the Dedicated Hosts that you own and Dedicated Hosts that are shared with you. The value of `Owner` is the account ID of the owner of the Dedicated Host. The `Instances` list describes the instances running on the host.

```
aws ec2 describe-hosts --filter "Name=state,Values=available"
```

PowerShell

To identify a shared Dedicated Host

Use the Get-EC2host cmdlet. The cmdlet returns the Dedicated Hosts that you own and Dedicated Hosts that are shared with you. The value of `Owner` in the response is the account ID of the owner of the Dedicated Host. The `Instances` list describes the instances running on the host.

```
Get-EC2Host -Filter @{Name="state"; Values="available"}
```

Amazon EC2 Dedicated Hosts on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to your premises. By providing local access to AWS managed infrastructure, AWS Outposts enables you to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can allocate Dedicated Hosts on Outposts that you own in your account. This makes it easier for you to bring your existing software licenses and workloads that require a dedicated physical server to AWS Outposts. You can also target specific hardware assets on an Outpost to help minimize latency between your workloads.

Dedicated Hosts allow you to use your eligible software licenses on Amazon EC2, so that you get the flexibility and cost effectiveness of using your own licenses. Other software licenses that are bound to virtual machines, sockets, or physical cores, can also be used on Dedicated Hosts, subject to their license terms. While Outposts have always been a single-tenant environments that are eligible for BYOL workloads, Dedicated Hosts allows you to limit the needed licenses to a single host as opposed to the entire Outpost deployment.

Additionally, using Dedicated Hosts on an Outpost gives you greater flexibility in instance type deployment, and more granular control over instance placement. You can target a specific host for instance launches and use host affinity to ensure that the instance always runs on that host, or you can use auto-placement to launch an instance onto any available host that has matching configurations and available capacity.

Contents

Prerequisites

You must have an Outpost installed at your site. For more information, see Create an Outpost and order Outpost capacity in the *AWS Outposts User Guide*.

Supported features

- The following instance families are supported: `C5`, `M5`, `R5`, `C5d`, `M5d`, `R5d`, `G4dn`, and `i3en`.

- Dedicated Hosts on Outposts can be configured to support multiple instance sizes. Support for multiple instance sizes is available for the following instance families: `C5`, `M5`, `R5`, `C5d`, `M5d`, and `R5d`. For more information, see Amazon EC2 Dedicated Host instance capacity configurations.
- Dedicated Hosts on Outposts support auto-placement and targeted instance launches. For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.
- Dedicated Hosts on Outposts support host affinity. For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.
- Dedicated Hosts on Outposts support sharing with AWS RAM. For more information, see Cross-account Amazon EC2 Dedicated Host sharing.

Considerations

- Dedicated Host Reservations are not supported on Outposts.
- Host resource groups and AWS License Manager are not supported on Outposts.
- Dedicated Hosts on Outposts do not support burstable T3 instances.
- Dedicated Hosts on Outposts do not support host recovery.
- Simplified automatic recovery is not supported for instances with Dedicated Host tenancy on Outposts.

Allocate an Amazon EC2 Dedicated Host on AWS Outposts

You allocate and use Dedicated Hosts on Outposts in the same way that would with Dedicated Hosts in an AWS Region.

Prerequisites

Create a subnet on the Outpost. For more information, see Create a subnet in the *AWS Outposts User Guide*.

To allocate a Dedicated Host on an Outpost, use one of the following methods:

Console

To allocate a Dedicated Host on an Outpost using the AWS Outposts console

1. Open the AWS Outposts console at https://console.aws.amazon.com/outposts/.

2. In the navigation pane, choose **Outposts**. Select the Outpost and then choose **Actions**, **Allocate Dedicated Host**.
3. Configure the Dedicated Host as needed. For more information, see [Allocate an Amazon EC2 Dedicated Host for use in your account](#).

> **Note**
>
> **Availability Zone** and **Outpost ARN** should be pre-populated with the Availability Zone and ARN of the selected Outpost.

4. Choose **Allocate**.

To allocate a Dedicated Host on an Outpost using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**, and then choose **Allocate Dedicated Host**.
3. For **Availability Zone**, select the Availability Zone associated with the Outpost.
4. For **Outpost ARN**, enter the ARN of the Outpost.
5. To target specific hardware assets on the Outpost, for **Target specific hardware assets on Outpost**, select **Enable**. For each hardware asset to target, choose **Add asset ID**, and then enter the ID of the hardware asset.

> **Note**
>
> The value that you specify for **Quantity** must be equal to the number of asset IDs that you specify. For example, if you specify 3 asset IDs, then Quantity must also be 3.

6. Configure the remaining Dedicated Host settings as needed. For more information, see [Allocate an Amazon EC2 Dedicated Host for use in your account](#).
7. Choose **Allocate**.

AWS CLI

To allocate a Dedicated Host on an Outpost

Use the allocate-hosts command. For `--availability-zone`, specify the Availability Zone associated with the Outpost. For `--outpost-arn`, specify the ARN of the Outpost. Optionally, for `--asset-ids`, specify the IDs of the Outpost hardware assets to target.

```
aws ec2 allocate-hosts \
    --availability-zone "us-east-1a" \
    --outpost-arn "arn:aws:outposts:us-east-1a:111122223333:outpost/
op-4fe3dc21baEXAMPLE" \
    --asset-ids asset_id \
    --instance-family "m5" \
    --auto-placement "off" \
    --quantity 1
```

PowerShell

To allocate a Dedicated Host on an Outpost

Use the New-EC2Host cmdlet. Specify the Availability Zone associated with the Outpost. Optionally, for `-AssetId`, specify the IDs of the Outpost hardware assets to target.

```
New-EC2Host `
    -AvailabilityZone "us-east-1a" `
    -OutpostArn "arn:aws:outposts:us-east-1a:111122223333:outpost/
op-4fe3dc21baEXAMPLE" `
    -AssetId asset_id `
    -InstanceFamily "m5" `
    -AutoPlacement "off" `
    -Quantity 1
```

To launch an instance onto a Dedicated Host on an Outpost

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**. Select the Dedicated Host that you allocated in the previous step and choose **Actions**, **Launch instance onto host**.
3. Configure the instance as needed and then launch the instance. For more information, see Launch Amazon EC2 instances on an Amazon EC2 Dedicated Host.

Amazon EC2 Dedicated Host recovery

Dedicated Host auto recovery restarts your instances on to a new replacement host when certain problematic conditions are detected on your Dedicated Host. Host recovery reduces the need for manual intervention and lowers the operational burden if there is an unexpected Dedicated Host failure concerning system power or network connectivity events. Other Dedicated Host issues will require manual intervention to recover from.

Contents

How Amazon EC2 Dedicated Host recovery works

Dedicated Hosts and the host resource groups recovery process use host-level health checks to assess Dedicated Host availability and to detect underlying system failures. The type of Dedicated Host failure determines if Dedicated Host auto recovery is possible. Examples of problems that can cause host-level health checks to fail include:

- Loss of network connectivity
- Loss of system power
- Hardware or software issues on the physical host

> **Important**
>
> Dedicated Host auto recovery does not occur when the host is scheduled for retirement.

Dedicated Host auto recovery

When a system power or network connectivity failure is detected on your Dedicated Host, Dedicated Host auto recovery is initiated and Amazon EC2 **automatically allocates a replacement**

Dedicated Host in the same Availability Zone as the original Dedicated Host. The replacement Dedicated Host receives a new host ID, but retains the same attributes as the original Dedicated Host, including:

- Availability Zone
- Instance type
- Tags
- Auto placement settings
- Reservation

When the replacement Dedicated Host is allocated, the **instances are recovered on to the replacement Dedicated Host**. The recovered instances retain the same attributes as the original instances, including:

- Instance ID
- Private IP addresses
- Elastic IP addresses
- EBS volume attachments
- All instance metadata

Additionally, the built-in integration with AWS License Manager automates the tracking and management of your licenses.

> **Note**
>
> AWS License Manager integration is supported only in Regions in which AWS License Manager is available.

If instances have a host affinity relationship with the impaired Dedicated Host, the recovered instances establish host affinity with the replacement Dedicated Host.

When all of the instances have been recovered on to the replacement Dedicated Host, **the impaired Dedicated Host is released**, and the replacement Dedicated Host becomes available for use.

When host recovery is initiated, the AWS account owner is notified by email and by an AWS Health Dashboard event. A second notification is sent after the host recovery has been successfully completed.

If you are using AWS License Manager to track your licenses, AWS License Manager allocates new licenses for the replacement Dedicated Host based on the license configuration limits. If the license configuration has hard limits that will be breached as a result of the host recovery, the recovery process is not allowed and you are notified of the host recovery failure through an Amazon SNS notification (if notification settings have been configured for AWS License Manager). If the license configuration has soft limits that will be breached as a result of the host recovery, the recovery is allowed to continue and you are notified of the limit breach through an Amazon SNS notification. For more information, see Using License Configurations and Settings in License Manager in the *AWS License Manager User Guide*.

Host recovery states

When a Dedicated Host failure is detected, the impaired Dedicated Host enters the `under-assessment` state, and all of the instances enter the `impaired` state. You can't launch instances on to the impaired Dedicated Host while it is in the `under-assessment` state.

After the replacement Dedicated Host is allocated, it enters the `pending` state. It remains in this state until the host recovery process is complete. You can't launch instances on to the replacement Dedicated Host while it is in the `pending` state. Recovered instances on the replacement Dedicated Host remain in the `impaired` state during the recovery process.

After the host recovery is complete, the replacement Dedicated Host enters the `available` state, and the recovered instances return to the `running` state. You can launch instances on to the replacement Dedicated Host after it enters the `available` state. The original impaired Dedicated Host is permanently released and it enters the `released-permanent-failure` state.

If the impaired Dedicated Host has instances that do not support host recovery, such as instances with instance store-backed root volumes, the Dedicated Host is not released. Instead, it is marked for retirement and enters the `permanent-failure` state.

Scenarios without Dedicated Host auto recovery

Dedicated Host auto recovery does not occur when the host is scheduled for retirement. You will receive a retirement notification in the AWS Health Dashboard, an Amazon CloudWatch event, and the AWS account owner email address receives a message regarding the Dedicated Host failure.

Follow the remedial steps described in the retirement notification within the specified time period to manually recover the instances on the retiring host.

Stopped instances are not recovered on to the replacement Dedicated Host. If you attempt to start a stopped instance that targets the impaired Dedicated Host, the instance start fails. We recommend that you modify the stopped instance to either target a different Dedicated Host, or to launch on any available Dedicated Host with matching configurations and auto-placement enabled.

Instances with instance storage are not recovered on to the replacement Dedicated Host. As a remedial measure, the impaired Dedicated Host is marked for retirement and you receive a retirement notification after the host recovery is complete. Follow the remedial steps described in the retirement notification within the specified time period to manually recover the remaining instances on the impaired Dedicated Host.

Supported instance types

Host recovery is supported for the following instance families: A1 | C3 | C4 | C5 | C5n | C6a | C6g | C6i | Inf1 | G3 | G5g | M3 | M4 | M5 | M5n | M5zn | M6a | M6g | M6i | Mac1 | Mac2 | Mac2-m1ultra | Mac2-m2 | Mac2-m2pro | P2 | P3 | R3 | R4 | R5 | R5b | R5n | R6g | R6i | T3 | X1 | X1e | X2iezn | u-6tb1 | u-9tb1 | u-12tb1 | u-18tb1 | u-24tb1.

To recover instances that are not supported, see Manually recover instances that are not supported by Amazon EC2 Dedicated Host recovery.

> **Note**
>
> Dedicated Host auto recovery of supported metal instance types will take longer to detect and recover from than non-metal instance types.

Pricing

There are no additional charges for using host recovery, but the usual Dedicated Host charges apply. For more information, see Amazon EC2 Dedicated Hosts Pricing.

As soon as host recovery is initiated, you are no longer billed for the impaired Dedicated Host. Billing for the replacement Dedicated Host begins only after it enters the `available` state.

If the impaired Dedicated Host was billed using the On-Demand rate, the replacement Dedicated Host is also billed using the On-Demand rate. If the impaired Dedicated Host had an active Dedicated Host Reservation, it is transferred to the replacement Dedicated Host.

Manage Amazon EC2 Dedicated Host recovery

Dedicated Host auto recovery restarts your instances on to a new replacement host when certain problematic conditions are detected on your Dedicated Host. You can enable host recovery when you allocate the Dedicated Host or after allocation.

Use the following procedures to enable host recovery when allocating the host.

Console

To enable host recovery at allocation

When allocating a Dedicated Host using the Amazon EC2 console, for **Host recovery**, choose **Enable**. For more information, see Allocate an Amazon EC2 Dedicated Host for use in your account.

AWS CLI

To enable host recovery at allocation

Use the allocate-hosts command.

```
aws ec2 allocate-hosts \
    --instance-type m5.large \
    --availability-zone eu-west-1a \
    --auto-placement on \
    --host-recovery on \
    --quantity 1
```

PowerShell

To enable host recovery at allocation

Use the New-EC2Host cmdlet.

```
New-EC2Host `
    -InstanceType m5.large `
    -AvailabilityZone eu-west-1a `
    -AutoPlacement on `
    -HostRecovery on `
    -Quantity 1
```

Use the following procedures to manage host recovery for a Dedicated Host.

Console

To manage host recovery after allocation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host.
4. Choose **Actions**, **Modify host**.
5. For **Host recovery**, select or clear **Enable**.
6. Choose **Save**.

AWS CLI

To enable host recovery after allocation

Use the modify-hosts command.

```
aws ec2 modify-hosts \
    --host-recovery on \
    --host-ids h-012a3456b7890cdef
```

To disable host recovery after allocation

Use the modify-hosts command and specify the `host-recovery` parameter with a value of `off`.

```
aws ec2 modify-hosts \
    --host-recovery off \
    --host-ids h-012a3456b7890cdef
```

PowerShell

To enable host recovery after allocation

Use the Edit-host cmdlet.

```
Edit-EC2Host `
    -HostRecovery on `
```

```
    -HostId h-012a3456b7890cdef
```

To disable host recovery after allocation

Use the Edit-EC2Host cmdlet.

```
Edit-EC2Host `
    -HostRecovery off `
    -HostId h-012a3456b7890cdef
```

View the host recovery setting for your Amazon EC2 Dedicated Host

You can view the host recovery configuration for a Dedicated Host at any time.

Console

To view the host recovery configuration for a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host, and in the **Description** tab, review the **Host Recovery** field.

AWS CLI

To view the host recovery configuration for a Dedicated Host

Use the describe-hosts command.

```
aws ec2 describe-hosts \
    --host-ids h-012a3456b7890cdef \
    --query Hosts[].HostRecovery
```

The following is example output.

```
on
```

PowerShell

To view the host recovery configuration for a Dedicated Host

Use the Get-EC2Host cmdlet.

```
(Get-EC2Host -HostId h-012a3456b7890cdef).Hosts | Select HostRecovery
```

The following is example output.

```
HostRecovery
------------
on
```

Manually recover instances that are not supported by Amazon EC2 Dedicated Host recovery

Host recovery does not support recovering instances that use instance store volumes. Follow the instructions below to manually recover any of your instances that could not be automatically recovered.

> **Warning**
>
> Data on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an EBS volume as the root device. To protect data from instance store volumes, back it up to persistent storage before the instance is stopped or terminated.

Manually recover EBS-backed instances

For EBS-backed instances that could not be automatically recovered, we recommend that you manually stop and start the instances to recover them onto a new Dedicated Host. For more information about stopping your instance, and about the changes that occur in your instance configuration when it's stopped, see Stop and start Amazon EC2 instances.

Manually recover instance store-backed instances

For instance store-backed instances that could not be automatically recovered, we recommend that you do the following:

1. Launch a replacement instance on a new Dedicated Host from your most recent AMI.
2. Migrate all of the necessary data to the replacement instance.

3. Terminate the original instance on the impaired Dedicated Host.

Host maintenance for Amazon EC2 Dedicated Host

With host maintenance, in the rare event that a Dedicated Host becomes degraded, we automatically migrate instances running on it onto a healthy replacement Dedicated Host. This helps to minimize the downtime for your workload, and simplify the management of your Dedicated Hosts. Host maintenance is also performed for planned and routine Amazon EC2 maintenance.

Amazon EC2 supports two types of host maintenance:

- **Live migration host maintenance** — Instances are automatically migrated to the replacement host within 24 hours, without stopping and restarting them.
- **Reboot-based host maintenance** — Instances are scheduled for *instance reboot* scheduled events, during which they are automatically stopped and restarted on the replacement host.

Contents

Host maintenance versus host recovery

The following table shows the main differences between host recovery and host maintenance.

	Host recovery	Host maintenance
Instance reachability	Unreachable	Reachable
Dedicated Host state	`under-assessment`	`permanent-failure`
Host resource group	Supported	Not supported

For more information about host recovery, see Host recovery.

Considerations

- Host maintenance is available in all AWS Regions, except the China Regions and AWS GovCloud (US) Regions.
- Host maintenance is not supported in AWS Outposts, AWS Local Zones, and AWS Wavelength Zones.
- Host maintenance can't be turned on or off for hosts already within a host resource group. Hosts added to a host resource group retain their host maintenance setting. For more information, see Host resource groups.
- Host maintenance is not supported with the following instance types, because they have instance store-backed root volumes: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

Related services

Dedicated Host integrates with **AWS License Manager**—Tracks licenses across your Amazon EC2 Dedicated Hosts (supported only in Regions in which AWS License Manager is available). For more information, see the AWS License Manager User Guide.

You must have sufficient licenses in your AWS account for your new Dedicated Host. The licenses associated with your degraded host are released when the host is released after the completion of the scheduled event.

Pricing

There are no additional charges for using host maintenance, but the usual Dedicated Host charges apply. For more information, see Amazon EC2 Dedicated Hosts Pricing.

As soon as host maintenance is initiated, you are no longer billed for the degraded Dedicated Host. Billing for the replacement Dedicated Host begins only after it enters the `available` state.

If the degraded Dedicated Host was billed using the On-Demand rate, the replacement Dedicated Host is also billed using the On-Demand rate. If the degraded Dedicated Host had an active Dedicated Host Reservation, it is transferred to the new Dedicated Host.

How host maintenance works for Amazon EC2 Dedicated Hosts

When a degradation is detected on a Dedicated Host that is enabled for host maintenance, we automatically allocate a replacement Dedicated Host in your account. The replacement Dedicated

Host receives a new host ID, but retains the same attributes as the original Dedicated Host, including:

- Auto placement settings
- Availability Zone
- Dedicated Host Reservation association
- Host affinity
- Host maintenance settings
- Host recovery settings
- Instance type
- Tags

After the replacement host has been allocated, we migrate the instances using either **live migration host maintenance** or **reboot-based host maintenance**, depending on the instance.

After the degraded host has no more running instances, it is permanently released from your account.

Live migration host maintenance

Instances that require live migration host maintenance are automatically migrated to the replacement host within 24 hours, without stopping and restarting them. The migrated instances retain their existing attributes, including:

- Instance ID
- Instance metadata
- Amazon EBS volume attachments
- Elastic IP addresses and private IP address
- Memory, CPU, and networking states

Some larger instance sizes might experience a slight performance decrease during the migration.

After the instances are automatically migrated to the replacement host, we send you email and AWS Health Dashboard notifications. Notifications include the IDs of the degraded and replacement hosts, information about the instances that were automatically migrated using live migration host maintenance, and information about the remaining instances.

Reboot-based host maintenance

Instances that require reboot-based host maintenance are scheduled for instance reboot scheduled events for 14 days from the date of the notification. You can continue to access your instances on the degraded Dedicated Host before the scheduled event.

You can reschedule reboot events for a date that is within 7 days of the original event date and time. For more information, see Reschedule a scheduled event for an EC2 instance.

Amazon EC2 automatically reserves capacity on the replacement host for these instances. You can't run instances in this reserved capacity.

The Amazon EC2 console shows the reserved capacity as used capacity. It could appear that the instances are running on both the degraded host and the replacement host. However, the instances will continue to run only on the degraded host until they are stopped or they are migrated into the reserved capacity on the replacement host.

At the date and time of the scheduled event, the instances are automatically stopped and restarted into the reserved capacity on the replacement host. The migrated instances retain their existing attributes, including:

- Instance ID
- Instance metadata
- Amazon EBS volume attachments
- Elastic IP addresses and private IP address

However, since the instances are stopped and restarted during the migration, they do not retain their memory, CPU, and networking states.

You can also manually stop and restart these instances at any time before the scheduled event to migrate them to the replacement host or to a different host. You might need to modify your instance's host affinity to restart it on a different host. If you stop an instance before the scheduled event, the reserved capacity on the replacement host is released and becomes available for use.

Host maintenance states

When a host becomes degraded, it enters the `permanent-failure` state. You can't launch instances on a Dedicated Host that is in the `permanent-failure` state.

After the replacement host is allocated, it remains in the `pending` state until the instances that support live migration host maintenance are automatically migrated from the degraded host, and until the scheduled events are scheduled for the remaining instances. After these tasks are completed, the replacement host enters the `available` state.

After the replacement host enters the `available` state, you can use it in the same way that you use any host in your account. However, some instance capacity on the replacement host is reserved for the instances that require reboot-based host migration. You can't launch new instances into this reserved capacity.

When the degraded host has no more running instances, it enters the `released, permanent-failure` state, and it is permanently released from your account. Note that the host and its resources remain visible in the console for a short time.

Automatic migration

Some instances can't be automatically migrated to the replacement host.

Instances with EBS-backed root volumes

For these instances, we schedule instance stop events for 28 days from the date of the notification. At the date and time of the scheduled event, the instances are stopped. We recommend that you manually stop on restart the instance on the replacement host or on a different host. You might need to modify your instance's host affinity to restart it on a different host.

Instances with instance store-backed root volumes

For these instances, we schedule instance retirement events for 28 days from the date of the notification. At the date and time of the scheduled event, the instances are permanently terminated. We recommend that you manually launch replacement instances on the replacement host and then migrate the required data to the replacement instances before the scheduled event.

The following instances have instance store-backed root volumes: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

You can continue to access your instances on the degraded Dedicated Host before the scheduled event.

Configure the host maintenance setting for an Amazon EC2 Dedicated Host

Enable host maintenance to ensure that your instances running on a Dedicated Host are automatically recovered onto a new Dedicated Host during a scheduled maintenance event.

If you disable host maintenance, you receive an email notification to evict the degraded host and manually migrate your instances to another host within 28 days. A replacement host is allocated if you have Dedicated Host reservation. After 28 days, the instances running on the degraded host are terminated, and the host is released automatically.

Console

To enable host maintenance for your Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host > **Actions** > **Modify host**.
4. Select *on* in the **Host maintenance** field.

To disable host maintenance for your Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host > **Actions** > **Modify host**.
4. Select *off* in the **Host maintenance** field.

AWS CLI

To enable host maintenance for your Dedicated Host

Use the modify-hosts command.

```
aws ec2 modify-hosts \
    --host-maintenance on \
    --host-ids h-0d123456bbf78910d
```

To disable host maintenance for your Dedicated Host

Use the modify-hosts command.

```
aws ec2 modify-hosts \
    --host-maintenance off \
    --host-ids h-0d123456bbf78910d
```

PowerShell

To enable host maintenance for your Dedicated Host

Use the Edit-EC2Host cmdlet.

```
Edit-EC2Host `
    -HostMaintenance on `
    -HostId h-0d123456bbf78910d
```

To disable host maintenance for your Dedicated Host

Use the Edit-EC2Host cmdlet.

```
Edit-EC2Host `
    -HostMaintenance off `
    -HostId h-0d123456bbf78910d
```

Monitor the state of your Amazon EC2 Dedicated Hosts

Amazon EC2 constantly monitors the state of your Dedicated Hosts. Updates are communicated on the Amazon EC2 console. You can view information about a Dedicated Host using the following methods.

Console

To view the state of a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Locate the Dedicated Host in the list and review the value in the **State** column.

AWS CLI

To view the state of a Dedicated Host

Use the describe-hosts command.

```
aws ec2 describe-hosts --host-id h-012a3456b7890cdef
```

PowerShell

To view the state of a Dedicated Host

Use the Get-EC2Host cmdlet.

```
Get-EC2Host -HostId h-012a3456b7890cdef
```

The following table explains the possible Dedicated Host states.

State	Description
`available`	AWS hasn't detected an issue with the Dedicated Host. No maintenance or repairs are scheduled. Instances can be launched onto this Dedicated Host.
`released`	The Dedicated Host has been released. The host ID is no longer in use. Released hosts can't be reused.
`under-assessment`	AWS is exploring a possible issue with the Dedicated Host. If action must be taken, you are notified via the AWS Management Console or email. Instances can't be launched onto a Dedicated Host in this state.
`pending`	The Dedicated Host can't be used for new instance launches. It is either being modified to support multiple instance types, or a host recovery is in progress.
`permanent-failure`	An unrecoverable failure has been detected. You receive an eviction notice through your instances and by email. Your instances might continue to run. If you stop or terminate all instances on a Dedicated Host with this state, AWS retires the host. AWS does not restart instances in this state. Instances can't be launched onto Dedicated Hosts in this state.
`released-permanent-failure`	AWS permanently releases Dedicated Hosts that have failed and no longer have running instances on them. The Dedicated Host ID is no longer available for use.

Track Amazon EC2 Dedicated Host configuration changes using AWS Config

You can use AWS Config to record configuration changes for Dedicated Hosts, and for instances that are launched, stopped, or terminated on them. You can then use the information captured by AWS Config as a data source for license reporting.

AWS Config records configuration information for Dedicated Hosts and instances individually, and pairs this information through relationships. There are three reporting conditions:

- **AWS Config recording status**—When **On**, AWS Config is recording one or more AWS resource types, which can include Dedicated Hosts and Dedicated Instances. To capture the information required for license reporting, verify that hosts and instances are being recorded with the following fields.
- **Host recording status**—When **Enabled**, the configuration information for Dedicated Hosts is recorded.
- **Instance recording status**—When **Enabled**, the configuration information for Dedicated Instances is recorded.

If any of these three conditions are disabled, the icon in the **Edit Config Recording** button is red. To derive the full benefit of this tool, ensure that all three recording methods are enabled. When all three are enabled, the icon is green. To edit the settings, choose **Edit Config Recording**. You are directed to the **Set up AWS Config** page in the AWS Config console, where you can set up AWS Config and start recording for your hosts, instances, and other supported resource types. For more information, see Setting up AWS Config using the Console in the *AWS Config Developer Guide*.

> **Note**
>
> AWS Config records your resources after it discovers them, which might take several minutes.

After AWS Config starts recording configuration changes to your hosts and instances, you can get the configuration history of any host that you have allocated or released and any instance that you have launched, stopped, or terminated. For example, at any point in the configuration history of a Dedicated Host, you can look up how many instances are launched on that host, along with the number of sockets and cores on the host. For any of those instances, you can also look up the ID of its Amazon Machine Image (AMI). You can use this information to report on licensing for your own server-bound software that is licensed per-socket or per-core.

You can view configuration histories in any of the following ways:

- By using the AWS Config console. For each recorded resource, you can view a timeline page, which provides a history of configuration details. To view this page, choose the gray icon in the **Config Timeline** column of the **Dedicated Hosts** page. For more information, see Viewing Configuration Details in the AWS Config Console in the *AWS Config Developer Guide*.
- By running AWS CLI commands. First, you can use the list-discovered-resources command to get a list of all hosts and instances. Then, you can use the get-resource-config-history command to get the configuration details of a host or instance for a specific time interval.
- By using the AWS Config API in your applications. First, you can use the ListDiscoveredResources action to get a list of all hosts and instances. Then, you can use the GetResourceConfigHistory action to get the configuration details of a host or instance for a specific time interval.

For example, to get a list of all of your Dedicated Hosts from AWS Config, run a CLI command such as the following.

```
aws configservice list-discovered-resources --resource-type AWS::EC2::Host
```

To obtain the configuration history of a Dedicated Host from AWS Config, run a CLI command such as the following.

```
aws configservice get-resource-config-history \
    --resource-type AWS::EC2::Instance \
    --resource-id i-1234567890abcdef0
```

To manage AWS Config settings using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the **Dedicated Hosts** page, choose **Edit Config Recording**.
3. In the AWS Config console, follow the steps provided to turn on recording. For more information, see Setting up AWS Config using the Console.

For more information, see Viewing Configuration Details in the AWS Config Console.

To activate AWS Config using the command line or API

- AWS CLI: Viewing Configuration Details (AWS CLI) in the *AWS Config Developer Guide*.
- Amazon EC2 API: GetResourceConfigHistory.

Amazon EC2 Dedicated Instances

By default, EC2 instances run on shared tenancy hardware. This means that multiple AWS accounts might share the same physical hardware.

Dedicated Instances are EC2 instances that run on hardware that's dedicated to a single AWS account. This means that Dedicated Instances are physically isolated at the host hardware level from instances that belong to other AWS accounts, even if those accounts are linked to a single payer account. However, Dedicated Instances might share hardware with other instances from the same AWS account that are not Dedicated Instances.

Dedicated Instances provide no visibility or control over instance placement, and they do not support host affinity. If you stop and start a Dedicated Instance, it might not run on the same host. Similarly, you cannot target a specific host on which to launch or run an instance. Additionally, Dedicated Instances provide limited support for Bring Your Own License (BYOL).

If you require visibility and control over instance placement and more comprehensive BYOL support, consider using a Dedicated Host instead. Dedicated Instances and Dedicated Hosts can both be used to launch Amazon EC2 instances onto dedicated physical servers. There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some key differences between them. The following table highlights some of the key differences between Dedicated Instances and Dedicated Hosts:

	Dedicated Host	Dedicated Instance
Dedicated physical server	Physical server with instance capacity fully dedicated to your use.	Physical server that's dedicated to a single customer account.
Instance capacity sharing	Can share instance capacity with other accounts.	Not supported

	Dedicated Host	Dedicated Instance
Billing	Per-host billing	Per-instance billing
Visibility of sockets, cores, and host ID	Provides visibility of the number of sockets and physical cores	No visibility
Host and instance affinity	Allows you to consistently deploy your instances to the same physical server over time	Not supported
Targeted instance placement	Provides additional visibility and control over how instances are placed on a physical server	Not supported
Automatic instance recovery	Supported. For more information, see Amazon EC2 Dedicated Host recovery.	Supported
Bring Your Own License (BYOL)	Supported	Partial support *
Capacity Reservations	Not supported	Supported

* Microsoft SQL Server with License Mobility through Software Assurance, and Windows Virtual Desktop Access (VDA) licenses can be used with Dedicated Instance.

For more information, see Amazon EC2 Dedicated Hosts.

Contents

- Launch Dedicated Instances into a VPC with default tenancy
- Change the tenancy of an EC2 instance
- Change the instance tenancy of a VPC

Dedicated Instance basics

A VPC can have a tenancy of either `default` or `dedicated`. By default, your VPCs have `default` tenancy and instances launched into a `default` tenancy VPC have `default` tenancy. To launch Dedicated Instances, do the following:

- Create a VPC with a tenancy of `dedicated`, so that all instances in the VPC run as Dedicated Instances. For more information, see Launch Dedicated Instances into a VPC with default tenancy.
- Create a VPC with a tenancy of `default` and manually specify a tenancy of `dedicated` for the instances to run as Dedicated Instances. For more information, see Launch Dedicated Instances into a VPC with default tenancy.

Supported features

Dedicated Instances support the following features and AWS service integrations:

Features

- Reserved Instances
- Automatic scaling
- Automatic recovery
- Dedicated Spot Instances
- Burstable performance instances

Reserved Instances

To reserve capacity for your Dedicated Instances, you can purchase Dedicated Reserved Instances or Capacity Reservations. For more information, see Reserved Instances for Amazon EC2 overview and Reserve compute capacity with EC2 On-Demand Capacity Reservations.

When you purchase a Dedicated Reserved Instance, you are purchasing the capacity to launch a Dedicated Instance at a much reduced usage fee; the price break in the usage charge applies only if you launch an instance with dedicated tenancy. When you purchase a Reserved Instance with default tenancy, it applies only to a running instance with `default` tenancy; it does not apply to a running instance with `dedicated` tenancy.

You can't use the modification process to change the tenancy of a Reserved Instance after you've purchased it. However, you can exchange a Convertible Reserved Instance for a new Convertible Reserved Instance with a different tenancy.

Automatic scaling

You can use Amazon EC2 Auto Scaling to launch Dedicated Instances. For more information, see Create a launch template using advanced settings in the *Amazon EC2 Auto Scaling User Guide*.

Automatic recovery

You can configure automatic recovery for a Dedicated Instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. For more information, see Automatic instance recovery.

Dedicated Spot Instances

You can run a Dedicated Spot Instance by specifying a tenancy of `dedicated` when you create a Spot Instance request. For more information, see Launch on single-tenant hardware.

Burstable performance instances

You can leverage the benefits of running on dedicated tenancy hardware with the section called "Burstable performance instances". T3 Dedicated Instances launch in unlimited mode by default, and they provide a baseline level of CPU performance with the ability to burst to a higher CPU level when required by your workload. The T3 baseline performance and ability to burst are governed by CPU credits. Because of the burstable nature of the T3 instance types, we recommend that you monitor how your T3 instances use the CPU resources of the dedicated hardware for the best performance. T3 Dedicated Instances are intended for customers with diverse workloads that display random CPU behavior, but that ideally have average CPU usage at or below the baseline usages. For more information, see the section called "Key concepts".

Amazon EC2 has systems in place to identify and correct variability in performance. However, it is still possible to experience short-term variability if you launch multiple T3 Dedicated Instances that have correlated CPU usage patterns. For these more demanding or correlated workloads, we recommend using M5 or M5a Dedicated Instances rather than T3 Dedicated Instances.

Dedicated Instances limitations

Keep the following in mind when using Dedicated Instances:

- Some AWS services or their features are not supported with a VPC with the instance tenancy set to `dedicated`. Refer to the respective service's documentation to confirm if there are any limitations.
- Some instance types can't be launched into a VPC with the instance tenancy set to `dedicated`. For more information about supported instance types, see Amazon EC2 Dedicated Instances.
- When you launch a Dedicated Instance backed by Amazon EBS, the EBS volume doesn't run on single-tenant hardware.

Pricing for Dedicated Instances

Pricing for Dedicated Instances is different from pricing for On-Demand Instances. For more information, see the Amazon EC2 Dedicated Instances.

Launch Dedicated Instances into a VPC with default tenancy

When you create a VPC, you have the option of specifying its instance tenancy. If you launch an instance into a VPC that has an instance tenancy of `dedicated`, it runs as a Dedicated Instance on hardware that's dedicated for your use.

For more information about launching an instance with a tenancy of `host`, see Launch Amazon EC2 instances on an Amazon EC2 Dedicated Host.

For more information about VPC tenancy options, see Create a VPC in the *Amazon VPC User Guide*.

Requirements

- Choose a supported instance type. For more information, see Amazon EC2 Dedicated Instances.

Console

To launch a Dedicated Instance into a default tenancy VPC

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, **Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.

4. In the **Instance type** section, select the instance type to launch.
5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, for **Tenancy**, select **Dedicated**.
7. Configure the remaining instance options as needed. For more information, see Reference for Amazon EC2 instance configuration parameters.
8. Choose **Launch instance**.

AWS CLI

To set the tenancy option for an instance during launch

Use the run-instances command and include `Tenancy` with the `--placement` option.

```
--placement Tenancy=dedicated
```

PowerShell

To set the tenancy option for an instance during launch

Use the New-EC2Instance cmdlet with the `-Placement_Tenancy` parameter.

```
-Placement_Tenancy dedicated
```

Change the tenancy of an EC2 instance

You can change the tenancy of a stopped instance after launch. The changes that you make take effect the next time the instance starts.

Alternatively, you can change the tenancy of your virtual private cloud (VPC). For more information, see the section called “Change the tenancy of a VPC”.

Limitations

- You can't change the tenancy of an instance using the AWS Management Console.
- The instance must be in the `stopped` state.
- The operating system details of your instance—and whether SQL Server is installed—affect what conversions are supported. For more information about the tenancy conversion paths available to your instance, see Tenancy conversion in the *License Manager User Guide*.

- For T3 instances, you must launch the instance on a Dedicated Host to use a tenancy of `host`. You can't change the tenancy from `host` to `dedicated` or `default`. Attempting to make one of these unsupported tenancy changes results in an `InvalidRequest` error code.

AWS CLI

To modify the tenancy value of an instance

Use the [modify-instance-placement](#) command.

```
aws ec2 modify-instance-placement \
    --instance-id i-1234567890abcdef0 \
    --tenancy dedicated
```

PowerShell

To modify the tenancy value of an instance

Use the [Edit-EC2InstancePlacement](#) cmdlet.

```
Edit-EC2InstancePlacement `
    -InstanceId i-1234567890abcdef0 `
    -Tenancy Dedicated
```

Change the instance tenancy of a VPC

You can change the instance tenancy of a virtual private cloud (VPC) from `dedicated` to `default` after you create it. Modifying the instance tenancy of a VPC does not affect the tenancy of any existing instances in the VPC. The next time that you launch an instance in the VPC, it has a tenancy of `default`, unless you specify otherwise during instance launch.

Alternatively, you can change the tenancy of specific instances. For more information, see the section called "Change the tenancy of an instance".

Limitations

- You can't change the instance tenancy of a VPC from `default` to `dedicated` after it is created.
- You can't modify the instance tenancy of a VPC using the AWS Management Console.

AWS CLI

To modify the instance tenancy attribute of a VPC

Use the modify-vpc-tenancy command. The only supported tenancy value is `default`.

```
aws ec2 modify-vpc-tenancy \
    --vpc-id vpc-1234567890abcdef0 \
    --instance-tenancy default
```

PowerShell

To modify the instance tenancy attribute of a VPC

Use the Edit-EC2VpcTenancy cmdlet. The only supported tenancy value is `Default`.

```
Edit-EC2VpcTenancy `
    -VpcId vpc-1234567890abcdef0 `
    -InstanceTenancy Default
```

On-Demand Capacity Reservations and Capacity Blocks for ML

Capacity Reservations allow you to reserve compute capacity for Amazon EC2 instances in a specific Availability Zone. There are two types of Capacity Reservations serving different use cases.

Types of Capacity Reservations

- On-Demand Capacity Reservations
- Capacity Blocks for ML

The following are some common use cases for On-Demand Capacity Reservations:

- **Scaling events** – Create On-Demand Capacity Reservations ahead of your business-critical events to ensure that you can scale when you need to.
- **Regulatory requirements and disaster recovery** – Use On-Demand Capacity Reservations to satisfy regulatory requirements for high availability, and reserve capacity in a different Availability Zone or Region for disaster recovery.

The following are some common use cases for Capacity Blocks for ML:

- **Machine learning (ML) model training and fine-tuning –** Get uninterrupted access to the GPU instances that you reserved to complete ML model training and fine-tuning.
- **ML experiments and prototypes –** Run experiments and build prototypes that require GPU instances for short durations.

When to use On-Demand Capacity Reservation

Use On-Demand Capacity Reservations if you have strict capacity requirements, and your current or future business-critical workloads require capacity assurance. With On-Demand Capacity Reservations, you can ensure that you'll always have access to the Amazon EC2 capacity you've reserved for as long as you need it.

When to use Capacity Blocks for ML

Use Capacity Blocks for ML when you need to ensure that you have uninterrupted access to GPU instances for a defined period of time starting on a future date. Capacity Blocks are ideal for training and fine-tuning ML models, short experimentation runs, and handling temporary surges in inference demand in the future. With Capacity Blocks, you can ensure that you'll have access to GPU resources on a specific date to run your ML workloads.

Reserve compute capacity with EC2 On-Demand Capacity Reservations

Amazon EC2 Capacity Reservations allow you to reserve compute capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. If you have strict capacity requirements for current or future business-critical workloads that require a certain level of long or short-term capacity assurance, we recommend that you create a Capacity Reservation to help ensure that you always have access to Amazon EC2 capacity when you need it, for as long as you need it.

You can create a Capacity Reservation at any time, and you can choose when it starts. You can request a Capacity Reservation for immediate use or you can request a Capacity Reservation for a future date.

- If you request a **Capacity Reservation for immediate use**, the Capacity Reservation becomes available for use immediately and there is no term commitment. You can modify the Capacity Reservation at any time, and you can cancel it at any time to release the reserved capacity and to stop incurring changes.
- If you request a **future-dated Capacity Reservation**, you specify the future date at which you need the Capacity Reservation to become available for use. You must also specify a commitment

duration for which you commit to keeping the requested capacity in your account after the specified date. At the requested date and time, the Capacity Reservation becomes available for use and the commitment duration starts. During the commitment duration, you can't decrease the instance count or commitment duration below your initial commitment, or cancel the Capacity Reservation. After the commitment duration elapses, you can modify the Capacity Reservation in any way or cancel it if you no longer need it.

Capacity Reservations can only be used by instances that match their attributes. By default, Capacity Reservations automatically match new instances and running instances that have matching attributes (instance type, platform, Availability Zone, and tenancy). This means that any instance with matching attributes automatically runs in the Capacity Reservation. However, you can also target a Capacity Reservation for specific workloads. This allows you to explicitly control which instances are allowed to run in that reserved capacity. You can also specify that instances will only run in a Capacity Reservation or Capacity Reservation resource group.

Important

Future-dated Capacity Reservations are for helping you launch and cover incremental instances, and not to cover existing running instances. If you need to cover existing running instances, use Capacity Reservations that start immediately instead.

All supported Amazon EC2 instances with matching attributes, that is instance type, platform, Availability Zone, and tenancy, are eligible to run in a Capacity Reservation. The Amazon EC2 instance can be launched by you (*non-managed instances*) or on your behalf by an AWS service (*managed instances*). This is particularly true for *open* Capacity Reservations, which automatically match with any running instances that have matching attributes. For example, managed instances launched on your behalf by the following services are eligible to run in Capacity Reservations that you create and manage.

- Amazon EC2 Auto Scaling
- Amazon ECS
- Amazon EKS
- Amazon EMR
- Amazon SageMaker AI
- AWS Batch

- AWS Elastic Beanstalk
- AWS ParallelCluster
- AWS Parallel Computing Service (AWS PCS)

Contents

Concepts for Amazon EC2 Capacity Reservations

The following key concepts apply to Capacity Reservations.

Topics

Start date and time

The start date and time defines when the Capacity Reservation becomes available for use. A Capacity Reservation can start **immediately**, or it can start at a **future date**.

- If you choose to start a Capacity Reservation immediately, the reserved capacity becomes available for use immediately after you create it, and billing starts as soon as the Capacity Reservation enters the active state. You do not need to enter into any term commitments. You can modify the Capacity Reservation as needed at any time to meet your needs, and you can cancel it at any time to release the capacity and to stop incurring charges.
- If you choose to start a Capacity Reservation at a future date, you specify a *future date and time* at which you will need the reserved capacity, and a *commitment duration*, which is the minimum duration for which you commit to keeping the requested Capacity Reservation in your account after it has been provisioned. At the specified future date, the Capacity Reservation becomes available for use and billing starts at that time, once the Capacity Reservation enters the active state. The commit duration starts as soon as the Capacity Reservation is provisioned in your account. During this time, you can't decrease the instance count below the committed instance count, choose an end date that is before the commitment duration, or cancel the Capacity Reservation. However, after the commitment duration lapses, you are free to modify the Capacity Reservation in any way, or cancel it to release the reserved capacity and to stop incurring charges.

End date and time

The end date and time defines when the Capacity Reservation ends and the reserved capacity is released from your account. You can configure a Capacity Reservation to **end automatically** at a specific date and time, or you can configure it to stay active indefinitely until you **manually cancel it**.

If you configure a Capacity Reservation to end automatically, the Capacity Reservation expires within an hour of the specified time. For example, if you specify `5/31/2019, 13:30:55`, the Capacity Reservation is guaranteed to end between `13:30:55` and `14:30:55` on `5/31/2019`.

After a reservation ends, the reserved capacity is released from your account and you can no longer target instances to the Capacity Reservation. Instances running in the reserved capacity continue to run uninterrupted. If instances targeting a Capacity Reservation are stopped, you can't restart them until you remove their Capacity Reservation targeting preference or configure them to target a different Capacity Reservation. For more information, see [Modify the Capacity Reservation settings of your instance](#).

Commitment duration

The commitment duration applies to future-dated Capacity Reservations only.

The commitment duration is a minimum duration for which you commit to having the future-dated Capacity Reservation in the active state in your account after it has been provisioned. You can keep a future-dated Capacity Reservation for longer than the commitment duration, but not shorter. The following apply during the commitment duration:

- You can't cancel a Capacity Reservation during the commitment duration.
- You can't decrease the instance count below the committed instance count, but you can increase it.
- You can't configure a Capacity Reservation to automatically end at a date or time that is within the commitment duration. You can extend the end date and time during the commitment period.

Amazon EC2 uses the commitment duration that you specify to assess whether the request can be supported. The minimum commitment duration is 14 days. While assessing a request, Amazon EC2 might determine that it can support a shorter commitment duration. In that case, Amazon EC2 will schedule the future-dated Capacity Reservation with the shorter commitment duration. This means that you are committed to keeping the Capacity Reservation in your account for a shorter period than you initially requested.

Future-dated Capacity Reservation assessment

When you request a future-dated Capacity Reservation, Amazon EC2 assesses the request to determine whether it can be supported based on capacity availability and the commitment duration you specify. The assessment is typically completed within 5 days. Amazon EC2 considers multiple factors when evaluating a request, including:

- Forecasted capacity supply
- The commitment duration
- How early you request the Capacity Reservation relative to your start date
- The size of your request

You can request a future-dated Capacity Reservation between 5 and 120 days in advance. We recommend that you make the request at least 56 days (8 weeks) in advance to improve our ability to support your request. The minimum commitment duration is 14 days and the minimum instance count is 64 vCPUs.

The Capacity Reservation remains in the `assessing` state while the request is being assessed.

If the request can be supported, the Capacity Reservation enters the `scheduled` state and it is scheduled for delivery on the requested date and time. The total instance count remains 0 during while the Capacity Reservation is in the `scheduled` state. A scheduled Capacity Reservation will become `active` and available for use at the requested date.

If a request can't be supported, the Capacity Reservation enters the `unsupported` state. Unsupported Capacity Reservations are not delivered.

You can cancel a future-dated Capacity Reservation while it is in the `assessing` state.

For more information, see [Create a future-dated Capacity Reservation].

Capacity Reservation attributes

When you create a Capacity Reservation, you must specify the following attributes:

- Availability Zone
- Instance type
- Platform (operating system type)
- Tenancy (`default` or `dedicated`)

Only instances that match these attributes can launch or run in the Capacity Reservation.

Instance matching criteria

Instance matching criteria, or instance eligibility, determines which instances are allowed to launch and run in the Capacity Reservation. A Capacity Reservation can have one of the following matching criteria:

- **Open** — The Capacity Reservation automatically matches all instances that have matching attributes (instance type, platform, and Availability Zone). New and existing instances that have matching attributes automatically run in the Capacity Reservation without any additional configuration.
- **Targeted** — The Capacity Reservation accepts only instances that have matching attributes (instance type, platform, and Availability Zone), and that explicitly target the Capacity Reservation. The instance must specifically target the Capacity Reservation to launch or run in its reserved capacity. This allows you to explicitly control which instances are allowed to run in the reserved capacity and helps you avoid unintentional reserved capacity usage.

When you request a future-dated Capacity Reservation, you can specify only targeted matching criteria. This ensures that the capacity delivered by the Capacity Reservation is incremental, or additional, to any running instances or reserved capacity that you have at the time of delivery. After the Capacity Reservation becomes active in your account, you can change the instance matching criteria to open if needed. However, keep in mind that any matching instances will automatically run in the Capacity Reservation, which could lead to unintentional capacity usage and prevent you from launching new instances for the full requested instance count.

Differences between Capacity Reservations, Reserved Instances, and Savings Plans

The following table highlights key differences between Capacity Reservations, Reserved Instances, and Savings Plans:

	Capacity Reservations	Zonal Reserved Instances	Regional Reserved Instances	Savings Plans
Term	No commitment required for immediate-use Capacity Reservati	Requires a fixed one-year or three-year commitment		

	Capacity Reservations	Zonal Reserved Instances	Regional Reserved Instances	Savings Plans
	ons. They can be created, modified, and canceled as needed. With future-dated Capacity Reservations, you specify a commitment duration for which you commit to keeping the capacity in your account. After the commitment duration elapses, you can cancel the Capacity Reservation at any time.			
Capacity benefit	Capacity reserved in a specific Availability Zone.		No capacity reserved.	
Billing discount	No billing discount. †	Provides a billing discount.		
Instance Limits	Your On-Demand Instance limits per Region apply.	Default is 20 per Availability Zone. You can request a limit increase.	Default is 20 per Region. You can request a limit increase.	No limit.

† You can combine Capacity Reservations with Savings Plans or Regional Reserved Instances to receive a discount.

For more information, see the following:

- Reserved Instances for Amazon EC2 overview
- Savings Plans User Guide

Supported platforms

You must create the Capacity Reservation with the correct platform to ensure that it properly matches with your instances. Capacity Reservations support the following values for `platform`:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
- SUSE Linux
- Red Hat Enterprise Linux
- RHEL with SQL Server Standard
- RHEL with SQL Server Enterprise
- RHEL with SQL Server Web
- RHEL with HA
- RHEL with HA and SQL Server Standard
- RHEL with HA and SQL Server Enterprise
- Ubuntu Pro
- Windows
- Windows with SQL Server
- Windows with SQL Server Web
- Windows with SQL Server Standard
- Windows with SQL Server Enterprise

To ensure that an instance runs in a specific Capacity Reservation, the platform of the Capacity Reservation must match the platform of the AMI used to launch the instance. For Linux AMIs, it is important to check whether the AMI platform uses the general value **Linux/UNIX** or a more specific value like **SUSE Linux**.

Console

To check the AMI platform

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **AMIs**.
3. Select the AMI.
4. On the **Details** tab, note the value of **Platform details**.

AWS CLI

To check the AMI platform

Use the describe-images command and check the value of `PlatformDetails`.

```
aws ec2 describe-images \
    --image-ids ami-0abcdef1234567890 \
    --query Images[*].PlatformDetails
```

The following is example output.

```
[
    "Linux/UNIX"
]
```

PowerShell

To check the AMI platform

Use the Get-EC2Image cmdlet and check the value of `PlatformDetails`.

```
Get-EC2Image `
    -ImageId ami-0abcdef1234567890 | `
    Select PlatformDetails
```

The following is example output.

```
PlatformDetails
---------------
Linux/UNIX
```

Quotas

The number of instances for which you are allowed to reserve capacity is based on your account's On-Demand Instance quota. You can reserve capacity for as many instances as that quota allows, minus the number of instances that are already running.

Capacity Reservations in the `assessing`, `scheduled`, `pending` , `active`, and `delayed` state count towards your On-Demand Instance quota.

Limitations

Before you create Capacity Reservations, take note of the following limitations and restrictions.

- Active and unused Capacity Reservations count toward your On-Demand Instance limits.
- Capacity Reservations are not transferable from one AWS account to another. However, you can share Capacity Reservations with other AWS accounts. For more information, see Shared Capacity Reservations.
- Zonal Reserved Instance billing discounts do not apply to Capacity Reservations.
- Capacity Reservations can be created in cluster placement groups. Spread and partition placement groups are not supported.
- Capacity Reservations can't be used with Dedicated Hosts. Capacity Reservations can be used with Dedicated Instances.
- [Windows instances] Capacity Reservations can't be used with Bring Your Own License (BYOL).
- [Red Hat instances] Capacity Reservations can be used with Bring Your Own License (BYOL).
- Capacity Reservations do not ensure that a hibernated instance can resume after you try to start it.
- You can request future-dated Capacity Reservations for an instance count with a minimum of 64 vCPUs. For example, if you request a future-dated Capacity Reservation for `m5.xlarge` instances, you must request at least 16 instances (*16 * m5.xlarge = 64 vCPUs*).
- You can request future-dated Capacity Reservations for instance types in the following series only: C, G, I, M, R, and T.

Capacity Reservation pricing and billing

The topics in this section provide an overview of pricing and billing for Capacity Reservations.

Topics

- Pricing
- Billing
- Billing discounts
- Viewing your bill

Pricing

Capacity Reservations are charged at the equivalent On-Demand rate whether you run instances in reserved capacity or not. If you do not use the reservation, this shows up as unused reservation on your Amazon EC2 bill. When you run an instance that matches the attributes of a reservation, you just pay for the instance and nothing for the reservation. There are no upfront or additional charges.

For example, if you create a Capacity Reservation for 20 `m4.large` Linux instances and run 15 `m4.large` Linux instances in the same Availability Zone, you will be charged for 15 active instances and for 5 unused instances in the reservation.

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. For more information, see Billing discounts.

For more information, see Amazon EC2 Pricing.

Billing

Billing starts as soon as the Capacity Reservation is provisioned in your account, and it continues while the Capacity Reservation remains provisioned in your account. For future-dated Capacity Reservations, this means that billing starts only once the Capacity Reservation is provisioned in your account at the requested future date.

Capacity Reservations are billed at per-second granularity. This means that you are charged for partial hours. For example, if a Capacity Reservation remains provisioned in your account for `24` hours and `15` minutes, you are billed for `24.25` reservation hours.

The following example shows how a Capacity Reservation is billed. The Capacity Reservation is created for one `m4.large` Linux instance, which has an On-Demand rate of $0.10 per usage hour. In this example, the Capacity Reservation is provisioned in the account for five hours. The Capacity Reservation is unused for the first hour, so it is billed for one unused hour at the `m4.large` instance type's standard On-Demand rate. In hours two through five, the Capacity Reservation is occupied by an `m4.large` instance. During this time, the Capacity Reservation accrues no charges, and the account is instead billed for the `m4.large` instance occupying it. In the sixth hour, the Capacity Reservation is canceled and the `m4.large` instance runs normally outside of the reserved capacity. For that hour, it is charged at the On-Demand rate of the `m4.large` instance type.

Hour	1	2	3	4	5	6	Total cost
Unused Capacity Reservation	$0.10	$0.00	$0.00	$0.00	$0.00	$0.00	$0.10
On-demand Instance Usage	$0.00	$0.10	$0.10	$0.10	$0.10	$0.10	$0.50
Hourly cost	$0.10	$0.10	$0.10	$0.10	$0.10	$0.10	$0.60

Billing discounts

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. AWS automatically applies these discounts to Capacity Reservations that have matching attributes. When a Capacity Reservation is used by an instance, the discount is applied to the instance. Discounts are preferentially applied to instance usage before covering unused Capacity Reservations.

Billing discounts for zonal Reserved Instances do not apply to Capacity Reservations.

For more information, see the following:

- Reserved Instances for Amazon EC2 overview
- Savings Plans User Guide
- Billing and purchase options

Viewing your bill

You can review the charges and fees to your account on the AWS Billing and Cost Management console.

- The **Dashboard** displays a spend summary for your account.
- On the **Bills** page, under **Details**, expand the **Elastic Compute Cloud** section and the Region to get billing information about your Capacity Reservations.

You can view the charges online, or you can download a CSV file. For more information, see Capacity Reservation line items.

Create a Capacity Reservation

You can create a Capacity Reservation at any time to ensure that you have compute capacity available in a specific Availability Zone. A Capacity Reservation can start immediately, or it can start at a future date. The capacity becomes available for use only once the Capacity Reservation enters the `active` state.

> **Note**
>
> If you create a Capacity Reservation with `open` instance matching criteria, and you have running instances with matching attributes at the time the Capacity Reservation becomes active, those instances automatically run in the reserved capacity. To avoid this, use `targeted` instance matching criteria. For more information, see [Instance matching criteria](#).

Your request to create a Capacity Reservation could fail if one of the following is true:

- Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller request. If your application is flexible across instance types and sizes, try different instance attributes.
- The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see [On-Demand Instance quotas](#).

Topics

Create a Capacity Reservation for immediate use

You create a Capacity Reservation for immediate use.

Console

To create a Capacity Reservation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Capacity Reservations**, and then choose **Create Capacity Reservation**.

3. Configure the following settings in the **Instance details** section.

   a. **Instance Type** — The instance type for which to reserve capacity.

   b. **Platform** — The operating system for your instances. For more information, see Supported platforms.

   c. **Availability Zone** — The Availability Zone in which to reserve the capacity.

   d. **Tenancy** — The type of tenancy to use for the reserved capacity. Choose Default to reserve capacity on shared hardware, or Dedicated to reserve capacity on hardware that is dedicated to your account.

   e. (*Optional*) **Placement group ARN** — The ARN of the cluster placement group in which to create the Capacity Reservation. For more information, see Use Capacity Reservations with cluster placement groups.

   f. **Total instance count** — The number of instances for which to reserve capacity. If you specify a quantity that exceeds your remaining On-Demand Instance quota for the selected instance type, the request fails.

4. Configure the following settings in the **Reservation details** section:

   a. **Capacity Reservation starts** — Choose **Immediately**.

   b. **Capacity Reservation ends** — Choose one of the following options:

      - **Manually** — Reserve the capacity until you explicitly cancel it.
      - **Specific time** — Cancel the capacity reservation automatically at the specified date and time.

   c. **Instance eligibility** — Choose one of the following options:

      - **open** — (Default) The Capacity Reservation matches any instance that has matching attributes (instance type, platform, Availability Zone, and tenancy). If you launch an instance with matching attributes, it is placed into the reserved capacity automatically.
      - **targeted** — The Capacity Reservation only accepts instances that have matching attributes (instance type, platform, Availability Zone, and tenancy), and that explicitly target the reservation.

5. Choose **Create**.

AWS CLI

To create a Capacity Reservation

Use the create-capacity-reservation command.

```
aws ec2 create-capacity-reservation \
    --availability-zone az_name \
    --instance-type instance_type \
    --instance-count number_of_instances \
    --instance-platform operating_system \
    --instance-match-criteria open|targeted
```

PowerShell

To create a Capacity Reservation

Use the Add-EC2CapacityReservation cmdlet.

```
Add-EC2CapacityReservation `
    -AvailabilityZone az_name `
    -InstanceType instance_type `
    -InstanceCount number_of_instances `
    -InstancePlatform operating_system `
    -InstanceMatchCriterion open|targeted
```

Create a future-dated Capacity Reservation

Request a future-dated Capacity Reservation if you need the reserved capacity to become available at a future date and time.

After you request a future-dated Capacity Reservation, the request undergoes an assessment to determine whether it can be supported. For more information, see Future-dated Capacity Reservation assessment.

Considerations

- You can request future-dated Capacity Reservations for instance types in the following series: C, G, I, M, R, and T.

- You can request future-dated Capacity Reservations for an instance count with a minimum of 64 vCPUs. For example, if you request a future-dated Capacity Reservation for `m5.xlarge` instances, you must request capacity for at least 16 instances (*16 * m5.xlarge = 64 vCPUs*).
- You can request a future-dated Capacity Reservation between 5 and 120 days in advance. However, we recommend that you request it at least 56 days (8 weeks) in advance to improve supportability.
- The minimum commitment duration is 14 days.

Console

To create a Capacity Reservation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Capacity Reservations**, and then choose **Create Capacity Reservation**.
3. Configure the following settings in the **Instance details** section.
   a. **Instance Type** — The instance type for which to reserve capacity.
   b. **Platform** — The operating system for your instances. For more information, see Supported platforms.
   c. **Availability Zone** — The Availability Zone in which to reserve the capacity.
   d. **Tenancy** — The type of tenancy to use for the reserved capacity. Choose Default to reserve capacity on shared hardware, or Dedicated to reserve capacity on hardware that is dedicated to your account.
   e. **Total instance count** — The number of instances for which to reserve capacity. If you specify a quantity that exceeds your remaining On-Demand Instance quota for the selected instance type, the request fails.
4. Configure the following settings in the **Reservation details** section:
   a. **Capacity Reservation starts** — Choose **At a specific time**.
   b. **Start date** — Specify the date and time at which the Capacity Reservation must become availble for use. For more information, see Start date and time.
   c. **Commitment duration** — Specify the minimum duration for which you commit keeping the Capacity Reservation after it has been delivered. For more information, see Commitment duration.
   d. **Capacity Reservation ends** — Choose one of the following options:

- **When I cancel it** — Reserve the capacity until you explicitly cancel it.
- **Specific time** — Cancel the capacity reservation automatically at the specified date and time.

5. Choose **Create**.

AWS CLI

To create a Capacity Reservation

Use the create-capacity-reservation command.

```
aws ec2 create-capacity-reservation \
    --availability-zone az_name \
    --instance-type instance_type \
    --instance-count number_of_instances \
    --instance-platform operating_system \
    --instance-match-criteria targeted \
    --delivery-preference incremental \
    --commitment-duration commitment_in_seconds \
    --start-date YYYY-MMDDThh:mm:ss.sssZ
```

PowerShell

To create a Capacity Reservation

Use the Add-EC2CapacityReservation cmdlet.

```
Add-EC2CapacityReservation `
    -AvailabilityZone az_name `
    -InstanceType instance_type `
    -InstanceCount number_of_instances `
    -InstancePlatform operating_system `
    -InstanceMatchCriterion targeted `
    -DeliveryPreference incremental `
    -CommitmentDuration commitment_in_seconds `
    -StartDate  YYYY-MMDDThh:mm:ss.sssZ
```

View the state of a Capacity Reservation

Amazon EC2 constantly monitors the state of your Capacity Reservations.

Due to the eventual consistency model followed by the Amazon EC2 API, after you create a Capacity Reservation, it can take up to 5 minutes for the state of the Capacity Reservation to reflect that it is `active`. During this time, the Capacity Reservation might remain in the `pending` state. However, it might already be available for use, in which case attempts to launch instances into the Capacity Reservation would succeed.

Console

To view your Capacity Reservations

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation.

AWS CLI

To describe your Capacity Reservations

Use the describe-capacity-reservations command.

For example, the following command describes all Capacity Reservations.

```
aws ec2 describe-capacity-reservations
```

The following is example output.

```
{
    "CapacityReservations": [
        {
            "CapacityReservationId": "cr-1234abcd56EXAMPLE",
            "EndDateType": "unlimited",
            "AvailabilityZone": "eu-west-1a",
            "InstanceMatchCriteria": "open",
            "Tags": [],
            "EphemeralStorage": false,
            "CreateDate": "2019-08-16T09:03:18.000Z",
            "AvailableInstanceCount": 1,
            "InstancePlatform": "Linux/UNIX",
            "TotalInstanceCount": 1,
            "State": "active",
```

```
                "Tenancy": "default",
                "EbsOptimized": true,
                "InstanceType": "a1.medium",
                "PlacementGroupArn": "arn:aws:ec2:us-east-1:123456789012:placement-
group/MyPG"
            },
            {
                "CapacityReservationId": "cr-abcdEXAMPLE9876ef",
                "EndDateType": "unlimited",
                "AvailabilityZone": "eu-west-1a",
                "InstanceMatchCriteria": "open",
                "Tags": [],
                "EphemeralStorage": false,
                "CreateDate": "2019-08-07T11:34:19.000Z",
                "AvailableInstanceCount": 3,
                "InstancePlatform": "Linux/UNIX",
                "TotalInstanceCount": 3,
                "State": "cancelled",
                "Tenancy": "default",
                "EbsOptimized": true,
                "InstanceType": "m5.large"
            }
        ]
}
```

PowerShell

To describe a Capacity Reservation

Use the Get-EC2CapacityReservation cmdlet.

```
Get-EC2CapacityReservation `
    -CapacityReservationId cr-1234abcd56EXAMPLE
```

Capacity Reservation states

Capacity Reservations have the following possible states.

State	Description
`active`	The capacity is available for use.

State	Description
`expired`	The Capacity Reservation expired automatically at the date and time specified in your reservation request. The reserved capacity is no longer available for your use.
`cancelled`	The Capacity Reservation was canceled. The reserved capacity is no longer available for your use.
`pending`	The Capacity Reservation request was successful but the capacity provisioning is still pending.
`failed`	The Capacity Reservation request has failed. A request can fail due to request parameters that are not valid, capacity constraints, or instance limit constraints. You can view a failed request for 60 minutes.
`scheduled`	(*Future-dated Capacity Reservations only*) The future-dated Capacity Reservation request was approved and the Capacity Reservation is scheduled for delivery on the requested start date.
`assessing`	(*Future-dated Capacity Reservations only*) Amazon EC2 is assessing your request for a future-dated Capacity Reservation. For more information, see Future-dated Capacity Reservation assessment.
`delayed`	(*Future-dated Capacity Reservations only*) Amazon EC2 encountered a delay in provisioning the requested future-dated Capacity Reservati on. Amazon EC2 is unable to deliver the requested capacity by the requested start date and time.
`unsupported`	(*Future-dated Capacity Reservations only*) Amazon EC2 can't support the future-dated Capacity Reservation request due to capacity constraints. You can view unsupported requests for 30 days. The Capacity Reservation will not be delivered.

Launch instances into an existing Capacity Reservation

You can only launch an instance into a Capacity Reservation that:

- Has matching attributes (instance type, platform, Availability Zone, and tenancy)

- Has sufficient available capacity
- Is in the `active` state

When you launch an instance, you can specify whether to launch the instance into any `open` Capacity Reservation, into a specific Capacity Reservation, or into a group of Capacity Reservations.

Alternatively, you can configure the instance to avoid running in a Capacity Reservation, even if you have an `open` Capacity Reservation that has matching attributes and available capacity.

Launching an instance into a Capacity Reservation reduces its available capacity by the number of instances launched. For example, if you launch three instances, the available capacity of the Capacity Reservation is reduced by three.

Console

To launch instances into an existing Capacity Reservation

1. Follow the procedure to launch an instance, but don't launch the instance until you've completed the following steps to specify the settings for the placement group and Capacity Reservation.
2. Expand **Advanced details** and do the following:
    a. For **Placement group**, select the cluster placement group in which to launch the instance.
    b. For **Capacity Reservation**, choose one of the following options depending on the configuration of the Capacity Reservation:
        - **None** – Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
        - **Open** – Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
        - **Specify Capacity Reservation** – Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.

- **Specify Capacity Reservation resource group –** Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.
- **Specify Capacity Reservation only –** Launches the instances into a Capacity Reservation. If a Capacity Reservation ID isn't specified, the instances launch into an open Capacity Reservation. If capacity isn't available, the instances fail to launch.
- **Specify Capacity Reservation resource group only –** Launches the instances into a Capacity Reservation in a Capacity Reservation resource group. If a Capacity Reservation resource group ARN isn't specified, the instances launch into an open Capacity Reservation. If capacity isn't available, the instances fail to launch.

3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**.

AWS CLI

To launch an instance into an existing Capacity Reservation

Use the run-instances command and specify the `--capacity-reservation-specification` option.

The following example launches an instance into any open Capacity Reservation with matching attributes and available capacity:

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --count 1 \
    --instance-type t2.micro \
    --key-name my-key-pair \
    --subnet-id subnet-0abcdef1234567890 \
    --capacity-reservation-specification CapacityReservationPreference=open
```

The following example launches an instance into a `targeted` Capacity Reservation:

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --count 1 \
```

```
    --instance-type t2.micro \
    --key-name my-key-pair \
    --subnet-id subnet-0abcdef1234567890 \
    --capacity-reservation-specification \
        CapacityReservationTarget={CapacityReservationId=cr-1234abcd56EXAMPLE}
```

The following example launches an instance into the specified Capacity Reservation group:

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --count 1 \
    --instance-type t2.micro \
    --key-name my-key-pair \
    --subnet-id subnet-0abcdef1234567890 \
    --capacity-reservation-specification \

 CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-
groups:us-west-2:123456789012:group/my-cr-group}
```

The following example launches an instance into a Capacity Reservation only. Because it does not specify a Capacity Reservation ID, the instance launches in any open Capacity Reservation with matching attributes and available capacity:

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --count 1 \
    --instance-type t2.micro \
    --key-name my-key-pair \
    --subnet-id subnet-0abcdef1234567890 \
    --capacity-reservation-specification \
        CapacityReservationPreference=capacity-reservations-only
```

The following example launches an instance into a specific Capacity Reservation only. If capacity isn't available in the specified Capacity Reservation, the instance fails to launch.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --count 1 \
    --instance-type t2.micro \
    --key-name my-key-pair \
    --subnet-id subnet-0abcdef1234567890 \
    --capacity-reservation-specification \
```

```
        CapacityReservationPreference=capacity-reservations-only \
        CapacityReservationTarget={CapacityReservationId=cr-1234abcd56EXAMPLE}
```

PowerShell

To launch an instance into an existing Capacity Reservation

Use the New-EC2Instance cmdlet.

The following example launches an instance into any open Capacity Reservation with matching attributes and available capacity:

```
New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType t2.micro `
    -KeyName "my-key-pair" `
    -SubnetId subnet-0abcdef1234567890 `
    -CapacityReservationSpecification_CapacityReservationPreference "open"
```

The following example launches an instance into a `targeted` Capacity Reservation:

```
New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType t2.micro `
    -KeyName "my-key-pair" `
    -SubnetId subnet-0abcdef1234567890 `
    -CapacityReservationTarget_CapacityReservationId cr-1234abcd56EXAMPLE
```

The following example launches an instance into the specified Capacity Reservation group:

```
New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType t2.micro `
    -KeyName "my-key-pair" `
    -SubnetId subnet-0abcdef1234567890 `
    -CapacityReservationTarget_CapacityReservationResourceGroupArn `
        "arn:aws:resource-groups:us-west-2:123456789012:group/my-cr-group"
```

The following example launches an instance into a Capacity Reservation only. Because it does not specify a Capacity Reservation ID, the instance launches in any open Capacity Reservation with matching attributes and available capacity:

```
New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType t2.micro `
    -KeyName "my-key-pair" `
    -SubnetId subnet-0abcdef1234567890 `
    -CapacityReservationSpecification_CapacityReservationPreference "capacity-reservations-only"
```

The following example launches an instance into a specific Capacity Reservation only. If capacity isn't available in the specified Capacity Reservation, the instance fails to launch.

```
New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType t2.micro `
    -KeyName "my-key-pair" `
    -SubnetId subnet-0abcdef1234567890 `
    -CapacityReservationSpecification_CapacityReservationPreference "capacity-reservations-only" `
    -CapacityReservationTarget_CapacityReservationId cr-1234abcd56EXAMPLE
```

Modify an active Capacity Reservation

If you have an existing Capacity Reservation which isn't a good fit for the workload that needs the capacity, you can modify the instance quantity, instance eligibility (`open` or `targeted`), and end time (`At specific time` or `Manually`). If you specify a new instance quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the update fails.

The allowed modifications depend on the state of the Capacity Reservation:

- `assessing` or `scheduled` state — You can modify the tags only.
- `pending` state — You can't modify the Capacity Reservation in any way.
- `active` state but still within the commitment duration — You can't decrease the instance count below the committed instance count, or set an end date that is before the committed duration. All other modifications are allowed.
- `active` state with no commitment duration or elapsed commitment duration — All modifications are allowed.
- `expired`, `cancelled`, `unsupported`, or `failed` state — You can't modify the Capacity Reservation in any way.

Considerations

- You can't change the instance type, platform, Availability Zone, or tenancy after creation. If you need to modify any of these attributes, we recommend that you cancel the reservation, and then create a new one with the required attributes.
- If you modify an existing Capacity Reservation by changing the instance eligibility from `targeted` to `open`, any running instances that match the attributes of the Capacity Reservation, have the `CapacityReservationPreference` parameter set to `open`, and are not yet running in a Capacity Reservation, will automatically use the modified Capacity Reservation.
- To change the instance eligibility, the Capacity Reservation must be completely idle (zero usage) because Amazon EC2 can't modify instance eligibility when instances are running inside the reservation.

Console

To modify a Capacity Reservation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Capacity Reservations**, select the Capacity Reservation to modify, and then choose **Edit**.
3. Modify the **Total capacity**, **Capacity Reservation ends**, or **Instance eligibility** options as needed, and choose **Save**.

AWS CLI

To modify a Capacity Reservation

Use the [modify-capacity-reservation](https://docs.aws.amazon.com/cli/latest/reference/ec2/modify-capacity-reservation.html) command. The following example modifies the specified Capacity Reservation to reserve capacity for eight instances.

```
aws ec2 modify-capacity-reservation \
    --capacity-reservation-id cr-1234567890abcdef0 \
    --instance-count 8
```

PowerShell

To modify a Capacity Reservation

Use the Edit-EC2CapacityReservation cmdlet. The following example modifies the specified Capacity Reservation to reserve capacity for eight instances.

```
Edit-EC2CapacityReservation `
    -CapacityReservationId cr-1234567890abcdef0 `
    -InstanceCount 8
```

Modify the Capacity Reservation settings of your instance

You can modify the following Capacity Reservation settings for a stopped instance at any time:

- Start in any Capacity Reservation that has matching attributes (instance type, platform, Availability Zone, and tenancy) and available capacity.
- Start the instance in a specific Capacity Reservation.
- Start in any Capacity Reservation that has matching attributes and available capacity in a Capacity Reservation group
- Prevent the instance from starting in a Capacity Reservation.

Console

To modify instance Capacity Reservation settings

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Instances** and select the instance to modify. Stop the instance if it is not already stopped.
3. Choose **Actions**, **Instance settings**, **Modify Capacity Reservation Settings**.
4. For **Capacity Reservation**, choose one of the following options:

   - **Open** – Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
   - **None** – Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.

- **Specify Capacity Reservation –** Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
- **Specify Capacity Reservation group –** Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.
- **Specify Capacity Reservation only –** Launches the instances into a Capacity Reservation. If a Capacity Reservation ID isn't specified, the instances launch into an open Capacity Reservation. If capacity isn't available, the instances fail to launch.
- **Specify Capacity Reservation resource group only –** Launches the instances into a Capacity Reservation in a Capacity Reservation resource group. If a Capacity Reservation resource group ARN isn't specified, the instances launch into an open Capacity Reservation. If capacity isn't available, the instances fail to launch.

AWS CLI

To modify instance Capacity Reservation settings

Use the modify-instance-capacity-reservation-attributes command.

The following example changes the Capacity Reservation preference to none.

```
aws ec2 modify-instance-capacity-reservation-attributes \
    --instance-id i-1234567890abcdef0 \
    --capacity-reservation-specification CapacityReservationPreference=none
```

The following example the target to a specific Capacity Reservation.

```
aws ec2 modify-instance-capacity-reservation-attributes \
    --instance-id i-1234567890abcdef0 \
    --capacity-reservation-specification \
    CapacityReservationTarget={CapacityReservationId=cr-1234567890abcdef0}
```

The following example changes the target to a specific Capacity Reservation group.

```
aws ec2 modify-instance-capacity-reservation-attributes \
```

```
    --instance-id i-1234567890abcdef0 \
    --capacity-reservation-specification \
 
 CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-
groups:us-west-2:123456789012:group/my-cr-group}
```

The following example changes the Capacity Reservation preference to `capacity-reservation-only`. Because it doesn't specify a Capacity Reservation, instances launch into any open Capacity Reservation with matching attributes and available capacity.

```
aws ec2 modify-instance-capacity-reservation-attributes \
    --instance-id i-1234567890abcdef0 \
    --capacity-reservation-specification CapacityReservationPreference=capacity-
reservation-only
```

The following example changes the Capacity Reservation preference to `capacity-reservation-only` and changes the target to a specific Capacity Reservation. If capacity isn't available in the specified Capacity Reservation, the instances fail to launch.

```
aws ec2 modify-instance-capacity-reservation-attributes \
    --instance-id i-1234567890abcdef0 \
    --capacity-reservation-specification \
        CapacityReservationPreference=capacity-reservation-only \
        CapacityReservationTarget={CapacityReservationId=cr-1234567890abcdef0}
```

PowerShell

To modify instance Capacity Reservation settings

Use the Edit-EC2InstanceCapacityReservationAttribute cmdlet.

The following example changes the Capacity Reservation preference to none.

```
Edit-EC2InstanceCapacityReservationAttribute `
    -InstanceId i-1234567890abcdef0 `
    -CapacityReservationSpecification_CapacityReservationPreference "none"
```

The following example the target to a specific Capacity Reservation.

```
Edit-EC2InstanceCapacityReservationAttribute `
    -InstanceId i-1234567890abcdef0 `
```

```
    -CapacityReservationTarget_CapacityReservationId cr-1234567890abcdef0
```

The following example changes the target to a specific Capacity Reservation group.

```
Edit-EC2InstanceCapacityReservationAttribute `
    -InstanceId i-1234567890abcdef0 `
    -CapacityReservationTarget_CapacityReservationResourceGroupArn `
        "arn:aws:resource-groups:us-west-2:123456789012:group/my-cr-group"
```

The following example changes the Capacity Reservation preference to `capacity-reservation-only`. Because it doesn't specify a Capacity Reservation, instances launch into any open Capacity Reservation with matching attributes and available capacity.

```
Edit-EC2InstanceCapacityReservationAttribute `
    -InstanceId i-1234567890abcdef0 `
    -CapacityReservationSpecification_CapacityReservationPreference "capacity-
reservation-only"
```

The following example changes the Capacity Reservation preference to `capacity-reservation-only` and changes the target to a specific Capacity Reservation. If capacity isn't available in the specified Capacity Reservation, the instances fail to launch.

```
Edit-EC2InstanceCapacityReservationAttribute `
    -InstanceId i-1234567890abcdef0 `
    -CapacityReservationSpecification_CapacityReservationPreference "capacity-
reservation-only" `
    -CapacityReservationTarget_CapacityReservationId cr-1234567890abcdef0
```

Move capacity between Capacity Reservations

You can move capacity from one Capacity Reservation to another to redistribute your reserved compute resources as needed. For example, if you need additional capacity in a reservation with growing usage, and you have capacity available in another reservation, then you can reallocate that capacity between the two reservations.

Prerequisites for moving capacity

As a prerequisite, the two Capacity Reservations must meet the following requirements:

- Both reservations must be in the active state.

- Both reservations must be owned by your AWS account. You cannot move capacity between reservations owned by different AWS accounts.
- Both reservations must have the same:
  - Instance type
  - Platform
  - Availability Zone
  - Tenancy
  - Placement group
  - End time

The destination Capacity Reservations instance eligibility (`open` or `targeted`), and tags, don't have to match the source reservation. The configuration of both reservations remains the same, except that the source reservation has reduced capacity and the destination reservation has increased capacity.

When you specify the quantity of instances to be moved, by default, any available capacity is moved first, followed by any eligible running instances (the used capacity in your reservation). For example, if you move 4 instances from a reservation with 5 used instances and 3 available instances, then the 3 available instances and 1 used instance will be moved.

> **Note**
>
> When you move used capacity from your reservation by specifying a **Quantity to move** that's greater than the available capacity, only the instances that were launched with their **Capacity Reservation Specification** as `open` will be moved.

Considerations

The following considerations apply when moving capacity from one reservation to another:

- The used capacity can only be moved between Capacity Reservations with `open` instance eligibility that are shared with the same set of accounts.
- When you move used capacity, the eligible instances are randomly selected. You cannot specify which running instances are moved. If a sufficient number of eligible instances are not found to fulfill the move quantity, the move operation will fail.

- If you move all of the capacity from the source reservation, the Capacity Reservation will be automatically canceled.
- **Future-dated Capacity Reservations** — You can't move capacity for a future-dated Capacity Reservation during the commitment period.

> **Note**
>
> Moving capacity from a Capacity Block isn't supported.

Move capacity

You can move capacity from a source Capacity Reservation to a destination Capacity Reservation.

Console

To move capacity

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Capacity Reservations**.
3. Select an On-Demand Capacity Reservation ID that has capacity to move.
4. Under **Actions**, **Manage capacity**, choose **Move**.
5. On the **Move capacity** page, under **Destination Capacity Reservation**, select a reservation from the list.
6. Under **Quantity to move**, use the slider or type the number of instances to move from the source Capacity Reservation to the destination Capacity Reservation.
7. Review the summary, and when you're ready, choose **Move**.

AWS CLI

To move capacity

Use the move-capacity-reservation-instances command. The following example moves 10 instances from the specified source Capacity Reservation to the specified destination Capacity Reservation.

```
aws ec2 move-capacity-reservation-instances \
```

```
    --source-capacity-reservation-id cr-1234567890abcdef0 \
    --destination-capacity-reservation-id cr-021345abcdef56789 \
    --instance-count 10
```

PowerShell

To move capacity

Use the [Move-EC2CapacityReservationInstance](#) cmdlet. The following example moves 10 instances from the specified source Capacity Reservation to the specified destination Capacity Reservation.

```
Move-EC2CapacityReservationInstance `
    -SourceCapacityReservationId cr-1234567890abcdef0 `
    -DestinationCapacityReservationId cr-021345abcdef56789 `
    -InstanceCount 10
```

Split off capacity from an existing Capacity Reservation

You can split off capacity from an existing Capacity Reservation to create a new reservation. By splitting capacity, you allocate a portion of the original reservation to a specific workload or share it with another AWS account. For example, to partially share a Capacity Reservation with another account, you can split off some of the capacity to create a smaller sized Capacity Reservation. The smaller sized Capacity Reservation can then be shared with the other accounts using AWS Resource Access Manager.

When you split capacity from an existing Capacity Reservation, a new Capacity Reservation is automatically created. The existing reservation will be unchanged, except for the reduced total capacity from the number of instances split off. Instances that are running in the existing Capacity Reservation are not affected. You can split the existing reservation into only one new Capacity Reservation.

The new Capacity Reservation will have the same configuration as the existing Capacity Reservation except for tags. By default, the new Capacity Reservation doesn't have any tags. You can specify new tags during the split operation. The new Capacity Reservation can also be modified after it is created, if necessary.

When you specify the quantity of instances to be split, by default, any available capacity is split first, followed by any eligible running instances (the used capacity in your reservation). For example: if you split 4 instances from a Capacity Reservation with 5 used instances and 3 available instances, then the 3 available instances and 1 used instance will be split into a new reservation.

Prerequisites for splitting capacity

As a prerequisite, your Capacity Reservation must meet the following requirements:

- The source reservation must be in the active state.
- The source reservation must be owned by your AWS account.

> **Note**
>
> When you split used capacity from your reservation by specifying a **Quantity to split** that's greater than the available capacity, only the instances that were launched with their **Capacity Reservation Specification** as open will be split.

Considerations

The following considerations apply when splitting off capacity from one reservation to a new one:

- The used capacity can only be split for Capacity Reservations with “open” instance eligibility that are not shared with any account.
- When you split the used capacity, the eligible instances are randomly selected. You cannot specify which running instances are split. If a sufficient number of eligible instances are not found to fulfill the split quantity, the split operation will fail.
- The maximum quantity of instances to split from an existing reservation is the size of the reservation minus one. For example, if your reservation’s total capacity is 5 instances, you can split a maximum of 4 instances into a new reservation.
- **Future-dated Capacity Reservations** – You can't split capacity for a future-dated Capacity Reservation during the commitment period.
- **Resource groups** – If the existing Capacity Reservation belongs to a resource group, the new Capacity Reservation will not be automatically added to the resource group. You can add the new Capacity Reservation to a resource group after it is created, if necessary.
- **Sharing** – If the existing Capacity Reservation is shared with a consumer account, the new Capacity Reservation will not be automatically shared with the consumer account. You can share the new Capacity Reservation after it is created, if necessary.

- **Cluster placement group** – If the existing Capacity Reservation is part of a cluster placement group, the new Capacity Reservation will be created in the same cluster placement group.

> **Note**
>
> Splitting capacity from a Capacity Block isn't supported.

Control access for splitting Capacity Reservations using tags

You can use tags to control access to Amazon EC2 resources, including splitting capacity from an existing Capacity Reservation to create a new Capacity Reservation. For more information, see [Controlling access to AWS resources using tags]() in the *IAM User Guide*.

To control access for splitting a Capacity Reservation using tags, make sure that you specify both resource and request tags in the policy statement because IAM policies are evaluated against both the source Capacity Reservation and the newly created Capacity Reservation. The following example policy includes the `ec2:ResourceTag` condition key with the tag `Owner=ExampleDepartment1` for the source Capacity Reservation and the `ec2:RequestTag` condition key with the tag `stack=production` for the newly created Capacity Reservation.

```
{
  "Statement": [
    {
      "Sid": "AllowSourceCapacityReservation",
      "Effect": "Allow",
      "Action": "ec2:CreateCapacityReservationBySplitting",
      "Resource": "arn:aws:ec2:us-east-1:111122223333:capacity-reservation/
cr-1234567890abcdef0",
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/Owner": "ExampleDepartment1"
        }
      }
    },
    {
      "Sid": "AllowNewlyCreatedCapacityReservation",
      "Effect": "Allow",
      "Action": ["ec2:CreateCapacityReservationBySplitting", "ec2:CreateTags"],
```

```
      "Resource": "arn:aws:ec2:us-east-1:111122223333:capacity-reservation/*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/stack": "production"
        }
      }
    }
  ]
}
```

Split off capacity

You can split off capacity from an existing Capacity Reservation to create a new Capacity Reservation.

Console

To split off capacity

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Capacity Reservations**.
3. Select an On-Demand Capacity Reservation ID that has capacity to split.
4. Under **Actions**, **Manage capacity**, choose **Split**.
5. On the **Split Capacity Reservation** page, under **Quantity to split**, use the slider or type the number of instances to split from the current reservation.
6. (Optional) Add tags for the new Capacity Reservation.
7. Review the summary, and when you're ready, choose **Split**.

AWS CLI

To split off capacity

Use the `create-capacity-reservation-by-splitting` command. The following example creates a new Capacity Reservation by splitting off 10 instances from the specified Capacity Reservation.

```
aws ec2 create-capacity-reservation-by-splitting \
    --source-capacity-reservation-id cr-1234567890abdef0 \
    --instance-count 10
```

PowerShell

To split off capacity

Use the New-EC2CapacityReservationBySplitting cmdlet. The following example creates a new Capacity Reservation by splitting off 10 instances from the specified Capacity Reservation.

```
New-EC2CapacityReservationBySplitting `
    -SourceCapacityReservationId cr-1234567890abdef0 `
    -InstanceCount 10
```

Cancel a Capacity Reservation

You can cancel a Capacity Reservation that is in one of the following states:

- `assessing`
- `active` and there is no commitment duration or the commitment duration has elapsed. You can't cancel a future-dated Capacity Reservation during the commitment duration.

> **Note**
>
> You can't modify or cancel a Capacity Block. For more information, see Capacity Blocks for ML.

If a future-dated Capacity Reservation enters the `delayed` state, the commitment duration is waived, and you can cancel it as soon as it enters the `active` state.

When you cancel a Capacity Reservation, the capacity is released immediately, and it is no longer reserved for your use.

You can cancel empty Capacity Reservations and Capacity Reservations that have running instances. If you cancel a Capacity Reservation that has running instances, the instances continue to run normally outside of the capacity reservation at standard On-Demand Instance rates or at a discounted rate if you have a matching Savings Plans or Regional Reserved Instance.

After you cancel a Capacity Reservation, instances that target it can no longer launch. Modify these instances so that they either target a different Capacity Reservation, launch into any open Capacity

Reservation with matching attributes and sufficient capacity, or avoid launching into a Capacity Reservation. For more information, see Modify the Capacity Reservation settings of your instance.

Console

To cancel a Capacity Reservation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Capacity Reservations** and select the Capacity Reservation to cancel.
3. Choose **Cancel reservation**, **Cancel reservation**.

AWS CLI

To cancel a Capacity Reservation

Use the cancel-capacity-reservation command.

```
aws ec2 cancel-capacity-reservation \
    --capacity-reservation-id cr-1234567890abcdef0
```

PowerShell

To cancel a Capacity Reservation

Use the Remove-EC2CapacityReservation cmdlet.

```
Remove-EC2CapacityReservation `
    -CapacityReservationId cr-1234567890abcdef0
```

Use Capacity Reservations with cluster placement groups

You can create Capacity Reservations in a cluster placement group to reserve Amazon EC2 compute capacity for your workloads. Cluster placement groups offer the benefit of low network latency and high network throughput.

Creating a Capacity Reservation in a cluster placement group ensures that you have access to compute capacity in your cluster placement groups when you need it, for as long as you need it. This is ideal for reserving capacity for high-performance (HPC) workloads that require compute scaling. It allows you to scale your cluster down while ensuring that the capacity remains available for your use so that you can scale back up when needed.

After you create a Capacity Reservation in a cluster placement group, you can share it with other AWS accounts. For more information, see Sharing Capacity Reservations in cluster placement groups.

Topics

- Limitations
- Work with Capacity Reservations in cluster placement groups
- Sharing Capacity Reservations in cluster placement groups

Limitations

Keep the following in mind when creating Capacity Reservations in cluster placement groups:

- If an existing Capacity Reservation is not in a placement group, you can't modify the Capacity Reservation to reserve capacity in a placement group. To reserve capacity in a placement group, you must create the Capacity Reservation in the placement group.
- After you create a Capacity Reservation in a placement group, you can't modify it to reserve capacity outside of the placement group.
- You can increase your reserved capacity in a placement group by modifying an existing Capacity Reservation in the placement group, or by creating additional Capacity Reservations in the placement group. However, you increase your chances of getting an insufficient capacity error.
- You can share Capacity Reservations only from the cluster placement group that you own. You cannot share Capacity Reservations from a cluster placement group that you do not own.
- You can't delete a cluster placement group that has `active` Capacity Reservations. You must cancel all Capacity Reservations in the cluster placement group before you can delete it.

Work with Capacity Reservations in cluster placement groups

To start using Capacity Reservations with cluster placement groups, perform the following steps.

> **Note**
>
> If you want to create a Capacity Reservation in an existing cluster placement group, skip Step 1. Then for Steps 2 and 3, specify the ARN of the existing cluster placement group.

Tasks

- Step 1: (Conditional) Create a cluster placement group for use with a Capacity Reservation
- Step 2: Create a Capacity Reservation in a cluster placement group
- Step 3: Launch instances into Capacity Reservations in a cluster placement group

Step 1: (*Conditional*) Create a cluster placement group for use with a Capacity Reservation

Perform this step only if you need to create a new cluster placement group. To use an existing cluster placement group, skip this step and then for Steps 2 and 3, use the ARN of that cluster placement group.

Console

To create a cluster placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Placement Groups**, and then choose **Create placement group**.
3. For **Name**, specify a descriptive name for the placement group.
4. For **Placement strategy**, choose **Cluster**.
5. Choose **Create group**.
6. In the **Placement groups** table, in the **Group ARN** column, make a note of the ARN of the cluster placement group that you created. You'll need it for the next step.

AWS CLI

To create a cluster placement group

Use the create-placement-group command.

```
aws ec2 create-placement-group \
    --group-name MyPG \
    --strategy cluster
```

Make a note of the placement group ARN returned in the output, because you'll need it for the next step.

PowerShell

To create a cluster placement group

Use the New-EC2PlacementGroup cmdlet.

```
New-EC2PlacementGroup `
    -GroupName my-placement-group `
    -Strategy "cluster"
```

Make a note of the placement group ARN returned in the output, because you'll need it for the next step.

Step 2: Create a Capacity Reservation in a cluster placement group

You create a Capacity Reservation in a cluster placement group in the same way that you create any Capacity Reservation. However, you must also specify the ARN of the cluster placement group in which to create the Capacity Reservation.

Considerations

- The specified cluster placement group must be in the `available` state. If the cluster placement group is in the `pending`, `deleting`, or `deleted` state, the request fails.
- The Capacity Reservation and the cluster placement group must be in the same Availability Zone. If the request to create the Capacity Reservation specifies an Availability Zone that is different from that of the cluster placement group, the request fails.
- You can create Capacity Reservations only for instance types that are supported by cluster placement groups. If you specify an unsupported instance type, the request fails.
- If you create an `open` Capacity Reservation in a cluster placement group and there are existing running instances that have matching attributes (placement group ARN, instance type, Availability Zone, platform, and tenancy), those instances automatically run in the Capacity Reservation.
- Your request to create a Capacity Reservation could fail if one of the following is true:
  - Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller capacity. If your workload is flexible across instance types and sizes, try different instance attributes.
  - The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see On-Demand Instance quotas.

Console

To create a Capacity Reservation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Capacity Reservations**, and then choose **Create Capacity Reservation**.
3. On the **Create a Capacity Reservation** page, specify the instance type, platform, Availability Zone, Tenancy, quantity, and end date as needed.
4. For **Placement group**, select the ARN of the cluster placement group in which to create the Capacity Reservation.
5. Choose **Create**.

For more information, see Create a Capacity Reservation.

AWS CLI

To create a Capacity Reservation

Use the create-capacity-reservation command. For `--placement-group-arn`, specify the ARN of the cluster placement group in which to create the Capacity Reservation.

```
aws ec2 create-capacity-reservation \
    --instance-type instance_type \
    --instance-platform platform \
    --availability-zone-id az_id \
    --instance-count quantity \
    --placement-group-arn "placement_group_arn"
```

PowerShell

To create a Capacity Reservation

Use the Add-EC2CapacityReservation cmdlet. For `-PlacementGroupArn`, specify the ARN of the cluster placement group in which to create the Capacity Reservation.

```
Add-EC2CapacityReservation `
    -InstanceType instance_type `
    -InstancePlatform platform `
    -AvailabilityZoneId az_id `
    -InstanceCount quantity `
```

```
    -PlacementGroupArn "placement_group_arn"
```

Step 3: Launch instances into Capacity Reservations in a cluster placement group

You can launch an instance into a Capacity Reservation that is in a cluster placement group with one of the following options:

- *Specifying the ARN of the cluster placement group in which to launch the instance* – When you provide the ARN of a cluster placement group, Amazon EC2 launches the instance into that cluster placement group. You can use one of the following methods:
  - *Specifying open* – You do not have to specify the Capacity Reservation in the instance launch request. If the instance has attributes (placement group ARN, instance type, Availability Zone, platform, and tenancy) that match a Capacity Reservation in the specified placement group, the instance automatically runs in the Capacity Reservation.
  - *Specifying a Capacity Reservation* – If the Capacity Reservation accepts only targeted instance launches, you must specify the target Capacity Reservation in addition to the cluster placement group in the request.
  - *Specifying a Capacity Reservation group* – For more information, see [Using Capacity Reservation in cluster placement groups with a Capacity Reservation group](#).
- *Specifying only a Capacity Reservation group* – For more information, see [Using Capacity Reservation in cluster placement groups with a Capacity Reservation group](#).
- *Specifying only a Capacity Reservation* – You can launch instances into a Capacity Reservation in a cluster placement group.

> **Note**
>
> When you launch instances by specifying only a Capacity Reservation or only a Capacity Reservation group, the instances are launched into the Capacity Reservations that are created in the cluster placement group, but the instances are not directly attached to the cluster placement group.

Console

To launch instances into an existing Capacity Reservation

1. Follow the procedure to [launch an instance](), but don't launch the instance until you've completed the following steps to specify the settings for the placement group and Capacity Reservation.
2. Expand **Advanced details** and do the following:

   a. For **Placement group**, select the cluster placement group in which to launch the instance.

   b. For **Capacity Reservation**, choose one of the following options depending on the configuration of the Capacity Reservation:

      - **Open** – To launch the instances into any `open` Capacity Reservation in the cluster placement group that has matching attributes and sufficient capacity.
      - **Target by ID** – To launch the instances into a Capacity Reservation that accepts only targeted instance launches.
      - **Target by group** – To launch the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group.
3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an EC2 instance using the launch instance wizard in the console]().

AWS CLI

To launch instances into an existing Capacity Reservation

Use the [run-instances]() command. If you need to target a specific Capacity Reservation or a Capacity Reservation group, specify the `--capacity-reservation-specification` parameter. For `--placement`, specify the `GroupName` parameter and then specify the name of the placement group that you created in the previous steps.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --count quantity \
    --instance-type instance_type \
```

```
    --key-name key_pair_name \
    --subnet-id subnet-0abcdef1234567890 \
    --capacity-reservation-specification
 CapacityReservationTarget={CapacityReservationId=capacity_reservation_id} \
    --placement "GroupName=cluster_placement_group_name"
```

PowerShell

To launch instances into an existing Capacity Reservation

Use the New-EC2Instance cmdlet. For `-Placement`, specify the `GroupName` parameter and then specify the name of the placement group that you created in the previous steps.

```
New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType instance_type `
    -KeyName key_pair_name `
    -SubnetId subnet-0abcdef1234567890 `
    -CapacityReservationTarget_CapacityReservationId capacity_reservation_id `
    -Placement_GroupName cluster_placement_group_name
```

Sharing Capacity Reservations in cluster placement groups

You can share Capacity Reservations in cluster placement groups by either sharing only the Capacity Reservations, or by sharing both the Capacity Reservations and the cluster placement group in which they were created.

By sharing only the Capacity Reservation, you give consumer accounts access to that Capacity Reservation only. Consumer accounts have no visibility or access to the cluster placement group in which the Capacity Reservation is created. This gives you fine-grained control over consumer account access. Consumer accounts can't view any information about the cluster placement group, including its ARN.

When you share the cluster placement group and the Capacity Reservation, the cluster placement group is visible and accessible to consumer accounts. They can launch instances and create their own Capacity Reservations in it.

For more information, see the following resources.

- Launch instances into Capacity Reservations in a cluster placement group

- Shared Capacity Reservations
- Shared placement groups

Capacity Reservation groups

You can use AWS Resource Groups to create logical collections of Capacity Reservations, called *resource groups*. A resource group is a logical grouping of AWS resources that are all in the same AWS Region. For more information about resource groups, see What are resource groups? in the *AWS Resource Groups User Guide*.

You can include Capacity Reservations that you own in your account, and Capacity Reservations that are shared with you by other AWS accounts in a single resource group. You can also include Capacity Reservations that have different attributes (instance type, platform, Availability Zone, and tenancy) in a single resource group.

When you create resource groups for Capacity Reservations, you can target instances to a group of Capacity Reservations instead of an individual Capacity Reservation. Instances that target a group of Capacity Reservations match with any Capacity Reservation in the group that has matching attributes (instance type, platform, Availability Zone, and tenancy) and available capacity. If the group does not have a Capacity Reservation with matching attributes and available capacity, the instances run using On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically matched with and moved into its reserved capacity.

To prevent unintended use of Capacity Reservations in a group, configure the Capacity Reservations in the group to accept only instances that explicitly target the capacity reservation. To do this, set **Instance eligibility** to **Only instances that specify this reservation** when creating the Capacity Reservation using the Amazon EC2 console. When using the AWS CLI, specify `--instance-match-criteria targeted` when creating the Capacity Reservation. Doing this ensures that only instances that explicitly target the group, or a Capacity Reservation in the group, can run in the group.

If a Capacity Reservation in a group is canceled or expires while it has running instances, the instances are automatically moved to another Capacity Reservation in the group that has matching attributes and available capacity. If there are no remaining Capacity Reservations in the group that have matching attributes and available capacity, the instances run in On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically moved into its reserved capacity.

Tasks

- [Create a Capacity Reservation group]
- [Add a Capacity Reservation to a group]
- [Remove a Capacity Reservation from a group]
- [Delete a Capacity Reservation group]
- [Using Capacity Reservation in cluster placement groups with a Capacity Reservation group]

Create a Capacity Reservation group

You can use the following examples to create a resource group for Capacity Reservations with the following request parameters.

- `AWS::EC2::CapacityReservationPool` – Ensures that the resource group can be targeted for instance launches.
- `AWS::ResourceGroups::Generic` with `allowed-resource-types` set to `AWS::EC2::CapacityReservation` – Ensures that the resource group accepts Capacity Reservations only.

After you create a group, you can add Capacity Reservations to the group.

AWS CLI

To create a group for Capacity Reservations

Use the create-group AWS CLI command.

```
aws resource-groups create-group \
    --name MyCRGroup \
    --configuration \
        '{"Type": "AWS::EC2::CapacityReservationPool"}' \
        '{"Type": "AWS::ResourceGroups::Generic", "Parameters": [{"Name": "allowed-
resource-types", "Values": ["AWS::EC2::CapacityReservation"]}]}'
```

PowerShell

To create a group for Capacity Reservations

Use the New-RGGroup cmdlet.

```
New-RGGroup `
    -Name MyCRGroup `
    -Configuration `
        @{"Type"="AWS::EC2::CapacityReserationPool"} `
        @{"Type"="AWS::ResourceGroups::Generic"; "Parameters"=@{"allowed-resource-
types"=@{"Values"="AWS::EC2::CapacityReservations"}}}
```

Add a Capacity Reservation to a group

If you add a Capacity Reservation that is shared with you to a group, and that Capacity Reservation is unshared, it is automatically removed from the group.

AWS CLI

To add a Capacity Reservation to a group

Use the group-resources command.

The following example adds two Capacity Reservations to the specified group.

```
aws resource-groups group-resources \
    --group MyCRGroup \
    --resource-arns \
        arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1
 \
        arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890
```

PowerShell

To add a Capacity Reservation to a group

Use the Add-RGResource cmdlet.

The following example adds two Capacity Reservations to the specified group.

```
Add-RGResource `
    -Group MyCRGroup `
    -ResourceArn `
        "arn:aws:ec2:sa-east-1:123456789012:capacity-
reservation/cr-1234567890abcdef1", `
```

```
        "arn:aws:ec2:sa-east-1:123456789012:capacity-
reservation/cr-54321abcdef567890"
```

Remove a Capacity Reservation from a group

You can use the following examples to remove a Capacity Reservation from a group.

AWS CLI

To remove a Capacity Reservation from a group

Use the ungroup-resources command.

The following example removes two Capacity Reservations from the specified group.

```
aws resource-groups ungroup-resources \
    --group MyCRGroup \
    --resource-arns \
        arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-0e154d26a16094dd
 \
        arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890
```

PowerShell

To remove a Capacity Reservation from a group

Use the Remove-RGResource cmdlet.

The following example removes two Capacity Reservations from the specified group.

```
Remove-RGResource `
    -Group MyCRGroup `
    -ResourceArn `
        "arn:aws:ec2:sa-east-1:123456789012:capacity-
reservation/cr-0e154d26a16094dd", `
        "arn:aws:ec2:sa-east-1:123456789012:capacity-
reservation/cr-54321abcdef567890"
```

Delete a Capacity Reservation group

You can use the following examples to delete a Capacity Reservation group.

AWS CLI

To delete a group

Use the delete-group command.

```
aws resource-groups delete-group --group MyCRGroup
```

PowerShell

To delete a group

Use the Remove-RGGroup cmdlet.

```
Remove-RGGroup -GroupName MyCRGroup
```

Using Capacity Reservation in cluster placement groups with a Capacity Reservation group

Amazon EC2 provides different launch methods for you to use Capacity Reservations in a cluster placement group with a Capacity Reservation group. You can choose one of the following methods to target a Capacity Reservation group based on your workload requirements:

- *Specifying the ARN of the cluster placement group and Capacity Reservation group* – This will use any available Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.

> **Note**
>
> When you launch instances using this method, the instances are placed in the specified cluster placement group.

- *Specifying only a Capacity Reservation group* – This will use all available capacity within the Capacity Reservation group by specifying only the Capacity Reservation group. While launching instances, capacity is used in the following order:
  - Capacity Reservations not associated with any cluster placement group.
  - Capacity Reservation in any cluster placement group within the Capacity Reservation group.

- If the group does not have a Capacity Reservation with matching attributes and available capacity, the instances run using On-Demand capacity and they are not placed in any cluster placement group.

> **Note**
>
> When you launch instances by specifying only a Capacity Reservation group, the instances are launched into the Capacity Reservations that are created in the cluster placement group, but the instances are not directly attached to the cluster placement group.

Capacity Reservations in Local Zones

A Local Zone is an extension of an AWS Region that is geographically close to your users. Resources created in a Local Zone can serve local users with very low-latency communications. For more information, see AWS Local Zones.

You can extend a VPC from its parent AWS Region into a Local Zone by creating a new subnet in that Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as the other subnets in your VPC.

By using Local Zones, you can place Capacity Reservations in multiple locations that are closer to your users. You create and use Capacity Reservations in Local Zones in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply. For more information about the pricing models that are supported in Local Zones, see AWS Local Zones FAQs.

Considerations

You can't use Capacity Reservation groups in a Local Zone.

To use a Capacity Reservation in a Local Zone

1. Enable the Local Zone for use in your AWS account. For more information, see Getting started with AWS Local Zones in the *AWS Local Zones User Guide*.
2. Create a Capacity Reservation in the Local Zone. For **Availability Zone**, choose the Local Zone. The Local Zone is represented by an AWS Region code followed by an identifier that indicates

the location, for example `us-west-2-lax-1a`. For more information, see Create a Capacity Reservation.

3. Create a subnet in the Local Zone. For **Availability Zone**, choose the Local Zone. For more information, see Create a subnet in your VPC in the *Amazon VPC User Guide*.
4. Launch an instance. For **Subnet**, choose the subnet in the Local Zone (for example `subnet-123abc | us-west-2-lax-1a`), and for **Capacity Reservation**, choose the specification (either `open` or target it by ID) that's required for the Capacity Reservation that you created in the Local Zone. For more information, see Launch instances into an existing Capacity Reservation.

Capacity Reservations in Wavelength Zones

AWS Wavelength enables developers to build applications that deliver ultra-low latencies to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. You can extend an Amazon Virtual Private Cloud (VPC) to one or more Wavelength Zones. You can then use AWS resources like Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region. For more information, see AWS Wavelength Zones.

When you create On-Demand Capacity Reservations, you can choose the Wavelength Zone and you can launch instances into a Capacity Reservation in a Wavelength Zone by specifying the subnet associated with the Wavelength Zone. A Wavelength Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example `us-east-1-wl1-bos-wlz-1`.

Wavelength Zones are not available in every Region. For information about the Regions that support Wavelength Zones, see Available Wavelength Zones in the *AWS Wavelength Developer Guide*.

Considerations

You can't use Capacity Reservation groups in a Wavelength Zone.

To use a Capacity Reservation in a Wavelength Zone

1. Enable the Wavelength Zone for use in your AWS account. For more information, see Get started with AWS Wavelength in the *AWS Wavelength Developer Guide*.
2. Create a Capacity Reservation in the Wavelength Zone. For **Availability Zone**, choose the Wavelength. The Wavelength is represented by an AWS Region code followed by an identifier

that indicates the location, for example `us-east-1-wl1-bos-wlz-1`. For more information, see Create a Capacity Reservation.

3. Create a subnet in the Wavelength Zone. For **Availability Zone**, choose the Wavelength Zone. For more information, see Create a subnet in your VPC in the *Amazon VPC User Guide*.
4. Launch an instance. For **Subnet**, choose the subnet in the Wavelength Zone (for example `subnet-123abc | us-east-1-wl1-bos-wlz-1`), and for **Capacity Reservation**, choose the specification (either `open` or target it by ID) that's required for the Capacity Reservation that you created in the Wavelength. For more information, see Launch instances into an existing Capacity Reservation.

Capacity Reservations on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can create Capacity Reservations on Outposts that you have created in your account. This allows you to reserve compute capacity on an Outpost at your site. You create and use Capacity Reservations on Outposts in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply.

You can also share Capacity Reservations on Outposts with other AWS accounts within your organization using AWS Resource Access Manager. For more information about sharing Capacity Reservations, see Shared Capacity Reservations.

Prerequisite

You must have an Outpost installed at your site. For more information, see Create an Outpost and order Outpost capacity in the *AWS Outposts User Guide*.

Considerations

- You can't use Capacity Reservation groups on an Outpost.

To use a Capacity Reservation on an Outpost

1. Create a subnet on the Outpost. For more information, see Create a subnet in the *AWS Outposts User Guide*.
2. Create a Capacity Reservation on the Outpost.
   a. Open the AWS Outposts console at https://console.aws.amazon.com/outposts/.
   b. In the navigation pane, choose **Outposts**, and then choose **Actions**, **Create Capacity Reservation**.
   c. Configure the Capacity Reservation as needed and then choose **Create**. For more information, see Create a Capacity Reservation.

   > **Note**
   >
   > The **Instance Type** drop-down lists only instance types that are supported by the selected Outpost, and the **Availability Zone** drop-down lists only the Availability Zone with which the selected Outpost is associated.

3. Launch an instance into the Capacity Reservation. For **Subnet** choose the subnet that you created in Step 1, and for **Capacity Reservation**, select the Capacity Reservation that you created in Step 2. For more information, see Launch an instance on the Outpost in the *AWS Outposts User Guide*.

Shared Capacity Reservations

Capacity Reservation sharing enables Capacity Reservation owners to share their reserved capacity with other AWS accounts or within an AWS organization. This enables you to create and manage Capacity Reservations centrally, and share the reserved capacity across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Capacity Reservation (owner) shares it with other AWS accounts (consumers). Consumers can launch instances into Capacity Reservations that are shared with them in the same way that they launch instances into Capacity Reservations that they own in their own account. The Capacity Reservation owner is responsible for managing the Capacity Reservation and the instances that they launch into it. Owners cannot modify instances that consumers launch into Capacity Reservations that they have shared. Consumers are responsible for managing the instances that they launch into Capacity Reservations shared with them. Consumers cannot view or modify instances owned by other consumers or by the Capacity Reservation owner.

A Capacity Reservation owner can share a Capacity Reservation with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Prerequisites for sharing Capacity Reservations

- To share a Capacity Reservation, you must own it in your AWS account. You cannot share a Capacity Reservation that has been shared with you.
- You can only share Capacity Reservations for shared tenancy instances. You cannot share Capacity Reservations for dedicated tenancy instances.
- Capacity Reservation sharing is not available to new AWS accounts or AWS accounts that have a limited billing history.
- To share a Capacity Reservation with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see Enable Sharing with AWS Organizations in the *AWS RAM User Guide*.

Related services

Capacity Reservation sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a *resource share*. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the *AWS RAM User Guide*.

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone `us-east-1a` for your AWS account might not have the same location as `us-east-1a` for another AWS account.

To identify the location of your Capacity Reservations relative to your accounts, you must use the *Availability Zone ID* (AZ ID). The AZ ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, `use1-az1` is an AZ ID for the `us-east-1` Region and it is the same location in every AWS account.

To view the AZ IDs for the Availability Zones in your account

1. Open the AWS RAM console at https://console.aws.amazon.com/ram/home.
2. The AZ IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

Share a Capacity Reservation

When you share a Capacity Reservation that you own with other AWS accounts, you enable them to launch instances into your reserved capacity. If you share an open Capacity Reservation, keep the following in mind as it could lead to unintended Capacity Reservation usage:

- If consumers have running instances that match the attributes of the Capacity Reservation, have the `CapacityReservationPreference` parameter set to `open`, and are not yet running in reserved capacity, they automatically use the shared Capacity Reservation.
- If consumers launch instances that have matching attributes (instance type, platform, Availability Zone, and tenancy) and have the `CapacityReservationPreference` parameter set to `open`, they automatically launch into the shared Capacity Reservation.

To share a Capacity Reservation, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. When you share a Capacity Reservation using the Amazon EC2 console, you add it to an existing resource share. To add the Capacity Reservation to a new resource share, you must create the resource share using the [AWS RAM console](https://console.aws.amazon.com/ram).

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are granted access to the shared Capacity Reservation if the [prequisites for sharing](#) are met. If the Capacity Reservation is shared with external accounts, they receive an invitation to join the resource share and are granted access to the shared Capacity Reservation after accepting the invitation.

Important

Before launching instances into a Capacity Reservation that is shared with you, verify that you have access to the shared Capacity Reservation by viewing it in the console or by describing it using the [describe-capacity-reservations] AWS CLI command. If you can view the shared Capacity Reservation in the console or describe it using the AWS CLI, it is available for your use and you can launch instances into it. If you attempt to launch instances into the Capacity Reservation and it is not accessible due to a sharing failure, the instances will launch into On-Demand capacity.

Console

To share a Capacity Reservation that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Capacity Reservations**.
3. Choose the Capacity Reservation to share and choose **Actions**, **Share reservation**.
4. Select the resource share to which to add the Capacity Reservation and choose **Share Capacity Reservation**.

   It could take a few minutes for consumers to get access to the shared Capacity Reservation.

To share a Capacity Reservation that you own using the AWS RAM console

See Creating a resource share in the *AWS RAM User Guide*.

AWS CLI

To share a Capacity Reservation that you own

Use the create-resource-share command.

```
aws ram create-resource-share \
    --name my-resource-share \
    --resource-arns arn:aws:ec2:us-east-2:123456789012:capacity-
reservation/cr-1234abcd56EXAMPLE
```

PowerShell

To share a Capacity Reservation that you own

Use the New-RAMResourceShare cmdlet.

```
New-RAMResourceShare `
    -Name my-resource-share `
    -ResourceArn "arn:aws:ec2:us-east-2:123456789012:capacity-
reservation/cr-1234abcd56EXAMPLE"
```

Stop sharing a Capacity Reservation

The Capacity Reservation owner can stop sharing a Capacity Reservation at any time. The following rules apply:

- Instances owned by consumers that were running in the shared capacity at the time sharing stops continue to run normally outside of the reserved capacity, and the capacity is restored to the Capacity Reservation subject to Amazon EC2 capacity availability.
- Consumers with whom the Capacity Reservation was shared can no longer launch new instances into the reserved capacity.

To stop sharing a Capacity Reservation that you own, you must remove it from the resource share.

Console

To stop sharing a Capacity Reservation that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Capacity Reservation has been added. Select the resource share from which to remove the Capacity Reservation and choose **Remove from resource share**.

To stop sharing a Capacity Reservation that you own using the AWS RAM console

See Updating a Resource Share in the *AWS RAM User Guide*.

AWS CLI

To stop sharing a Capacity Reservation that you own

Use the disassociate-resource-share command.

```
aws ram disassociate-resource-share \
    --resource-share-arn arn:aws:ram:us-east-2:123456789012:resource-share/7ab63972-b505-7e2a-420d-6f5d3EXAMPLE \
 --resource-arns arn:aws:ec2:us-east-2:123456789012:capacity-reservation/cr-1234abcd56EXAMPLE
```

PowerShell

To stop sharing a Capacity Reservation that you own

Use the Disconnect-RAMResourceShare cmdlet.

```
Disconnect-RAMResourceShare `
    -ResourceShareArn "arn:aws:ram:us-east-2:123456789012:resource-share/7ab63972-b505-7e2a-420d-6f5d3EXAMPLE" `
    -ResourceArn "arn:aws:ec2:us-east-2:123456789012:capacity-reservation/cr-1234abcd56EXAMPLE"
```

Billing assignment for shared Amazon EC2 Capacity Reservations

By default, when a Capacity Reservation is shared, the owner is billed for the instances they run in the Capacity Reservation and for any available capacity, also called *unused capacity*, in the Capacity Reservation; while consumers are billed only for the instances they run in the shared Capacity Reservation.

If needed, the Capacity Reservation owner can assign the billing of any available capacity in the Capacity Reservation to any one of the accounts with which the Capacity Reservation is shared. After billing is assigned to another account, that account becomes the *billing owner* of any available capacity in the Capacity Reservation. Any charges for available capacity in the Capacity Reservation, from that point onward, are billed to the assigned account instead of the owner's account. The Capacity Reservation owner and the accounts with which the Capacity Reservation is shared continue to be billed for the instances they run in the Capacity Reservation.

> **Important**
>
> The Capacity Reservation owner remains the resource owner and they remain responsible for managing the Capacity Reservation. The account to which billing is assigned does not get any additional privileges; they can't cancel, modify, or share the Capacity Reservation in any way.

Topics

How it works

Only the Capacity Reservation owner can assign billing of a shared Capacity Reservation to another account. Billing can be assigned only to an account with which the Capacity Reservation is shared and that is consolidated under the same AWS Organizations payer account as the Capacity Reservation owner.

To assign billing of the available capacity of a Capacity Reservation to another account, the Capacity Reservation owner must initiate a request to the required account. The specified account receives the request and they must either accept or reject it within 12 hours.

- If they **accept**, they become the *billing owner* of any available capacity, also called *unused capacity*, in the Capacity Reservation. From that point onward, charges for any available capacity in the Capacity Reservation are billed to their account instead of the owner's account. After it is accepted, only the Capacity Reservation owner can revoke billing from the assigned account.
- If they **reject**, the Capacity Reservation owner remains the billing owner of the available capacity in the Capacity Reservation. Charges for any available capacity in the Capacity Reservation continue to be billed to the owner's account.

- If they **do not accept or reject** the request within 12 hours, it expires and charges for any available capacity in the Capacity Reservation continue to be billed to owner's account.

For the period that billing is assigned to another account, the `Reservation` and `UnusedBox` line items appear in the assigned account's Cost and Usage Report (CUR) instead of the owner's CUR.

The following table shows which line items appear in the CUR for the Capacity Reservation owner and consumer accounts **before** billing is assigned to another account.

Account	CUR line items before billing is assigned
Capacity Reservation owner	• `Reservation` • `BoxUsage` * • `UnusedBox`
Consumer accounts with which the Capacity Reservation is shared	• `BoxUsage` *

The following table shows which line items appear in the CUR for the Capacity Reservation owner and consumer accounts **after** billing is assigned to another account.

Account	CUR line items after billing is assigned
Capacity Reservation owner	• `BoxUsage` *
Consumer account to which billing is assigned	• `Reservation`

Account	CUR line items after billing is assigned
	• `BoxUsage` * • `UnusedBox`
Other consumer accounts with which the Capacity Reservation is shared	• `BoxUsage` *

> **Note**
>
> - * The `BoxUsage` line item appears in an account's CUR only if they have running instances in the Capacity Reservation. For more information about the CUR line items, see [Monitoring Capacity Reservations](#).
> - Use the Capacity Reservation ARN in the CUR to determine who owns the Capacity Reservation. If the ARN includes your AWS account ID, you are the Capacity Reservation owner. Otherwise, the Capacity Reservation is owned by a different account but billing is assigned to you.
> - Cost allocation tags assigned to Capacity Reservation by the owner will not appear in the consumer account's CUR. Cost allocation tags appear in the Capacity Reservation owner's CUR only.

Considerations

Keep the following in mind when assigning billing of a shared Capacity Reservation:

- You can't do partial or split billing assignments. Billing of all available capacity of a Capacity Reservation can be assigned to one account at a time.
- The available capacity of a Capacity Reservation can change over time. This will impact billing for the assigned account. For example, available capacity can increase if the Capacity Reservation owner increases the size of the Capacity Reservation, or if other consumer accounts stop or terminate their instances running in the Capacity Reservation.

- Billing can be assigned only to a consumer account that is consolidated under the same AWS Organizations payer account. Billing is automatically revoked from the consumer account if they leave the organization, or if the Capacity Reservation is no longer shared with them.
- Only the Capacity Reservation owner can cancel a pending billing assignment request and revoke billing from an assigned account after the request has been accepted.

Assign billing of a shared EC2 Capacity Reservation to another account

To assign billing of the available capacity of a shared Capacity Reservation to another account, the Capacity Reservation owner must initiate a request to the required account. In the Amazon EC2 console, this request is called a *transfer request*.

A Capacity Reservation owner can assign billing of the available capacity of Capacity Reservation to an account only if:

- The Capacity Reservation is already shared with that account.
- The account is consolidated under the same AWS Organizations payer account as the Capacity Reservation owner.

Billing is assigned to the specified account only once they accept the request.

When a Capacity Reservation owner initiates a request, an Amazon EventBridge event is sent to the requested account. For more information, see Monitor billing assignment requests for shared Capacity Reservations.

Console

To assign billing of a shared Capacity Reservation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, select **Capacity Reservations** and then choose the shared Capacity Reservation.
3. In the **Billing of available capacity** section, choose **Assign billing**.
4. In the **Assign billing** screen, select the consumer account to which to assign billing, and then choose **Request**.

AWS CLI

To assign billing of a shared Capacity Reservation

Use the associate-capacity-reservation-billing-owner command. For `--capacity-reservation-id`, specify the ID of the shared Capacity Reservation. For `--unused-reservation-billing-owner-id`, specify the ID of the AWS account to which to assign billing.

```
aws ec2 associate-capacity-reservation-billing-owner \
    --capacity-reservation-id cr-01234567890abcdef \
    --unused-reservation-billing-owner-id 123456789012
```

PowerShell

To assign billing of a shared Capacity Reservation

Use the Register-EC2CapacityReservationBillingOwner cmdlet. For `-CapacityReservationId`, specify the ID of the shared Capacity Reservation. For `-UnusedReservationBillingOwnerId`, specify the ID of the AWS account to which to assign billing.

```
Register-EC2CapacityReservationBillingOwner `
    -CapacityReservationId cr-01234567890abcdef `
    -UnusedReservationBillingOwnerId 123456789012
```

View billing assignment requests for shared EC2 Capacity Reservations

A Capacity Reservation owner can view only the most recent billing assignment request that they initiated. And consumer accounts can view only the most recent billing assignment requests sent to them.

Requests can be viewed for 24 hours after they enter the `cancelled`, `expired`, or `revoked` state. After 24 hours, they can no longer be viewed.

Console

(Capacity Reservation owner) To view requests you initiated

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation panel, select **Capacity Reservations** and then choose the shared Capacity Reservation for which to view requests.
3. The **Billing of available capacity** section shows the most recent request and its current state.

(Consumer account) To requests sent to you

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, select **Capacity Reservations**.
3. If you have pending requests, the **Pending billing assignment requests** banner appears at the top of the screen. If the banner does not appear, you do not have pending requests.

   To view the requests, choose **Review requests** in the banner.

AWS CLI

(Capacity Reservation owner) To view requests you initiated

Use the describe-capacity-reservation-billing-requests command.

```
aws ec2 describe-capacity-reservation-billing-requests \
    --role odcr-owner
```

(Consumer account) To view requests sent to you

Use the describe-capacity-reservation-billing-requests command.

```
aws ec2 describe-capacity-reservation-billing-requests \
    --role unused-reservation-billing-owner
```

PowerShell

(Capacity Reservation owner) To view requests you initiated

Use the Get-EC2CapacityReservationBillingRequest cmdlet.

```
Get-EC2CapacityReservationBillingRequest `
    -Role odcr-owner
```

(Consumer account) To view requests sent to you

Use the Get-EC2CapacityReservationBillingRequest cmdlet.

```
Get-EC2CapacityReservationBillingRequest `
    -Role unused-reservation-billing-owner
```

A request can be in one of the following states.

State	Description
`pending`	The request has not been accepted or rejected, but it has not yet expired.
`accepted`	The request was accepted by the specified account. Billing of available capacity of the Capacity Reservation is assigned to the consumer account.
`rejected`	The request was rejected by the consumer account.
`cancelled`	The request was cancelled by the Capacity Reservation owner while it was in the `pending` state.
`revoked`	Billing was revoked from the consumer account for one of the following reasons: • It was explicitly revoked by the Capacity Reservation owner.

State	Description
	• The Capacity Reservation is no longer shared with the consumer account. • The consumer account is no longer part of the AWS organization.
`expired`	The request expired because the consumer account did not accept or reject it within 12 hours.

Accept or reject billing of a shared EC2 Capacity Reservation

If you receive a billing assignment request for a Capacity Reservation that is shared with you, you can either accept or reject it. The request remains in the `pending` state until it is accepted or rejected.

If you accept the request, it enters the `accepted` state, and billing of any available, or *unused*, capacity of that Capacity Reservation is assigned to your account from that point onward. After you accept a request, only the Capacity Reservation owner can revoke billing from your account.

If you reject the request, it enters the `rejected` state, and billing of the available capacity of the Capacity Reservation remains assigned to the Capacity Reservation owner.

Requests expire if they are not accepted or rejected within 12 hours. If a request expires, billing of any unused capacity of the Capacity Reservation remains assigned to the Capacity Reservation owner.

When a request is accepted or rejected, an Amazon EventBridge event is sent to the Capacity Reservation owner's account. When a request expires, an Amazon EventBridge event is sent to the Capacity Reservation owner and the consumer account. For more information, see Monitor billing assignment requests for shared Capacity Reservations.

Console

To accept or reject a request

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, select **Capacity Reservations**.
3. If you have pending requests, the **Pending billing assignment requests** banner appears at the top of the screen. If the banner does not appear, you do not have pending requests.

   To view the requests, choose **Review requests** in the banner.
4. Select the request to accept or reject, and then choose either **Accept** or **Reject**.

AWS CLI

To accept a request

Use the accept-capacity-reservation-billing-ownership command. For `--capacity-reservation-id`, specify the ID of the Capacity Reservation for which to accept the request.

```
aws ec2 accept-capacity-reservation-billing-ownership \
    --capacity-reservation-id cr-01234567890abcdef
```

To reject a request

Use the reject-capacity-reservation-billing-ownership command. For `--capacity-reservation-id`, specify the ID of the Capacity Reservation for which to reject the request.

```
aws ec2 reject-capacity-reservation-billing-ownership \
    --capacity-reservation-id cr-01234567890abcdef
```

PowerShell

To accept a request

Use the Approve-EC2CapacityReservationBillingOwnership cmdlet.

```
Approve-EC2CapacityReservationBillingOwnership `
    -CapacityReservationId cr-01234567890abcdef
```

To reject a request

Use the [Deny-EC2CapacityReservationBillingOwnership](#) cmdlet.

```
Deny-EC2CapacityReservationBillingOwnership `
    -CapacityReservationId cr-01234567890abcdef
```

Cancel or revoke billing assignment requests for shared EC2 Capacity Reservations

Only the Capacity Reservation owner can cancel a `pending` billing assignment request. If a pending request is cancelled, it enters the `cancelled` state and billing of any available, or *unused*, capacity of the Capacity Reservation remains assigned to Capacity Reservation owner.

After a request is `accepted`, only the Capacity Reservation owner can revoke billing from the assigned account. If billing is revoked, the request enters the `revoked` state and billing of any available capacity of the Capacity Reservation is reassigned to Capacity Reservation owner.

When a request is cancelled or revoked, Amazon EventBridge events are sent to the Capacity Reservation owner and specified consumer account. For more information, see Monitor billing assignment requests for shared Capacity Reservations.

Console

To cancel or revoke a request

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, select **Capacity Reservations** and then choose the Capacity Reservation for which to cancel or revoke the request.
3. In the **Billing of available capacity** section, choose **Cancel transfer** or **Revoke transfer**, depending on the current state of the request.

AWS CLI

To cancel or revoke a request

Use the disassociate-capacity-reservation-billing-owner command. For `--unused-reservation-billing-owner-id`, specify the ID of the AWS account to which the request was sent.

```
aws ec2 disassociate-capacity-reservation-billing-owner \
```

```
    --capacity-reservation-id cr-01234567890abcdef \
    --unused-reservation-billing-owner-id 123456789012
```

PowerShell

To cancel or revoke a request

Use the Unregister-EC2CapacityReservationBillingOwner cmdlet. For -UnusedReservationBillingOwnerId, specify the ID of the AWS account to which the request was sent.

```
Unregister-EC2CapacityReservationBillingOwner `
    -CapacityReservationId cr-01234567890abcdef `
    -UnusedReservationBillingOwnerId 123456789012
```

Monitor billing assignment requests for shared Capacity Reservations

Amazon EC2 sends Amazon EventBridge events when the state of a billing assignment request changes.

- Events are sent to the Capacity Reservation owner when a request enters the following states: `accepted` | `rejected` | `expired` | `revoked`.
- Events are sent to the requested consumer account when a request enters the following states: `pending` | `expired` | `cancelled` | `revoked`.

For more information about Amazon EventBridge, see the Amazon EventBridge User Guide.

The following is the Amazon EventBridge event pattern.

```
{
   "version":"0",
   "id":"12345678-1234-1234-1234-123456789012",
   "detail-type":"On-Demand Capacity Reservation Billing Ownership Request pending|
accepted|rejected|cancelled|revoked|expired",
   "source":"aws.ec2",
   "account":"account_id",
   "time":"state_change_timestamp",
   "region":"region",
   "resources":[
      "arn:aws:ec2:region:cr_owner_account_id:capacity-reservation/cr_id"
```

```
    ],
    "detail":{
        "capacity-reservation-id":"cr_id",
        "updateTime":timestamp,
        "ownerAccountId":"cr_owner_account_id",
        "unusedReservationChargesOwnerID":"consumer_account_id",
        "status":"pending|accepted|rejected|cancelled|revoked|expired",
        "statusMessage":"message
    }
}
```

The following is an exmaple of an event that is sent to the Capacity Reservation owner (222222222222) when a consumer account (111111111111) accepts a billing assignment request for a shared Capacity Reservation (`cr-01234567890abcdef`).

```
{
    "version":"0",
    "id":"12345678-1234-1234-1234-123456789012",
    "detail-type":"On-Demand Capacity Reservation Billing Ownership Request accepted",
    "source":"aws.ec2",
    "account":"222222222222",
    "time":"2024-09-01Thh:59:59Z",
    "region":"us-east-1",
    "resources":[
        "arn:aws:ec2:us-east-1:222222222222:capacity-reservation/cr-01234567890abcdef"
    ],
    "detail":{
        "capacity-reservation-id":"cr-01234567890abcdef",
        "updateTime":"2024-08-01Thh:59:59Z",
        "ownerAccountId":"222222222222",
        "unusedReservationChargesOwnerID":"111111111111",
        "status":"accepted",
        "statusMessage":"billing transfer status message"
    }
}
```

Shared Capacity Reservation permissions

Permissions for owners

Owners are responsible for managing and canceling their shared Capacity Reservations. Owners cannot modify instances running in the shared Capacity Reservation that are owned by other accounts. Owners remain responsible for managing instances that they launch into the shared Capacity Reservation.

Permissions for consumers

Consumers are responsible for managing their instances that are running the shared Capacity Reservation. Consumers cannot modify the shared Capacity Reservation in any way, and they cannot view or modify instances that are owned by other consumers or the Capacity Reservation owner.

Billing and metering

There are no additional charges for sharing Capacity Reservations.

By default, the Capacity Reservation owner is billed for instances that they run inside the Capacity Reservation and for unused reserved capacity, while consumers are billed for the instances that they run inside the shared Capacity Reservation. However, you can assign billing of the available capacity of a shared Capacity Reservation to a specific consumer account. For more information, see Billing assignment for shared Amazon EC2 Capacity Reservations.

If the Capacity Reservation owner belongs to a different payer account and the Capacity Reservation is covered by a Regional Reserved Instance or a Savings Plan, the Capacity Reservation owner continues to be billed for the Regional Reserved Instance or Savings Plan. In these cases, the Capacity Reservation owner pays for the Regional Reserved Instance or Savings Plan, and consumers are billed for the instances that the run in the shared Capacity Reservation.

Instance limits

All Capacity Reservation usage counts toward the Capacity Reservation owner's On-Demand Instance limits. This includes:

- Unused reserved capacity
- Usage by instances owned by the Capacity Reservation owner
- Usage by instances owned by consumers

Instances launched into the shared capacity by consumers count towards the Capacity Reservation owner's On-Demand Instance limit. Consumers' instance limits are a sum of their own On-Demand Instance limits and the capacity available in the shared Capacity Reservations to which they have access.

Capacity Reservation Fleets

An *On-Demand Capacity Reservation Fleet* is a group of Capacity Reservations.

A Capacity Reservation Fleet request contains all of the configuration information that's needed to launch a Capacity Reservation Fleet. Using a single request, you can reserve large amounts of Amazon EC2 capacity for your workload across multiple instance types, up to a target capacity that you specify.

After you create a Capacity Reservation Fleet, you can manage the Capacity Reservations in the fleet collectively by modifying or canceling the Capacity Reservation Fleet.

Topics

How Capacity Reservation Fleets work

When you create a Capacity Reservation Fleet, the Fleet attempts to create individual Capacity Reservations to meet the total target capacity that you specified in the Fleet request.

The number of instances for which the Fleet reserves capacity depends on the *total target capacity* and the *instance type weights* that you specify. The instance type for which it reserves capacity depends on the *allocation strategy* and *instance type priorities* that you use.

If there is insufficient capacity at the time the Fleet is created, and it is unable to immediately meet its total target capacity, the Fleet asynchronously attempts to create Capacity Reservations until it has reserved the requested amount of capacity.

When the Fleet reaches its total target capacity, it attempts to maintain that capacity. If a Capacity Reservation in the Fleet is cancelled, the Fleet automatically creates one or more Capacity

Reservations, depending on your Fleet configuration, to replace the lost capacity and to maintain its total target capacity.

The Capacity Reservations in the Fleet can't be managed individually. They must be managed collectively by modifying the Fleet. When you modify a Fleet, the Capacity Reservations in the Fleet are automatically updated to reflect the changes.

Currently, Capacity Reservation Fleets support the `open` instance matching criteria, and all Capacity Reservations launched by a Fleet automatically use this instance matching criteria. With this criteria, new instances and existing instances that have matching attributes (instance type, platform, Availability Zone, and tenancy) automatically run in the Capacity Reservations created by a Fleet. Capacity Reservation Fleets do not support targeted instance matching criteria.

Considerations

Keep the following in mind when working with Capacity Reservation Fleets:

- A Capacity Reservation Fleet can be created, modified, viewed, and cancelled using the AWS CLI and AWS API.
- The Capacity Reservations in a Fleet can't be managed individually. They must be managed collectively by modifying or cancelling the Fleet.
- A Capacity Reservation Fleet can't span across Regions.
- A Capacity Reservation Fleet can't span across Availability Zones.
- Capacity Reservations created by a Capacity Reservation Fleet are automatically tagged with the following AWS generated tag:
  - Key — `aws:ec2-capacity-reservation-fleet`
  - Value — *`fleet_id`*

  You can use this tag to identify Capacity Reservations that were created by a Capacity Reservation Fleet.

Pricing

There are no additional charges for using Capacity Reservation Fleets. You are billed for the individual Capacity Reservations that are created by your Capacity Reservation Fleets. For more information about how Capacity Reservations are billed, see Capacity Reservation pricing and billing.

Capacity Reservation Fleet concepts and planning

The following information describes how to plan a Capacity Reservation Fleet and describes Capacity Reservation Fleet concepts including total target capacity, allocation strategy, instance type weight, and instance type priority.

Topics

Plan a Capacity Reservation Fleet

When planning your Capacity Reservation Fleet, we recommend that you do the following:

1. Determine the amount of compute capacity that is needed by your workload.
2. Decide on the instance types and Availability Zones that you want to use.
3. Assign each instance type a priority based on your needs and preferences. For more information, see Instance type priority.
4. Create a capacity weighting system that makes sense for your workload. Assign a weight to each instance type and determine your total target capacity. For more information, see Instance type weight and Total target capacity.
5. Determine whether you need the Capacity Reservation indefinitely or only for a specific period of time.

Total target capacity

The *total target capacity* defines the total amount of compute capacity that the Capacity Reservation Fleet reserves. You specify the total target capacity when you create the Capacity Reservation Fleet. After the Fleet has been created, Amazon EC2 automatically creates Capacity Reservations to reserve capacity up to the total target capacity.

The number of instances for which the Capacity Reservation Fleet reserves capacity is determined by the total target capacity and the *instance type weight* that you specify for each instance type in the Capacity Reservation Fleet (`total target capacity/instance type weight=number of instances`).

You can assign a total target capacity based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign the total target capacity based on the number of vCPUs required. If your workload requires `2048` vCPUs, specify a total target capacity of `2048` and then assign instance type weights based on the number of vCPUs provided by the instance types in the Fleet. For an example, see Instance type weight.

Allocation strategy

The allocation strategy for your Capacity Reservation Fleet determines how it fulfills your request for reserved capacity from the instance type specifications in the Capacity Reservation Fleet configuration.

Currently, only the `prioritized` allocation strategy is supported. With this strategy, the Capacity Reservation Fleet creates Capacity Reservations using the priorities that you have assigned to each of the instance type specifications in the Capacity Reservation Fleet configuration. Lower priority values indicate higher priority for use. For example, say you create a Capacity Reservation Fleet that uses the following instance types and priorities:

- `m4.16xlarge` — priority = 1
- `m5.16xlarge` — priority = 3
- `m5.24xlarge` — priority = 2

The Fleet first attempts to create Capacity Reservations for `m4.16xlarge`. If Amazon EC2 has insufficient `m4.16xlarge` capacity, the Fleet attempts to create Capacity Reservations for `m5.24xlarge`. If Amazon EC2 has insufficient `m5.24xlarge` capacity, the Fleet creates Capacity Reservations for `m5.16xlarge`.

Instance type weight

The *instance type weight* is a weight that you assign to each instance type in the Capacity Reservation Fleet. The weight determines how many units of capacity each instance of that specific instance type counts toward the Fleet's *total target capacity*.

You can assign weights based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign weights based on the number of vCPUs provided by each instance type in the Capacity Reservation Fleet. In this case, if you create a Capacity Reservation Fleet using `m4.16xlarge` and `m5.24xlarge` instances, you would assign weights that correspond to the number of vCPUs for each instance as follows:

- `m4.16xlarge` — 64 vCPUs, weight = 64 units
- `m5.24xlarge` — 96 vCPUs, weight = 96 units

The instance type weight determines the number of instances for which the Capacity Reservation Fleet reserves capacity. For example, if a Capacity Reservation Fleet with a total target capacity of `384` units uses the instance types and weights in the preceding example, the Fleet could reserve capacity for 6 `m4.16xlarge` instances (384 total target capacity/64 instance type weight=6 instances), or 4 `m5.24xlarge` instances (384 / 96 = 4).

If you do not assign instance type weights, or if you assign an instance type weight of `1`, the total target capacity is based purely on instance count. For example, if a Capacity Reservation Fleet with a total target capacity of `384` units uses the instance types in the preceding example, but omits the weights or specifies a weight of `1` for both instance types, the Fleet could reserve capacity for either `384` `m4.16xlarge` instances or `384` `m5.24xlarge` instances.

Instance type priority

The *instance type priority* is a value that you assign to the instance types in the Fleet. The priorities are used to determine which of the instance types specified for the Fleet should be prioritized for use.

Lower priority values indicate a higher priority for use.

Create a Capacity Reservation Fleet

When you create a Capacity Reservation Fleet it automatically creates Capacity Reservations for the instance types specified in the Fleet request, up to the specified total target capacity. The number of instances for which the Capacity Reservation Fleet reserves capacity depends on the total target capacity and instance type weights that you specify in the request. For more information, see Instance type weight and Total target capacity.

When you create the Fleet, you must specify the instance types to use and a priority for each of those instance types. For more information, see Allocation strategy and Instance type priority.

Note

The **AWSServiceRoleForEC2CapacityReservationFleet** service-linked role is automatically created in your account the first time that you create a Capacity Reservation Fleet. For more information, see Using service-linked roles for Capacity Reservation Fleet.

Currently, Capacity Reservation Fleets support the open instance matching criteria only.

AWS CLI

To create a Capacity Reservation Fleet

Use the create-capacity-reservation-fleet command.

```
aws ec2 create-capacity-reservation-fleet \
    --total-target-capacity 24 \
    --allocation-strategy prioritized \
    --instance-match-criteria open \
    --tenancy default \
    --end-date 2021-12-31T23:59:59.000Z \
    --instance-type-specifications file://instanceTypeSpecification.json
```

The following are the contents of instanceTypeSpecification.json.

```
[
  {
    "InstanceType": "m5.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "Weight": 3.0,
    "AvailabilityZone":"us-east-1a",
    "EbsOptimized": true,
    "Priority" : 1
  }
]
```

The following is example output.

```
{
    "Status": "submitted",
    "TotalFulfilledCapacity": 0.0,
```

```
    "CapacityReservationFleetId": "crf-abcdef01234567890",
    "TotalTargetCapacity": 24
}
```

PowerShell

To create a Capacity Reservation Fleet

Use the New-EC2CapacityReservationFleet cmdlet.

```
New-EC2CapacityReservationFleet `
    -TotalTargetCapacity 24 `
    -AllocationStrategy "prioritized" `
    -InstanceMatchCriterion "open" `
    -Tenancy "default" `
    -EndDate 2021-12-31T23:59:59.000Z `
    -InstanceTypeSpecification $specification
```

The specification is defined as follows.

```
$specification = New-Object Amazon.EC2.Model.ReservationFleetInstanceSpecification
$specification.InstanceType = "m5.xlarge"
$specification.InstancePlatform = "Linux/UNIX"
$specification.Weight = 3.0
$specification.AvailabilityZone = "us-east-1a"
$specification.EbsOptimized = $true
$specification.Priority = 1
```

Modify a Capacity Reservation Fleet

You can modify the total target capacity and date of a Capacity Reservation Fleet at any time. When you modify the total target capacity of a Capacity Reservation Fleet, the Fleet automatically creates new Capacity Reservations, or modifies or cancels existing Capacity Reservations in the Fleet to meet the new total target capacity. When you modify the end date for the Fleet, the end dates for all of the individual Capacity Reservations are updated accordingly.

Considerations

- After you modify a Fleet, its status transitions to `modifying`. You can't attempt additional modifications to a Fleet while it is in the `modifying` state.

- You can't modify the tenancy, Availability Zone, instance types, instance platforms, priorities, or weights used by a Capacity Reservation Fleet. If you need to change any of these parameters, you might need to cancel the existing Fleet and create a new one with the required parameters.
- You can't specify `--end-date` and `--remove-end-date` in the same command.

AWS CLI

To modify a Capacity Reservation Fleet

Use the [modify-capacity-reservation-fleet](#) command.

Example 1: Modify total target capacity

```
aws ec2 modify-capacity-reservation-fleet \
    --capacity-reservation-fleet-id crf-01234567890abcedf \
    --total-target-capacity 160
```

Example 2: Modify end date

```
aws ec2 modify-capacity-reservation-fleet \
    --capacity-reservation-fleet-id crf-01234567890abcedf \
    --end-date 2021-07-04T23:59:59.000Z
```

Example 3: Remove end date

```
aws ec2 modify-capacity-reservation-fleet \
    --capacity-reservation-fleet-id crf-01234567890abcedf \
    --remove-end-date
```

PowerShell

To modify a Capacity Reservation Fleet

Use the [Edit-EC2CapacityReservationFleet](#) cmdlet.

Example 1: Modify total target capacity

```
Edit-EC2CapacityReservationFleet `
    -CapacityReservationFleetId crf-01234567890abcedf `
    -TotalTargetCapacity 160
```

Example 2: Modify end date

```
Edit-EC2CapacityReservationFleet `
    -CapacityReservationFleetId crf-01234567890abcedf `
    -EndDate 2021-07-04T23:59:59.000Z
```

Example 3: Remove end date

```
Edit-EC2CapacityReservationFleet `
    -CapacityReservationFleetId crf-01234567890abcedf `
    -RemoveEndDate
```

Cancel a Capacity Reservation Fleet

When you no longer need a Capacity Reservation Fleet and the capacity it reserves, you can cancel it. When you cancel a Fleet, its status changes to `cancelled` and it can no longer create new Capacity Reservations. Additionally, all of the individual Capacity Reservations in the Fleet are canceled. The instances that were previously running in the reserved capacity continue to run normally in the shared capacity.

AWS CLI

To cancel a Capacity Reservation Fleet

Use the cancel-capacity-reservation-fleets command.

```
aws ec2 cancel-capacity-reservation-fleets \
    --capacity-reservation-fleet-ids crf-abcdef01234567890
```

The following is example output.

```
{
    "SuccessfulFleetCancellations": [
        {
            "CurrentFleetState": "cancelling",
            "PreviousFleetState": "active",
            "CapacityReservationFleetId": "crf-abcdef01234567890"
        }
    ],
    "FailedFleetCancellations": []
```

```
}
```

PowerShell

To cancel a Capacity Reservation Fleet

Use the Stop-EC2CapacityReservationFleet cmdlet.

```
Stop-EC2CapacityReservationFleet `
    -CapacityReservationFleetId crf-abcdef01234567890
```

Example Capacity Reservation Fleet configurations

The following example creates a Capacity Reservation Fleet that uses two instance types: `m5.4xlarge` and `m5.12xlarge`.

It uses a weighting system based on the number of vCPUs provided by the specified instance types. The total target capacity is `480` vCPUs. The `m5.4xlarge` provides 16 vCPUs and gets a weight of `16`, while the `m5.12xlarge` provides 48 vCPUs and gets a weight of `48`. This weighting system configures the Capacity Reservation Fleet to reserve capacity for either 30 `m5.4xlarge` instances (480/16=30), or 10 `m5.12xlarge` instances (480/48=10).

The Fleet is configured to prioritize the `m5.12xlarge` capacity and gets priority of `1`, while the `m5.4xlarge` gets a lower priority of `2`. This means that the fleet will attempt to reserve the `m5.12xlarge` capacity first, and only attempt to reserve the `m5.4xlarge` capacity if Amazon EC2 has insufficient `m5.12xlarge` capacity.

The Fleet reserves the capacity for `Windows` instances and the reservation automatically expires on `October 31, 2021` at `23:59:59` UTC.

```
aws ec2 create-capacity-reservation-fleet \
    --total-target-capacity 480 \
    --allocation-strategy prioritized \
    --instance-match-criteria open \
    --tenancy default \
    --end-date 2021-10-31T23:59:59.000Z \
    --instance-type-specifications file://instanceTypeSpecification.json
```

The following is the contents of `instanceTypeSpecification.json`.

```
[
    {
        "InstanceType": "m5.4xlarge",
        "InstancePlatform":"Windows",
        "Weight": 16,
        "AvailabilityZone":"us-east-1a",
        "EbsOptimized": true,
        "Priority" : 2
    },
    {
        "InstanceType": "m5.12xlarge",

Using service-linked roles for Capacity Reservation Fleet

On-Demand Capacity Reservation Fleet uses AWS Identity and Access Management (IAM) [service-linked roles](). A service-linked role is a unique type of IAM role that is linked directly to Capacity Reservation Fleet. Service-linked roles are predefined by Capacity Reservation Fleet and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Capacity Reservation Fleet easier because you don't have to manually add the necessary permissions. Capacity Reservation Fleet defines the permissions of its service-linked roles, and unless defined otherwise, only Capacity Reservation Fleet can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Capacity Reservation Fleet resources because you can't inadvertently remove permission to access the resources.

Service-linked role permissions for Capacity Reservation Fleet

Capacity Reservation Fleet uses the service-linked role named **AWSServiceRoleForEC2CapacityReservationFleet** to create, describe, modify, and cancel Capacity Reservations in a Capacity Reservation Fleet on your behalf.

The AWSServiceRoleForEC2CapacityReservationFleet service-linked role trusts the following entity to assume the role:

- `capacity-reservation-fleet.amazonaws.com`

The role uses the `AWSEC2CapacityReservationFleetRolePolicy` AWS managed policy. For more information, see AWS managed policy: AWSEC2CapacityReservationFleetRolePolicy.

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the *IAM User Guide*.

Create a service-linked role for Capacity Reservation Fleet

You don't need to manually create a service-linked role. When you create a Capacity Reservation Fleet using the `create-capacity-reservation-fleet` AWS CLI command or the `CreateCapacityReservationFleet` API, the service-linked role is automatically created for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a Capacity Reservation Fleet, Capacity Reservation Fleet creates the service-linked role for you again.

Edit a service-linked role for Capacity Reservation Fleet

Capacity Reservation Fleet does not allow you to edit the AWSServiceRoleForEC2CapacityReservationFleet service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Edit a service-linked role description in the *IAM User Guide*.

Delete a service-linked role for Capacity Reservation Fleet

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don’t have an unused entity that is not actively monitored or maintained. However, you must delete the resources for your service-linked role before you can manually delete it.

> **Note**
>
> If the Capacity Reservation Fleet service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the AWSServiceRoleForEC2CapacityReservationFleet service-linked role

1. Use the `delete-capacity-reservation-fleet` AWS CLI command or the `DeleteCapacityReservationFleet` API to delete the Capacity Reservation Fleets in your account.
2. Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForEC2CapacityReservationFleet service-linked role. For more information, see Delete a service-linked role in the *IAM User Guide*.

Supported Regions for Capacity Reservation Fleet service-linked roles

Capacity Reservation Fleet supports using service-linked roles in all of the Regions where the service is available. For more information, see AWS Regions and Endpoints.

Monitor Capacity Reservations usage with CloudWatch metrics

With CloudWatch metrics, you can efficiently monitor your Capacity Reservations and identify unused capacity by setting CloudWatch alarms to notify you when usage thresholds are met. This can help you maintain a constant Capacity Reservation volume and achieve a higher level of utilization.

Capacity Reservations send metric data to CloudWatch every five minutes. Metrics are not supported for Capacity Reservations that are active for less than five minutes.

For more information about viewing metrics in the CloudWatch console, see Using Amazon CloudWatch Metrics. For more information about creating alarms, see Creating Amazon CloudWatch Alarms.

Contents

- View CloudWatch metrics for Capacity Reservations

Capacity Reservation usage metrics

The `AWS/EC2CapacityReservations` namespace includes the following usage metrics you can use to monitor and maintain on-demand capacity within thresholds you specify for your reservation.

Metric	Description
`UsedInstanceCount`	The number of instances that are currently in use. Unit: Count
`AvailableInstanceCount`	The number of instances that are available. Unit: Count
`TotalInstanceCount`	The total number of instances you have reserved. Unit: Count
`InstanceUtilization`	The percentage of reserved capacity instances that are currently in use. Unit: Percent

Capacity Reservation metric dimensions

You can use the following dimensions to refine the metrics listed in the previous table within the selected Region and account.

Dimension	Description
(No dimension)	

Dimension	Description
	This dimension filters the specified metric for all Capacity Reservations.
`CapacityReservationId`	This dimension filters the specified metric for the identified Capacity Reservation.
`InstanceType`	This dimension filters the specified metric for the identified instance type.
`AvailabilityZone`	This dimension filters the specified metric for the identified Availability Zone.
`InstanceMatchCriteria`	This dimension filters the specified metric for the identified instance match criteria (`open` or `targeted`).
`InstancePlatform`	This dimension filters the specified metric data for the identified platform.
`Tenancy`	This dimension filters the specified metric for the identified tenancy.

View CloudWatch metrics for Capacity Reservations

Metrics are grouped first by the service namespace, and then by the supported dimensions. You can use the following procedures to view the metrics for your Capacity Reservations.

To view Capacity Reservation metrics using the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the Region. From the navigation bar, select the Region where your Capacity Reservation resides. For more information, see [Regions and Endpoints](#).
3. In the navigation pane, choose **Metrics**.

4. For **All metrics**, choose **EC2 Capacity Reservations**.
5. Choose from the preceding metric dimensions **Across All Capacity Reservations**, **By Capacity Reservation**, **By Instance Type**, **By Availability Zone**, **By Platform**, **By Instance Match Criteria** or **By Tenancy** and metrics will be grouped by No dimension, `CapacityReservationId`, `InstanceType`, `AvailabilityZone`, `Platform`, `InstanceMatchCriteria`, and `Tenancy` respectively.
6. To sort the metrics, use the column heading. To graph a metric, select the checkbox next to the metric.

To view Capacity Reservation metrics using the AWS CLI

Use the following list-metrics command:

```
aws cloudwatch list-metrics --namespace "AWS/EC2CapacityReservations"
```

Monitor Capacity Reservation underutilization

You can monitor Capacity Reservation underutilization using the following:

Topics

- Amazon EventBridge events
- Email and AWS Health Dashboard notifications

Amazon EventBridge events

AWS Health sends events to Amazon EventBridge when a Capacity Reservation in your account is below 20 percent usage over certain periods. With EventBridge, you can establish rules that trigger programmatic actions in response to such events. For example, you can create a rule that automatically cancels a Capacity Reservation when its utilization drops below 20 percent utilization over a 7-day period.

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the "detail" section of the JSON object. The "event" field contains the event name. The "result" field contains the completed status of the action that triggered the event. For more information, see Amazon EventBridge event patterns in the *Amazon EventBridge User Guide*.

For more information, see the Amazon EventBridge User Guide.

This feature is not supported in AWS GovCloud (US).

Events

AWS Health sends the following events when capacity usage for a Capacity Reservation is below 20 percent.

- `AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION`

  The following is an example of an event that is generated when a newly created Capacity Reservation is below 20 percent capacity usage over a 24-hour period.

```
{
    "version": "0",
    "id": "b3e00086-f271-12a1-a36c-55e8ddaa130a",

    }
}
```

Create an EventBridge rule

To receive email notifications when your Capacity Reservation utilization drops below 20 percent, create an Amazon SNS topic, and then create an EventBridge rule for the `AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION` event.

To create the Amazon SNS topic

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home.
2. In the navigation pane, choose **Topics**, and then choose **Create topic**.
3. For **Type**, choose **Standard**.
4. For **Name**, enter a name for the new topic.
5. Choose **Create topic**.
6. Choose **Create subscription**.
7. For **Protocol**, choose **Email**, and then for **Endpoint**, enter the email address that receives the notifications.
8. Choose **Create subscription**.
9. The email address entered above will receive email message with the following subject line: `AWS Notification - Subscription Confirmation`. Follow the directions to confirm your subscription.

To create the EventBridge rule

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose **Rules**, and then choose **Create rule**.
3. For **Name**, enter a name for the new rule.
4. For **Rule type**, choose **Rule with an event pattern**.
5. Choose **Next**.

6. In the **Event pattern**, do the following:

   a. For **Event source**, choose **AWS services**.

   b. For **AWS service**, choose **AWS Health**.

   c. For **Event type**, choose **EC2 ODCR Underutilization Notification**.

7. Choose **Next**.

8. For **Target 1**, do the following:

   a. For **Target types**, choose **AWS service**.

   b. For **Select a target**, choose **SNS topic**.

   c. For **Topic**, choose the topic that you created earlier.

9. Choose **Next** and then **Next** again.

10. Choose **Create rule**.

Email and AWS Health Dashboard notifications

AWS Health sends the following email and AWS Health Dashboard notifications when capacity utilization for Capacity Reservations in your account drops below 20 percent.

- Individual notifications for each newly created Capacity Reservation that has been below 20 percent utilization over the last 24-hour period.
- A summary notification for all Capacity Reservations that have been below 20 percent utilization over the last 7-day period.

The email notifications and AWS Health Dashboard notifications are sent to the email address associated with the AWS account that owns the Capacity Reservations. The notifications include the following information:

- The ID of the Capacity Reservation.
- The Availability Zone of the Capacity Reservation.
- The average utilization rate for the Capacity Reservation.
- The instance type and platform (operating system) of the Capacity Reservation.

Additionally, when capacity utilization for a Capacity Reservation in your account drops below 20 percent over a 24-hour and 7-day period, AWS Health sends events to EventBridge. With

EventBridge, you can create rules that activate automatic actions, such as sending email notifications or triggering AWS Lambda functions, in response to such events. For more information, see Monitor Capacity Reservation underutilization.

Monitor state changes for future-dated Capacity Reservations

Amazon EC2 sends an event to Amazon EventBridge when the state of a future-dated Capacity Reservation changes.

The following is example of this event. In this example, the future-dated Capacity Reservation entered the `scheduled` state. Note the state highlighted in the `detail-type` field.

```
{
   "version":"0",
   "id":"12345678-1234-1234-1234-123456789012",
   "detail-type":"EC2 Capacity Reservation Scheduled",
   "source":"aws.ec2",
   "account":"123456789012",
   "time":"yyyy-mm-ddThh:mm:ssZ",
   "region":"us-east-1",
   "resources":[
      "arn:aws:ec2:us-east-1:123456789012:capacity-reservation/cr-1234567890abcdefg"
   ],
   "detail":{
      "capacity-reservation-id":"cr-1234567890abcdefg",
      "state":"scheduled"
   }
}
```

The possible values for the `detail-type` field are:

- `Scheduled`
- `Active`
- `Delayed`
- `Unsupported`
- `Failed`
- `Expired`

For more information about these states, see View the state of a Capacity Reservation.

You can create Amazon EventBridge events that monitor for these events and then trigger specific actions when they occur. For more information, see [Creating rules that react to events in Amazon EventBridge](#).

To create a rule that monitors for all state change events, you can use the following event pattern.

```
{
  "source": ["aws.ec2"],
  "detail-type": [{
    "prefix": "EC2 Capacity Reservation"
  }]
}
```

To create a rule that monitors for only specific state changes, you can use the following event pattern.

```
{
  "source": ["aws.ec2"],
  "detail-type": [{
    "prefix": "EC2 Capacity Reservation state"
  }]
}
```

For example, the following event pattern monitors for events that are sent when a future-dated Capacity Reservation enters the `active` state.

```
{
  "source": ["aws.ec2"],
  "detail-type": [{
    "prefix": "EC2 Capacity Reservation Active"
  }]
}
```

Capacity Blocks for ML

Capacity Blocks for ML allow you to reserve GPU-based accelerated computing instances on a future date to support your short duration machine learning (ML) workloads. Instances that run inside a Capacity Block are automatically placed close together inside [Amazon EC2 UltraClusters](#), for low-latency, petabit-scale, non-blocking networking.

You can also use Capacity Blocks to reserve capacity for Amazon EC2 UltraServers. UltraServers connect multiple Amazon EC2 instances within a low-latency, high-bandwidth accelerator interconnect. You can use UltraServers to handle the most compute and memory intensive AI/ML workloads in training, fine-tuning, and inference. For more information, see Amazon EC2 UltraServers.

With Capacity Blocks, you can see when GPU instance capacity is available on future dates, and you can schedule a Capacity Block to start at a time that works best for you. When you reserve a Capacity Block, you get predictable capacity assurance for GPU instances while paying only for the amount of time that you need. We recommend Capacity Blocks when you need GPUs to support your ML workloads for days or weeks at a time and don't want to pay for a reservation while your GPU instances aren't in use.

The following are some common use cases for Capacity Blocks.

- **ML model training and fine-tuning –** Get uninterrupted access to the GPU instances that you reserved to complete ML model training and fine-tuning.
- **ML experiments and prototypes –** Run experiments and build prototypes that require GPU instances for short durations.

You can reserve a Capacity Block with the following specifications:

- Reserve a start time up to 8 weeks in advance
- Set a reservation duration of one to 14 days or a multiple of 7 days, up to 182 days (Examples: 21 days, 28 days)
- Configure up to 64 instances per Capacity Block
- Configure up to 256 instances across multiple Capacity Blocks

For Amazon EC2 UltraServers, each UltraServer corresponds to one Capacity Block. You can request multiple UltraServers through a single request.

You can use Capacity Blocks to reserve `p6-b200`, `p5`, `p5e`, `p5en`, `p4d`, `p4de`, `trn1`, and `trn2` instances. You can purchase the following UltraServer types through Capacity Blocks: `P6e-GB200` and `Trn2` (in preview).

To reserve a Capacity Block, you start by specifying your capacity needs, including the instance type or UltraServer type, the number of instances or UltraServers, amount of time, earliest start date, and latest end date that you need. Then, you can see an available Capacity Block offering that meets your specifications. The Capacity Block offering includes details such as start time, Availability Zone, and reservation price. The price of a Capacity Block offering depends on available supply and demand at the time the offering was delivered. After you reserve a Capacity Block, the price doesn't change. For more information, see Capacity Blocks pricing and billing.

When you purchase a Capacity Block offering, your reservation is created for the date and number of instances that you selected. When your Capacity Block reservation begins, you can target instance launches by specifying the reservation ID in your launch requests.

You can use all the instances you reserved until 30 minutes (for instance types) or 60 minutes (for UltraServer type) before the end time of the Capacity Block. With 30 minutes (for instance types) or 60 minutes (for UltraServer types) left in your Capacity Block reservation, we begin terminating any instances that are running in the Capacity Block. We use this time to clean up your instances before delivering the Capacity Block to the next customer. We emit an event through EventBridge 10 minutes before the termination process begins. For more information, see Monitor Capacity Blocks using EventBridge.

Topics

Supported platforms

Capacity Blocks for ML currently support instances and UltraServers with default tenancy only. When you use the AWS Management Console to purchase a Capacity Block, the default platform option is Linux/UNIX. When you use the AWS Command Line Interface (AWS CLI) or AWS SDK to purchase a Capacity Block, the following platform options are available:

- Linux/Unix
- Red Hat Enterprise Linux
- RHEL with HA
- SUSE Linux
- Ubuntu Pro

Considerations

Before you use Capacity Blocks, consider the following details and limitations.

- If we detect impairment impacting an UltraServer Capacity Block, we will notify you but generally will not take action to terminate your instances on the Capacity Block. This is to minimize unintended disruption to your workloads. You can continue using the UltraServer Capacity Block as is after receiving this notification or request remediation by terminating all instances on the capacity block and submitting an AWS support case. After we receive your support case, we will notify you when we have completed remediation and you can relaunch instances onto your UltraServer Capacity Block.
- For `P6e-GB200` UltraServer Capacity Blocks, you must terminate your instances at least 60 minutes before the Capacity Block end time.
- To use `P6e-GB200` UltraServer Capacity Blocks, you must be opted in to the Dallas Local Zone (N. Virginia) Local Zone.
- Each Capacity Block can have up to 64 instances, and you can have up to 256 instances across Capacity Blocks.
- You can describe Capacity Block offerings that can start in as soon as 30 minutes.
- Capacity Blocks end at 11:30AM Coordinated Universal Time (UTC).
- The termination process for instances running in a Capacity Block begins at 11:00AM Coordinated Universal Time (UTC) on the final day of the reservation.
- Capacity Blocks can be reserved with a start time up to 8 weeks in the future.

- Capacity Block cancellations aren't allowed.
- Capacity Block can't be moved or split.
- Capacity Blocks can't be shared across AWS accounts or within your AWS Organization.
- Only UltraServer Capacity Blocks can be used with resource groups. Instance Capacity Blocks can't be used with resource groups. For more information, see Create a resource group for UltraServer Capacity Blocks.
- The total number of instances that can be reserved in Capacity Blocks across all accounts in your AWS Organization can't exceed 256 instances on a particular date.
- To use a Capacity Block, instances must specifically target the reservation ID.
- Instances in a Capacity Block don't count against your On-Demand Instances limits.
- For P5 instances using a custom AMI, ensure that you have the required software and configuration for EFA.
- For Amazon EKS managed node groups, see Create a managed node group with Amazon EC2 Capacity Blocks for ML. For Amazon EKS self-managed node groups, see Use Capacity Blocks for ML with self-managed nodes.

Related resources

After you create a Capacity Block, you can do the following with the Capacity Block:

- Launch instances into the Capacity Block. For more information, see Launch instances using Capacity Blocks.
- Create an Amazon EC2 Auto Scaling group. For more information, see Use Capacity Blocks for machine learning workloads in the *Amazon EC2 Auto Scaling User Guide*.

> **Note**
>
> If you use Amazon EC2 Auto Scaling or Amazon EKS, you can schedule scaling to run at the start of the Capacity Block reservation. With scheduled scaling, AWS automatically handles retries for you, so you don't need to worry about implementing retry logic to handle transient failures.

- Enhance ML workflows with AWS ParallelCluster. For more information, see Enhancing ML workflows with AWS ParallelCluster and Amazon EC2 Capacity Blocks for ML.

For more information about AWS ParallelCluster, see What is AWS ParallelCluster.

Capacity Blocks pricing and billing

With Amazon EC2 Capacity Blocks for ML, you pay only for what you reserve. The price of a Capacity Block depends on available supply and demand for Capacity Blocks at the time of purchase. You can view the price of a Capacity Block offering before you reserve it. The price of the Capacity Block is charged up front at the time the reservation is made. When you search for a Capacity Block across a range of dates, we return the lowest-priced Capacity Block offering available. After you've reserved a Capacity Block, the price doesn't change.

When you use a Capacity Block, you pay for the operating system you use when your instances are running. For more information about operating system prices, see Amazon EC2 Capacity Blocks for ML Pricing.

Billing

The price of a Capacity Block offering is charged up front. Payment is billed to your AWS account within 5 minutes to 12 hours after you purchase a Capacity Block. While your payment is processing, your Capacity Block reservation resource remains in a state of `payment-pending`. If your payment can't be processed at least 5 minutes before your block start time, or within 12 hours (whichever comes first), your Capacity Block is released and the reservation state changes to `payment-failed`.

After your payment is processed successfully, the Capacity Block resource state changes from `payment-pending` to `scheduled`. You receive an invoice that reflects the one-time upfront payment. In the invoice, you can associate the paid amount with the Capacity Block reservation ID.

When your Capacity Block reservation begins, you are billed based only on the operating system you use while your instances are running in the reservation. You can view your usage and associated charges in your anniversary bill for the month of usage in your AWS Cost and Usage Report.

> **Note**
>
> Savings Plans and Reserved Instance discounts don't apply to Capacity Blocks.

Viewing your bill

You can view your bill in the AWS Billing and Cost Management console. The upfront payment for your Capacity Block appears in the month that you purchased the reservation.

After your reservation begins, your bill shows separate lines for the block reservation used and unused time. You can use these line items to see how much time was used in your reservation. You will see only a usage charge in the line for used time if you use a premium operating system. For more information, see [Capacity Blocks pricing and billing](). There is no additional charge for unused time.

For more information, see [Viewing your bill]() in the *AWS Billing and Cost Management User Guide*.

If your Capacity Block starts in a different month then the month you purchased your reservation, the upfront price and reservation usage show up under separate billing months. In your AWS Cost and Usage Report, the Capacity Block reservation ID is listed in the **reservation/ReservationARN** line item of your upfront fee and the **lineitem/ResourceID** in your anniversary bill so that you can associate the usage to the corresponding upfront price.

Prerequisites for Capacity Blocks

You must launch instances into an AWS Region that supports the instance type that you want to use.

Capacity Blocks with **`p6-b200.48xlarge`** instances are available in the following AWS Regions.

Region code	Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)
us-west-2	US West (Oregon)

Capacity Blocks with **`p5.4xlarge`** instances are available in the following AWS Regions.

Region code	Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)

Region code	Region name
us-west-2	US West (Oregon)
eu-west-2	Europe (London)
ap-south-1	Asia Pacific (Mumbai)
ap-northeast-1	Asia Pacific (Tokyo)
ap-southeast-2	Asia Pacific (Sydney)
sa-east-1	South America (São Paulo)

Capacity Blocks with **`p5.48xlarge`** instances are available in the following AWS Regions.

Region code	Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)
us-west-1	US West (N. California)
us-west-2	US West (Oregon)
eu-north-1	Europe (Stockholm)
eu-west-2	Europe (London)
sa-east-1	South America (São Paulo)
ap-northeast-1	Asia Pacific (Tokyo)
ap-south-1	Asia Pacific (Mumbai)
ap-southeast-2	Asia Pacific (Sydney)
ap-southeast-3	Asia Pacific (Jakarta)

Capacity Blocks with **`p5e.48xlarge`** instances are available in the following AWS Regions.

Region code	Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)
us-west-1	US West (N. California)
us-west-2	US West (Oregon)
eu-north-1	Europe (Stockholm)
eu-west-2	Europe (London)
sa-east-1	South America (São Paulo)
ap-northeast-1	Asia Pacific (Tokyo)
ap-south-1	Asia Pacific (Mumbai)
ap-southeast-2	Asia Pacific (Sydney)
ap-southeast-3	Asia Pacific (Jakarta)

Capacity Blocks with **`p5en.48xlarge`** instances are available in the following AWS Regions.

Region code	Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)
us-west-1	US West (N. California)
us-west-2	US West (Oregon)
eu-north-1	Europe (Stockholm)

Region code	Region name
eu-west-2	Europe (London)
eu-south-2	Europe (Spain)
sa-east-1	South America (São Paulo)
ap-northeast-1	Asia Pacific (Tokyo)
ap-northeast-2	Asia Pacific (Seoul)
ap-south-1	Asia Pacific (Mumbai)
ap-southeast-3	Asia Pacific (Jakarta)

Capacity Blocks with **`p4d.24xlarge`** instances are available in the following AWS Regions.

Region code	Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)
us-west-2	US West (Oregon)

Capacity Blocks with **`p4de.24xlarge`** instances are available in the following AWS Regions.

Region code	Region name
us-east-1	US East (N. Virginia)
us-west-2	US West (Oregon)

Capacity Blocks with **`trn1.32xlarge`** instances are available in the following AWS Regions.

Region code	Region name
us-east-1	US East (N. Virginia)
us-east-2	US East (Ohio)
us-west-1	US West (N. California)
us-west-2	US West (Oregon)
eu-north-1	Europe (Stockholm)
ap-south-1	Asia Pacific (Mumbai)
ap-southeast-2	Asia Pacific (Sydney)
ap-southeast-4	Asia Pacific (Melbourne)

Capacity Blocks with **`trn2.48xlarge`** instances are available in the following AWS Region.

Region code	Region name
us-east-2	US East (Ohio)

Amazon EC2 UltraServers Capacity Blocks

Capacity Blocks with **`Trn2`** UltraServers are available in preview the following AWS Region.

Region code	Region name
us-east-2	US East (Ohio)

Capacity Blocks with **`P6e-GB200`** UltraServers are available in the following AWS local zone.

Region code	Region name
us-east-1-dfw-2a	Dallas Local Zone (N. Virginia)

> **Note**
>
> Capacity Block sizes of 64 instances are not supported for all instance types in all AWS Regions.

Find and purchase Capacity Blocks

To reserve a Capacity Block, you first need to find a block of time when capacity is available that matches your needs. To find a Capacity Block that is available to reserve, you specify the following.

- The number of instances that you need
- The duration of time you that you need the instances
- The date range that you need your reservation

To search for an available Capacity Block offering, you specify a reservation duration and instance count. You must specify reservation durations in **1-day increments up to 14 days, and in 7-day increments up to 182 days**. Each Capacity Block can have up to 64 instances, and you can have up to 256 instances across Capacity Blocks.

When you request a Capacity Block that matches your specifications, we provide the details of up to 3 available blocks. All Capacity Blocks end at 11:30AM UTC, so the blocks starting on the same day will have durations that are the closest match to your desired duration. One block will have a duration that is slightly less than your desired duration, while the other will have a duration slightly greater than your desired duration.

The offering details include the start time of the reservation, the Availability Zone for the reservation, and the price of the reservation. For more information, see Capacity Blocks pricing and billing.

You can purchase the Capacity Block offering you are shown, or you can modify your search criteria to see the other options that are available. There is no predefined expiration time for the offering, but offerings are only available on a first-come, first-served basis.

When you purchase a Capacity Block offering, you get an immediate response confirming that your Capacity Block was reserved. After confirmation, you will see a new Capacity Reservation in your account with a reservation type of `capacity-block` and a `start-date` set to the start time of the offering that you purchased. Your Capacity Block reservation is created with a state of payment-pending. After the upfront payment is successfully processed, the reservation state changes to scheduled. For more information, see Billing.

> **Note**
>
> To use P6e-GB200 UltraServer Capacity Blocks, you must be opted in to the Dallas Local Zone (N. Virginia) Local Zone.

Console

To find and purchase a Capacity Block

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, select an AWS Region. This choice is important because Capacity Block sizes of 64 instances are not supported for all instance types in all Regions.
3. In the navigation pane, choose **Capacity Reservations**, **Create Capacity Block**.
4. Under **Capacity Block types**, choose either **Instances** or **UltraServers**.
5. Under **Capacity attributes**, you can define your Capacity Block search parameters. By default, the platform is Linux. If you want to select a different operating system, use the AWS CLI. For more information, see Supported platforms.
6. Under **Total capacity** (for Instances) or **UltraServer count** (for UltraServers), specify the number of instances or UltraServers you want to reserve.
7. Under **Duration**, enter the number of days or weeks you need the reservation for.
8. Under **Date range to search for Capacity Blocks**, enter the earliest date that you want your reservation to start.
9. Choose **Find Capacity Blocks**.
10. If a Capacity Block is available that meets your specifications, you see an offering under **Recommended Capacity Blocks**. If there are multiple offerings that meet your specifications, the earliest available Capacity Block offering is shown. To view other Capacity Block offerings, adjust your search inputs and choose **Find Capacity Blocks** again.
11. When you find a Capacity Block offering that you want to purchase, choose **Next**.
12. (Optional) On the **Add tags** page, choose **Add new tag**.

13. The **Review and purchase** page lists the start and end date, duration, total number of instances, and price.

> **Note**
>
> Capacity Blocks can't be canceled after you reserve them.

14. In the popup window **Purchase a Capacity Block**, type confirm, then choose **Purchase**.

AWS CLI

To find an instance Capacity Block

Use the describe-capacity-block-offerings command.

The following example finds instance Capacity Blocks.

```
aws ec2 describe-capacity-block-offerings \
--instance-type p5.48xlarge \
--instance-count 16 \
--start-date-range 2023-08-14T00:00:00Z \
--end-date-range 2023-10-22-T00:00:00Z \
--capacity-duration-hours 48
```

The following example finds UltraServer Capacity Blocks.

```
aws ec2 describe-capacity-block-offerings \
--ultraserver-type u-p6e-gb200x72 \
--ultraserver-count 1 \
--start-date-range 2023-08-14T00:00:00Z \
--end-date-range 2023-10-22-T00:00:00Z \
--capacity-duration-hours 48
```

To purchase a Capacity Block

Use the purchase-capacity-block command with the offering ID of the Capacity Block from the output of the previous example.

```
aws ec2 purchase-capacity-block \
--capacity-block-offering-id cb-0123456789abcdefg \
```

```
--instance-platform Linux/UNIX
```

PowerShell

To find Capacity Blocks

Use the Get-EC2CapacityBlockOffering cmdlet.

The following example finds instance Capacity Blocks.

```
Get-EC2CapacityBlockOffering `
-InstanceType p5.48xlarge `
-InstanceCount 16 `
-CapacityDurationHour 48 `
-StartDateRange 2023-08-14T00:00:00Z `
-EndDateRange 2023-10-22-T00:00:00Z
```

The following example finds UltraServer Capacity Blocks.

```
Get-EC2CapacityBlockOffering `
-UltraserverType u-p6e-gb200x72 `
-UltraserverCount  1 `
-CapacityDurationHour 48 `
-StartDateRange 2023-08-14T00:00:00Z `
-EndDateRange 2023-10-22-T00:00:00Z
```

To purchase a Capacity Block

Use the New-EC2EC2CapacityBlock cmdlet with the offering ID of the Capacity Block from the output of the previous example.

```
New-EC2EC2CapacityBlock `
-CapacityBlockOfferingId cb-0123456789abcdefg `
-InstancePlatform Linux/UNIX
```

Launch instances using Capacity Blocks

To use your Capacity Block, you must specify the Capacity Block reservation ID when launching instances. Launching an instance into a Capacity Block reduces the available capacity by the number of instances launched. For example, if your purchased instance capacity is eight instances and you launch four instances, the available capacity is reduced by four.

If you terminate an instance running in the Capacity Block before the reservation ends, you can launch a new instance in its place. When you stop or terminate an instance in a Capacity Block, it takes several minutes to clean up your instance before you can launch another instance to replace it. During this time, your instance will be in a stopping or `shutting-down` state. After this process is complete, your instance state will change to `stopped` or `terminated`. Then, the available capacity in your Capacity Block will update to show another instance available to use.

Requirements

- Your instance can't launch in a subnet in a different Availability Zone from the Availability Zone where your Capacity Block is located.
- Your instance can't launch using an AMI with a different platform than the platform for your Capacity Block.
- To use `P6e-GB200` UltraServer Capacity Blocks, you must be opted in to the Dallas Local Zone (N. Virginia) Local Zone.

Console

To launch instances into a Capacity Block

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, select the Region for your Capacity Block reservation.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. Follow the procedure to launch an instance.
5. Expand **Advanced details**, and for **Purchasing option**, choose **Capacity Blocks**. Then do one of the following:
   - To launch the instances into a specific Capacity Block, for **Capacity Reservation** choose **Specify Capacity Reservation**, and then select the Capacity Block.
   - (*UltraServers only*) To launch the instances into an UltraServer Capacity Block resource group, for **Capacity Reservation** choose **Specify Capacity Reservation resource group**, and then select the resource group.
6. Choose **Launch instance**.

AWS CLI

To launch instances using into a Capacity Block

Use the [run-instances](https://docs.aws.amazon.com/cli/latest/reference/ec2/run-instances.html) command with the `instance-market-options MarketType` option.

The following example launches an instance into a specific Capacity Block.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--count 1 \
--instance-type p5.48xlarge \
--key-name my-key-pair \
--subnet-id subnet-0abcdef1234567890 \
--instance-market-options MarketType='capacity-block' \
--capacity-reservation-specification
 CapacityReservationTarget={CapacityReservationId=capacity_block_id}
```

The following example launches an instance into an UltraServer Capacity Block resource group.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--count 1 \
--instance-type p6e-gb200.36xlarge \
--key-name my-key-pair \
--subnet-id subnet-0abcdef1234567890 \
--instance-market-options MarketType='capacity-block' \
--capacity-reservation-specification
 CapacityReservationTarget={CapacityReservationResourceGroupArn=resource_group_arn}
```

PowerShell

To launch instances into a Capacity Block

Use the [New-EC2Instance](https://docs.aws.amazon.com/powershell/latest/reference/items/New-EC2Instance.html) cmdlet with the `-InstanceMarketOption` option defined as follows.

```
$marketoption = New-Object Amazon.EC2.Model.InstanceMarketOptionsRequest
$marketoption.MarketType = "capacity-block"
```

The following example launches an instance into a specific Capacity Block.

```
New-EC2Instance `
```

```
-ImageId ami-0abcdef1234567890 `
-InstanceType p5.48xlarge `
-KeyName "my-key-pair" `
-SubnetId subnet-0abcdef1234567890 `
-InstanceMarketOptions $marketoption `
-CapacityReservationTarget_CapacityReservationId capacity_block_id
```

The following example launches an instance into an UltraServer Capacity Block resource group.

```
New-EC2Instance `
-ImageId ami-0abcdef1234567890 `
-InstanceType p6e-gb200.36xlarge `
-KeyName "my-key-pair" `
-SubnetId subnet-0abcdef1234567890 `
-InstanceMarketOptions $marketoption `
-CapacityReservationTarget_CapacityReservationResourceGroupArn "resource_group_arn"
```

View Capacity Blocks

After you reserve a Capacity Block, you can view the Capacity Block reservation in your AWS account. You can view the `start-date` and `end-date` to see when your reservation will begin and end. Before a Capacity Block reservation begins, the available capacity appears as zero. You can see how many instances will be available in your Capacity Block by the tag value for the tag key `aws:ec2capacityreservation:incrementalRequestedQuantity`.

When a Capacity Block reservation begins, the reservation state changes from `scheduled` to `active`. We emit an event through Amazon EventBridge to notify you that the Capacity Block is available to use. For more information, see Monitor Capacity Blocks using EventBridge.

Capacity Blocks have the following states:

- `payment-pending` – The upfront payment hasn't been processed yet.
- `payment-failed`—The payment couldn't be processed in the 12 hour time frame. Your Capacity Block was released.
- `scheduled` – The payment was processed and the Capacity Block reservation hasn't started yet.
- `active` – The reserved capacity is available for your use.
- `expired` – The Capacity Block reservation expired automatically at the date and time specified in your reservation request. The reserved capacity is no longer available for your use.

Console

To view Capacity Blocks

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Capacity Reservations**.
3. On the **Capacity Reservations overview** page, you see a resource table with details about all of your Capacity Reservation resources. To find your Capacity Blocks reservations, select **Capacity Blocks** from the dropdown list above **Capacity Reservation ID**. In the table, you can see information about your Capacity Blocks such as start and end dates, duration, and status.
4. For more details about a Capacity Block, select the reservation ID for the Capacity Block that you want to view. The **Capacity Reservation details** page displays all the properties of the reservation and the number of instances in use and available in the Capacity Block.

> **Note**
>
> Before a Capacity Block reservation begins, the available capacity appears as zero. You can see how many instances will be available when the Capacity Block reservation starts by using the following tag value for the tag key: `aws:ec2capacityreservation:incrementalRequestedQuantity`.

AWS CLI

To view Capacity Blocks

By default, when you use the [describe-capacity-reservations] command both On-Demand Capacity Reservations and Capacity Block reservations are listed. To view only your Capacity Block reservations, filter for reservations of type `capacity-block`.

```
aws ec2 describe-capacity-reservations \
    --filters Name=reservation-type,Values=capacity-block
```

PowerShell

To view Capacity Blocks

Use the [Get-EC2CapacityReservation] cmdlet. By default, both On-Demand Capacity Reservations and Capacity Block reservations are listed. To view only your Capacity Block reservations, filter for reservations of type `capacity-block`.

```
Get-EC2CapacityReservation `
    -Filter @{Name="reservation-type"; Values="capacity-block"}
```

Extend Capacity Blocks

With Capacity Blocks, you reserve compute capacity for your workloads, ensuring availability and consistency. To accommodate your changing needs, you can extend the duration of your existing Capacity Blocks as required.

To extend a Capacity Block, it must have a status of `active` or `scheduled`, and have no extensions that are `payment-pending`. You can request to extend the duration of your Capacity Block up to a minimum of 1 hour or a maximum of 56 days before it expires. You can extend your Capacity Block by 1-day increments up to 14 days, and 7-day increments up to 182 days (26 weeks) total. When you extend your Capacity Block, its end date will be updated so that your instances can continue to run without disruption.

- There is no limit to the number of extensions you can apply to a Capacity Block
- Your Capacity Reservation ID will remain the same after extending the block
- Capacity Blocks can only be extended if there is sufficient capacity available to support them, which is not guaranteed.

Billing

The price of a Capacity Block offering is charged up front. The extension will remain in `payment-pending` until the bill is paid. If your payment can't be processed within 12 hours, or up to 35 minutes before the Capacity Block is scheduled to end (whichever comes first), your extension is not successful and the status changes to `payment-failed`. Your Capacity Block reservation will remain `active` and will be terminated on the original end date.

After your payment is processed successfully, the Capacity Block extension status changes to `payment-succeeded` and the end date of the Capacity Block reservation will be updated to the new end date. The details of your extension can be viewed in the **Capacity Block Extension details** section of the console, or by using the describe-capacity-block-extension-history command.

Extend your Capacity Block

Console

To extend a Capacity Block

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Capacity Reservations**.
3. On the **Capacity Reservations overview** page, you see a resource table with details about all of your Capacity Reservations resources. Select the reservation ID for the Capacity Block that you want to extend.
4. From the **Actions** drop down menu, choose **Extend Capacity Block**.
5. Under **Duration**, enter the number of days or weeks you need to extend the reservation for.
6. Choose **Find Capacity Block**.
7. If a Capacity Block is available that meets your specifications, an offering appears under **Recommended Capacity Blocks**. To view other Capacity Block offerings, adjust your search inputs and choose **Find Capacity Blocks** again.
8. When you find a Capacity Block offering that you want to purchase, choose **Extend**.
9. In the pop-up window **Extend Capacity Block**, enter *confirm*, then choose **Extend**.

AWS CLI

To find a Capacity Block extension

Use the [describe-capacity-block-extension-offerings] command. The following example searches for a 48 hour Capacity Block extension for the specified Reservation.

```
aws ec2 describe-capacity-block-extension-offerings \
    --capacity-reservation-id cr-1234567890abcdefg \
    --capacity-block-extension-duration-hours 48
```

To extend a Capacity Block

Use the [purchase-capacity-block-extension] command. Specify the extension offering ID from the output of the previous example.

```
aws ec2 purchase-capacity-block-extension \
    --capacity-block-extension-offering-id cbe-0123456789abcdefg \
    --capacity-reservation-id cr-1234567890abcdefg
```

PowerShell

To find a Capacity Block extension

Use the [Get-EC2CapacityBlockExtensionOffering] cmdlet. The following example searches for a 48 hour Capacity Block extension for the specified Reservation.

```
Get-EC2CapacityBlockExtensionOffering `
    -CapacityReservationId cr-1234567890abcdefg `
    -CapacityBlockExtensionDurationHour 48
```

To extend a Capacity Block

Use the [Invoke-EC2CapacityBlockExtension] cmdlet. Specify the extension offering ID from the output of the previous example.

```
Invoke-EC2CapacityBlockExtension `
    -CapacityBlockExtensionOfferingId cbe-0123456789abcdefg `
    -CapacityReservationId cr-1234567890abcdefg
```

Create a resource group for UltraServer Capacity Blocks

You can use AWS Resource Groups to create logical collections of UltraServer Capacity Blocks. After you create the resource group, you can add UltraServer Capacity Blocks that you own in your account. After you add the UltraServer Capacity Blocks, you can target instances launches to the resource group instead of the individual Capacity Blocks. Instances that target a resource group match with any UltraServer Capacity Blocks in the group that has matching attributes and available capacity. If the resource group does not have an UltraServer Capacity Block with matching attributes and available capacity, the instance launch fails.

If an UltraServer Capacity Block is removed from a resource group while it has running instances, those instances continue to run in the Capacity Block. If an UltraServer Capacity Block in a group ends while it has running instances, the instances are terminated.

You can't add instance Capacity Blocks to a resource group.

To create a resource group for UltraServer Capacity Blocks, use one of the following methods.

AWS CLI

To create a resource group for UltraServer Capacity Blocks

Use the create-group AWS CLI command, and for `--configuration`, specify the following:

```
{
  "Configuration": [
    {
      "Type": "AWS::EC2::CapacityReservationPool",
      "Parameters": [
        {
          "Name": "instance-type",
          "Values": [
            "instance_type"
          ]
        },
        {
          "Name": "reservation-type",
          "Values": [
            "capacity-block"
          ]
        }
      ]
    },
    {
      "Type": "AWS::ResourceGroups::Generic",
      "Parameters": [
        {
          "Name": "allowed-resource-types",
```

```
            "Values": [
              "AWS::EC2::CapacityReservation"
            ]
          }
        ]
      }
    ]
}
```

PowerShell

To create a resource group for UltraServer Capacity Blocks

Use the New-RGGroup cmdlet. For `-Configuration`, specify the following:

```
{
  "Configuration": [
    {
      "Type": "AWS::EC2::CapacityReservationPool",
      "Parameters": [
        {
          "Name": "instance-type",
          "Values": [
            "instance_type"
          ]
        },
        {
          "Name": "reservation-type",
          "Values": [
            "capacity-block"
          ]
        }
      ]
    },
    {
      "Type": "AWS::ResourceGroups::Generic",
      "Parameters": [
        {
          "Name": "allowed-resource-types",
          "Values": [
            "AWS::EC2::CapacityReservation"
          ]
        }
      ]
```

```
        }
    ]
}
```

After you create a resource group for UltraServer Capacity Block, use one of the following methods to add existing UltraServer Capacity Blocks to it.

AWS CLI

To add an UltraServer Capacity Block to a resource group

Use the group-resources command. For `--group` specify the name of the resource group you created. For `--resource-arns`, specify the ARNs of the UltraServer Capacity Blocks to add.

```
aws resource-groups group-resources \
--group MyCRGroup \
--resource-arns capacity_block_arn
```

PowerShell

To add an UltraServer Capacity Block to a resource group

Use the Add-RGResource cmdlet. For `-Group` specify the name of the resource group you created. For `-ResourceArn` , specify the ARNs of the UltraServer Capacity Blocks to add.

The following example adds two Capacity Reservations to the specified group.

```
Add-RGResource `
-Group MyCRGroup `
-ResourceArn capacity_block_arn
```

Monitor Capacity Blocks using EventBridge

When your Capacity Block reservation starts, Amazon EC2 will emit an event through EventBridge that indicates your capacity is ready to use. Forty minutes before your Capacity Block reservation ends, you receive another EventBridge event that tells you that any instances running in the reservation will begin to terminate in 10 minutes. For more information about EventBridge events, see Amazon EventBridge Events.

The following event structures for events emitted for Capacity Blocks:

Capacity Block Delivered

The following example shows an event for Capacity Block Delivered.

```
{
  "customer_event_id": "[Capacity Reservation Id]-delivered",
  "detail_type": "Capacity Block Reservation Delivered",
  "source": "aws.ec2",
  "account": "[Customer Account ID]",
  "time": "[Current time]",
  "resources": [
    "[ODCR ARN]"
  ],
  "detail": {
    "capacity-reservation-id": "[ODCR ID]",
    "end-date": "[ODCR End Date]"
  }
}
```

Capacity Block Expiration Warning

The following example shows an event for Capacity Block Expiration Warning.

```
{
  "customer_event_id": "[Capacity Reservation Id]-approaching-expiry",
  "detail_type": "Capacity Block Reservation Expiration Warning",
  "source": "aws.ec2",
  "account": "[Customer Account ID]",
  "time": "[Current time]",
  "resources": [
    "[ODCR ARN]"
  ],
  "detail": {
    "capacity-reservation-id": "[ODCR ID]",
    "end-date": "[ODCR End Date]"
  }
}
```

Logging Capacity Blocks API calls with AWS CloudTrail

Capacity Blocks is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Capacity Blocks. CloudTrail captures API calls for Capacity Blocks as events. The calls captured include calls from the Capacity Blocks console and code calls to the Capacity Blocks API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Capacity Blocks. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to Capacity Blocks, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Capacity Blocks information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Capacity Blocks, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see Viewing events with CloudTrail Event history.

For an ongoing record of events in your AWS account, including events for Capacity Blocks, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple regions and Receiving CloudTrail log files from multiple accounts

All Capacity Blocks actions are logged by CloudTrail and are documented in the Amazon EC2 API Reference. For example, calls to the `CapacityBlockScheduled`, and `CapacityBlockActive` actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.

- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity element.

Understanding Capacity Blocks log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following examples show CloudTrail log entries for:

- TerminateCapacityBlocksInstances
- CapacityBlockPaymentFailed
- CapacityBlockScheduled
- CapacityBlockActive
- CapacityBlockFailed
- CapacityBlockExpired

> **Note**
>
> Some fields have been redacted from the examples for data privacy.

TerminateCapacityBlocksInstances

```
{
  "eventVersion": "1.05",

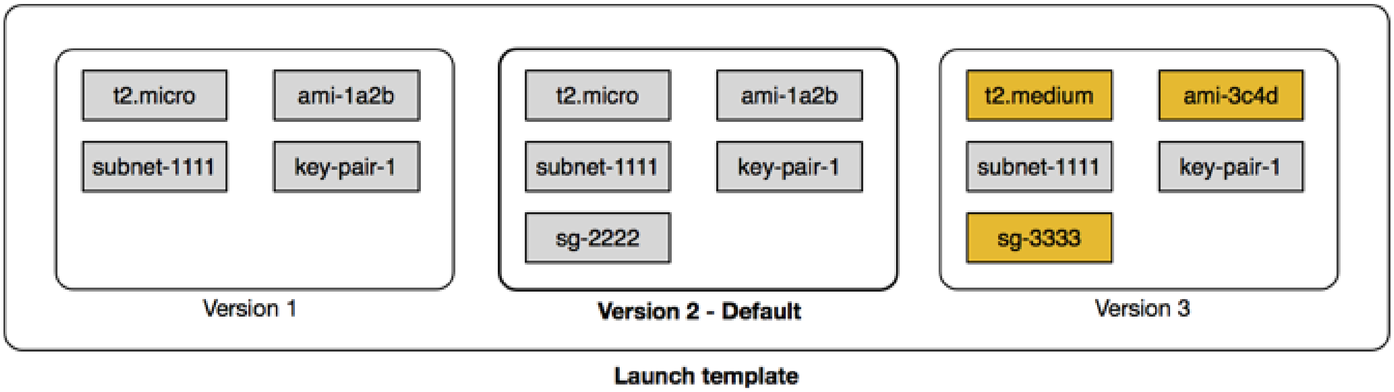
Store instance launch parameters in Amazon EC2 launch templates

You can use an Amazon EC2 *launch template* to store instance launch parameters so that you don't have to specify them every time you launch an Amazon EC2 instance. For example, you can create a launch template that stores the AMI ID, instance type, and network settings that you typically use to launch instances. When you launch an instance using the Amazon EC2 console, an AWS SDK, or a command line tool, you can specify the launch template instead of entering the parameters again.

For each launch template, you can create one or more numbered *launch template versions*. Each version can have different launch parameters. When you launch an instance from a launch template, you can use any version of the launch template. If you don't specify a version, the default version is used. You can set any version of the launch template as the default version—by default, it's the first version of the launch template.

The following diagram shows a launch template with three versions. The first version specifies the instance type, AMI ID, subnet, and key pair to use to launch the instance. The second version is based on the first version and also specifies a security group for the instance. The third version uses different values for some of the parameters. Version 2 is set as the default version. If you launched an instance from this launch template, the launch parameters from version 2 would be used if no other version were specified.



Contents

Restrictions for Amazon EC2 launch templates

The following restrictions apply to launch templates and launch template versions:

- **Quotas** – To view the quotas for your launch templates and launch template versions, open the Service Quotas console or use the list-service-quotas AWS CLI command. Each AWS account can have up to a maximum of 5,000 launch templates per Region and up to 10,000 versions per launch template. Your accounts might have different quotas based on their age and usage history.
- **Parameters are optional** – Launch template parameters are optional. However, you must ensure that your instance launch request includes all required parameters. For example, if your launch template does not include an AMI ID, you must specify an AMI ID when launching an instance with this launch template.
- **Parameters not validated** – Launch template parameters are not fully validated when you create the launch template. If you specify incorrect values or use unsupported parameter combinations, instances will fail to launch using this launch template. To avoid issues, make sure to specify

correct values and use supported parameter combinations. For example, to launch an instance in a placement group, you must specify a supported instance type.

- **Tags** – You can tag a launch template, but you can't tag a launch template version.
- **Immutable** – Launch templates are immutable. To modify a launch template, you must create a new version of the launch template.
- **Version numbers** – Launch template versions are numbered in the order in which they are created. When you create a launch template version, you can't specify the version number yourself.

IAM permissions required for Amazon EC2 launch templates

You can use IAM permissions to control whether users can list, view, create, or delete launch templates or launch template versions.

> **Important**
>
> You can't use resource-level permissions to restrict the resources that users can specify in a launch template when they create a launch template or launch template version. Therefore, make sure that only trusted administrators are granted permission to create launch templates and launch template versions.

You must grant anyone that will use a launch template the permissions required to create and access the resources that are specified in the launch template. For example:

- To launch an instance from a shared private Amazon Machine Image (AMI), the user must have launch permission for the AMI.
- To create EBS volumes with tags from existing snapshots, the user must have read access to the snapshots, and permissions to create and tag volumes.

Contents

- [Control versioning permissions]
- [Control access to tags on launch templates]

ec2:CreateLaunchTemplate

To create a launch template in the console or by using the APIs, the principal must have the `ec2:CreateLaunchTemplate` permission in an IAM policy. Whenever possible, use tags to help you control access to the launch templates in your account.

For example, the following IAM policy statement gives the principal permission to create launch templates only if the template uses the specified tag (*purpose*=*testing*).

```
{
    "Sid": "IAMPolicyForCreatingTaggedLaunchTemplates",
    "Action": "ec2:CreateLaunchTemplate",
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/purpose": "testing"
        }
    }
}
```

Principals who create launch templates might need some related permissions, such as:

- **ec2:CreateTags** – To add tags to the launch template during the `CreateLaunchTemplate` operation, the `CreateLaunchTemplate` caller must have the `ec2:CreateTags` permission in an IAM policy.
- **ec2:RunInstances** – To launch EC2 instances from the launch template that they created, the principal must also have the `ec2:RunInstances` permission in an IAM policy.

For resource-creating actions that apply tags, users must have the `ec2:CreateTags` permission. The following IAM policy statement uses the `ec2:CreateAction` condition key to allow users to create tags only in the context of `CreateLaunchTemplate`. Users cannot tag existing launch templates or any other resources. For more information, see [Grant permission to tag Amazon EC2 resources during creation].

```
{
```

```
    "Sid": "IAMPolicyForTaggingLaunchTemplatesOnCreation",
    "Action": "ec2:CreateTags",
    "Effect": "Allow",
    "Resource": "arn:aws:ec2:us-east-1:111122223333:launch-template/*",
    "Condition": {
        "StringEquals": {
            "ec2:CreateAction": "CreateLaunchTemplate"
        }
    }
}
```

The IAM user who creates a launch template doesn't automatically have permission to use the launch template that they created. Like any other principal, the launch template creator needs to get permission through an IAM policy. If an IAM user wants to launch an EC2 instance from a launch template, they must have the `ec2:RunInstances` permission. When granting these permissions, you can specify that users can only use launch templates with specific tags or specific IDs. You can also control the AMI and other resources that anyone using launch templates can reference and use when launching instances by specifying resource-level permissions for the `RunInstances` call. For example policies, see Launch templates.

ec2:DescribeLaunchTemplates

To list and view launch templates in the account, the principal must have the `ec2:DescribeLaunchTemplates` permission in an IAM policy. Because `Describe` actions do not support resource-level permissions, you must specify them without conditions and the value of the resource element in the policy must be `"*"`.

For example, the following IAM policy statement gives the principal permission to list and view all launch templates in the account.

```
{
    "Sid": "IAMPolicyForDescribingLaunchTemplates",
    "Action": "ec2:DescribeLaunchTemplates",
    "Effect": "Allow",
    "Resource": "*"
}
```

ec2:DescribeLaunchTemplateVersions

Principals who list and view launch templates should also have the `ec2:DescribeLaunchTemplateVersions` permission to retrieve the entire set of attributes that make up the launch templates.

To list and view launch template versions in the account, the principal must have the `ec2:DescribeLaunchTemplateVersions` permission in an IAM policy. Because `Describe` actions do not support resource-level permissions, you must specify them without conditions and the value of the resource element in the policy must be `"*"`.

For example, the following IAM policy statement gives the principal permission to list and view all launch template versions in the account.

```
{
    "Sid": "IAMPolicyForDescribingLaunchTemplateVersions",
    "Effect": "Allow",
    "Action": "ec2:DescribeLaunchTemplateVersions",
    "Resource": "*"
}
```

ec2:DeleteLaunchTemplate

> **Important**
>
> Use caution when giving principals permission to delete a resource. Deleting a launch template might cause a failure in an AWS resource that relies on the launch template.

To delete a launch template, the principal must have the `ec2:DeleteLaunchTemplate` permission in an IAM policy. Whenever possible, use tag-based condition keys to limit the permissions.

For example, the following IAM policy statement gives the principal permission to delete launch templates only if the template has the specified tag (*`purpose`*=*`testing`*).

```
{
    "Sid": "IAMPolicyForDeletingLaunchTemplates",
    "Action": "ec2:DeleteLaunchTemplate",
    "Effect": "Allow",
    "Resource": "*",
```

```
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/purpose": "testing"
        }
    }
}
```

Alternatively, you can use ARNs to identify the launch template that the IAM policy applies to.

A launch template has the following ARN.

```
"Resource": "arn:aws:ec2:us-east-1:111122223333:launch-template/lt-09477bcd97b0d310e"
```

You can specify multiple ARNs by enclosing them in a list, or you can specify a `Resource` value of `"*"` without the `Condition` element to allow the principal to delete any launch template in the account.

Control versioning permissions

For trusted administrators, you can grant access for creating and deleting versions of a launch template, and for changing the default version of a launch template, by using IAM policies similar to the following examples.

> **Important**
>
> Be cautious when giving principals permission to create launch template versions or modify launch templates.
>
> - When you create a launch template version, you affect any AWS resources that allow Amazon EC2 to launch instances on your behalf with the `Latest` version.
> - When you modify a launch template, you can change which version is the `Default` and therefore affect any AWS resources that allow Amazon EC2 to launch instances on your behalf with this modified version.
>
> You also need to be cautious in how you handle AWS resources that interact with the `Latest` or `Default` launch template version, such as EC2 Fleet and Spot Fleet. When a different launch template version is used for `Latest` or `Default`, Amazon EC2 does not re-check user permissions for actions to be completed when launching new instances to fulfil the fleet's target capacity because there is no user interaction with the AWS

resource. By granting a user permission to call the `CreateLaunchTemplateVersion` and `ModifyLaunchTemplate` APIs, the user is effectively also granted the `iam:PassRole` permission if they point the fleet to a different launch template version that contains an instance profile (a container for an IAM role). It means that a user can potentially update a launch template to pass an IAM role to an instance even if they don't have the `iam:PassRole` permission. You can manage this risk by being careful when granting permissions to who can create and manage launch template versions.

ec2:CreateLaunchTemplateVersion

To create a new version of a launch template, the principal must have the `ec2:CreateLaunchTemplateVersion` permission for the launch template in an IAM policy.

For example, the following IAM policy statement gives the principal permission to create launch template versions only if the version uses the specified tag (*`environment`*=*`production`*). Alternatively, you can specify one or multiple launch template ARNs, or you can specify a `Resource` value of `"*"` without the `Condition` element to allow the principal to create versions of any launch template in the account.

```
{
    "Sid": "IAMPolicyForCreatingLaunchTemplateVersions",
    "Action": "ec2:CreateLaunchTemplateVersion",
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/environment": "production"
        }
    }
}
```

ec2:DeleteLaunchTemplateVersion

Important

As always, you should exercise caution when giving principals permission to delete a resource. Deleting a launch template version might cause a failure in an AWS resource that relies on the launch template version.

To delete a launch template version, the principal must have the `ec2:DeleteLaunchTemplateVersion` permission for the launch template in an IAM policy.

For example, the following IAM policy statement gives the principal permission to delete launch template versions only if the version uses the specified tag (*environment*=*production*). Alternatively, you can specify one or multiple launch template ARNs, or you can specify a `Resource` value of `"*"` without the `Condition` element to allow the principal to delete versions of any launch template in the account.

```
{
    "Sid": "IAMPolicyForDeletingLaunchTemplateVersions",
    "Action": "ec2:DeleteLaunchTemplateVersion",
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/environment": "production"
        }
    }
}
```

ec2:ModifyLaunchTemplate

To change the `Default` version that is associated with a launch template, the principal must have the `ec2:ModifyLaunchTemplate` permission for the launch template in an IAM policy.

For example, the following IAM policy statement gives the principal permission to modify launch templates only if the launch template uses the specified tag (*environment*=*production*). Alternatively, you can specify one or multiple launch template ARNs, or you can specify a `Resource` value of `"*"` without the `Condition` element to allow the principal to modify any launch template in the account.

```
{
    "Sid": "IAMPolicyForModifyingLaunchTemplates",
    "Action": "ec2:ModifyLaunchTemplate",
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/environment": "production"
        }
```

```
    }
}
```

Control access to tags on launch templates

You can use condition keys to limit tagging permissions when the resource is a launch template. For example, the following IAM policy allows removing only the tag with the *temporary* key from launch templates in the specified account and Region.

```
{
    "Sid": "IAMPolicyForDeletingTagsOnLaunchTemplates",
    "Action": "ec2:DeleteTags",
    "Effect": "Allow",
    "Resource": "arn:aws:ec2:us-east-1:111122223333:launch-template/*",
    "Condition": {
        "ForAllValues:StringEquals": {
            "aws:TagKeys": ["temporary"]
        }
    }
}
```

For more information about conditions keys that you can use to control the tag keys and values that can be applied to Amazon EC2 resources, see Control access to specific tags.

Use Amazon EC2 launch templates to control launching Amazon EC2 instances

You can control the configuration of your Amazon EC2 instances by specifying that users can only launch instances if they use a launch template, and that they can only use a specific launch template. You can also control who can create, modify, describe, and delete launch templates and launch template versions.

Use launch templates to control launch parameters

A launch template can contain all or some of the parameters to configure an instance at launch. However, when you launch an instance using a launch template, you can override parameters that are specified in the launch template. Or, you can specify additional parameters that are not in the launch template.

> **Note**
>
> You can't remove launch template parameters during launch (for example, you can't specify a null value for the parameter). To remove a parameter, create a new version of the launch template without the parameter and use that version to launch the instance.

To launch instances, users must have permission to use the `ec2:RunInstances` action. Users must also have permissions to create or use the resources that are created or associated with the instance. You can use resource-level permissions for the `ec2:RunInstances` action to control the launch parameters that users can specify. Alternatively, you can grant users permissions to launch an instance using a launch template. This enables you to manage launch parameters in a launch template rather than in an IAM policy, and to use a launch template as an authorization vehicle for launching instances. For example, you can specify that users can only launch instances using a launch template, and that they can only use a specific launch template. You can also control the launch parameters that users can override in the launch template. For example policies, see Launch templates.

Control the use of launch templates

By default, users do not have permissions to work with launch templates. You can create a policy that grants users permissions to create, modify, describe, and delete launch templates and launch template versions. You can also apply resource-level permissions to some launch template actions to control a user's ability to use specific resources for those actions. For more information, see the following example policies: Example: Work with launch templates.

Take care when granting users permissions to use the `ec2:CreateLaunchTemplate` and `ec2:CreateLaunchTemplateVersion` actions. You can't use resource-level permissions to control which resources users can specify in the launch template. To restrict the resources that are used to launch an instance, ensure that you grant permissions to create launch templates and launch template versions only to appropriate administrators.

Important security concerns when using launch templates with EC2 Fleet or Spot Fleet

To use launch templates, you must grant your users permissions to create, modify, describe, and delete launch templates and launch template versions. You can control who can create launch templates and launch template versions by controlling access to the `ec2:CreateLaunchTemplate` and `ec2:CreateLaunchTemplateVersion` actions. You can also control who can modify launch templates by controlling access to the `ec2:ModifyLaunchTemplate` action.

> **Important**
>
> If an EC2 Fleet or Spot Fleet is configured to use the Latest or Default launch template version, the fleet is not aware if Latest or Default are later changed to point to a different launch template version. When a different launch template version is used for Latest or Default, Amazon EC2 does not re-check permissions for actions to be completed when launching new instances to fulfil the fleet's target capacity. This is an important consideration when granting permissions to who can create and manage launch template versions, particularly the `ec2:ModifyLaunchTemplate` action that allows a user to change the Default launch template version.

By granting a user permission to use the EC2 actions for the launch template APIs, the user is effectively also granted the `iam:PassRole` permission if they create or update an EC2 Fleet or Spot Fleet to point to a different launch template version that contains an instance profile (a container for an IAM role). It means that a user can potentially update a launch template to pass an IAM role to an instance even if they don't have the `iam:PassRole` permission. For more information and an example IAM policy, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the *IAM User Guide*.

For more information, see Control the use of launch templates and Example: Work with launch templates.

Create an Amazon EC2 launch template

You can create an Amazon EC2 launch template by specifying your own values for the instance configuration parameters, or by getting the values from an existing launch template or Amazon EC2 instance.

You don't need to specify a value for every parameter in the launch template; you need only specify one instance configuration parameter to create a launch template. To indicate parameters that you choose not to specify, select **Don't include in launch template** when using the console. When using a command line tool, don't include the parameters to indicate that you're choosing not to specify them in the launch template.

If you want to specify an AMI in the launch template, you can either select an AMI, or specify a Systems Manager parameter that will point to an AMI on instance launch.

When an instance is launched with a launch template, the values that are specified in the launch template are used to configure the corresponding instance parameters. If a value isn't specified in the launch template, then the default value for the corresponding instance parameter is used.

Tasks

- Create a launch template by specifying parameters
- Create a launch template from an existing launch template
- Create a launch template from an instance
- Use a Systems Manager parameter instead of an AMI ID

Create a launch template by specifying parameters

To create a launch template, you must specify the launch template name and at least one instance configuration parameter.

For a description of each parameter, see Reference for Amazon EC2 instance configuration parameters.

Console

To create a launch template

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. Under **Launch template name and description**, do the following:
   a. For **Launch template name**, enter a descriptive name for the launch template.
   b. For **Template version description**, provide a brief description of this version of the launch template.
   c. To tag the launch template on creation, expand **Template tags**, choose **Add new tag**, and then enter a tag key and value pair. Choose **Add new tag** again for each additional tag to add.

> **Note**
>
> To tag the resources that are created when an instance is launched, you must specify the tags under **Resource tags**. For more information, see Step 9 in this procedure.

4. Under **Application and OS Images (Amazon Machine Image)**, you can either keep **Don't include in launch template** selected, or choose the operating system (OS) for the instance, and then choose an AMI. Alternatively, you can specify a Systems Manager parameter instead of specifying an AMI. For more information, see [Use a Systems Manager parameter instead of an AMI ID](#).

   An AMI is a template that contains the operating system and software required to launch an instance.

5. Under **Instance type**, you can either keep **Don't include in launch template** selected, or select an instance type, or specify instance attributes and let Amazon EC2 identify the instance types with those attributes.

   > **Note**
   >
   > Specifying instance attributes is supported only when the launch template is used by Auto Scaling groups, EC2 Fleet, and Spot Fleet to launch instances. For more information, see [Create mixed instances group using attribute-based instance type selection](#) and [Specify attributes for instance type selection for EC2 Fleet or Spot Fleet](#).
   > If you plan to use the launch template in the [launch instance wizard](#) or with the [RunInstances API](#), you can't specify instance type attributes.

   The instance type determines the hardware configuration (CPU, memory, storage, and networking capacity) and size of the host computer used for an instance.

   If you're not sure which instance type to choose, you can do the following:

   - Choose **Compare instance types** to compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.

- Choose **Get advice** to get guidance and suggestions for instance types from the EC2 instance type finder. For more information, see Get recommendations from EC2 instance type finder.

> **Note**
>
> Depending on when you created your account, you might be eligible to use Amazon EC2 under the Free Tier.
> If your created your AWS account before July 15, 2025 and it's less than 12 months old, you can use Amazon EC2 under the Free Tier by selecting the **t2.micro** instance type, or the **t3.micro** instance type in Regions where **t2.micro** is unavailable. Be aware that when you launch a **t3.micro** instance, it defaults to **Unlimited** mode, which might incur additional charges based on CPU usage. If an instance type can be used under the Free Tier, it is labeled **Free tier eligible**.
> If you created your AWS account on or after July 15, 2025, you can use **t3.micro**, **t3.small**, **t4g.micro**, **t4g.small**, **c7i-flex.large**, and **m7i-flex.large** instance types for 6 months or until your credits are used up.
> For more information, see Free Tier benefits before and after July 15, 2025.

6. Under **Key pair (login)**, for **Key pair name**, either keep **Don't include in launch template** selected, or choose an existing key pair, or create a new one.
7. Under **Network settings**, you can either keep **Dont include in launch template** selected, or you can specify values for the various network settings.
8. Under **Configure storage**, if you specified an AMI in the launch template, the AMI includes one or more volumes of storage, including the root volume (**Volume 1 (AMI Root)**. You can optionally specify additional volumes to attach to the instance. To add a new volume, choose **Add new volume**.
9. Under **Resource tags**, to tag the resources that are created when an instance is launched, choose **Add tag**, and then enter a tag key and value pair. For **Resource types**, specify the resources to tag on creation. You can specify the same tag for all the resources, or specify different tags for different resources. Choose **Add tag** again for each additional tag to add.

   You can specify tags for the following resources that are created when a launch template is used:

   - Instances

- Volumes
- Elastic graphics
- Spot Instance requests
- Network interfaces

> **Note**
>
> To tag the launch template itself, you must specify the tags under **Template tags**. For more information, see Step 3 in this procedure.

10. For **Advanced details**, expand the section to view the fields and optionally specify any additional parameters for your instance.
11. Use the **Summary** panel to review your launch template configuration. You can navigate to any section by choosing its link and then make any necessary changes.
12. When you're ready to create your launch template, choose **Create launch template**.

AWS CLI

To create a launch template

Use the create-launch-template command.

```
aws ec2 create-launch-template \
    --launch-template-name TemplateForWebServer \
    --version-description WebVersion1 \
    --tag-specifications 'ResourceType=launch-
template,Tags=[{Key=purpose,Value=production}]' \
    --launch-template-data file://template-data.json
```

The following is example JSON that specifies the launch template data for the instance configuration. Save the JSON to a file and include it in the `--launch-template-data` parameter as shown in the example command.

```
{
    "NetworkInterfaces": [{
        "AssociatePublicIpAddress": true,
        "DeviceIndex": 0,
```

```
        "Ipv6AddressCount": 1,
        "SubnetId": "subnet-0abcdef1234567890"
    }],
    "ImageId": "ami-0abcdef1234567890",
    "InstanceType": "r5.4xlarge",
    "TagSpecifications": [{
        "ResourceType": "instance",
        "Tags": [{
            "Key":"Name",
            "Value":"webserver"
        }]
    }],
    "CpuOptions": {
        "CoreCount":4,
        "ThreadsPerCore":2
    }
}
```

The following is example output.

```
{
    "LaunchTemplate": {
        "LatestVersionNumber": 1,
        "LaunchTemplateId": "lt-01238c059e3466abc",
        "LaunchTemplateName": "TemplateForWebServer",
        "DefaultVersionNumber": 1,
        "CreatedBy": "arn:aws:iam::123456789012:root",
        "CreateTime": "2017-11-27T09:13:24.000Z"
    }
}
```

PowerShell

To create a launch template

Use the New-EC2LaunchTemplate cmdlet.

```
$launchTemplateData = [Amazon.EC2.Model.RequestLaunchTemplateData]@{
    ImageId = 'ami-0abcdef1234567890'
    InstanceType = 'r5.4xlarge'
    NetworkInterfaces = @(

 [Amazon.EC2.Model.LaunchTemplateInstanceNetworkInterfaceSpecificationRequest]@{
```

```
            AssociatePublicIpAddress = $true
            DeviceIndex = 0
            Ipv6AddressCount = 1
            SubnetId = 'subnet-0abcdef1234567890'
        }
    )
    TagSpecifications = @(
        [Amazon.EC2.Model.LaunchTemplateTagSpecificationRequest]@{
            ResourceType = 'instance'
            Tags = [Amazon.EC2.Model.Tag]@{
                Key = 'Name'
                Value = 'webserver'
            }
        }
    )
    CpuOptions = [Amazon.EC2.Model.LaunchTemplateCpuOptionsRequest]@{
        CoreCount = 4
        ThreadsPerCore = 2
    }
}
$tagSpecificationData = [Amazon.EC2.Model.TagSpecification]@{
    ResourceType = 'launch-template'
    Tags = [Amazon.EC2.Model.Tag]@{
        Key = 'purpose'
        Value = 'production'
    }
}
New-EC2LaunchTemplate -LaunchTemplateName 'TemplateForWebServer' `
    -VersionDescription 'WebVersion1' `
    -LaunchTemplateData $launchTemplateData `
    -TagSpecification $tagSpecificationData
```

The following is example output.

```
CreatedBy            : arn:aws:iam::123456789012:root
CreateTime           : 9/19/2023 16:57:55
DefaultVersionNumber : 1
LatestVersionNumber  : 1
LaunchTemplateId     : lt-01238c059eEXAMPLE
LaunchTemplateName   : TemplateForWebServer
Tags                 : {purpose}
```

Create a launch template from an existing launch template

You can clone an existing launch template and then adjust the parameters to create a new launch template. However, you can only do this when using the Amazon EC2 console. The AWS CLI does not support cloning a template. For a description of each parameter, see Reference for Amazon EC2 instance configuration parameters.

Console

To create a launch template from an existing launch template

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. For **Launch template name**, enter a descriptive name for the launch template.
4. For **Template version description**, provide a brief description of this version of the launch template.
5. To tag the launch template on creation, expand **Template tags**, choose **Add new tag**, and then enter a tag key and value pair.
6. Expand **Source template**, and for **Launch template name** choose a launch template on which to base the new launch template.
7. For **Source template version**, choose the launch template version on which to base the new launch template.
8. Adjust any launch parameters as required, and then choose **Create launch template**.

Create a launch template from an instance

You can clone the parameters of an existing Amazon EC2 instance and then adjust the parameters to create a launch template. For a description of each parameter, see Reference for Amazon EC2 instance configuration parameters.

Console

To create a launch template from an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.

3. Select the instance, and choose **Actions**, **Image and templates**, **Create template from instance**.
4. Provide a name, description, and tags, and adjust the launch parameters as required.

> **Note**
>
> When you create a launch template from an instance, the instance's network interface IDs and IP addresses are not included in the template.

5. Choose **Create launch template**.

AWS CLI

You can use the AWS CLI to create a launch template from an existing instance by first getting the launch template data from an instance, and then creating a launch template using the launch template data.

To get launch template data from an instance

- Use the get-launch-template-data command and specify the instance ID. You can use the output as a base to create a new launch template or launch template version. By default, the output includes a top-level `LaunchTemplateData` object, which cannot be specified in your launch template data. Use the `--query` option to exclude this object.

```
aws ec2 get-launch-template-data \
    --instance-id i-0123d646e8048babc \
    --query "LaunchTemplateData"
```

The following is example output.

```
    {
        "Monitoring": {},
        "ImageId": "ami-8c1be5f6",
        "BlockDeviceMappings": [
            {
                "DeviceName": "/dev/xvda",
                "Ebs": {
                    "DeleteOnTermination": true
                }
            }
```

```
        ],
        "EbsOptimized": false,
        "Placement": {
            "Tenancy": "default",
            "GroupName": "",
            "AvailabilityZone": "us-east-1a"
        },
        "InstanceType": "t2.micro",
        "NetworkInterfaces": [
            {
                "Description": "",
                "NetworkInterfaceId": "eni-35306abc",
                "PrivateIpAddresses": [
                    {
                        "Primary": true,
                        "PrivateIpAddress": "10.0.0.72"
                    }
                ],
                "SubnetId": "subnet-7b16de0c",
                "Groups": [
                    "sg-7c227019"
                ],
                "Ipv6Addresses": [
                    {
                        "Ipv6Address": "2001:db8:1234:1a00::123"
                    }
                ],
                "PrivateIpAddress": "10.0.0.72"
            }
        ]
    }
```

You can write the output directly to a file, for example:

```
aws ec2 get-launch-template-data \
    --instance-id i-0123d646e8048babc \
    --query "LaunchTemplateData" >> instance-data.json
```

To create a launch template using launch template data

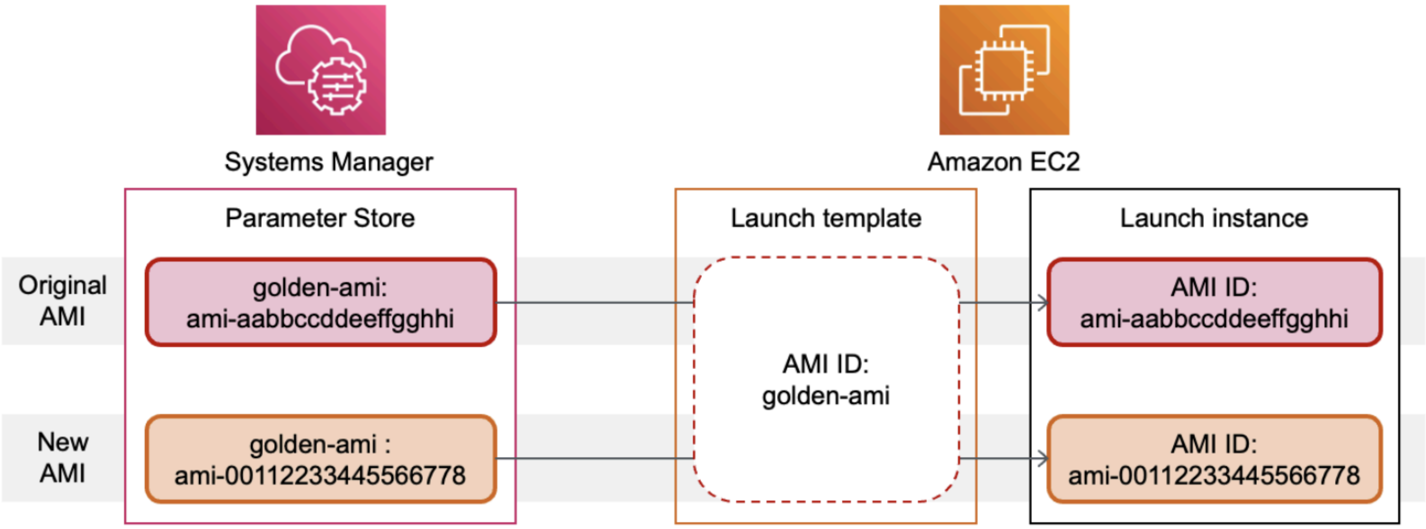
- Use the create-launch-template command to create a launch template using the output from the previous procedure. For more information about creating a launch template using the AWS CLI, see Create a launch template by specifying parameters.

Use a Systems Manager parameter instead of an AMI ID

Instead of specifying an AMI ID in your launch templates, you can specify an AWS Systems Manager parameter. If the AMI ID changes, you can update the AMI ID in one place by updating the Systems Manager parameter in the Systems Manager Parameter Store. Parameters can also be shared with other AWS accounts. You can centrally store and manage AMI parameters in one account and share them with every other account that needs to reference them. By using a Systems Manager parameter, all your launch templates can be updated in a single action.

A Systems Manager parameter is a user-defined key-value pair that you create in the AWS Systems Manager Parameter Store. The Parameter Store provides a central place to store your application configuration values.

In the following diagram, the `golden-ami` parameter is first mapped to the original AMI `ami-aabbccddeeffgghhi` in the Parameter Store. In the launch template, the value for the AMI ID is `golden-ami`. When an instance is launched using this launch template, the AMI ID resolves to `ami-aabbccddeeffgghhi`. Later, the AMI is updated resulting in a new AMI ID. In the Parameter Store, the `golden-ami` parameter is mapped to the new `ami-00112233445566778`. *The launch template remains unchanged.* When an instance is launched using this launch template, the AMI ID resolves to the new `ami-00112233445566778`.



Systems Manager parameter format for AMI IDs

Launch templates require that user-defined Systems Manager parameters adhere to the following format when used in place of an AMI ID:

- Parameter type: `String`
- Parameter data type: `aws:ec2:image` – This ensures that Parameter Store validates that the value you enter is in the proper format for an AMI ID.

For more information about creating a valid parameter for an AMI ID, see [Creating Systems Manager parameters] in the *AWS Systems Manager User Guide*.

Systems Manager parameter format in launch templates

To use a Systems Manager parameter in place of an AMI ID in a launch template, you must use one of the following formats when specifying the parameter in the launch template:

To reference a public parameter:

- `resolve:ssm:public-parameter`

To reference a parameter stored in the same account:

- `resolve:ssm:parameter-name`
- `resolve:ssm:parameter-name:version-number` – The version number itself is a default label
- `resolve:ssm:parameter-name:label`

To reference a parameter shared from another AWS account:

- `resolve:ssm:parameter-ARN`
- `resolve:ssm:parameter-ARN:version-number`
- `resolve:ssm:parameter-ARN:label`

Parameter versions

Systems Manager parameters are versioned resources. When you update a parameter, you create new, successive versions of the parameter. Systems Manager supports [parameter labels] that you can map to specific versions of a parameter.

For example, the `golden-ami` parameter can have three versions: `1`, `2`, and `3`. You can create a parameter label `beta` that maps to version `2`, and a parameter label `prod` that maps to version `3`.

In a launch template, you can specify version 3 of the `golden-ami` parameter by using either of the following formats:

- `resolve:ssm:golden-ami:3`
- `resolve:ssm:golden-ami:prod`

Specifying the version or label is optional. If a version or label is not specified, the latest version of the parameter is used.

Specify a Systems Manager parameter in a launch template

You can specify a Systems Manager parameter in a launch template instead of an AMI ID when you create a launch template or a new version of a launch template.

Console

To specify a Systems Manager parameter in a launch template

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. For **Launch template name**, enter a descriptive name for the launch template.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**.
5. Choose the arrow button to the right of the search bar, and then choose **Specify custom value/Systems Manager parameter**.
6. In the **Specify custom value or Systems Manager parameter** dialog box, do the following:

   a. For **AMI ID or Systems Manager parameter string**, enter the Systems Manager parameter name using one of the following formats:

      To reference a public parameter:

- **`resolve:ssm:`*`public-parameter`***

To reference a parameter stored in the same account:

- **`resolve:ssm:`*`parameter-name`***
- **`resolve:ssm:`*`parameter-name`*`:`*`version-number`***
- **`resolve:ssm:`*`parameter-name`*`:`*`label`***

To reference a parameter shared from another AWS account:

- **`resolve:ssm:`*`parameter-ARN`***
- **`resolve:ssm:`*`parameter-ARN`*`:`*`version-number`***
- **`resolve:ssm:`*`parameter-ARN`*`:`*`label`***

b. Choose **Save**.

7. Specify any other launch template parameters as needed, and then choose **Create launch template**.

For more information, see [Create a launch template by specifying parameters](#).

AWS CLI

To specify a Systems Manager parameter in a launch template

- Use the [create-launch-template](#) command to create the launch template. To specify the AMI to use, enter the Systems Manager parameter name using one of the following formats:

  To reference a public parameter:

  - **`resolve:ssm:`*`public-parameter`***

  To reference a parameter stored in the same account:

  - **`resolve:ssm:`*`parameter-name`***
  - **`resolve:ssm:`*`parameter-name`*`:`*`version-number`***
  - **`resolve:ssm:`*`parameter-name`*`:`*`label`***

To reference a parameter shared from another AWS account:

- **resolve:ssm:*parameter-ARN***
- **resolve:ssm:*parameter-ARN*:*version-number***
- **resolve:ssm:*parameter-ARN*:*label***

The following example creates a launch template that specifies the following:

- A name for the launch template (*TemplateForWebServer*)
- A tag for the launch template (*purpose*=*production*)
- The data for the instance configuration, specified in a JSON file:
  - The AMI to use (resolve:ssm:*golden-ami*)
  - The instance type to launch (*m5.4xlarge*)
  - A tag for the instance (*Name*=*webserver*)

```
aws ec2 create-launch-template \
    --launch-template-name TemplateForWebServer \
    --tag-specifications 'ResourceType=launch-
template,Tags=[{Key=purpose,Value=production}]' \
    --launch-template-data file://template-data.json
```

The following is an example JSON file that contains the launch template data for the instance configuration. The value for ImageId is the Systems Manager parameter name, entered in the required format resolve:ssm:*golden-ami*.

```
{"LaunchTemplateData": {
    "ImageId": "resolve:ssm:golden-ami",
    "InstanceType": "m5.4xlarge",
    "TagSpecifications": [{
        "ResourceType": "instance",
        "Tags": [{
            "Key":"Name",
            "Value":"webserver"
        }]
    }]
  }
```

```
}
```

Verify that a launch template gets the correct AMI ID

To resolve the Systems Manager parameter to the actual AMI ID

Use the describe-launch-template-versions command and include the `--resolve-alias` parameter.

```
aws ec2 describe-launch-template-versions \
    --launch-template-name my-launch-template \
    --versions $Default \
    --resolve-alias
```

The response includes the AMI ID for `ImageId`. In this example, when an instance is launched using this launch template, the AMI ID resolves to `ami-0ac394d6a3example`.

```
{
    "LaunchTemplateVersions": [
        {
            "LaunchTemplateId": "lt-089c023a30example",
            "LaunchTemplateName": "my-launch-template",
            "VersionNumber": 1,
            "CreateTime": "2022-12-28T19:52:27.000Z",
            "CreatedBy": "arn:aws:iam::123456789012:user/Bob",
            "DefaultVersion": true,
            "LaunchTemplateData": {
                "ImageId": "ami-0ac394d6a3example",
                "InstanceType": "t3.micro",
            }
        }
    ]
}
```

Related resources

For more information about working with Systems Manager parameters, see the following reference materials in the Systems Manager documentation.

- For information about how to look up the AMI public parameters supported by Amazon EC2, see Calling AMI public parameters.

- For information about sharing parameters with other AWS accounts or through AWS Organizations, see Working with shared parameters.
- For information about monitoring whether your parameters are created successfully, see Native parameter support for Amazon Machine Image IDs.

Limitations

- Only EC2 Fleets of type `instant` support using a launch template that has a Systems Manager parameter specified in place of an AMI ID.
- EC2 Fleets of type `maintain` and `request`, and Spot Fleets do not support using a launch template that has a Systems Manager parameter specified in place of an AMI ID. For EC2 Fleets of type `maintain` and `request`, and for Spot Fleets, if you specify an AMI in the launch template, you must specify the AMI ID.
- If you use attribute-based instance selection in your EC2 Fleet, you can't specify a Systems Manager parameter in place of an AMI ID. When using attribute-based instance selection, you must specify the AMI ID.
- Amazon EC2 Auto Scaling provides other restrictions. For more information, see Use AWS Systems Manager parameters instead of AMI IDs in launch templates in the *Amazon EC2 Auto Scaling User Guide*.

Modify a launch template (manage launch template versions)

Launch templates are immutable; after you create a launch template, you can't modify it. Instead, you can create a new version of the launch template that includes any changes you require.

You can create different versions of a launch template, set the default version, describe a launch template version, and delete versions you no longer need.

Tasks

- Create a launch template version
- Set the default launch template version
- Describe a launch template version

Create a launch template version

When you create a launch template version, you can specify new launch parameters or use an existing version as the base for the new version. For a description of each parameter, see [Reference for Amazon EC2 instance configuration parameters](#).

Console

To create a launch template version

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**.
3. Select a launch template, and then choose **Actions**, **Modify template (Create new version)**.
4. For **Template version description**, enter a description for this version of the launch template.
5. (Optional) Expand **Source template** and select a version of the launch template to use as a base for the new launch template version. The new launch template version inherits the launch parameters from this launch template version.
6. Modify the launch parameters as required.
7. Choose **Create launch template**.

AWS CLI

To create a launch template version

Use the create-launch-template-version command. You can specify a source version on which to base the new version. The new version inherits the launch parameters from this version, and you can override parameters using `--launch-template-data`. The following example creates a new version based on version 1 of the launch template and specifies a different AMI ID.

```
aws ec2 create-launch-template-version \
    --launch-template-id lt-0abcd290751193123 \
    --version-description WebVersion2 \
    --source-version 1 \
    --launch-template-data "ImageId=ami-0abcdef1234567890"
```

PowerShell

To create a launch template version

Use the New-EC2LaunchTemplateVersion Cmdlet. You can specify a source version on which to base the new version. The new version inherits the launch parameters from this version, and you can override parameters using `LaunchTemplateData`. The following example creates a new version based on version 1 of the launch template and specifies a different AMI ID.

```
New-EC2LaunchTemplateVersion `
    -LaunchTemplateId lt-0abcd290751193123 `
    -VersionDescription WebVersion2 `
    -SourceVersion 1 `
    -LaunchTemplateData (
        New-Object `
            -TypeName Amazon.EC2.Model.RequestLaunchTemplateData `
            -Property @{ImageId = 'ami-0abcdef1234567890'}
    )
```

Set the default launch template version

You can set the default version for the launch template. When you launch an instance from a launch template and do not specify a version, the instance is launched using the parameters of the default version.

Console

To set the default launch template version

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions**, **Set default version**.
4. For **Template version**, select the version number to set as the default version and choose **Set as default version**.

AWS CLI

To set the default launch template version

Use the modify-launch-template command.

```
aws ec2 modify-launch-template \
```

```
    --launch-template-id lt-0abcd290751193123 \
    --default-version 2
```

PowerShell

To set the default launch template version

Use the Edit-EC2LaunchTemplate cmdlet.

```
Edit-EC2LaunchTemplate `
    -LaunchTemplateId lt-0abcd290751193123 `
    -DefaultVersion 2
```

Describe a launch template version

Using the console, you can view all the versions of the selected launch template, or get a list of the launch templates whose latest or default version matches a specific version number. Using the AWS CLI, you can describe all versions, individual versions, or a range of versions of a specified launch template. You can also describe all the latest versions or all the default versions of all the launch templates in your account.

Console

To describe a launch template version

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**.
3. You can view a version of a specific launch template, or get a list of the launch templates whose latest or default version matches a specific version number.
   - To view a version of a launch template: Select the launch template. On the **Versions** tab, from **Version**, select a version to view its details.
   - To get a list of all the launch templates whose latest version matches a specific version number: From the search bar, choose **Latest version**, and then choose a version number.
   - To get a list of all the launch templates whose default version matches a specific version number: From the search bar, choose **Default version**, and then choose a version number.

AWS CLI

To describe a launch template version

Use the [describe-launch-template-versions](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-launch-template-versions.html) command and specify the version numbers. In the following example, versions *1* and *3* are specified.

```
aws ec2 describe-launch-template-versions \
    --launch-template-id lt-0abcd290751193123 \
    --versions 1 3
```

To describe the latest and default launch template versions in your account

Use the [describe-launch-template-versions](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-launch-template-versions.html) command and specify `$Latest`, `$Default`, or both. You must omit the launch template ID and name in the call. You can't specify version numbers.

```
aws ec2 describe-launch-template-versions \
    --versions "$Latest,$Default"
```

PowerShell

To describe a launch template version

Use the [Get-EC2TemplateVersion](https://docs.aws.amazon.com/powershell/latest/reference/items/Get-EC2TemplateVersion.html) Cmdlet and specify the version numbers. In the following example, versions *1* and *3* are specified.

```
Get-EC2TemplateVersion `
    -LaunchTemplateId lt-0abcd290751193123 `
    -Version 1,3
```

To describe the latest and default launch template versions in your account

Use the [Get-EC2TemplateVersion](https://docs.aws.amazon.com/powershell/latest/reference/items/Get-EC2TemplateVersion.html) Cmdlet and specify `$Latest`, `$Default`, or both. You must omit the launch template ID and name in the call. You can't specify version numbers.

```
Get-EC2TemplateVersion `
    -Version '$Latest','$Default'
```

Delete a launch template or a launch template version

If you no longer require a launch template, you can delete it. Deleting a launch template deletes all of its versions. If you only want to delete a specific version of a launch template, you can do so while retaining the other versions of the launch template.

Deleting a launch template or launch template version doesn't affect any instances that you've launched from the launch template.

Delete a launch template and all of its versions

If you no longer require a launch template, including all of its versions, you can delete the launch template. Deleting a launch template deletes all of its versions.

Console

To delete a launch template and all its versions

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions**, **Delete template**.
4. Enter **`Delete`** to confirm deletion, and then choose **Delete**.

AWS CLI

To delete a launch template and all its versions

Use the delete-launch-template command and specify the launch template.

```
aws ec2 delete-launch-template --launch-template-id lt-01238c059e3466abc
```

PowerShell

To delete a launch template and all its versions

Use the Remove-EC2LaunchTemplate (AWS Tools for PowerShell) command and specify the launch template. If `-Force` is omitted, PowerShell prompts for a confirmation.

```
Remove-EC2LaunchTemplate -LaunchTemplateId lt-0123456789example -Force
```

Delete a launch template version

If you no longer require a launch template version, you can delete it.

Considerations

- You can't replace the version number after you delete it.
- You can't delete the default version of the launch template; you must first assign a different version as the default. If the default version is the only version for the launch template, you must delete the entire launch template.
- When using the console, you can delete one launch template version at a time. When using the AWS CLI, you can delete up to 200 launch template versions in a single request. To delete more than 200 versions in a single request, you can delete the launch template, which also deletes all of its versions.

Console

To delete a launch template version

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions**, **Delete template version**.
4. Select the version to delete and choose **Delete**.

AWS CLI

To delete a launch template version

Use the delete-launch-template-versions command and specify the version numbers to delete. You can specify up to 200 launch template versions to delete in a single request.

```
aws ec2 delete-launch-template-versions \
    --launch-template-id lt-0abcd290751193123 \
    --versions 1
```

PowerShell

To delete a launch template version

Use the Remove-EC2TemplateVersion cmdlet and specify the version numbers to delete. You can specify up to 200 launch template versions to delete in a single request.

```
Remove-EC2TemplateVersion `
    -LaunchTemplateId lt-0abcd290751193123 `
    -Version 1
```

Launch an Amazon EC2 instance

An instance is a virtual server in the AWS Cloud. You launch an instance from an Amazon Machine Image (AMI). The AMI provides the operating system, application server, and applications for your instance.

When you create your AWS account, you can get started with Amazon EC2 for free using the AWS Free Tier. Your Free Tier benefits depend on when you created your AWS account. If your created your AWS account before July 15, 2025 and it's less than 12 months old, you can use the Free Tier to launch and use a `t2.micro` instance for free (in Regions where `t2.micro` is unavailable, you can use a `t3.micro` instance under the Free Tier). You incur charges for your instance or usage that counts against your Free Tier limits while the instance is running, even if it remains idle. For more information, see Amazon EC2 pricing. If you created your AWS account on or after July 15, 2025, you can use `t3.micro`, `t3.small`, `t4g.micro`, `t4g.small`, `c7i-flex.large`, and `m7i-flex.large` instance types for 6 months or until your credits are used up. For more information, see Free Tier benefits before and after July 15, 2025.

When you launch your instance, you can launch your instance in a subnet that is associated with one of the following resources:

- An Availability Zone – This option is the default.
- A Local Zone – To launch an instance in a Local Zone, you must opt in to the Local Zone, and then create a subnet in the zone. For more information, see Get started with Local Zones.
- A Wavelength Zone – To launch an instance in a Wavelength Zone, you must opt in to the Wavelength Zone, and then create a subnet in the zone. For information about how to launch an instance in a Wavelength Zone, see Get started with AWS Wavelength.
- An Outpost – To launch an instance in an Outpost, you must create an Outpost. For information about how to create an Outpost, see Get started with AWS Outposts.

After you launch your instance, you can connect to it and use it. To begin, the instance state is `pending`. When the instance state is `running`, the instance has started booting. There might be a short time before you can connect to the instance. Note that bare metal instance types might take longer to launch.

Depending on how you plan to connect to your instance, you might want to make certain configurations while launching your instance. These configurations could include specifying inbound security group rules for certain traffic or associating an instance profile role. For more information on the connection methods you can use to connect and their requirements, see Connect to your EC2 instance.

The instance receives a public DNS name that you can use to contact the instance from the internet. The instance also receives a private DNS name that other instances within the same VPC can use to contact the instance.

When you're finished with an instance, to avoid incurring unnecessary costs, be sure to terminate it. For more information, see Terminate Amazon EC2 instances.

The following methods are some of the ways that you can launch an instance.

Method	Tool	Documentation
Use the launch instance wizard to specify the launch parameters.	Amazon EC2 console	Launch an EC2 instance using the launch instance wizard in the console
Create a launch template and launch the instance from the launch template.	Amazon EC2 console	Launch EC2 instances using a launch template
Use an existing instance as the base.	Amazon EC2 console	Launch an EC2 instance using details from an existing instance
Use an AMI that you purchased from the AWS Marketplace.	Amazon EC2 console	Launch an Amazon EC2 instance from an AWS Marketplace AMI

Method	Tool	Documentation
Use an AMI that you specify.	AWS CLI	Launching, listing, and deleting Amazon EC2 instances in the AWS CLI
Use an AMI that you specify.	AWS Tools for Windows PowerShell	Launch an Amazon EC2 Instance Using Windows PowerShell
Use EC2 Fleet to provision capacity across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchasing options.	AWS CLI	EC2 Fleet and Spot Fleet
Use a AWS CloudFormation template to specify an instance.	AWS CloudFormation	AWS::EC2::Instance in the *AWS CloudFormation User Guide*
Use a language-specific AWS SDK to launch an instance.	AWS SDK	AWS SDK for .NET AWS SDK for C++ AWS SDK for Go AWS SDK for Java AWS SDK for JavaScript AWS SDK for PHP V3 AWS SDK for Python AWS SDK for Ruby V3

Tutorials for launching EC2 instances

There are different ways to launch and configure an Amazon EC2 instance. The method and configuration you use depends on your specific use case.

The following tutorials can help you learn how to launch EC2 instances. If you're new to Amazon EC2, we recommend that you start with the first tutorial. The tutorials start by introducing you to the basics, and help you build on the basics by introducing more configuration options.

Objective	Link to tutorial
Launch my very first EC2 instance Learn how to quickly launch an Amazon EC2 instance by using the default settings in the Amazon EC2 launch instance wizard. Also learn how to review the instance configuration fields and terminate the instance. Duration: 10 minutes	Tutorial 1: Launch my very first Amazon EC2 instance
Launch a test EC2 instance and connect to it Learn how to launch an Amazon EC2 instance that you can use for testing purposes. This instance will have no advanced configuration and won't store sensitive information. You will also learn about the essential instance configuration settings, how to connect to the instance, and how to stop it. Duration: 30 minutes	Tutorial 2: Launch a test EC2 instance and connect to it

- Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database

Tutorial 1: Launch my very first Amazon EC2 instance

Tutorial objective	Learn how to quickly launch an Amazon EC2 instance by using the default settings in the Amazon EC2 launch instance wizard. Also learn how to review the instance configuration fields and terminate the instance.
EC2 experience	Beginner
Duration	10 minutes
Cost	Free Tier eligible When you create your AWS account, you can get started with Amazon EC2 for free using the AWS Free Tier. If you created your AWS account before July 15, 2025, it's less than 12 months old, and you haven't already exceeded the Free Tier benefits for Amazon EC2, it won't cost you anything to complete this tutorial, because we help you select options that are within the Free Tier benefits. Otherwise, you'll incur the standard Amazon EC2 usage fees from the time that you launch the instance (even if it remains idle) until you terminate it. If you created your AWS account on or after July 15, 2025, it's less than 6 months old, and you haven't used up all your credits, it won't cost you anything to complete this tutorial,

	because we help you select options that are within the Free Tier benefits. For information on how to determine whether you're eligible for the Free Tier, see the section called "Track your Free Tier usage".
Prerequisites	• You must have an AWS account, configure a user with administrator access, and use the administrator user to sign into the AWS Management Console. Not sure how to do this? Try this tutorial: Setting Up Your AWS Environment • You must have general familiarity with the AWS console. Not sure where to start? Try this getting started guide: Getting Started with the AWS Management Console

Tutorial overview

This tutorial is designed for beginners with no prior experience using Amazon EC2. We'll guide you through the steps for creating—we call it *launching*—your very first EC2 instance using the EC2 console. An *instance* is essentially a web server in the AWS Cloud. After launching your instance, we'll show you how to find it in the console. Finally, to help you manage costs, we'll show you how to delete—we call it *terminate*—your instance.

This tutorial is divided into the following short tasks. You must complete each task before moving to the next one.

- Task 1: Launch your instance
- Task 2: Find your instance
- Task 3: View your instance configuration
- Task 4: Terminate your instance

Task 1: Launch your instance

In this task, you'll take the quickest path to launching your instance by doing only the essentials. We'll use the EC2 launch instance wizard, a web-based form that provides all the fields for configuring and launching your instance. It simplifies the process by providing default values for the instance configuration fields.

Before you start

Make sure you've completed the prerequisites listed in the preceding table, including signing into the AWS Management Console with your administrator user.

Follow these steps to quickly launch your instance

1. **Open the Amazon EC2 console:**

   Go to https://console.aws.amazon.com/ec2/.
2. **Open the EC2 launch instance wizard:**

   From the EC2 dashboard, choose **Launch instance**.

   The **Launch an instance** web-based form opens. This is the EC2 launch instance wizard.
3. **Name your instance:**

   Under **Name and tags**, for **Name**, enter a descriptive name like **`My first EC2 instance`**.

   While naming your instance isn't required, it helps identify your instance later.
4. **Proceed without a key pair:**

   Under **Key pair (login)**, for **Key pair name**, choose **Proceed without a key pair (Not recommended)**.

   A key pair can be used for secure login. However, because we won't be logging into the instance in this tutorial, you don't need a key pair for now.
5. **Launch your instance:**

   In the **Summary** panel on the right, choose **Launch instance**.

   Amazon EC2 quickly launches your instance using the default settings. A **Success** banner confirms the launch.

Congratulations! You've successfully launched your very first EC2 instance!

Task 2: Find your instance

In this task, you'll locate the instance that you just launched in the EC2 console.

Follow these steps to find your instance in the EC2 console

1. **Open the Instances page:**

   If you're still on the success page, choose **Instances** in the breadcrumb at the top of the screen. You might need to choose the three ellipses first to access it.

   If you've navigated away, choose **Instances** from the navigation pane.
2. **Locate your instance:**

   In the **Name** column, find your instance by the name you gave it.

Task 3: View your instance configuration

In this task, you'll become familiar with viewing your instance's configuration details.

Follow these steps to view your instance's configuration

1. **Locate the instance ID:**

   In the **Instance ID** column, take note of your instance's unique ID. It begins with **i–** followed by 17 alphanumeric characters, for example, **i-01aeed690c9fb5322**.

   The instance ID is automatically assigned to your instance when it's launched.
2. **Open the instance details page:**

   In the **Instance ID** column, choose the ID link to open the instance details page where you can review its configuration.
3. **Explore instance configuration details:**

   Take a few minutes to explore the configuration details of your instance. In the next tutorial, we'll dive deeper into the configuration. For now, use this time to familiarize yourself with the instance details page.

   Tip: To quickly find a field, press Ctrl+F or command+F on your keyboard.

a. **Instance type:** Can you find the instance type? It might be **t3.micro**, for example.

b. **Public IPv4 address:** Can you find the public IPv4 address that was allocated to your instance? It's in a format similar to the following example: **34.242.148.128**.

c. **Instance owner:** Can you identify the owner of this instance? It's you! Your AWS account number is listed under the **Owner** field.

d. **Instance tags:** The name you gave your instance is actually a tag. Can you find your instance tags? Choose the **Tags** tab. The key is **Name**, and the value is the name you provided.

e. **Launch time:** Can you find when you launched your instance? Choose the **Details** tab and find the **Launch time** field.

f. **Instance state:** Can you verify the state of your instance? It should be **Running**.

Take a few more minutes to explore the other instance configuration fields. When you're ready, proceed to the next task.

Task 4: Terminate your instance

In this task, you'll delete your instance to preserve your Free Tier benefits. In EC2, *terminate* is the term used for deleting an instance.

Follow these steps to terminate your instance

1. **Initiate termination:**

   If you're still on the instance details page, choose the **Instance state** menu (top right), and then choose **Terminate (delete) instance**.

   If you've navigated away, choose **Instances** from the navigation pane. Then, on the **Instances** page, select the checkbox next to the name of your instance, and then choose the **Instance state** menu (top right), and choose **Terminate (delete) instance**.

2. **Confirm termination:**

   In the **Terminate (delete) instance** window that opens, choose the **Terminate (delete)** button to confirm that you want to terminate your instance.

3. **Monitor instance state:**

On the **Instances** page, check the **Instance state** column. The state of your instance changes to **Shutting-down**. If you don't see the full text, try widening the column.

Once the instance has shut down, Amazon EC2 deletes the instance, and it disappears from the **Instances** page.

Key takeaways

In this tutorial, you covered the following key concepts:

- *Instance* refers to an Amazon EC2 web server in the AWS Cloud.
- *Launch* refers to creating an EC2 instance.
- *Terminate* refers to deleting an EC2 instance.
- The EC2 launch instance wizard contains default values for instance configuration, allowing for a quick and easy instance launch.
- The instance ID is a unique identifier automatically assigned to your instance, while the instance name is an optional tag that you can assign for easier identification.

Next steps

To build confidence in launching and terminating instances, consider repeating the steps in this tutorial. Be sure to terminate any instances that you launch to preserve your Free Tier benefits.

Once you're comfortable with these basics, move onto the next tutorial, which provides a deeper dive into key instance configuration fields.

Tutorial 2: Launch a test EC2 instance and connect to it

Tutorial objective	Learn how to launch an Amazon EC2 instance that you can use for testing purposes. This instance will have no advanced configuration and won't store sensitive information. You will also learn about the essential instance configuration settings, how to connect to the instance, and how to stop it.
EC2 experience	Beginner

Duration	30 minutes
Cost	Free Tier eligible When you create your AWS account, you can get started with Amazon EC2 for free using the AWS Free Tier. If you created your AWS account before July 15, 2025, it's less than 12 months old, and you haven't already exceeded the Free Tier benefits for Amazon EC2, it won't cost you anything to complete this tutorial, because we help you select options that are within the Free Tier benefits. Otherwise, you'll incur the standard Amazon EC2 usage fees from the time that you launch the instance (even if it remains idle) until you terminate it. If you created your AWS account on or after July 15, 2025, it's less than 6 months old, and you haven't used up all your credits, it won't cost you anything to complete this tutorial, because we help you select options that are within the Free Tier benefits. For information on how to determine whether you're eligible for the Free Tier, see the section called “Track your Free Tier usage”.
Prerequisites	Complete Tutorial 1: Launch my very first Amazon EC2 instance.

Tutorial overview

This tutorial is designed for beginners who want to launch an EC2 instance that they can use for testing purposes.

We'll explain the key instance configuration fields, and then guide you through the steps for launching a test instance using the default values in the EC2 console. After launching your instance, we'll show you how to log into—we call it *connect to*—your instance. We'll also show you how to create a key pair, which is required for connecting to your instance in this tutorial. Finally, to help manage costs, we'll show you to stop your instance to avoid usage charges.

You'll launch a Linux instance in this tutorial. While the steps in this tutorial can be used for launching instances with other operating systems, the instructions for *connecting* to an instance are specific to Linux instances.

This tutorial is divided into the following short tasks. You must complete each task before moving to the next one.

- Task 1: Familiarize yourself with key components for launching an instance
- Task 2: Review a technical diagram
- Task 3: Create a key pair
- Task 4: Launch your test instance
- Task 5: Find your instance
- Task 6: View your instance configuration
- Task 7: Familiarize yourself with key components for connecting to an instance
- Task 8: Connect to your instance
- Task 9: Stop your instance

Task 1: Familiarize yourself with key components for launching an instance

In this task, you'll explore the key components required to launch an EC2 instance. These are the AMI, instance type, key pair, security group, network (VPC and subnet), and Amazon EBS volume. You'll also explore an optional component, the **Name** tag.

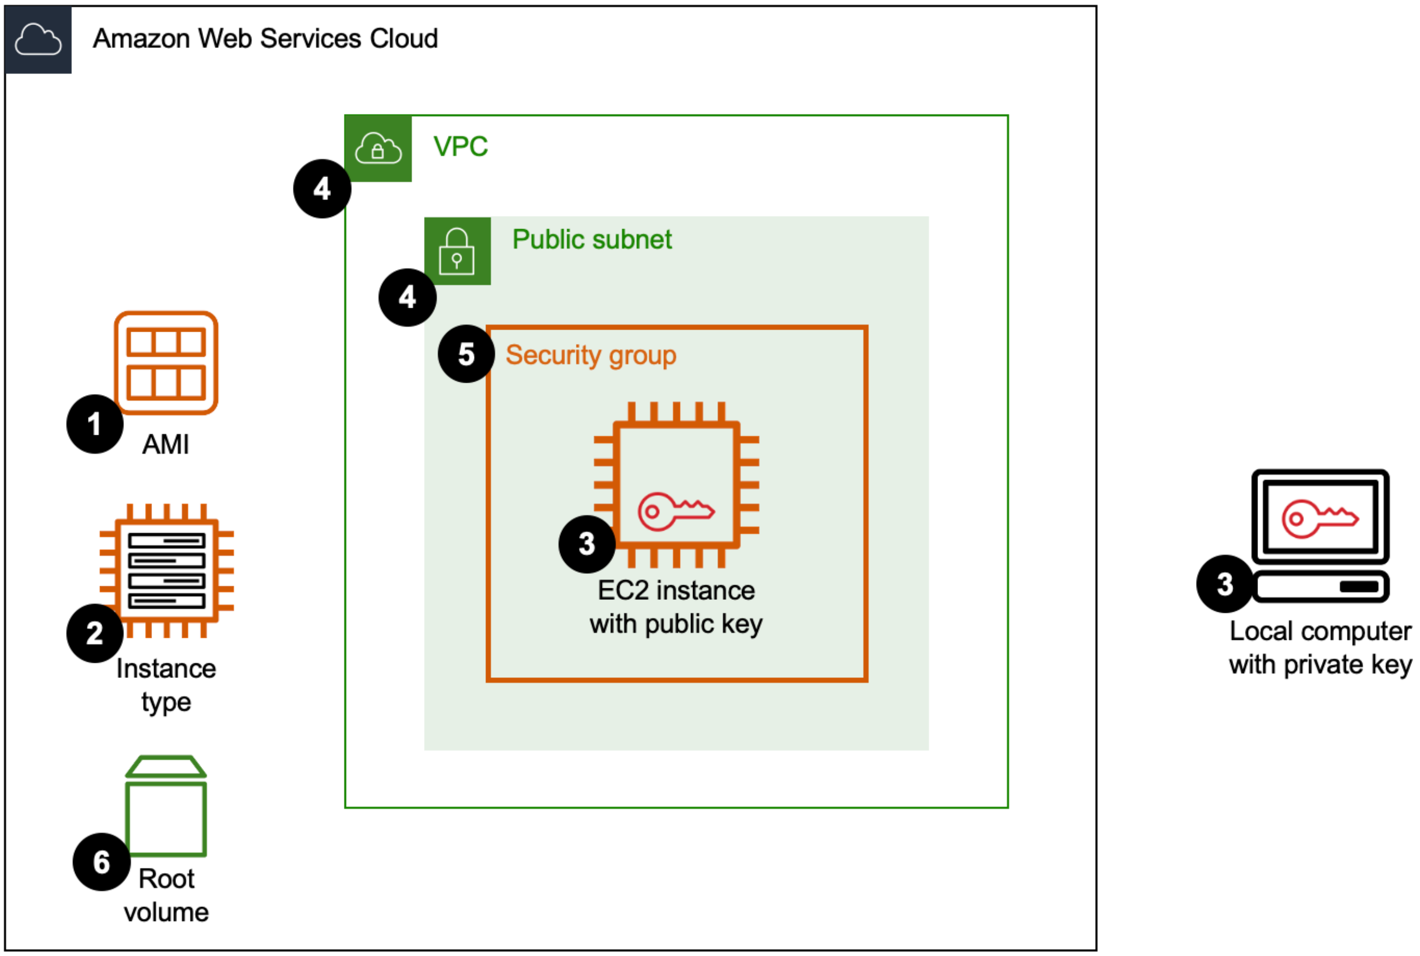
To help visualize these components, think of an instance like a rental house. Just as renting a house gives you a place to live without your needing to own and maintain the property, EC2 instances provide computing power without your needing to own and maintain the underlying infrastructure.

When deciding on the kind of instance to launch, you'll consider the configuration criteria for the instance, just as you would consider the criteria you want from a house. While this analogy simplifies things, it offers a helpful way to visualize the components until you're more familiar with them.

- **AMI – House building materials and amenities:** The Amazon Machine Image (AMI) determines the operating system and applications your instance starts with. This is like choosing the building materials (like brick, steel, or wood) and amenities (like appliances and furnishings) of your house. A base AMI is like an unfurnished house with basic appliances, while a custom AMI with pre-installed software is like a fully furnished house.
- **Instance type – House size and power:** The instance type defines the size and capabilities of your EC2 instance, much like choosing the size of a house, number of rooms, and energy capacity. Each instance type determines the amount of CPU, memory, storage, and networking capacity of your instance. The selected AMI might limit what instance types you can choose.
- **Key pair – Front door key**: A key pair is like the lock and key to the front door of your house. The public key acts as the lock on your instance, while the private key is the key you must keep securely on your local computer. If someone else gets hold of your private key, they can access your instance, much like how someone with your front door key can enter your house.
- **Network (VPC and subnet) – Property boundary, sectioned areas, and house number**: Your virtual private cloud (VPC) is like the entire property where your house is located, and the subnet is the sectioned-off area around the house. If you have multiple houses (instances) on your property, you might want to section them off into distinct areas (different subnets) depending on their purpose. Some houses allow visitors to roam freely through the gardens (public subnets with internet access), while others have fenced-off gardens to restrict entry (private subnets without internet access). Each subnet contains a range of IP addresses, much like house numbers, which can be assigned to instances within the subnet.
- **Security group – The gatekeeper**: The security group acts like a gatekeeper, controlling who is allowed to visit your house. It enforces a set of rules that controls what traffic is allowed to reach your instance. For example, a rule that allows SSH traffic from a specific IP address is like the gatekeeper letting in only a specific person to deliver groceries. Similarly, allowing HTTPS traffic from anywhere is like letting the public come and take a look at the exterior of your house.
- **Amazon EBS volume – Storage units**: EBS volumes are like storage units where you can store your belongings. Each instance has a root volume (where the AMI is stored), and you can add more volumes (storage) at any time as needed.
- **Name tag – The house name:** The **Name** tag functions like a sign on a house, helping you easily identify who lives there. While the **Name** tag makes it easier to distinguish between instances, it's not required when launching an instance.

Task 2: Review a technical diagram

In this task, you'll become familiar with a typical technical diagram that we use in the AWS documentation. The following diagram represents the configuration for the test instance you'll launch in this tutorial. In the previous task, we introduced these components using the analogy of a rental house. Now, we'll focus on the actual EC2 components themselves. The numbered labels correspond to the descriptions that follow.



1. **AMI** – The AMI is the image you choose when launching an instance. It's a template that contains the operating system and software to run on your instance. For example, if you want to launch a Linux instance, you can choose the Amazon Linux 2023 AMI. Or, if you want to launch a Windows instance, you can choose the Microsoft Windows Server 2022 Base AMI. The AMI catalog in the Amazon EC2 console contains 1000s of images to choose from.
2. **Instance type** – The instance type is the hardware that determines the CPU, memory, storage, and networking capacity of the host computer used for your instance. Amazon EC2 offers over

600 instance types to choose from, each varying in hardware configuration and size, allowing you to choose the best fit for your application's needs.

3. **Key pair –** A key pair is set of security credentials that you use to prove your identity when connecting to your instance. The public key is on your instance and the private key is on your local computer.

   In EC2, *connecting to your instance* refers to logging into your instance from your local computer. While there are other ways to securely connect to your instance, in this tutorial we use a key pair.
4. **Network –** The network is made up of a VPC and one or more subnets. A VPC is a virtual network within the AWS Cloud. Every AWS customer has their own VPC dedicated to their AWS account. You'll launch your instance into a subnet in your VPC. A subnet is a range of IP addresses within a VPC. Your default subnet is a public subnet, which means it will assign a public IP address and provide internet access to your instance from outside the Amazon network.
5. **Security group** – A security group acts as a firewall to control the traffic to your instance. A security group contains rules that allow certain types of traffic to enter your instance. To connect through SSH from your local computer to your instance (using your key pair), you need a rule that allows SSH traffic from your local computer.
6. **EBS volume –** An Amazon EBS volume is a storage device that functions like a physical hard drive. Your instance comes with a root volume, which is a special EBS volume that stores the AMI with the operating system and software needed to boot your instance. You can optionally add data volumes. However, since your test instance won't store any sensitive data, you don't need additional encrypted data volumes.

Congratulations! You've completed the conceptual tasks in this tutorial. In the following tasks, you'll use the Amazon EC2 console to create the components you've learned about.

Task 3: Create a key pair

In this task, you'll create a key pair. A key pair consists of two parts: a public key, which you'll add to your instance, and a matching private key, which you'll use to securely connect to your instance. In the next task, you'll select this key pair when launching your instance, which automatically adds the public key to the instance. It's crucial to store the private key securely on your local computer, because anyone with access to it can connect to your instance.

If you prefer to use an existing key pair when you launch your test instance, feel free to skip this task. Otherwise, proceed to create a new key pair.

Before you start

Make sure you've completed the prerequisites listed in the preceding table, including signing into the AWS Management Console with your administrator user.

Follow these steps to create a key pair

1. **Open the Amazon EC2 console:**

   Go to https://console.aws.amazon.com/ec2/.
2. **Navigate to the Key pairs console page:**

   In the navigation pane, under **Network & Security**, choose **Key Pairs**.

   - If you previously created key pairs, they appear in the table.
   - If no key pairs exist, the table is empty.
3. **Create a new key pair:**

   Choose the **Create key pair** button (top right) to open the **Create key pair** web-based form, and enter your key pair details, as follows:

   a. **Name your key pair:** For **Name**, enter a name that will help you recognize the key pair, like **`test-instance-key-pair`**.

      The name can be up to 255 ASCII characters long. It can’t include leading or trailing spaces.
   b. **Choose the key pair type:** For **Key pair type**, choose **ED25519**.

      Linux instances support both RSA and ED25519 key types, while Windows instances support only RSA. Since you'll be launching a Linux instance in this tutorial, you can use an ED25519 key.
   c. **Choose the private key file format:** For **Private key file format**, choose **.pem**.

      This is the format in which your private key file will be saved.
4. **Save the public key to Amazon EC2 and download the private key:**

   Choose the **Create key pair** button (bottom right).

   Amazon EC2 saves the public key, while your browser downloads the private key file automatically to your local computer. The file is named according to the name that you specified for the key pair, and the extension is the file format that you chose. Move the private key file to a secure location on your computer.

> **Important**
>
> This is the only chance you'll have to save the private key file.

5. **Set the permissions on the key (for macOS and Linux users):**

   If you plan to connect to your instance using SSH on a macOS or Linux computer, you must set the correct permissions for your private key file. Open a terminal window and run the following command, replacing *test-instance-key-pair* with the name of your key pair:

   ```
   chmod 400 test-instance-key-pair.pem
   ```

   This command ensures that only you can read the private key file, which is necessary for establishing a secure connection to your instance. Without these permissions, you won't be able to connect using this key pair.

Congratulations! You've successfully created a key pair!

Task 4: Launch your test instance

In this task, you'll quickly launch a test instance using the EC2 launch instance wizard. You'll configure the main instance configuration settings for a Linux instance and use the default values for the other fields.

To help you manage costs, we recommend choosing **Free tier eligible** components.

Follow these steps to launch a test instance

1. **Open the Amazon EC2 console:**

   Go to https://console.aws.amazon.com/ec2/.

2. **Open the EC2 launch instance wizard:**

   From the EC2 dashboard, choose **Launch instance**.

   The **Launch an instance** web-based form opens. This is the EC2 launch instance wizard.

3. **Name your instance:**

Under **Name and tags**, for **Name**, enter a descriptive name like `Test instance`.

The instance name is a tag, where the key is **Name**, and the value is the name that you specify.

Tip: For test instances, a name tag is sufficient. However, for production instances, it’s best practice to establish a tagging policy to standardize tagging across all your resources.

4. **Choose your operating system and software—the Amazon Machine Image (AMI):**

   Under **Application and OS Images (Amazon Machine Image)**, for **Amazon Machine Image (AMI)**, the default selection is **Amazon Linux 2023 AMI**. This AMI is marked **Free tier eligible**. In this tutorial, you'll be launching a Linux instance, so leave the default setting to keep under the Free Tier limits.

5. **Choose your hardware—the instance type:**

   Under **Instance type**, for **Instance type**, keep the default selection for this tutorial. The default instance type can be used under the Free Tier and its hardware is suitable for your test instance.

6. **Prepare for secure login with a key pair:**

   Under **Key pair (login)**, for **Key pair name**, choose the key pair you created in the previous task. If you don't see your key pair in the list, choose the refresh icon (to the right of the list).

   When your instance launches, it will place the public key on the instance. To connect to your instance after it has launched, you'll use the corresponding private key that you downloaded in the previous task.

7. **Configure the network settings to enable internet access:**

   Under **Network settings**, the **Network** (your VPC) and **Subnet** fields are configured by default. Keep the default settings for this tutorial to help you get started quickly. If you haven’t modified your default subnet, your instance will have internet access.

   Tip: Your default subnet is a public subnet, which means it will assign a public IP address and provide internet access to your instance from outside the Amazon network. For test instances, it’s okay to use the default subnet settings that provide internet access. However, for production instances, it’s best practice to only assign a public IP address and use a subnet with internet access when absolutely necessary.

8. **Set up the instance firewall (security group):**

Under **Network settings**, under **Firewall (security groups)**, keep the checkbox **Allow SSH traffic from Anywhere (0.0.0.0)** selected. This will create a new security group for your test instance that allows SSH traffic from any IP address.

A security group acts as a firewall to control the traffic to your instance. To connect through SSH from your local computer to your instance, you need a rule that allows SSH traffic from your local computer.

Tip: The IP address of your local computer might change over time if your internet service provider uses dynamic IP assignment. We're assuming that when you use an instance for testing purposes, you won't use the instance to store sensitive information, and therefore security measures can be less restrictive. For test instances, it's generally acceptable to allow traffic from any IP address (`0.0.0.0/0`) so that you can always connect even if your IP address changes. However, for production instances, especially those with sensitive data, it's best practice to allow traffic only from known IP addresses.

9. **Configure the instance storage:**

   Under **Configure storage**, the **Root volume (Encrypted)** fields are configured by default. Leave the settings as they are to keep under the Free Tier limits.

   Since our test instance won't store any sensitive data, we don't need additional encrypted data volumes.

10. **Review the instance configuration:**

    In the **Summary** panel on the right, you can review your high-level settings before launching your instance.

11. **Launch your instance:**

    When you're ready to launch your instance, in the **Summary** panel, choose **Launch instance**.

    Amazon EC2 quickly launches your instance using the settings that you specified. If you didn't specify a setting, the default is used. A **Success** banner confirms the launch.

Congratulations! You've successfully launched your test instance!

Task 5: Find your instance

In this task, you'll locate the instance that you just launched in the EC2 console.

Follow these steps to find your instance in the EC2 console

1. **Open the Instances page:**

   If you're still on the success page, choose the instance ID in the **Success** banner.

   If you've navigated away, choose **Instances** from the navigation pane.
2. **Locate your instance:**

   In the **Name** column, find your instance by the name you gave it.

Task 6: View your instance configuration

In this task, you'll become familiar with viewing your instance's configuration details.

Follow these steps to view your instance's configuration

1. **Locate your instance:**

   In the **Name** column, find your instance by the name you gave it.
2. **Open the instance details page:**

   Select the checkbox next to the name of your instance, and then choose the **Actions** menu (top right), and choose **View details** to open the instance details page where you can review its configuration.

   In the previous tutorial, you chose the instance's ID link to open the instance details page. You'll discover that there's more than one way to accomplish a task in the EC2 console.
3. **Explore instance configuration details:**

   Take a few minutes to explore the configuration details of your instance.

   Tip: To quickly find a field, press Ctrl+F or command+F on your keyboard.

   a. **AMI:** Can you find the AMI that you used to launch your instance? You can find the information in **AMI ID** and **AMI name** on the **Details** tab.
   b. **Instance type:** Can you find the instance type? It's might be **t3.micro**, for example.
   c. **Key pair:** Can you find the key pair that you selected when you launched your instance? It's specified for **Key pair assigned at launch**. Note that if you change the key pair in the future, the value here won't change.

d. **VPC:** Can you find the ID of your VPC? You'll find all networking-related configuration settings on the **Networking** tab. The VPC ID is in a format similar to the following example: **vpc-1a2b3c4d**

e. **Subnet:** Can you find the ID of the subnet in which you launched your instance? It's in a format similar to the following example: **subnet-1a2b3c4d**

f. **Public IPv4 address:** Can you find the public IPv4 address that was allocated to your instance? It's in a format similar to the following example: **34.242.148.128**.

g. **Security group:** Can you find the inbound rule that was created to allow SSH traffic from anywhere (0.0.0.0./0)? You'll find all security-related configuration settings on the **Security** tab.

h. **Storage:** Can you find the volume that was created for this instance? You'll find all storage-related configuration settings on the **Storage** tab.

i. **Instance tags:** The name you gave your instance is actually a tag. Can you find your instance tags? Choose the **Tags** tab. The key is **Name**, and the value is the name you provided.

j. **Instance state:** Can you verify the state of your instance? It should be **Running**.

Take a few more minutes to explore the other instance configuration fields. When you're ready, proceed to the next task.

Task 7: Familiarize yourself with key components for connecting to an instance

In this task, you'll explore the key components required to connect to an EC2 instance. These are the connection protocol, public DNS, security group, key pair, and instance username.

To help visualize these components, think of connecting to an instance like going to your house:

- **Connection protocol – Your mode of transport:** Just like choosing how to get home, you choose the connection protocol that will take you to your instance. In this tutorial, we'll use SSH (Secure Shell), which creates a secure tunnel for connecting your computer to your instance over the internet.
- **Public DNS – The house address:** Just like your house has a unique address, your EC2 instance has its own public DNS name (for example, `ec2-18-201-118-201.eu-west-1.compute.amazonaws.com`). This public DNS name enables SSH to connect directly to your instance.

- **Security group – The gatekeeper:** Imagine your house has a gatekeeper who controls who may enter or leave. Similarly, the EC2 instance has a security group that acts like a gatekeeper, controlling which types of network traffic are allowed in or out of your instance. Only the traffic you explicitly permit (for example, SSH traffic from your computer's IP address) is allowed in.
- **Private key – Your front door key:** When you launched the instance, you specified a key pair. The public key was placed on the instance, and you kept the private key on your computer. The private key acts as your front door key—without it, you can't get into your instance.
- **Instance username – The resident:** When you arrive at your house, you need to identify yourself to prove you're a resident. Similarly, when connecting to an instance, you provide a username. Different instances have different default usernames, depending on their operating system. For example, Amazon Linux instances use `ec2-user` as the default username.

The connection command

To connect to your EC2 instance, use the following command in a terminal window:

```
ssh -i "test-instance-key-pair.pem" ec2-user@ec2-18-201-118-201.eu-
west-1.compute.amazonaws.com
```

Here's a breakdown of what the command does:

- `ssh` – This command specifies the connection protocol, initiating an SSH (Secure Shell) connection to your instance.
- `-i "test-instance-key-pair.pem"` – The `-i` flag indicates the private key file needed to authenticate the connection. This private key file must match the key pair you specified when launching the instance. If your private key file is saved in a specific folder, specify the full path to the file.
- `ec2-user` – This is the username for logging into the instance. For Amazon Linux instances, the default username is `ec2-user`. Other AMIs might use different default usernames, such as `ubuntu` for Ubuntu instances.
- `@` – This symbol separates the username from the instance's address.
- `ec2-18-201-118-201.eu-west-1.compute.amazonaws.com` – This is the public address of your instance (the public DNS), which includes the public IPv4 address and the AWS Region. It uniquely identifies the instance.

What happens when you run the command

After you run the command, SSH establishes a secure tunnel and authenticates with your private key. If the instance's security group permits the traffic, you gain access to your EC2 instance. You can now control the instance from your computer as if you were sitting right in front of it. You can run commands, install software, and manage files—just like you would on your local machine.

Task 8: Connect to your instance

In this task, you'll connect to your instance using an SSH client on your computer. In the previous task, we introduced the components for connecting to an instance using the analogy of going to your house. Now, we'll focus on connecting to the actual EC2 instance.

There are different ways to connect to an instance. The method you use to connect depends on the instance's operating system. Since you've launched a Linux instance, you'll use an SSH client on your local computer.

First, check if your computer has an SSH client installed

Most computers come with an SSH client pre-installed. To check, open a terminal window on your computer and run the following command:

```
ssh
```

If the command is recognized, you're ready to connect.

If the command isn't recognized, you must install an SSH client. Instructions for installing an SSH client are beyond the scope of this tutorial. If you need help, see SSH connection prerequisites in this user guide or search online for instructions on how to install an SSH client on your operating system.

Follow these steps to connect to your instance

1. **Initiate connecting:**

   If you're on the instance details page in the Amazon EC2 console, choose the **Connect** button (top right).

   If you've navigated away, choose **Instances** from the navigation pane. Then, on the **Instances** page, select the checkbox next to the name of your instance and choose the **Connect** button (top right).

   This opens the **Connect to instance** page.

2. **Choose the connection method:**

   On the **Connect to instance** page, choose the **SSH client** tab.

   Take a moment to review the text on this page, as these are the steps that you'll follow next.

3. **Review the SSH command:**

   Under **Example**, you'll see a command that is automatically generated and customized with your instance's details. The private key name is derived from the name of the public key specified at launch.

   The command looks something like this:

   ```
   ssh -i "test-instance-key-pair.pem" ec2-user@ec2-18-201-118-201.eu-
   west-1.compute.amazonaws.com
   ```

4. **Copy the SSH command:**

   Choose the copy icon next to the example SSH command.

5. **Open a terminal window:**

   On your local computer, open a terminal window.

6. **Paste and run the SSH command:**

   Paste the SSH command into the terminal window. If you saved your private key file in a specific folder, edit the command to include the full file path.

   Press Enter on your keyboard.

   You'll see a response similar to the following:

   ```
   The authenticity of host 'ec2-18-201-118-201.eu-west-1.compute.amazonaws.com
    (18-201-118-201)' can't be established.
   ED25519 key fingerprint is SHA256:examplehxj9aOr1MogvKOoMNskVVIRBQBoq0example.This
    key is not known by any other names.
   Are you sure you want to continue connecting (yes/no/[fingerprint])?
   ```

7. **Complete the connection:**

   Enter **yes** and press Return on your keyboard.

Verifying the fingerprint is beyond the scope of this tutorial. To learn more, see (Optional) Get the instance fingerprint.

Upon a successful connection, the terminal prompt changes to display your instance's public DNS.

Congratulations! You've successfully connected to your instance!

Task 9: Stop your instance

In this task, you'll stop your instance to preserve your Free Tier benefits. When your instance is stopped, you stop incurring costs for it. If you created your AWS account before July 15, 2025 and your qualify for the Free Tier, you will continue to incur costs for the EBS storage.

Follow these steps to stop your instance

1. **Initiate stopping:**

   If you're still on the **Connect to instance** page, choose **Instances** from the breadcrumb. If you've navigated away, choose **Instances** from the navigation pane.

   Then, on the **Instances** page, select the checkbox next to the name of your instance, and then choose the **Instance state** menu (top right), and choose **Stop instance**. When prompted, choose **Stop**.

2. **Monitor instance state:**

   On the **Instances** page, check the **Instance state** column. The state of your instance changes to **Stopping** and then **Stopped**. If you don't see the full text, try widening the column.

   If you think the instance state has changed from **Stopping** to **Stopped**, but you don't see it yet, choose the refresh icon (above the table) to refresh the **Instances** table.

Key takeaways

In this tutorial, you covered the following key concepts:

- *AMI* refers to an Amazon Machine Image, which is a template that contains the operating system and software required to launch an instance.

- *Instance type* refers to the hardware of the host computer used for your instance. It determines the CPU, memory, storage, and networking capacity of your instance.
- *Key pair* refers to the set of public and private keys that you can use for securely connecting to your instance.
- *Network* refers to a *VPC* (a virtual private cloud dedicated to your account within the AWS Cloud) and a *subnet* (a range of IP addresses within your VPC).
- *Security group* refers to a set of rules that controls what traffic can reach your instance.
- *EBS volume* refers to the data storage for your instance. Every instance has a root volume for storing the AMI and one or more optional data volumes.
- *Tags* are metadata that you can optionally assign to your instance. The instance name is a tag, whose **Key** is **Name**, and the **Value** is your choice.
- *Connecting* refers to accessing your instance over the internet.
- *SSH* refers to the Secure Shell connection protocol that you can use to connect to your instance.
- *Public DNS* is your instance's unique public address.
- *Instance username* is determined by the operating system of your instance and required for connecting.
- *Stopping* your instance stops the charges for the instance, but EBS storage charges continue.

Next steps

To build confidence in launching, connecting to, and stopping instances, consider repeating the steps in this tutorial. Be sure to terminate any instances that you launch to preserve your Free Tier benefits.

Once you're comfortable with these basics, you can explore more advanced tutorials. For more tutorials, see Looking for other tutorials?

If you created your AWS account before July 15, 2025, consider watching the following 6-minute video: How can I avoid charges on my account when using AWS Free Tier services

If you created your AWS account on or after July 15, 2025, consider reviewing the following information: Explore AWS services with AWS Free Tier in the *AWS Billing User Guide*

Reference for Amazon EC2 instance configuration parameters

The launch instance wizard and launch template in the Amazon EC2 console provide all the parameters for configuring an Amazon EC2 instance.

Except for the key pair, the launch instance wizard provides a default value for each parameter. You can accept any or all of the defaults, or configure an instance with your own values. When creating a launch template, the parameters are optional. If you use a launch template to launch an instance, the parameters specified in the launch template override the default values in the launch instance wizard. Any parameter not specified in the launch template will default to the value provided by the launch instance wizard.

The parameters are grouped in the launch instance wizard and launch template. The following descriptions are presented according to the parameter groupings in the console.

Parameters for instance configuration

- Name and tags
- Application and OS Images (Amazon Machine Image)
- Instance type
- Key pair (login)
- Network settings
- Configure storage
- Advanced details
- Summary

Name and tags

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. You can tag the instance, volumes, and network interfaces. For Spot Instances, you can tag the Spot Instance request only. For information about tags, see Tag your Amazon EC2 resources.

Specifying an instance name and additional tags is optional.

- For **Name**, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
- To add additional tags, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

You can only specify the instance name when launch an instance. You can't name the instance when you create a launch template, but you can add tags for the resources that are created when the instance is launched.

Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Linux, Apache, and your website.

You can find a suitable AMI as follows. With each option for finding an AMI, you can choose **Cancel** (at top right) to return to the launch instance wizard without choosing an AMI.

Search bar

To search through all available AMIs, enter a keyword in the AMI search bar and then press **Enter**. To select an AMI, choose **Select**.

Recents

The AMIs that you've recently used.

Choose **Recently launched** or **Currently in use**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you.

Choose **Owned by me** or **Shared with me**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

Quick Start

AMIs are grouped by operating system (OS) to help you get started quickly.

First select the OS that you need, and then, from **Amazon Machine Image (AMI)**, select an AMI. To select an AMI that can be used under the AWS Free Tier, make sure that the AMI is marked **Free tier eligible**.

Browse more AMIs

Choose **Browse more AMIs** to browse the full AMI catalog.

- To search through all available AMIs, enter a keyword in the search bar and then press **Enter**.
- To find an AMI by using a Systems Manager parameter, choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**. For more information, see Reference AMIs using Systems Manager parameters.

- To search by category, choose **Quickstart AMIs**, **My AMIs**, **AWS Marketplace AMIs**, or **Community AMIs**.

  The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see Launch an Amazon EC2 instance from an AWS Marketplace AMI. In **Community AMIs**, you can find AMIs that AWS community members have made available for others to use. AMIs from Amazon or a verified partner are marked **Verified provider**.
- To filter the list of AMIs, select one or more check boxes under **Refine results** on the left of the screen. The filter options are different depending on the selected search category.
- Check the **Root device type** listed for each AMI. Notice which AMIs are the type that you need: either **ebs** (backed by Amazon EBS) or **instance-store** (backed by instance store). For more information, see Root device type.
- Check the **Virtualization** type listed for each AMI. Notice which AMIs are the type that you need: either **hvm** or **paravirtual**. For example, some instance types require HVM. For more information about Linux virtualization types, see Virtualization types.
- Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need: either **legacy-bios**, **uefi**, or **uefi-preferred**. For more information, see Instance launch behavior with Amazon EC2 boot modes.
- Choose an AMI that meets your needs, and then choose **Select**.

Warning when changing the AMI

When you launch an instance, if you modify the configuration of any volumes or security groups associated with the selected AMI, and then you choose a different AMI, a window opens to warn you that some of your current settings will be changed or removed. You can review the changes to the security groups and volumes. Furthermore, you can either view which volumes will be added and deleted, or view only the volumes that will be added. This warning does not appear when creating a launch template.

Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see Amazon EC2 instance types.

- **Instance type**: Ensure that the instance type is compatible with the AMI that you've specified. For more information, see Amazon EC2 instance types.

Free Tier – You can use instance types that are labeled **Free tier eligible** for free under the Free Tier. The specific instance types depend on when you created your AWS account.

If your created your AWS account before July 15, 2025 and it's less than 12 months old, you can use Amazon EC2 under the Free Tier by selecting the **t2.micro** instance type, or the **t3.micro** instance type in Regions where **t2.micro** is unavailable. Be aware that when you launch a **t3.micro** instance, it defaults to **Unlimited** mode, which might incur additional charges based on CPU usage.

If you created your AWS account on or after July 15, 2025, you can use **t3.micro**, **t3.small**, **t4g.micro**, **t4g.small**, **c7i-flex.large**, and **m7i-flex.large** instance types for 6 months or until your credits are used up.

For more information, see Free Tier benefits before and after July 15, 2025.

- **Compare instance types**: You can compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.
- **Get advice**: You can get guidance and suggestions for instance types from the EC2 instance type finder. For more information, see Get recommendations from EC2 instance type finder.
- (Launch templates only) **Advanced**: To specify instance attributes and let Amazon EC2 identify the instance types with those attributes, choose **Advanced**, and then choose **Specify instance type attributes**.
  - **Number of vCPUs**: Enter the minimum and maximum number of vCPUs for your compute requirements. To indicate no limits, enter a minimum of `0`, and leave the maximum blank.
  - **Amount of memory (MiB)**: Enter the minimum and maximum amount of memory, in MiB, for your compute requirements. To indicate no limits, enter a minimum of `0`, and leave the maximum blank.
  - Expand **Optional instance type attributes** and choose **Add attribute** to express your compute requirements in more detail. For information about each attribute, see InstanceRequirementsRequest in the *Amazon EC2 API Reference*.
  - **Resulting instance types**: You can preview the instance types that match the specified attributes. To exclude instance types, choose **Add attribute**, and from the **Attribute** list, choose **Excluded instance types**. From the **Attribute value** list, select the instance types to exclude.

Key pair (login)

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see Amazon EC2 key pairs and Amazon EC2 instances.

> **Important**
>
> If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

Network settings

The network settings define the IP addresses, security groups, and network interfaces for your instances. You can use the default network settings or configure them as needed.

- (Launch instance wizard only) **VPC**: Choose an existing VPC for your instance. The default VPC for the Region is selected by default. Alternatively, you can choose a VPC that you created or that was shared with you. For more information, see Virtual private clouds for your EC2 instances.
- **Subnet**: Choose a subnet for your instance or choose **Create new subnet** to create a new subnet using the Amazon VPC console.
  - You can create a subnet in any Availability Zone, Local Zone, Wavelength Zone, or Outpost Zone for the selected VPC.
  - To launch the instance in an IPv6-only subnet, the instance must be a Nitro-based instance.
- (Launch instance wizard only) **Auto-assign Public IP**: Enable or disable auto-assignment of public IPv4 addresses. When launching instances into a default subnet, the default value is **Enable**. When launching instances into a nondefault subnet the default value is **Disable**. For more information, see Public IPv4 addresses.

  You can't enable this option for nondefault subnets if you add a secondary network interface. For more information, see the section called “Assign a public IPv4 address at launch”.
- (Launch instance wizard only) **Auto-assign IPv6 IP**: Enable or disable auto-assignment of IPv6 addresses. For more information, see IPv6 addresses.
- **Firewall (security groups)**: Choose an existing security group or create a new one. Ensure that your security group has rules that allow traffic to and from your instances. All other traffic is ignored.

If you create a new security group, we automatically create an inbound rule that allows you to connect to your instance from all IP addresses over SSH (Linux instances) or RDP (Windows instances. You can remove or modify this rule as needed. You can add rules as needed. For more information, see Configure security group rules.

> **Warning**
>
> Rules that enable all IP addresses to access your instance over SSH or RDP are acceptable if you are briefly launching a test instance and will stop or terminate it after a short time. They are unsafe for production environments. You should authorize only a specific IP address range to access your instances.

This security group is added to the primary network interface and any secondary network interfaces. You can select additional security groups for your network interfaces, but you can't remove the one that you select here.

- **Advanced network configuration** – You can configure the primary network interface as needed. To add a secondary network interface, choose **Add network interface**. The number of network interfaces that you can add depends on the instance type that you selected. Note that this section is available only if you choose a subnet.
  - **Device index**: The device index. The primary network interface must be assigned to index 0.
  - **Network interface**: The network interface. Select **New interface** to let Amazon EC2 create a new interface, or select an existing, available network interface. If you select an existing network interface as the primary network interface, you can't enable **Auto-assign Public IP** for nondefault subnets.
  - **Description**: A description for the new network interface.
  - **Subnet**: The subnet in which to create the new network interface. The instance is launched in the same subnet as the primary network interface.

    You must choose a subnet for a secondary network interface from the same Availability Zone as the subnet for the primary network interface. If you select a subnet from another VPC, the label **Multi-VPC** appears next to the network interface. This enables you to create multi-homed instances across VPCs with different networking and security configurations.

    To launch an EC2 instance into an IPv6-only subnet, you must use a Nitro-based instance. When launching an IPv6-only instance, it is possible that DHCPv6 might not immediately provide the instance with the IPv6 DNS name server. During this initial delay, the instance might not resolve public domains. You can change the configuration file and re-image your AMI so that the file has the IPv6 DNS name server address immediately on booting.

- **Security groups**: The security groups to associate with the network interface. You must choose a security group from the same VPC as the subnet for the network interface.
- (Launch templates only) **Auto-assign public IP**: Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address and instances in a nondefault subnet do not. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see Public IPv4 addresses.
- **Primary IP**: A private IPv4 address from the range of your subnet. Leave blank to let Amazon EC2 choose a private IPv4 address for you.
- **Secondary IP**: Additional private IPv4 addresses from the range of your subnet. Choose **Manually assign** and enter an IPv4 address. Choose **Add IP** to add another IPv4 address. Alternatively, choose **Automatically assign** and enter a value to indicate the number of IPv4 addresses that Amazon EC2 chooses for you.
- (IPv6-only) **IPv6 IPs**: IPv6 addresses from the range of the subnet. Choose **Manually assign** and enter an IPv6 address. Choose **Add IP** to add another IPv6 address. Alternatively, choose **Automatically assign** and enter a value to indicate the number of IPv6 addresses that Amazon EC2 chooses for you.
- **IPv4 Prefixes**: The IPv4 prefixes for the network interface. Choose **Manually assign** and enter an IPv4 prefix. Alternatively, choose **Automatically assign** and enter a value to indicate the number of IPv4 prefixes that Amazon EC2 chooses for you.
- **IPv6 Prefixes**: The IPv6 prefixes for the network interface. Choose **Manually assign** and enter an IPv6 prefix. Alternatively, choose **Automatically assign** and enter a value to indicate the number of IPv6 prefixes that Amazon EC2 chooses for you.
- (Dual-stack and IPv6-only) **Assign Primary IPv6 IP**: If you select a dual-stack or IPv6-only subnet, assign a primary IPv6 address. This helps prevent disruptions to traffic to the instance or network interface. Enable this option if you rely on the IPv6 address not changing. You can't remove the primary IPv6 address later on. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA becomes the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with a network interface and you let Amazon EC2 assign a primary IPv6 address, the first IPv6 GUA address associated with the network interface is the primary IPv6 address.
- **Delete on termination**: Indicates whether the network interface is deleted when the instance is deleted.

- **Interface type**: The network interface type:
  - **ENA**: A high-performance network interface designed to handle high throughput and packet-per-second rates for TCP/IP protocols while minimizing CPU usage. This is the default value. For more information about ENA, see Elastic Network Adapter.
  - **EFA with ENA**: A network interface that supports both ENA and EFA devices for traditional TCP/IP based transport along with SRD based transport. For more information about EFA, see Elastic Fabric Adapter.
  - **EFA-only**: A high-performance network interface designed to handle high throughput, low latency inter-node communication for SRD based transport while bypassing the operating system stack. EFA-only network interfaces do not support IP addresses. For more information about EFA, see Elastic Fabric Adapter.
- **Elastic Fabric Adapter**: Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see Elastic Fabric Adapter for AI/ML and HPC workloads on Amazon EC2.
- **Network card index**: The index of the network card. The primary network interface must be assigned to network card index 0. Some instance types support multiple network cards.
- **ENA Express**: ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. SRD technology uses a packet spraying mechanism to distribute load and avoid network congestion. Enabling ENA Express allows supported instances to communicate using SRD on top of regular TCP traffic when possible. The launch instance wizard or launch template does not include ENA Express configuration for the instance unless you select **Enable** or **Disable** from the list.
- **ENA Express UDP**: If you've enabled ENA Express, you can optionally use it for UDP traffic. The launch instance wizard or launch template does not include ENA Express configuration for the instance unless you select **Enable** or **Disable**.

Configure storage

The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

(Launch instance wizard only) You can use the **Simple** or **Advanced** view. With the **Simple** view, you specify the size and type of the volume. To specify all volume parameters, choose the **Advanced** view (at top right of the card).

By using the **Advanced** view, you can configure each volume as follows:

- **Storage type**: Select Amazon EBS or instance store volumes to associate with your instance. The volume types available in the list depend on the instance type that you've chosen. For more information, see Instance store temporary block storage for EC2 instances and Amazon EBS volumes.
- **Device name**: Select from the list of available device names for the volume.
- **Snapshot**: Select the snapshot from which to restore the volume. You can search for available shared and public snapshots by entering text into the **Snapshot** field.
- **Size (GiB)**: For EBS volumes, you can specify a storage size.
- **Volume type**: For EBS volumes, select a volume type. For more information, see Amazon EBS volume types in the *Amazon EBS User Guide*.
- **IOPS**: If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.
- **Delete on termination**: For Amazon EBS volumes, choose **Yes** to delete the volume when the instance is terminated, or choose **No** to keep the volume. For more information, see Preserve data when an instance is terminated.
- **Encrypted**: If the instance type supports EBS encryption, you can choose **Yes** to enable encryption for the volume. If you have enabled encryption by default in this Region, encryption is enabled for you. For more information, see Amazon EBS encryption in the *Amazon EBS User Guide*.
- **KMS key**: If you selected **Yes** for **Encrypted**, then you must select a customer managed key to use to encrypt the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or specify the ARN of any customer managed key that you created.
- **Throughput**: If you have selected the `gp3` volume type, then you can enter the throughput, in MiB/s, that the volume can support.
- **Volume initialization rate**: If you have selected a snapshot, you can optionally specify the volume initialization rate, in MiB/s, at which the snapshot blocks are to be downloaded from Amazon S3 to the volume. For more information, see Use an Amazon EBS Provisioned Rate for Volume Initialization. To use the default initialization rate or fast snapshot restore (if it is enabled for the selected snapshot), don't specify a rate.
- **File systems**: Mount an Amazon EFS or Amazon FSx file system to the instance. For more information about mounting an Amazon EFS file system, see Use Amazon EFS with Amazon EC2 Linux instances. For more information about mounting an Amazon FSx file system, see Use Amazon FSx with Amazon EC2 instances

Advanced details

For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

- (Launch instance wizard only) **Domain join directory**: Select the AWS Directory Service directory (domain) to which your instance is joined to after launch. If you select a domain, you must select an IAM role with the required permissions. For more information about domain joining, see Seamlessly join an Amazon EC2 Linux instance to your AWS Managed Microsoft AD directory (Linux instances) and Seamlessly join an Amazon EC2 Windows instance to your AWS Managed Microsoft AD directory (Windows instances).
- **IAM instance profile**: Select an IAM instance profile to associate with the instance. This is a container for an IAM role. For more information, see IAM roles for Amazon EC2.
- **Hostname type**: Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see EC2 instance hostnames and domains.
- **DNS Hostname**: Determines if the DNS queries to the resource name or the IP name (depending on what you selected for **Hostname type**) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see EC2 instance hostnames and domains.
- **Instance auto-recovery**: When enabled, recovers your instance if system status checks fail. This setting is enabled by default at launch for supported instance types. For more information, see Configure simplified automatic recovery on an Amazon EC2 instance.
- **Shutdown behavior**: Select whether the instance should stop or terminate when shut down. For more information, see Change instance initiated shutdown behavior.
- **Stop - Hibernate behavior**: To enable hibernation, choose **Enable**. This field is available only if your instance meets the hibernation prerequisites. For more information, see Hibernate your Amazon EC2 instance.
- **Termination protection**: To prevent accidental termination, choose **Enable**. For more information, see Change instance termination protection.
- **Stop protection**: To prevent accidental stopping, choose **Enable**. For more information, see Enable stop protection.
- **Detailed CloudWatch monitoring**: Choose **Enable** to turn on detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see Monitor your instances using CloudWatch.

- **Credit specification**: Choose **Unlimited** to enable applications to burst beyond the baseline for as long as needed. This field is only valid for **T** instances. Additional charges may apply. For more information, see Burstable performance instances.
- **Placement group**: Specify a placement group in which to launch the instance. You can select an existing placement group, or create a new one. Not all instance types support launching an instance in a placement group. For more information, see Placement groups for your Amazon EC2 instances.
- **EBS-optimized instance**: An instance that's optimized for Amazon EBS uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, choose **Enable** to enable it. Additional charges apply. For more information, see the section called "EBS optimization".
- **Instance bandwidth configuration**: You can boost either your networking bandwidth or your EBS bandwidth. For supported instance types only. For more information, see EC2 instance bandwidth weighting configuration.
- **Purchasing option**: Choose **Spot Instances** to request Spot Instances at the Spot price, capped at the On-Demand price, and choose **Customize Spot Instance options** to change the default Spot Instance settings. You can set your maximum price (not recommended), and change the request type, request duration, and interruption behavior. If you do not request a Spot Instance, Amazon EC2 launches an On-Demand Instance by default. For more information, see Manage your Spot Instances.
- **Capacity Reservation**: Specify whether to launch the instance into any open Capacity Reservation (**Open**), a specific Capacity Reservation (**Target by ID**), or a Capacity Reservation group (**Target by group**). To specify that a Capacity Reservation should not be used, choose **None**. For more information, see Launch instances into an existing Capacity Reservation.
- **Tenancy**: Choose whether to run your instance on shared hardware (**Shared**), isolated, dedicated hardware (**Dedicated**), or on a Dedicated Host (**Dedicated host**). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see Amazon EC2 Dedicated Instances and Amazon EC2 Dedicated Hosts.
- **RAM disk ID**: (Only valid for paravirtual (PV) AMIs) Select a RAM disk for the instance. If you have selected a kernel, you might need to select a specific RAM disk with the drivers to support it.
- **Kernel ID**: (Only valid for paravirtual (PV) AMIs) Select a kernel for the instance.
- **Nitro Enclave**: Allows you to create isolated execution environments, called enclaves, from Amazon EC2 instances. Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see What is AWS Nitro Enclaves? in the *AWS Nitro Enclaves User Guide*.

- **License configurations**: You can launch instances against the specified license configuration to track your license usage. For more information, see Create a license configuration in the *AWS License Manager User Guide*.
- **Specify CPU options**: In the launch instance wizard, this field is only visible if the selected instance type supports specifying CPU options. Choose **Specify CPU options** to specify a custom number of vCPUs during launch. Set the number of CPU cores and threads per core. For more information, see CPU options for Amazon EC2 instances.
- **Metadata accessible**: You can enable or disable access to the Instance Metadata Service (IMDS). For more information, see Configure instance metadata options for new instances.
- **Metadata IPv6 endpoint**: You can enable the instance to use the IMDS IPv6 address `[fd00:ec2::254]` to retrieve instance metadata. This option is only available if you are launching Nitro-based instances into an IPv6-supported subnet (dual stack or IPv6 only). For more information about retrieving instance metadata, see Access instance metadata for an EC2 instance.
- **Metadata version**: If you enable access to the IMDS, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see Configure instance metadata options for new instances.
- **Metadata response hop limit**: If you enable the IMDS, you can set the allowable number of network hops for the metadata token. For more information, see Configure instance metadata options for new instances.
- **Allow tags in metadata**: If you select **Enable**, the instance will allow access to all of its tags from its metadata. If no value is specified, then by default, access to the tags in instance metadata is not allowed. For more information, see Enable access to tags in instance metadata.
- **User data**: You can specify user data to configure an instance during launch, or to run a configuration script. For more information about user data for Linux instances, see Run commands when you launch an EC2 instance with user data input. For more information about user data for Windows instances, see How Amazon EC2 handles user data for Windows instances.

Summary

Use the **Summary** panel to specify the number of instances to launch, to review your instance configuration, and to launch your instances.

- **Number of instances**: Enter the number of instances to launch. All of the instances will launch with the same configuration.

> **Tip**
>
> To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

- (Optional) If you specify more than one instance, to help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **consider EC2 Auto Scaling** to create a launch template and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the Amazon EC2 Auto Scaling User Guide.

> **Note**
>
> If Amazon EC2 Auto Scaling marks an instance that is in an Auto Scaling group as unhealthy, the instance is automatically scheduled for replacement where it is terminated and another is launched, and you lose your data on the original instance. An instance is marked as unhealthy if you stop or reboot the instance, or if another event marks the instance as unhealthy. For more information, see Health checks for instances in an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.

- Review the details of your instance, and make any necessary changes. You can navigate directly to a section by choosing its link in the **Summary** panel.
- When you're ready to launch your instance, choose **Launch instance**.

Launch an EC2 instance using the launch instance wizard in the console

You can launch an Amazon EC2 instance using the launch instance wizard in the Amazon EC2 console. The wizard provides default values for the launch parameters, which you can either accept or modify to suit your requirements. The only parameter that is not specified is the key pair. If you choose to accept the default values, you can quickly launch an instance by selecting only a key pair.

> **Important**
>
> You incur charges for the instance while the instance is in the `running` state, even if it remains idle. However, if you qualify for the Free Tier, you might not incur charges. For more information, see Track your Free Tier usage for Amazon EC2.

For a description of each parameter in the launch instance wizard, see Reference for Amazon EC2 instance configuration parameters.

Topics

- Quickly launch an instance
- Launch an instance using defined parameters

Quickly launch an instance

To set up an instance quickly for testing purposes, follow these steps. You'll select the operating system and your key pair, and accept the default values. Except for the key pair, the launch instance wizard provides default values for all of the parameters. You can accept any or all of the defaults, or configure an instance by specifying your own values for each parameter.

For a description of each parameter in the launch instance wizard, see Reference for Amazon EC2 instance configuration parameters.

To quickly launch an instance using the launch instance wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). If needed, select a different Region in which to launch the instance.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
5. Under **Application and OS Images (Amazon Machine Image)**, choose **Quick Start**, and then choose the operating system (OS) for your instance.
6. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
7. In the **Summary** panel, choose **Launch instance**.

Launch an instance using defined parameters

If you're launching an instance that you'll use in production, you'll need to configure the instance to suit your requirements. For a description of each parameter in the launch instance wizard, see Reference for Amazon EC2 instance configuration parameters.

To launch an instance by defining all the launch parameters using the launch instance wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). If needed, select a different Region in which to launch the instance.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance so that you can easily keep track of it.

   The instance name is a tag, where the key is **Name**, and the value is the name that you specify.
5. Under **Application and OS Images (Amazon Machine Image)**, choose the operating system (OS) for your instance, and then choose an AMI.

   An AMI is a template that contains the operating system and software required to launch your instance.
6. Under **Instance type**, choose an instance type.

   The instance type determines the hardware configuration (CPU, memory, storage, and networking capacity) and size of the host computer used for your instance.

   If you're not sure which instance type to choose, you can do the following:

   - Choose **Compare instance types** to compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.
   - Choose **Get advice** to get guidance and suggestions for instance types from the EC2 instance type finder. For more information, see Get recommendations from EC2 instance type finder.

   > **Note**
   >
   > Depending on when you created your account, you might be able to use instance types for free under the Free Tier. These instance types are labeled **Free tier eligible**.

> If your created your AWS account before July 15, 2025 and it's less than 12 months old, you can use Amazon EC2 under the Free Tier by selecting the **t2.micro** instance type, or the **t3.micro** instance type in Regions where **t2.micro** is unavailable. Be aware that when you launch a **t3.micro** instance, it defaults to **Unlimited** mode, which might incur additional charges based on CPU usage.
> If you created your AWS account on or after July 15, 2025, you can use **t3.micro**, **t3.small**, **t4g.micro**, **t4g.small**, **c7i-flex.large**, and **m7i-flex.large** instance types for 6 months or until your credits are used up.
> For more information, see Free Tier benefits before and after July 15, 2025.

7. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one. If you do not require a key pair to connect to your instance, you can choose **Proceed without a key pair (not recommended)**.
8. Under **Network settings**, you can keep the defaults if you're launching a test instance. If you're launching a production instance, it's best practice to control traffic into and out of your instance using network settings and security groups that you define.
9. Under **Configure storage**, you can keep the defaults or specify additional storage. The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

   You can use the **Simple** or **Advanced** view. With the **Simple** view, you specify the size and type of the volume. To specify all volume parameters, choose the **Advanced** view (at top right of the card).
10. For **Advanced details**, expand the section to view the fields and specify any additional parameters for your instance.
11. In the **Summary** panel, you can do the following:

    a. Specify the number of instances to launch.

    b. Review your instance configuration, and navigate directly to a section by choosing its link.

    c. When you're ready to launch your instance, choose **Launch instance**.

    If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.
12. (Optional) You can create a billing alert for the instance. On the confirmation screen, under **Next Steps**, choose **Create billing alerts** and follow the directions. Billing alerts can also be

created after you launch the instance. For more information, see Creating a billing alarm to monitor your estimated AWS charges in the *Amazon CloudWatch User Guide*.

Launch EC2 instances using a launch template

An Amazon EC2 launch template stores instance launch parameters so that you don't have to specify them every time you launch an instance.

Several instance launch services can optionally use launch templates when launching instances, while for other services, like EC2 Fleet, instances can't be launched unless a launch template is used. This topic describes how to use a launch template when launching an instance using the EC2 launch instance wizard, Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet.

For more information about launch templates, including how to create a launch template, see Store instance launch parameters in Amazon EC2 launch templates.

Topics

Launch an Amazon EC2 instance using a launch template

You can use the parameters contained in a launch template to launch an Amazon EC2 instance. After selecting the launch template, but before launching the instance, you can modify the launch parameters.

Instances that are launched using a launch template are automatically assigned two tags with the keys `aws:ec2launchtemplate:id` and `aws:ec2launchtemplate:version`. You can't remove or edit these tags.

Console

To launch an instance using a launch template

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. Use one of the following options to select the launch template:

   - From the Amazon EC2 console dashboard, choose the down arrow next to **Launch instance**, choose **Launch instance from template**, and then for **Source template**, select a launch template.
   - In the navigation pane, choose **Launch Templates**, select the launch template, and choose **Actions**, **Launch instance from template**.

3. For **Source template version**, select the launch template version to use.
4. (Optional) You can modify the values for any of the launch parameters. If you don't modify a value, the value defined by the launch template is used. If no value was specified in the launch template, the default value for the parameter is used.
5. In the **Summary** panel, for **Number of instances**, specify the number of instances to launch.
6. Choose **Launch instance**.

   If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.

AWS CLI

To launch an instance from a launch template

- Use the run-instances command and specify the `--launch-template` parameter. Optionally specify the launch template version to use. If you don't specify the version, the default version is used.

```
aws ec2 run-instances \
    --launch-template LaunchTemplateId=lt-0abcd290751193123,Version=1
```

- To override a launch template parameter, specify the parameter in the run-instances command. The following example overrides the instance type that's specified in the launch template (if any).

```
aws ec2 run-instances \
    --launch-template LaunchTemplateId=lt-0abcd290751193123 \
    --instance-type t2.small
```

- If you specify a nested parameter that's part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

  In the following example, the instance is launched with the tag *Owner*=*TeamA* as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of *Owner*, the value is replaced with *TeamA*.

```
aws ec2 run-instances \
    --launch-template LaunchTemplateId=lt-0abcd290751193123 \
    --tag-specifications "ResourceType=instance,Tags=[{Key=Owner,Value=TeamA}]"
```

  In the following example, the instance is launched with a volume with the device name */dev/xvdb* as well as any other block device mappings that are specified in the launch template. If the launch template has an existing volume defined for */dev/xvdb*, its values are replaced with the specified values.

```
aws ec2 run-instances \
    --launch-template LaunchTemplateId=lt-0abcd290751193123 \
    --block-device-mappings "DeviceName=/dev/
xvdb,Ebs={VolumeSize=20,VolumeType=gp2}"
```

If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.

PowerShell

To launch an instance from a launch template using the AWS Tools for PowerShell

- Use the New-EC2Instance command and specify the `-LaunchTemplate` parameter. Optionally specify the launch template version to use. If you don't specify the version, the default version is used.

```
Import-Module AWS.Tools.EC2
New-EC2Instance `
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -
Property @{
            LaunchTemplateId = 'lt-0abcd290751193123';
            Version          = '4'
```

```
    }
)
```

- To override a launch template parameter, specify the parameter in the [New-EC2Instance](#) command. The following example overrides the instance type that's specified in the launch template (if any).

```
Import-Module AWS.Tools.EC2
New-EC2Instance `
    -InstanceType t4g.small `
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -
Property @{
            LaunchTemplateId = 'lt-0abcd290751193123';
            Version          = '4'
    }
)
```

- If you specify a nested parameter that's part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

  In the following example, the instance is launched with the tag *Owner*=*TeamA* as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of *Owner*, the value is replaced with *TeamA*.

```
Import-Module AWS.Tools.EC2
New-EC2Instance `
    -InstanceType t4g.small  `
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -
Property @{
            LaunchTemplateId = 'lt-0abcd290751193123';
            Version          = '4'
        }
) `
    -TagSpecification (
        New-Object -TypeName Amazon.EC2.Model.TagSpecification -Property @{
            ResourceType = 'instance';
            Tags         = @(
                @{key = "Owner"; value = "TeamA" },
                @{key = "Department"; value = "Operations" }
```

```
            )
        }
)
```

In the following example, the instance is launched with a volume with the device name */dev/xvdb* as well as any other block device mappings that are specified in the launch template. If the launch template has an existing volume defined for */dev/xvdb*, its values are replaced with the specified values.

```
Import-Module AWS.Tools.EC2
New-EC2Instance `
    -InstanceType t4g.small  `
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -
Property @{
            LaunchTemplateId = 'lt-0abcd290751193123';
            Version          = '4'
    }
) `
    -BlockDeviceMapping  (
        New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping -Property @{
            DeviceName = '/dev/xvdb';
            EBS        = (
                New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice -Property @{
                    VolumeSize = 25;
                    VolumeType = 'gp3'
                }
            )
        }
)
```

If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.

Launch instances in an Amazon EC2 Auto Scaling group using a launch template

You can create an Auto Scaling group and specify a launch template to use for the group. When Amazon EC2 Auto Scaling launches instances in the Auto Scaling group, it uses the launch parameters defined in the associated launch template.

Before you can create an Auto Scaling group using a launch template, you must first create a launch template that includes the parameters required to launch an instance in an Auto Scaling group. Some parameters are required, such as the ID of the AMI, and some parameters are not available to use with an Auto Scaling group. The console provides guidance to help you create a template that you can use with Amazon EC2 Auto Scaling.

To create an Auto Scaling group with a launch template using the console

- For the instructions, see Create an Auto Scaling group using a launch template in the *Amazon EC2 Auto Scaling User Guide*.

To create or update an Auto Scaling group with a launch template using the AWS CLI

- Use the create-auto-scaling-group or the update-auto-scaling-group command and specify the `--launch-template` parameter.

For more information, see the following topics in the *Amazon EC2 Auto Scaling User Guide*:

- Create a launch template for an Auto Scaling group
- Create a launch template using advanced settings
- Examples for creating and managing launch templates with the AWS Command Line Interface (AWS CLI) – Provides examples that show how to create launch templates with various parameter combinations.
- Create Auto Scaling groups using launch templates
- Update an Auto Scaling group

Launch an EC2 Fleet using a launch template

A launch template is a requirement when creating an EC2 Fleet request. When Amazon EC2 fulfills the EC2 Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template. For more information, see Create an EC2 Fleet.

To create an EC2 Fleet with a launch template using the AWS CLI

- Use the create-fleet command. Use the `--launch-template-configs` parameter to specify the launch template and any overrides for the launch template.

Launch a Spot Fleet using a launch template

A launch template is optional when creating a Spot Fleet request. If you don't use a launch template, you can manually specify the launch parameters. If you use a launch template, when Amazon EC2 fulfills the Spot Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template. For more information, see [Create a Spot Fleet](#).

To create a Spot Fleet request using a launch template

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Request Spot Instances**.
4. Under **Launch parameters**, choose **Use a launch template**.
5. For **Launch template**, choose a launch template, and then, from the field to the right, choose the launch template version.
6. Configure your Spot Fleet by selecting different options on this screen. For more information about the options, see [Create a Spot Fleet request using defined parameters](#).
7. When you're ready to create your Spot Fleet, choose **Launch**.

To create a Spot Fleet request using a launch template

- Use the [request-spot-fleet](#) command. Use the `LaunchTemplateConfigs` parameter to specify the launch template and any overrides for the launch template.

Launch an EC2 instance using details from an existing instance

The Amazon EC2 console provides a **Launch more like this** option that enables you to use a current instance as a base for launching other instances. This option automatically populates the Amazon EC2 launch instance wizard with certain configuration details from the selected instance.

Considerations

- We do not clone your instances; we only replicate some of the configuration details. To create a copy of your instance, first create an AMI from it, then launch more instances from the AMI. Create a [launch template](#) to ensure that you launch your instances using the same launch details.
- The current instance must be in the `running` state.

Copied details

The following configuration details are copied from the selected instance into the launch instance wizard:

- AMI ID
- Instance type
- Availability Zone, or the VPC and subnet in which the selected instance is located
- Public IPv4 address. If the selected instance currently has a public IPv4 address, the new instance receives a public IPv4 address, regardless of the selected instance's default public IPv4 address setting. For more information about public IPv4 addresses, see Public IPv4 addresses.
- Placement group, if applicable
- IAM role associated with the instance, if applicable
- Shutdown behavior setting (stop or terminate)
- Termination protection setting (true or false)
- CloudWatch monitoring (enabled or disabled)
- Amazon EBS-optimization setting (true or false)
- Tenancy setting, if launching into a VPC (shared or dedicated)
- Kernel ID and RAM disk ID, if applicable
- User data, if specified
- Tags associated with the instance, if applicable
- Security groups associated with the instance
- [Windows instances] Association information. If the selected instance is associated with a configuration file, the same file is automatically associated with the new instance. If the configuration file includes a joined domain configuration, the new instance is joined to the same domain. For more information about joining a domain, see Seamlessly join a Windows EC2 instance to your AWS Managed Microsoft AD Active Directory in the *AWS Directory Service Administration Guide*.

Details not copied

The following configuration details are not copied from your selected instance. Instead, the wizard applies their default settings or behavior:

- Number of network interfaces – The default is one network interface, which is the primary network interface (eth0).
- Storage – The default storage configuration is determined by the AMI and the instance type.

To launch more instances like an existing instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and then choose **Actions**, **Images and templates**, **Launch more like this**.
4. The launch instance wizard opens. You can make any necessary changes to the instance configuration by selecting different options on this screen.

   When you are ready to launch your instance, choose **Launch instance**.
5. If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.

Launch an Amazon EC2 instance from an AWS Marketplace AMI

You can subscribe to an AWS Marketplace AMI and launch an instance from it using the Amazon EC2 console or a command line tool. For more information about AWS Marketplace AMIs, see Paid AMIs in the AWS Marketplace for Amazon EC2 instances.

To cancel your subscription to the AMI after launch, you must first terminate all instances that were launched from the AMI. For more information, see Manage your AWS Marketplace subscriptions.

To launch an instance from an AWS Marketplace AMI using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the Amazon EC2 console dashboard, choose **Launch instance**.
3. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**, and then choose the **AWS Marketplace AMIs** tab. Find a suitable AMI by browsing the categories or using the search functionality. To choose a product, choose **Select**.
5. A window opens with an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, choose one of the following buttons:

- **Subscribe on instance launch** – Your subscription starts when you choose **Launch instance** (at Step 10).
- **Subscribe now** – Your subscription starts immediately. While the subscription is underway, you can configure the instance by continuing with the steps in this procedure. If there are any problems with your credit card details, you will be asked to update your account details.

> **Note**
>
> You're not charged for using the product until you have launched an instance with the AMI. Take note of the pricing for each supported instance type when you select an instance type. Additional taxes might also apply to the product.

6. For **Instance type**, select an instance type for your instance. The instance type defines the hardware configuration and size of the instance to launch.
7. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
8. Under **Network settings**, for **Firewall (security groups)**, take note of the new security group that was created according to the vendor's specifications for the product. The security group might include rules that allow all IPv4 addresses (`0.0.0.0/0`) access on SSH (port 22) on Linux or RDP (port 3389) on Windows. We recommend that you adjust these rules to allow only a specific address or range of addresses to access your instance over those ports.
9. You can use the other fields on the screen to configure your instance, add storage, and add tags. For information about the different options that you can configure, see [Reference for Amazon EC2 instance configuration parameters](https://docs.aws.amazon.com).
10. In the **Summary** panel, under **Software Image (AMI)**, check the details of the AMI from which you're about to launch the instance. Also check the other configuration details that you specified. When you're ready to launch your instance, choose **Launch instance**.
11. Depending on the product you've subscribed to, the instance might take a few minutes or more to launch. If you chose **Subscribe on instance launch** at Step 5, you are first subscribed to the product before your instance can launch. If there are any problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, choose **View all instances** to go to the **Instances** page.

> **Note**
>
> You are charged the subscription price as long as your instance is in the `running` state, even if it is idle. If your instance is stopped, you might still be charged for storage.

12. When your instance is in the `running` state, you can connect to it. To do this, select your instance in the list, choose **Connect**, and choose a connection option. For more information about connecting to your instance, see Connect to your EC2 instance.

> **Important**
>
> Check the vendor's usage instructions carefully, as you might need to use a specific username to connect to your instance. For information about accessing your subscription details, see Manage your AWS Marketplace subscriptions.

13. If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see Troubleshoot Amazon EC2 instance launch issues.

To launch an instance from an AWS Marketplace AMI using a command line tool

To launch instances from AWS Marketplace products using a command line tool, first ensure that you are subscribed to the product. You can then launch an instance with the product's AMI ID using the following methods:

Method	Documentation
AWS CLI	Use the run-instances command, or see the following topic for more information: Launch your instance in the *AWS Command Line Interface User Guide*.
AWS Tools for Windows PowerShell	Use the New-EC2Instance command, or see the following topic for more information: Launch an Amazon EC2 Instance Using Windows PowerShell
Query API	Use the RunInstances request.

Connect to your EC2 instance

Your Amazon EC2 instance is a virtual server in the AWS Cloud. To log on to your instance, you must establish a connection to the instance. How you connect to your instance depends on the operating system of the instance and the operating system on the computer that you use to connect to the instance. The following table details the requirements for each connection method.

Connection option	Instance operating system	Inbound traffic rule	IAM permissions	Instance profile role	Software on instance	Software on connecting system	Key pair
SSH client	Linux	Yes	No	No	No	Yes	Yes
EC2 Instance Connect	Linux	Yes	Yes	No	Yes [1]	No	No
PuTTY	Linux	Yes	No	No	No	Yes	Yes
RDP client	Windows	Yes	No	No	No	Yes	Yes [2]
Fleet Manager	Windows	No	Yes	Yes	Yes [1]	No	Yes
Session Manager	Linux, Windows	No	Yes	Yes	Yes [1]	No	No
EC2 Instance Connect Endpoint	Linux, Windows	Yes	Yes	No	No	No	Yes

[1] The required software is only pre-installed on certain AMIs. You can manually install the required software as needed on supported operating systems.

[2] The key pair is only required if you are using the randomly generated password for the local Administrator user account.

For more information, see the documentation for the connection option that you intend to use.

Connection options

- Connect to your Linux instance using an SSH client
- Connect to your Linux instance using PuTTY
- Connect to your Windows instance using an RDP client
- Connect to your Windows instance using Fleet Manager
- Connect using Session Manager
- Connect using a public IP and EC2 Instance Connect
- Connect using a private IP and EC2 Instance Connect Endpoint

General connection prerequisites

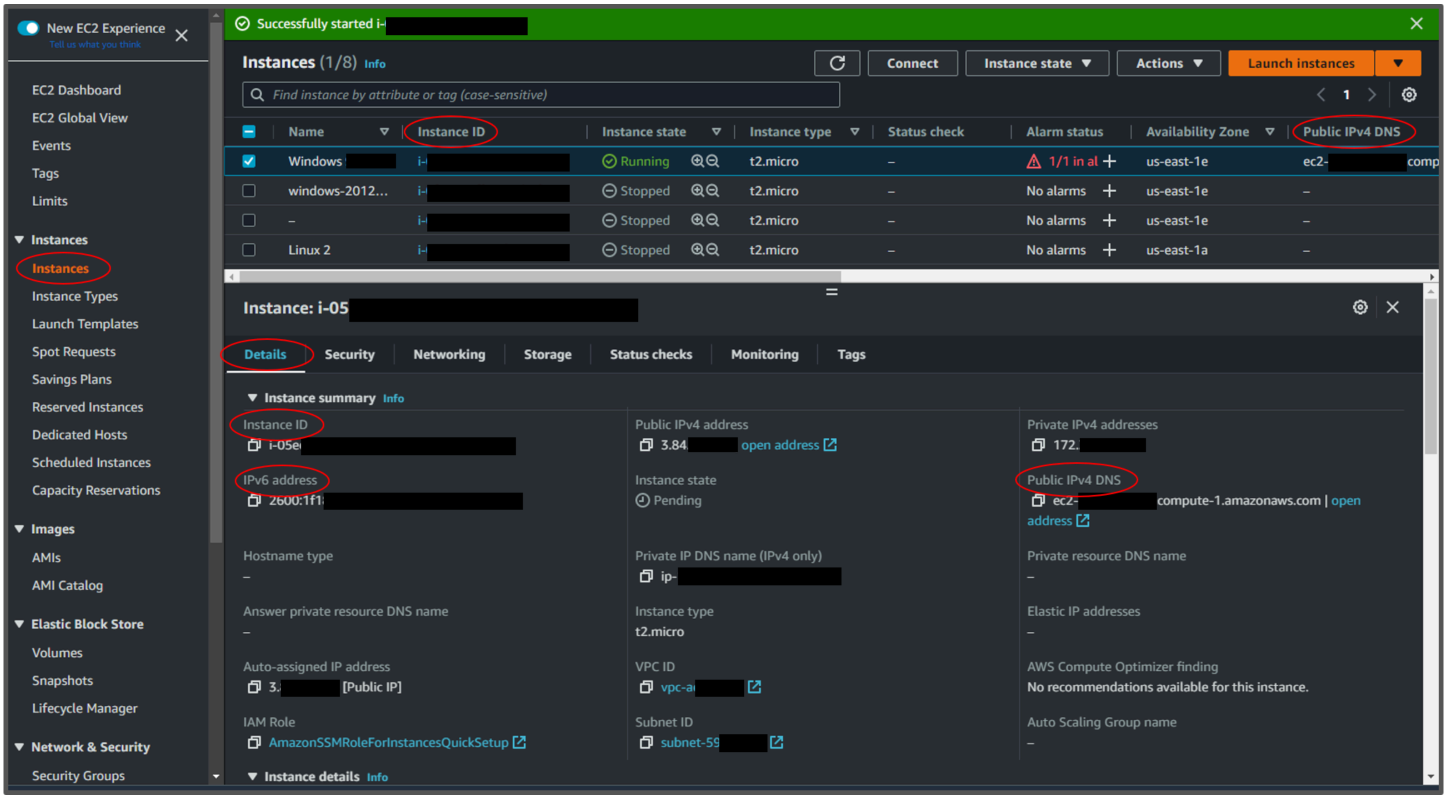
The following are general prerequisites to connect to an instance. Note that there might be additional prerequisites that are specific to the connection option that you choose.

General prerequisites

- Check that your instance has passed its status checks. It can take a few minutes for an instance to be ready to accept connection requests. For more information, see View status checks.
- Get the required instance details.
- Locate the private key and set permissions.
- (Optional) Get the instance fingerprint.

Get the required instance details

To prepare to connect to your instance, get the following information from the Amazon EC2 console or by using the command line.



- **Get the public DNS name of the instance.**

  You can get the public DNS for your instance from the Amazon EC2 console. Check the **Public IPv4 DNS** column of the **Instances** pane. If this column is hidden, choose the settings icon (

) in the top-right corner of the screen, and select **Public IPv4 DNS**. You can also find the public DNS in the instance information section of the **Instances** pane. When you select the instance in the **Instances** pane of the Amazon EC2 console, information about that instance will appear on the lower half of the page. Under the **Details** tab, look for **Public IPv4 DNS**.

  If you prefer, you can use the describe-instances (AWS CLI) or Get-EC2Instance (AWS Tools for Windows PowerShell) commands.

  If no **Public IPv4 DNS** is displayed, verify that the **Instance state** is **Running**, and that you have not launched the instance in a private subnet. If you launched your instance using the launch instance wizard, you may have edited the **Auto-assign public IP** field under **Network settings** and changed the value to **Disable**. If you disable the **Auto-assign public IP** option, the instance is not assigned a public IP address when it is launched.

- **(IPv6 only instances) Get the IPv6 address of the instance.**

If you assigned an IPv6 address to your instance, you can optionally connect to the instance using its IPv6 address instead of a public IPv4 address or public IPv4 DNS hostname. Your local computer must have an IPv6 address and must be configured to use IPv6. You can get the IPv6 address of your instance from the Amazon EC2 console. Check the **IPv6 IPs** column of the **Instances** pane. Or, you can find the IPv6 address in the instance information section. When you select the instance in the **Instances** pane of the Amazon EC2 console, information about that instance will appear on the lower half of the page. Under the **Details** tab, look for **IPv6 address**.

If you prefer, you can use the describe-instances (AWS CLI) or Get-EC2Instance (AWS Tools for Windows PowerShell) commands. For more information about IPv6, see IPv6 addresses.

- **(Linux instances) Get the username for your instance.**

  You can connect to your instance using the username for your user account or the default username for the AMI that you used to launch your instance.

  - **Get the username for your user account.**

    For more information about how to create a user account, see Manage system users on your Amazon EC2 Linux instance.

  - **Get the default username for the AMI that you used to launch your instance.**
    - **Amazon Linux** – `ec2-user`
    - **CentOS** – `centos` or `ec2-user`
    - **Debian** – `admin`
    - **Fedora** – `fedora` or `ec2-user`
    - **RHEL** – `ec2-user` or `root`
    - **SUSE** – `ec2-user` or `root`
    - **Ubuntu** – `ubuntu`
    - **Oracle** – `ec2-user`
    - **Bitnami** – `bitnami`
    - **Rocky Linux** – `rocky`
    - **Other** – Check with the AMI provider

Locate the private key and set permissions

You must know the location of your private key file to make the initial connection to a Linux instance using SSH or a Windows instances using RDP. For SSH connections, you must set file permissions so that only you can read the private key.

For information about how key pairs work when using Amazon EC2, see Amazon EC2 key pairs and Amazon EC2 instances.

- **Locate the private key.**

  Get the fully-qualified path to the location on your computer of the `.pem` file for the key pair that you specified when you launched the instance. For more information, see the section called "Identify the public key specified at launch".

  If you can't find your private key file, see I've lost my private key. How can I connect to my instance?

  (Linux instances) If you are connecting to your instance using PuTTY and need to convert the `.pem` file to `.ppk`, see Convert your private key using PuTTYgen.

- **(Linux instances) Set the permissions of your private key so that only you can read it.**
  - **Connect from macOS or Linux**

    If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

    ```
    chmod 400 key-pair-name.pem
    ```

    If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file.
  - **Connect from Windows**

    Open File Explorer and right-click on the `.pem` file. Select **Properties** > **Security tab** and choose **Advanced**. Choose **Disable inheritance**. Remove access to all users except for the current user.

(Optional) Get the instance fingerprint

To protect yourself from man-in-the-middle attacks, you can verify the authenticity of the instance you're about to connect to by verifying the fingerprint that is displayed. Verifying the fingerprint is useful if you launched your instance from a public AMI provided by a third party.

Task overview

First, get the instance fingerprint from the instance. Then, when you connect to the instance and are prompted to verify the fingerprint, compare the fingerprint you obtained in this procedure with the fingerprint that is displayed. If the fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, you can confidently connect to your instance.

Prerequisites to get the instance fingerprint

- The instance must not be in the `pending` state. The fingerprint is available only after the first boot of the instance is complete.
- You must be the instance owner to get the console output.
- There are various ways to get the instance fingerprint. If you want to use the AWS CLI, it must be installed on your local computer. For information about installing the AWS CLI, see Getting started with the AWS CLI in the *AWS Command Line Interface User Guide*.

To get the instance fingerprint

In Step 1, you get the console output, which includes the instance fingerprint. In Step 2, you find the instance fingerprint in the console output.

1. Get the console output using one of the following methods.

   Console

   1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   2. From the left navigator, choose **Instances**.
   3. Select your instance, and then choose **Actions**, **Monitor and troubleshoot**, **Get system log**.

AWS CLI

On your local computer (not on the instance you're connecting to), use the [get-console-output](#) command. If the output is large, [you can pipe it to a text file](#), where it might be easier to read.

```
aws ec2 get-console-output \
    --instance-id i-1234567890abcdef0 \
    --query Output \
    --output text > temp.txt
```

PowerShell

On your local computer, use the following [Get-EC2ConsoleOutput](#) cmdlet.

```
$encodedOutput = (Get-EC2ConsoleOutput -InstanceId i-1234567890abcdef0).Output
[System.Text.Encoding]::UTF8.GetString([System.Convert]::FromBase64String($encodedOutput
```

2. In the console output, find the instance (host) fingerprint, which is located under `BEGIN SSH HOST KEY FINGERPRINTS`. There might be several instance fingerprints. When you connect to your instance, it will display only one of the fingerprints.

   The exact output can vary by operating system, AMI version, and whether AWS created the key pairs. The following is example output.

```
ec2:#############################################################
ec2: -----BEGIN SSH HOST KEY FINGERPRINTS-----
ec2: 256 SHA256:l4UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY no comment (ECDSA)
ec2: 256 SHA256:kpEa+rw/Uq3zxaYZN8KT501iBtJOIdHG52dFi66EEfQ no comment (ED25519)
ec2: 2048 SHA256:L8l6pepcA7iqW/jBecQjVZClUrKY+o2cHLI0iHerbVc no comment (RSA)
ec2: -----END SSH HOST KEY FINGERPRINTS-----
ec2: #############################################################
```

> **Note**
>
> You'll reference this fingerprint when you connect to the instance.

Connect to your Linux instance using SSH

There are multiple ways to connect to your Linux instance using SSH. Some ways depend on the operating system of the local computer that you connect from. Other methods are browser-based, such as EC2 Instance Connect or AWS Systems Manager Session Manager, and can be used from any computer. You can use SSH to connect to your Linux instance and run commands, or use SSH to transfer files between your local computer and your instance.

Before you connect to your Linux instance using SSH, complete the following prerequisites:

- Check that your instance has passed its status checks. It can take a few minutes for an instance to be ready to accept connection requests. For more information, see View status checks.
- Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. For more information, see Rules to connect to instances from your computer.
- Get the required instance details.
- Locate the private key and set permissions.
- (Optional) Get the instance fingerprint.

Then, choose from one of the following options to connect to your Linux instance using SSH.

- Connect using an SSH client
- Connect using PuTTY
- Transfer files using SCP

If you can't connect to your instance and need help troubleshooting, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

Connect to your Linux instance using an SSH client

You can use Secure Shell (SSH) to connect to your Linux instance from your local computer. For more information about other options, see Connect to your EC2 instance.

> **Note**
>
> If you receive an error while attempting to connect to your instance, make sure that your instance meets all of the SSH connection prerequisites. If it meets all of the prerequisites,

and you're still not able to connect to your Linux instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

Contents

SSH connection prerequisites

Before you can connect to your Linux instance using SSH, complete the following tasks.

Complete the general prerequisites.

- Check that your instance has passed its status checks. It can take a few minutes for an instance to be ready to accept connection requests. For more information, see View status checks.
- Get the required instance details.
- Locate the private key and set permissions.
- (Optional) Get the instance fingerprint.

Allow inbound SSH traffic from your IP address.

Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. For more information, see Rules to connect to instances from your computer.

Install an SSH client on your local computer (if needed).

Your local computer might have an SSH client installed by default. You can verify this by entering the following command in a terminal window. If your computer doesn't recognize the command, you must install an SSH client.

```
ssh
```

The following are some of the possible options for Windows. If your computer runs a different operating system, see the documentation for that operating system for SSH client options.

Install OpenSSH on Windows

After you install OpenSSH on Windows, you can connect to your Linux instance from your Windows computer using SSH. Before you begin, ensure that you meet the following requirements.

Windows version

The version of Windows on your computer must be Windows Server 2019 or later.

For earlier versions of Windows, download and install Win32-OpenSSH instead.

PowerShell requirements

To install OpenSSH on your Windows OS using PowerShell, you must be running PowerShell version 5.1 or later, and your account must be a member of the built-in Administrators group. Run `$PSVersionTable.PSVersion` from PowerShell to check your PowerShell version.

To check whether you are a member of the built-in Administrators group, run the following PowerShell command:

```
(New-Object
 Security.Principal.WindowsPrincipal([Security.Principal.WindowsIdentity]::GetCurrent())).Is
```

If you are a member of the built-in Administrators group, the output is `True`.

To install OpenSSH for Windows using PowerShell, run the following PowerShell command.

```
Add-WindowsCapability -Online -Name OpenSSH.Client~~~~0.0.1.0
```

The following is example output.

```
Path          :
Online        : True
RestartNeeded : False
```

To uninstall OpenSSH from Windows using PowerShell, run the following PowerShell command.

```
Remove-WindowsCapability -Online -Name OpenSSH.Client~~~~0.0.1.0
```

The following is example output.

```
Path          :
Online        : True
RestartNeeded : True
```

Install Windows Subsystem for Linux (WSL)

After you install WSL on Windows, you can connect to your Linux instance from your Windows computer using Linux command line tools, such as an SSH client.

Follow the instructions in Install Windows Subsystem for Linux on your EC2 Windows instance. If you follow the instructions in Microsoft's installation guide, they install the Ubuntu distribution of Linux. You can install a different Linux distribution if you prefer.

In a WSL terminal window, copy the `.pem` file (for the key pair that you specified for your instance at launch) from Windows to WSL. Note the fully-qualified path to the `.pem` file on WSL to use when connecting to your instance. For information about how to specify the path to your Windows hard drive, see How do I access my C drive?.

```
cp /mnt/<Windows drive letter>/path/my-key-pair.pem ~/WSL-path/my-key-pair.pem
```

For information about uninstalling Windows Subsystem for Linux, see How do I uninstall a WSL Distribution?.

Connect to your Linux instance using an SSH client

Use the following procedure to connect to your Linux instance using an SSH client.

To connect to your instance using an SSH client

1. Open a terminal window on your computer.
2. Use the **ssh** command to connect to the instance. You need the details about your instance that you gathered as part of the prerequisites. For example, you need the location of the private key (`.pem` file), the username, and the public DNS name or IPv6 address. The following are example commands.
   - (Public DNS) To use the public DNS name, enter the following command.

     ```
     ssh -i /path/key-pair-name.pem instance-user-name@instance-public-dns-name
     ```

   - (IPv6) Alternatively, if your instance has an IPv6 address, enter the following command to use the IPv6 address.

```
ssh -i /path/key-pair-name.pem instance-user-name@2001:db8::1234:5678:1.2.3.4
```

The following is an example response.

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (198-51-100-1)'
 can't be established.
ECDSA key fingerprint is l4UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY.
Are you sure you want to continue connecting (yes/no)?
```

3. (Optional) Verify that the fingerprint in the security alert matches the fingerprint. If these fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, continue to the next step. For more information, see Get the instance fingerprint.
4. Enter **yes**.

   You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (ECDSA) to
 the list of known hosts.
```

Connect to your Linux instance using PuTTY

You can connect to your Linux instance using PuTTY, a free SSH client for Windows.

If you're running Windows Server 2019 or later, we recommend that you use OpenSSH, an open source connectivity tool for remote login using the SSH protocol.

> **Note**
>
> If you receive an error while attempting to connect to your instance, make sure that your instance meets all of the SSH connection prerequisites. If it meets all of the prerequisites, and you're still not able to connect to your Linux instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

Contents

- Connect to your Linux instance

Prerequisites

Before you connect to your Linux instance using PuTTY, complete the following tasks.

Complete the general prerequisites.

- Check that your instance has passed its status checks. It can take a few minutes for an instance to be ready to accept connection requests. For more information, see View status checks.
- Get the required instance details.
- Locate the private key and set permissions.
- (Optional) Get the instance fingerprint.

Allow inbound SSH traffic from your IP address.

Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. For more information, see Rules to connect to instances from your computer.

Install PuTTY on your local computer (if needed).

Download and install PuTTY from the PuTTY download page. If you already have an earlier version of PuTTY installed, we recommend that you download the latest version. Be sure to install the entire suite.

Convert your private key to PPK format using PuTTYgen.

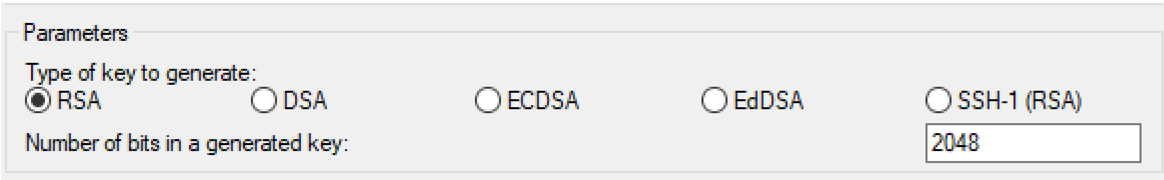
You must specify the private key for the key pair that you specified when you launched the instance. If you created the private key in .pem format, you must convert it to a PPK file for use with PuTTY. Locate the private key (.pem file), and then follow the steps in Convert your private key using PuTTYgen.

(Optional) Convert your private key using PuTTYgen

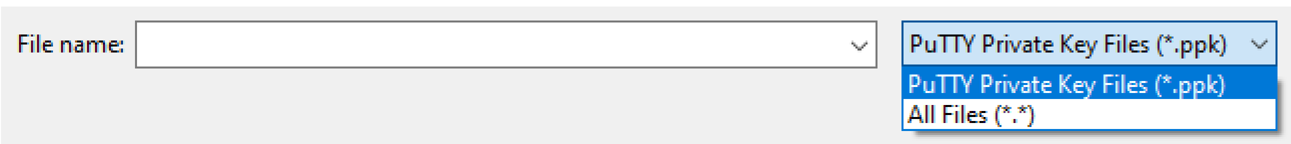
PuTTY does not natively support the PEM format for SSH keys. PuTTY provides a tool named PuTTYgen, which converts PEM keys to the required PPK format for PuTTY. If you created the key using PEM format instead of PPK format, you must convert your private key (.pem file) into this format (.ppk file) for use with PuTTY.

To convert your private key from PEM to PPK format

1. From the **Start** menu, choose **All Programs**, **PuTTY**, **PuTTYgen**.
2. Under **Type of key to generate**, choose **RSA**. If your version of PuTTYgen does not include this option, choose **SSH-2 RSA**.

3. Choose **Load**. By default, PuTTYgen displays only files with the extension `.ppk`. To locate your `.pem` file, choose the option to display files of all types.

4. Select your `.pem` file for the key pair that you specified when you launched your instance and choose **Open**. PuTTYgen displays a notice that the `.pem` file was successfully imported. Choose **OK**.
5. To save the key in the format that PuTTY can use, choose **Save private key**. PuTTYgen displays a warning about saving the key without a passphrase. Choose **Yes**.

   Note

   A passphrase on a private key is an extra layer of protection. Even if your private key is discovered, it can't be used without the passphrase. The downside to using a passphrase is that it makes automation harder because human intervention is needed to log on to an instance, or to copy files to an instance.

6. Specify the same name for the key that you used for the key pair (for example, `key-pair-name`) and choose **Save**. PuTTY automatically adds the `.ppk` file extension.

Your private key is now in the correct format for use with PuTTY. You can now connect to your instance using PuTTY's SSH client.

Connect to your Linux instance

Use the following procedure to connect to your Linux instance using PuTTY. You need the `.ppk` file that you created for your private key. For more information, see (Optional) Convert your private key using PuTTYgen in the preceding section. If you receive an error while attempting to connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

Last tested version – PuTTY .78

To connect to your instance using PuTTY

1. Start PuTTY (from the **Start** menu, search for **PuTTY** and then choose **Open**).
2. In the **Category** pane, choose **Session** and complete the following fields:

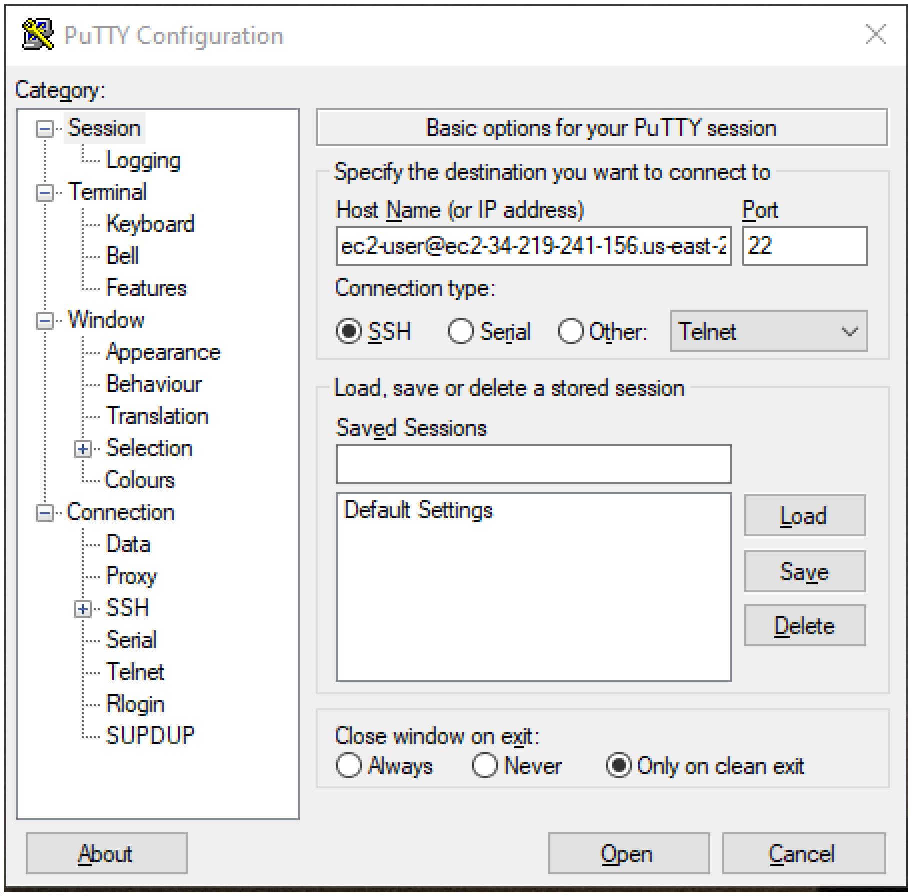
   a. In the **Host Name** box, do one of the following:

      - (Public DNS) To connect using your instance's public DNS name, enter *`instance-user-name`*@*`instance-public-dns-name`*.
      - (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter *`instance-user-name`*@*`2001:db8::1234:5678:1.2.3.4`*.

      For information about how to get the username for your instance, and the public DNS name or IPv6 address of your instance, see Get the required instance details.

   b. Ensure that the **Port** value is 22.

   c. Under **Connection type**, select **SSH**.



3. (Optional) You can configure PuTTY to automatically send 'keepalive' data at regular intervals to keep the session active. This is useful to avoid disconnecting from your instance due to session inactivity. In the **Category** pane, choose **Connection**, and then enter the required interval in **Seconds between keepalives**. For example, if your session disconnects after 10 minutes of inactivity, enter 180 to configure PuTTY to send keepalive data every 3 minutes.
4. In the **Category** pane, expand **Connection**, **SSH**, and **Auth**. Choose **Credentials**.
5. Next to **Private key file for authentication**, choose **Browse**. In the **Select private key file** dialog box, select the `.ppk` file that you generated for your key pair. You can either double-click the file or choose **Open** in the **Select private key file** dialog box.
6. (Optional) If you plan to connect to this instance again after this session, you can save the session information for future use. In the **Category** pane, choose **Session**. Enter a name for the session in **Saved Sessions**, and then choose **Save**.
7. To connect to the instance, choose **Open**.
8. If this is the first time you have connected to this instance, PuTTY displays a security alert dialog box that asks whether you trust the host to which you are connecting.

a. (Optional) Verify that the fingerprint in the security alert dialog box matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.

b. Choose **Accept**. A window opens and you are connected to your instance.

> **Note**
>
> If you specified a passphrase when you converted your private key to the PuTTY format, you must provide that passphrase when you log in to the instance.

If you receive an error while attempting to connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

Transfer files to a Linux instance using SCP

One way to transfer files between your local computer and a Linux instance is to use the secure copy protocol (SCP). SCP is a good option for simple operations, such as as one-time file copies. SCP secures files transfers using the same .pem file that you use to connect to an instance using SSH. If you need to keep files synchronized, or if the files are large, **rsync** is faster and more efficient than SCP. For security, use **rsync** over SSH, as **rsync** transfers data using plain text by default.

Before you connect to your Linux instance using SCP, complete the following tasks:

- **Complete the general prerequisites.**
  - Check that your instance has passed its status checks. It can take a few minutes for an instance to be ready to accept connection requests. For more information, see View status checks.
  - Get the required instance details.
  - Locate the private key and set permissions.
  - (Optional) Get the instance fingerprint.
- **Allow inbound SSH traffic from your IP address.**

  Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. For more information, see Rules to connect to instances from your computer.
- **Install an SCP client.**

Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn't, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, see https://www.openssh.com.

The following procedure steps you through using SCP to transfer a file using the instance's public DNS name, or the IPv6 address if your instance has one.

To use SCP to transfer files between your computer and your instance

1. Determine the location of the source file on your computer and the destination path on the instance. In the following examples, the name of the private key file is `key-pair-name.pem`, the file to transfer is `my-file.txt`, the username for the instance is ec2-user, the public DNS name of the instance is `instance-public-dns-name`, and the IPv6 address of the instance is `2001:db8::1234:5678:1.2.3.4`.

   - (Public DNS) To transfer a file to the destination on the instance, enter the following command from your computer.

     ```
     scp -i /path/key-pair-name.pem /path/my-file.txt ec2-user@instance-public-dns-name:path/
     ```

   - (IPv6) To transfer a file to the destination on the instance if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets (`[ ]`), which must be escaped (`\`).

     ```
     scp -i /path/key-pair-name.pem /path/my-file.txt ec2-user@
     \[2001:db8::1234:5678:1.2.3.4\]:path/
     ```

2. If you haven't already connected to the instance using SSH, you see a response like the following:

   ```
   The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)'
   can't be established.
   RSA key fingerprint is 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f.
   Are you sure you want to continue connecting (yes/no)?
   ```

   (Optional) You can optionally verify that the fingerprint in the security alert matches the instance fingerprint. For more information, see (Optional) Get the instance fingerprint.

Enter **yes**.

3. If the transfer is successful, the response is similar to the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA)
to the list of known hosts.
my-file.txt                                100%   480     24.4KB/s   00:00
```

4. To transfer a file in the other direction (from your Amazon EC2 instance to your computer), reverse the order of the host parameters. For example, you can transfer `my-file.txt` from your EC2 instance to the a destination on your local computer as `my-file2.txt`, as shown in the following examples.

   - (Public DNS) To transfer a file to a destination on your computer, enter the following command from your computer.

     ```
     scp -i /path/key-pair-name.pem ec2-user@instance-public-dns-name:path/my-
     file.txt path/my-file2.txt
     ```

   - (IPv6) To transfer a file to a destination on your computer if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets (`[ ]`), which must be escaped (`\`).

     ```
     scp -i /path/key-pair-name.pem ec2-user@\[2001:db8::1234:5678:1.2.3.4\]:path/
     my-file.txt path/my-file2.txt
     ```

Manage system users on your Amazon EC2 Linux instance

Each Linux instance launches with a default Linux system user. You can add users to your instance and delete users.

For the default user, the default username is determined by the AMI that was specified when you launched the instance.

> **Note**
>
> By default, password authentication and root login are disabled, and sudo is enabled. To log in to your instance, you must use a key pair. For more information about logging in, see Connect to your Linux instance using SSH.

You can allow password authentication and root login for your instance. For more information, see the documentation for your operating system.

Note

Linux system users should not be confused with IAM users. For more information, see IAM users in the *IAM User Guide*.

Contents

Default usernames

The default username for your EC2 instance is determined by the AMI that was specified when you launched the instance.

The default usernames are:

- For an Amazon Linux AMI, the username is `ec2-user`.
- For a CentOS AMI, the username is `centos` or `ec2-user`.
- For a Debian AMI, the username is `admin`.
- For a Fedora AMI, the username is `fedora` or `ec2-user`.
- For a RHEL AMI, the username is `ec2-user` or `root`.
- For a SUSE AMI, the username is `ec2-user` or `root`.
- For an Ubuntu AMI, the username is `ubuntu`.
- For an Oracle AMI, the username is `ec2-user`.
- For a Bitnami AMI, the username is `bitnami`.

> **Note**
>
> To find the default username for other Linux distributions, check with the AMI provider.

Considerations

Using the default user is adequate for many applications. However, you may choose to add users so that individuals can have their own files and workspaces. Furthermore, creating users for new users is much more secure than granting multiple (possibly inexperienced) users access to the default user, because the default user can cause a lot of damage to a system when used improperly. For more information, see Tips for Securing Your EC2 Instance.

To enable users SSH access to your EC2 instance using a Linux system user, you must share the SSH key with the user. Alternatively, you can use EC2 Instance Connect to provide access to users without the need to share and manage SSH keys. For more information, see Connect to your Linux instance using a public IP address and EC2 Instance Connect.

Create a user

First create the user, and then add the SSH public key that allows the user to connect to and log into the instance.

> **Important**
>
> In Step 1 of this procedure, you create a new key pair. Because a key pair functions like a password, it's crucial to handle it securely. If you create a key pair for a user, you must ensure that the private key is sent to them securely. Alternatively, the user can complete Steps 1 and 2 by creating their own key pair, keeping the private key secure on their machine, and then sending you the public key to complete the procedure from Step 3.

To create a user

1. Create a new key pair. You must provide the `.pem` file to the user for whom you are creating the user. They must use this file to connect to the instance.
2. Retrieve the public key from the key pair that you created in the previous step.

   ```
   $ ssh-keygen -y -f /path_to_key_pair/key-pair-name.pem
   ```

The command returns the public key, as shown in the following example.

```
ssh-rsa
 AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS7O6Vhz2ItxCih
+PnDSUaw+WNQn/mZphTk/a/gU8jEzoOWbkM4yxyb/wB96xbiFveSFJuOp/
d6RJhJOI0iBXrlsLnBItntckiJ7FbtxJMXLvvwJryDUilBMTjYtwB+QhYXUMOzce5Pjz5/
i8SeJtjnV3iAoG/cQk+0FzZqaeJAAHco
+CY/5WrUBkrHmFJr6HcXkvJdWPkYQS3xqC0+FmUZofz221CBt5IMucxXPkX4rWi
+z7wB3RbBQoQzd8v7yeb7OzlPnWOyN0qFU0XA246RA8QFYiCNYwI3f05p6KLxEXAMPLE
```

3. Connect to the instance.

4. Use the **adduser** command to create the user and add it to the system (with an entry in the `/etc/passwd` file). The command also creates a group and a home directory for the user. In this example, the user is named *newuser*.

   - AL2023 and Amazon Linux 2

     With AL2023 and Amazon Linux 2, the user is created with password authentication disabled by default.

     ```
     [ec2-user ~]$ sudo adduser newuser
     ```

   - Ubuntu

     Include the `--disabled-password` parameter to create the user with password authentication disabled.

     ```
     [ubuntu ~]$ sudo adduser newuser --disabled-password
     ```

5. Switch to the new user so that the directory and file that you create will have the proper ownership.

   ```
   [ec2-user ~]$ sudo su - newuser
   ```

   The prompt changes from `ec2-user` to *newuser* to indicate that you have switched the shell session to the new user.

6. Add the SSH public key to the user. First create a directory in the user's home directory for the SSH key file, then create the key file, and finally paste the public key into the key file, as described in the following sub-steps.

a. Create a `.ssh` directory in the *newuser* home directory and change its file permissions to `700` (only the owner can read, write, or open the directory).

```
[newuser ~]$ mkdir .ssh
```

```
[newuser ~]$ chmod 700 .ssh
```

> **Important**
>
> Without these exact file permissions, the user will not be able to log in.

b. Create a file named `authorized_keys` in the `.ssh` directory and change its file permissions to `600` (only the owner can read or write to the file).

```
[newuser ~]$ touch .ssh/authorized_keys
```

```
[newuser ~]$ chmod 600 .ssh/authorized_keys
```

> **Important**
>
> Without these exact file permissions, the user will not be able to log in.

c. Open the `authorized_keys` file using your favorite text editor (such as **vim** or **nano**).

```
[newuser ~]$ nano .ssh/authorized_keys
```

Paste the public key that you retrieved in **Step 2** into the file and save the changes.

> **Important**
>
> Ensure that you paste the public key in one continuous line. The public key must not be split over multiple lines.

The user should now be able to log into the *newuser* user on your instance, using the private key that corresponds to the public key that you added to the `authorized_keys` file. For more information about the different methods of connecting to a Linux instance, see [Connect to your Linux instance using SSH](#).

Remove a user

If a user is no longer needed, you can remove that user so that it can no longer be used.

Use the **userdel** command to remove the user from the system. When you specify the `-r` parameter, the user's home directory and mail spool are deleted. To keep the user's home directory and mail spool, omit the `-r` parameter.

```
[ec2-user ~]$ sudo userdel -r olduser
```

Connect to your Windows instance using RDP

You can connect to Amazon EC2 instances created from most Windows Amazon Machine Images (AMIs) using Remote Desktop. Remote Desktop uses the Remote Desktop Protocol (RDP) to connect to and use your instance in the same way you use a computer sitting in front of you (local computer). It is available on most editions of Windows and is also available for Mac OS.

The license for the Windows Server operating system allows two simultaneous remote connections for administrative purposes. The license for Windows Server is included in the price of your Windows instance. If you require more than two simultaneous remote connections, you must purchase a Remote Desktop Services (RDS) license. If you attempt a third connection, an error occurs.

> **Tip**
>
> If you need to connect to your instance in order to troubleshoot boot, network configuration, and other issues for instances built on the AWS Nitro System, you can use the EC2 Serial Console for instances.

Contents

Connect to your Windows instance using an RDP client

You can connect to your Windows instance using an RDP client as follows.

> **Tip**
>
> Alternatively, you can connect to your Windows instance using Systems Manager Fleet Manager or EC2 Instance Connect Endpoint.

Prerequisites

You must meet the following prerequisites to connect to your Windows instance using an RDP client.

- **Complete the general prerequisites.**
  - Check that your instance has passed its status checks. It can take a few minutes for an instance to be ready to accept connection requests. For more information, see View status checks.
  - Get the required instance details.
  - Locate the private key and set permissions.
  - (Optional) Get the instance fingerprint.
- **Install an RDP client.**
  - (Windows) Windows includes an RDP client by default. To verify, type **mstsc** at a Command Prompt window. If your computer doesn't recognize this command, download the Microsoft Remote Desktop app from the Microsoft Store.
  - (macOS X) Download the Windows App for Mac (previously named Microsoft Remote Desktop from the Mac App Store.
  - (Linux) Use Remmina.
- **Allow inbound RDP traffic from your IP address.**

  Ensure that the security group associated with your instance allows incoming RDP traffic from your IP address. For more information, see Rules to connect to instances from your computer.

Retrieve the administrator password

If you joined your instance to a domain, you can connect to your instance using the domain credentials from AWS Directory Service. On the Remote Desktop login screen, instead of using the local computer name and the generated password, use the fully-qualified username for the administrator (for example, **corp.example.com\Admin**), and the password for this account.

To connect to a Windows instance using RDP, you must retrieve the initial administrator password and then enter this password when you connect to your instance. It takes a few minutes after instance launch before this password is available. Your account must have permission to call the GetPasswordData action. For more information, see Example policies to control access the Amazon EC2 API.

The default username for the Administrator account depends on the language of the operating system (OS) contained in the AMI. To determine the correct username, identify the language of the OS, and then choose the corresponding username. For example, for an English OS, the username is `Administrator`, for a French OS it's `Administrateur`, and for a Portuguese OS it's `Administrador`. If a language version of the OS does not have a username in the same language, choose the username `Administrator (Other)`. For more information, see Localized Names for Administrator Account in Windows in the Microsoft website.

To retrieve the initial administrator password

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and then choose **Connect**.
4. On the **Connect to instance** page, choose the **RDP client** tab.
5. For **Username**, choose the default username for the Administrator account. The username you choose must match the language of the operating system (OS) contained in the AMI that you used to launch your instance. If there is no username in the same language as your OS, choose **Administrator (Other)**.
6. Choose **Get password**.
7. On the **Get Windows password** page, do the following:

    a. Choose **Upload private key file** and navigate to the private key (`.pem`) file that you specified when you launched the instance. Select the file and choose **Open** to copy the entire contents of the file to this window.

    b. Choose **Decrypt password**. The **Get Windows password** page closes, and the default administrator password for the instance appears under **Password**, replacing the **Get password** link shown previously.

c. Copy the password and save it in a safe place. This password is required to connect to the instance.

Connect to your Windows instance

The following procedure uses the Remote Desktop Connection client for Windows (MSTSC). If you're using a different RDP client, download the RDP file and then see the documentation for the RDP client for the steps to establish the RDP connection.

To connect to a Windows instance using an RDP client

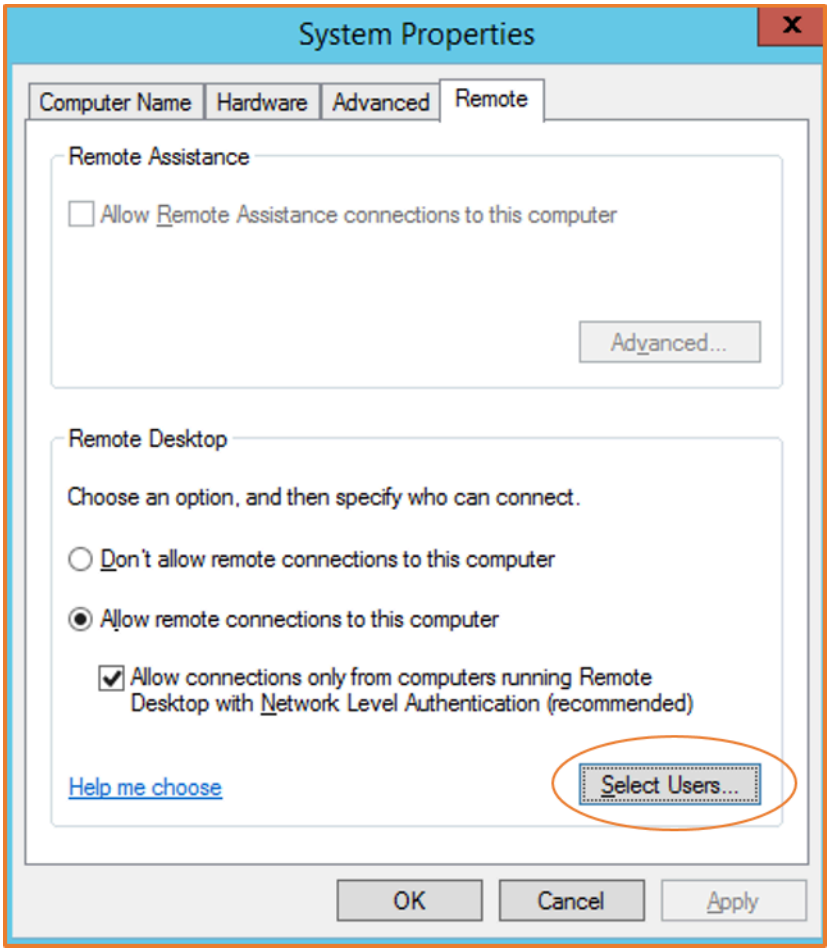
1. On the **Connect to instance** page, choose **Download remote desktop file**. When the file download is finished, choose **Cancel** to return to the **Instances** page. The RDP file is downloaded to your `Downloads` folder.
2. Run `mstsc.exe` to open the RDP client.
3. Expand **Show options**, choose **Open**, and select the .rdp file from your `Downloads` folder.
4. By default, **Computer** is the public IPv4 DNS name of the instance and **User name** is the administrator account. To connect to the instance using IPv6 instead, replace the public IPv4 DNS name of the instance with its IPv6 address. Review the default settings and change them as needed.
5. Choose **Connect**. If you receive a warning that the publisher of the remote connection is unknown, choose **Connect** to continue.
6. Enter the password that you saved previously, and then choose **OK**.
7. Due to the nature of self-signed certificates, you might get a warning that the security certificate could not be authenticated. Do one of the following:
   - If you trust the certificate, choose **Yes** to connect to your instance.
   - [Windows] Before you proceed, compare the thumbprint of the certificate with the value in the system log to confirm the identity of the remote computer. Choose **View certificate** and then choose **Thumbprint** from the **Details** tab. Compare this value to the value of `RDPCERTIFICATE-THUMBPRINT` in **Actions**, **Monitor and troubleshoot**, **Get system log**.
   - [Mac OS X] Before you proceed, compare the fingerprint of the certificate with the value in the system log to confirm the identity of the remote computer. Choose **Show Certificate**, expand **Details**, and choose **SHA1 Fingerprints**. Compare this value to the value of `RDPCERTIFICATE-THUMBPRINT` in **Actions**, **Monitor and troubleshoot**, **Get system log**.

8. If the RDP connection is successful, the RDP client displays the Windows login screen and then the Windows desktop. If you receive an error message instead, see the section called “Remote Desktop can't connect to the remote computer”. When you are finished with the RDP connection, you can close the RDP client.

Configure user accounts

After you connect to your instance over RDP, we recommend that you perform the following tasks:

- Change the administrator password from the default value. You can change the password while you are logged on to the instance itself, just as you would on any computer running Windows Server.
- Create another user with administrator privileges on the instance. This is a safeguard in case you forget the administrator password or have a problem with the administrator account. The new user must have permission to access the instance remotely. Open **System Properties** by right-clicking on the **This PC** icon on your Windows desktop or File Explorer and selecting **Properties**. Choose **Remote settings**, and choose **Select Users** to add the user to the **Remote Desktop Users** group.



Connect to your Windows instance using Fleet Manager

You can use Fleet Manager, a capability of AWS Systems Manager, to connect to Windows instances using the Remote Desktop Protocol (RDP) and display up to four Windows instances on the same page in the AWS Management Console. You can connect to the first instance in the Fleet Manager Remote Desktop directly from the **Instances** page in the Amazon EC2 console. For more information about Fleet Manager, see Connect to a managed instance using Remote Desktop in the *AWS Systems Manager User Guide*.

You do not need to specifically allow incoming RDP traffic from your IP address if you use Fleet Manager to connect. Fleet Manager handles that for you.

Prerequisites

Before attempting to connect to an instance using Fleet Manager, you must set up your environment. For more information, see Setting up your environment in the *AWS Systems Manager User Guide*.

To connect to a Windows instance using Fleet Manager

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation pane, choose **Instances**.
3. Select the instance and then choose **Connect**.
4. On the **RDP client** tab, for **Connection Type**, choose **Connect using Fleet Manager**.
5. Choose **Fleet Manager Remote Desktop**. This opens the **Fleet Manager Remote Desktop** page in the AWS Systems Manager console.
6. Enter your credentials and then choose **Connect**.
7. If the RDP connection is successful, Fleet Manager displays the Windows desktop. When you are finished with the session, choose **Actions**, **End session**.

For more information, see Connecting to a Windows Server managed instance using Remote Desktop in the *AWS Systems Manager User Guide*.

Transfer files to a Windows instance using RDP

You can work with your Windows instance in the same way that you would work with any Windows server. For example, you can transfer files between a Windows instance and your local computer using the local file sharing feature of the Microsoft Remote Desktop Connection (RDP) software. You can access local files on hard disk drives, DVD drives, portable media drives, and mapped network drives.

To access your local files from your Windows instances, you must enable the local file sharing feature by mapping the remote session drive to your local drive. The steps are slightly different depending on whether your local computer operating system is Windows or macOS X.

For more information about the prerequisites to connect using RDP, see Prerequisites.

Windows

To map the remote session drive to your local drive on your local Windows computer

1. Open the Remote Desktop Connection client.
2. Choose **Show Options**.
3. Add the instance host name to the **Computer** field and username to the **User name** field, as follows:

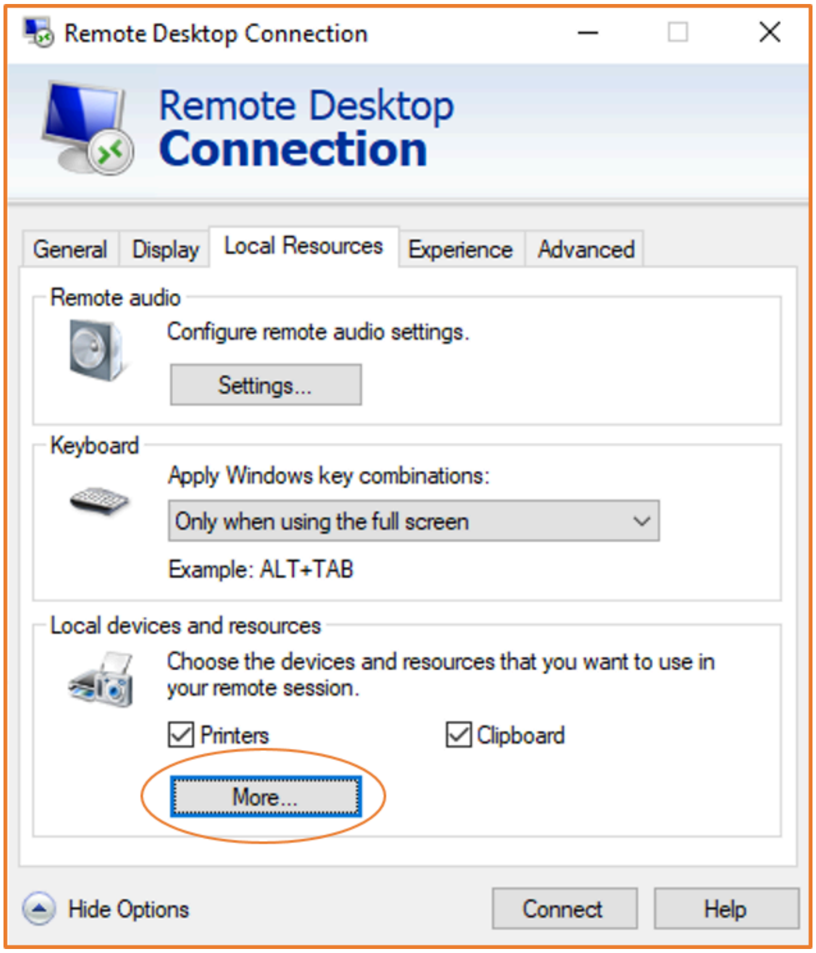
a. Under **Connection settings**, choose **Open...**, and browse to the RDP shortcut file that you downloaded from the Amazon EC2 console. The file contains the Public IPv4 DNS host name, which identifies the instance, and the Administrator user name.

b. Select the file and choose **Open**. The **Computer** and **User name** fields are populated with the values from the RDP shortcut file.

c. Choose **Save**.

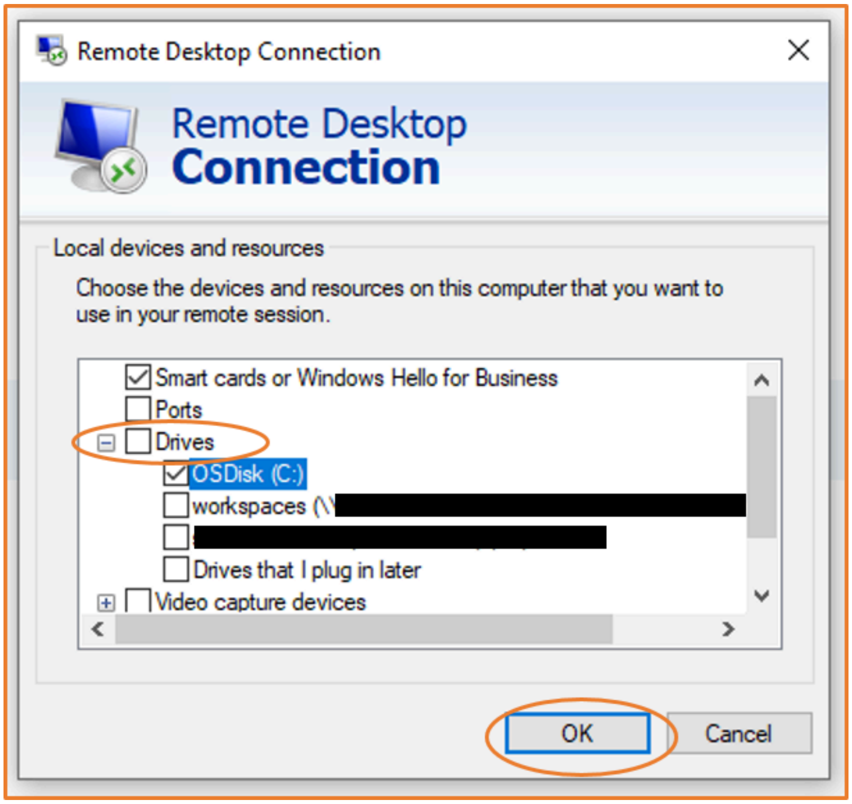
4. Choose the **Local Resources** tab.

5. Under **Local devices and resources**, choose **More...**



6. Open **Drives** and select the local drive to map to your Windows instance.

7. Choose **OK**.

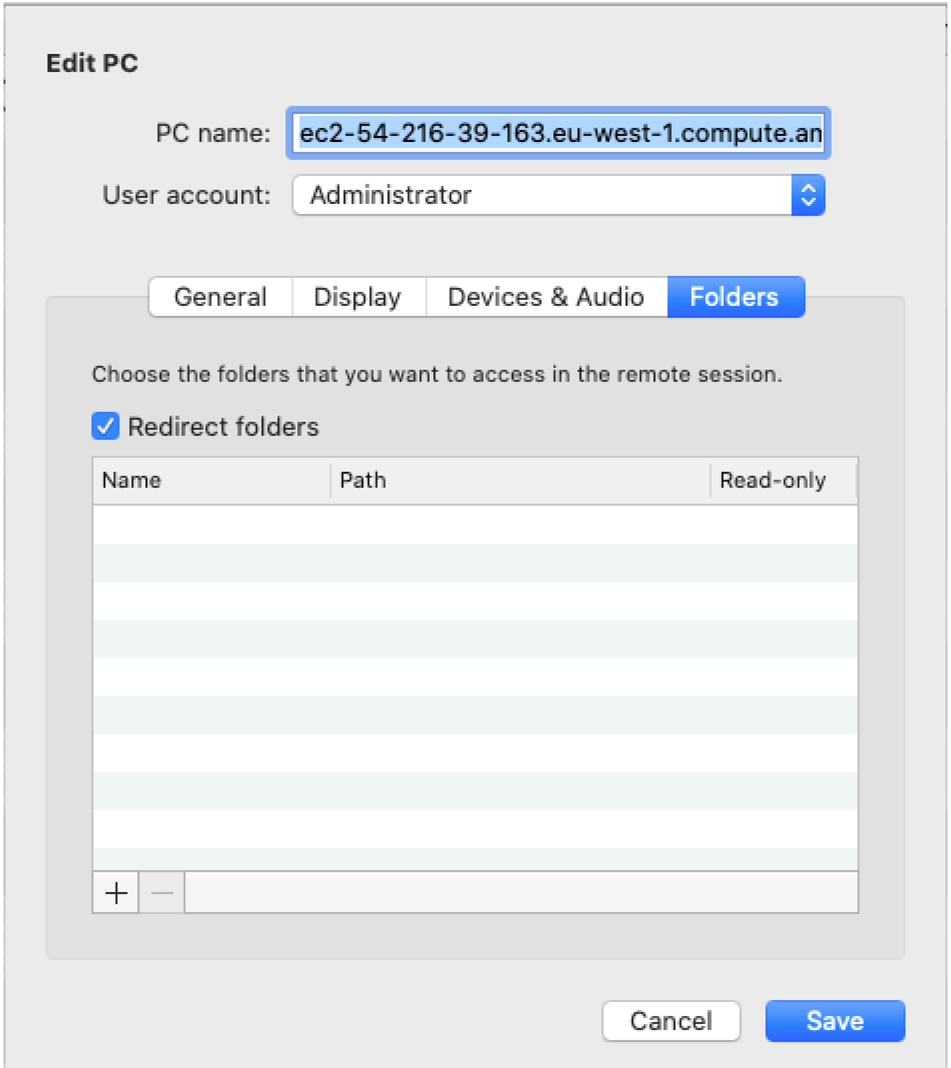


8. Choose **Connect** to connect to your Windows instance.

macOS X

To map the remote session drive to your local folder on your local macOS X computer

1. Open the Remote Desktop Connection client.
2. Browse to the RDP file that you downloaded from the Amazon EC2 console (when you initially connected to the instance), and drag it onto the Remote Desktop Connection client.
3. Right-click the RDP file, and choose **Edit**.
4. Choose the **Folders** tab, and select the **Redirect folders** checkbox.

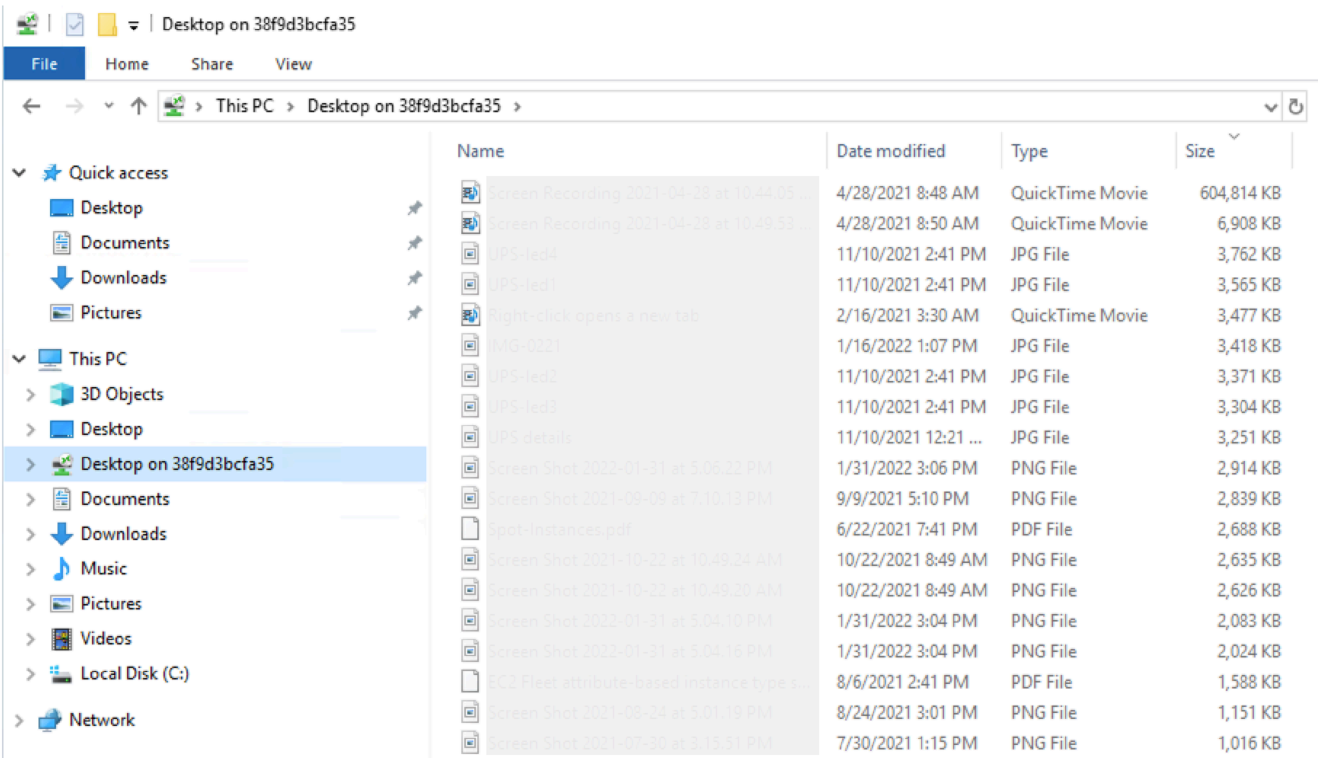


5. Choose the **+** icon at bottom left, browse to the folder to map, and choose **Open**. Repeat this step for every folder to map.

6. Choose **Save**.

7. Choose **Connect** to connect to your Windows instance. You'll be prompted for the password.

8. On the instance, in File Explorer, expand **This PC**, and find the shared folder from which you can access your local files. In the following screenshot, the **Desktop** folder on the local computer was mapped to the remote session drive on the instance.



For more information on making local devices available to a remote session on a Mac computer, see Get started with the macOS client.

Connect to your Amazon EC2 instance using Session Manager

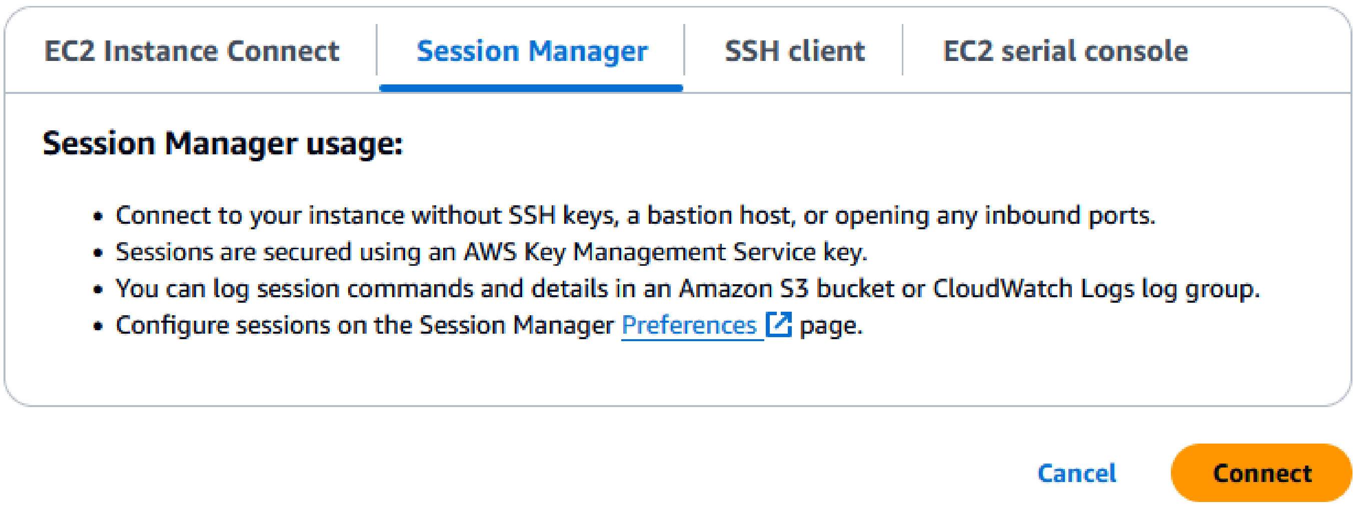
Session Manager is a fully-managed AWS Systems Manager capability for managing your Amazon EC2 instances through an interactive, one-click, browser-based shell, or through the AWS CLI. You can use Session Manager to start a session with an instance in your account. After the session is started, you can run interactive commands on the instance as you would for any other connection type. For more information about Session Manager, see AWS Systems Manager Session Manager in the *AWS Systems Manager User Guide*.

Prerequisites

Before you attempt to connect to an instance using Session Manager, you must complete the required setup steps. For example, the instance must be managed by SSM and must have an attached IAM role with the **AmazonSSMManagedInstanceCore** policy. For more information, see Setting up Session Manager.

To connect to an Amazon EC2 instance using Session Manager on the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. For the connection method, choose **Session Manager**.
5. Choose **Connect** to start the session.



Troubleshooting

If you receive an error that you're not authorized to perform one or more Systems Manager actions (`ssm:`*`command-name`*), you must update your policies to allow you to start sessions from the Amazon EC2 console. For more information and instructions, see [Quickstart default IAM policies for Session Manager]() in the *AWS Systems Manager User Guide*.

Connect to your Linux instance using a public IP address and EC2 Instance Connect

Amazon EC2 Instance Connect provides a secure way to connect to your Linux instances over Secure Shell (SSH). With EC2 Instance Connect, you use AWS Identity and Access Management (IAM) [policies]() and [principals]() to control SSH access to your instances, removing the need to share and manage SSH keys. All connection requests using EC2 Instance Connect are [logged to AWS CloudTrail]() so that you can audit connection requests.

You can use EC2 Instance Connect to connect to your instances using the Amazon EC2 console or the SSH client of your choice.

When you connect to an instance using EC2 Instance Connect, the EC2 Instance Connect API pushes an SSH public key to the instance metadata where it remains for 60 seconds. An IAM policy attached to your user authorizes your user to push the public key to the instance metadata. The SSH daemon uses `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, which are configured when EC2 Instance Connect is installed, to look up the public key from the instance metadata for authentication, and connects you to the instance.

> **Tip**
>
> EC2 Instance Connect is one of the options to connect to your Linux instance. For other options, see Connect to your Linux instance using SSH. To connect to a Windows instance, see Connect to your Windows instance using RDP.

Pricing

EC2 Instance Connect is available at no additional cost.

Region availability

EC2 Instance Connect is available in all AWS Regions, except Asia Pacific (Taipei). It is not supported in Local Zones.

Contents

For a blog post that discusses how to improve the security of your bastion hosts using EC2 Instance Connect, see Securing your bastion hosts with Amazon EC2 Instance Connect.

Tutorial: Complete the configuration required to connect to your instance using EC2 Instance Connect

To connect to your instance using EC2 Instance Connect in the Amazon EC2 console, you first need to complete the prerequisite configuration that will allow you to successfully connect to your instance. The purpose of this tutorial is to guide you through the tasks to complete the prerequisite configuration.

Tutorial overview

In this tutorial, you'll complete the following four tasks:

- Task 1: Grant permissions required to use EC2 Instance Connect

  First you'll create an IAM policy that contains the IAM permissions that allow you to push a public key to the instance metadata. You'll attach this policy to your IAM identity (user, user group, or role) so that your IAM identity gets these permissions.
- Task 2: Allow inbound traffic from the EC2 Instance Connect service to your instance

  Then you'll create a security group that allows traffic from the EC2 Instance Connect service to your instance. This is required when you use EC2 Instance Connect in the Amazon EC2 console to connect to your instance.
- Task 3: Launch your instance

  You'll then launch an EC2 instance using an AMI that is pre-installed with EC2 Instance Connect and you'll add the security group that you created in the previous step.
- Task 4: Connect to your instance

  Finally, you'll use EC2 Instance Connect in the Amazon EC2 console to connect to your instance. If you can connect, then you can be sure that the prerequisite configuration you completed in Tasks 1, 2, and 3 were successful.

Task 1: Grant permissions required to use EC2 Instance Connect

When you connect to an instance using EC2 Instance Connect, the EC2 Instance Connect API pushes an SSH public key to the instance metadata where it remains for 60 seconds. You need an IAM policy attached to your IAM identity (user, user group, or role) to grant you the required permission to push the public key to the instance metadata.

Task objective

You'll create the IAM policy that grants the permission to push the public key to the instance. The specific action to allow is `ec2-instance-connect:SendSSHPublicKey`. You must also allow the `ec2:DescribeInstances` action so that you can view and select your instance in the Amazon EC2 console.

After you've created the policy, you'll attach the policy to your IAM identity (user, user group, or role) so that your IAM identity gets the permissions.

You'll create a policy that is configured as follows:

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
            "Effect": "Allow",
            "Action": "ec2-instance-connect:SendSSHPublicKey",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ec2:DescribeInstances",
            "Resource": "*"
        }
    ]
}
```

> **Important**
>
> The IAM policy created in this tutorial is a highly permissive policy; it allows you to connect to any instance using any AMI username. We're using this highly permissive policy to keep the tutorial simple and focused on the specific configurations that this tutorial is teaching. However, in a production environment, we recommend that your IAM policy is configured to provide least-privilege permissions. For example IAM policies, see Grant IAM permissions for EC2 Instance Connect.

To create and attach an IAM policy that allows you to use EC2 Instance Connect to connect to your instances

1. **First create the IAM policy**

   a. Open the IAM console at https://console.aws.amazon.com/iam/.

   b. In the navigation pane, choose **Policies**.

   c. Choose **Create policy**.

   d. On the **Specify permission** page, do the following:

      i. For **Service**, choose **EC2 Instance Connect**.

      ii. Under **Actions allowed**, in the search field start typing **`send`** to show the relevant actions, and then select **SendSSHPublicKey**.

      iii. Under **Resources**, choose **All**. For a production environment, we recommend specifying the instance by its ARN, but for this tutorial, you're allowing all instances.

      iv. Choose **Add more permissions**.

      v. For **Service**, choose **EC2**.

      vi. Under **Actions allowed**, in the search field start typing **`describein`** to show the relevant actions, and then select **DescribeInstances**.

      vii. Choose **Next**.

   e. On the **Review and create** page, do the following:

      i. For **Policy name**, enter a name for the policy.

      ii. Choose **Create policy**.

2. **Then attach the policy to your identity**

   a. In the IAM console, in the navigation pane, choose **Policies**.

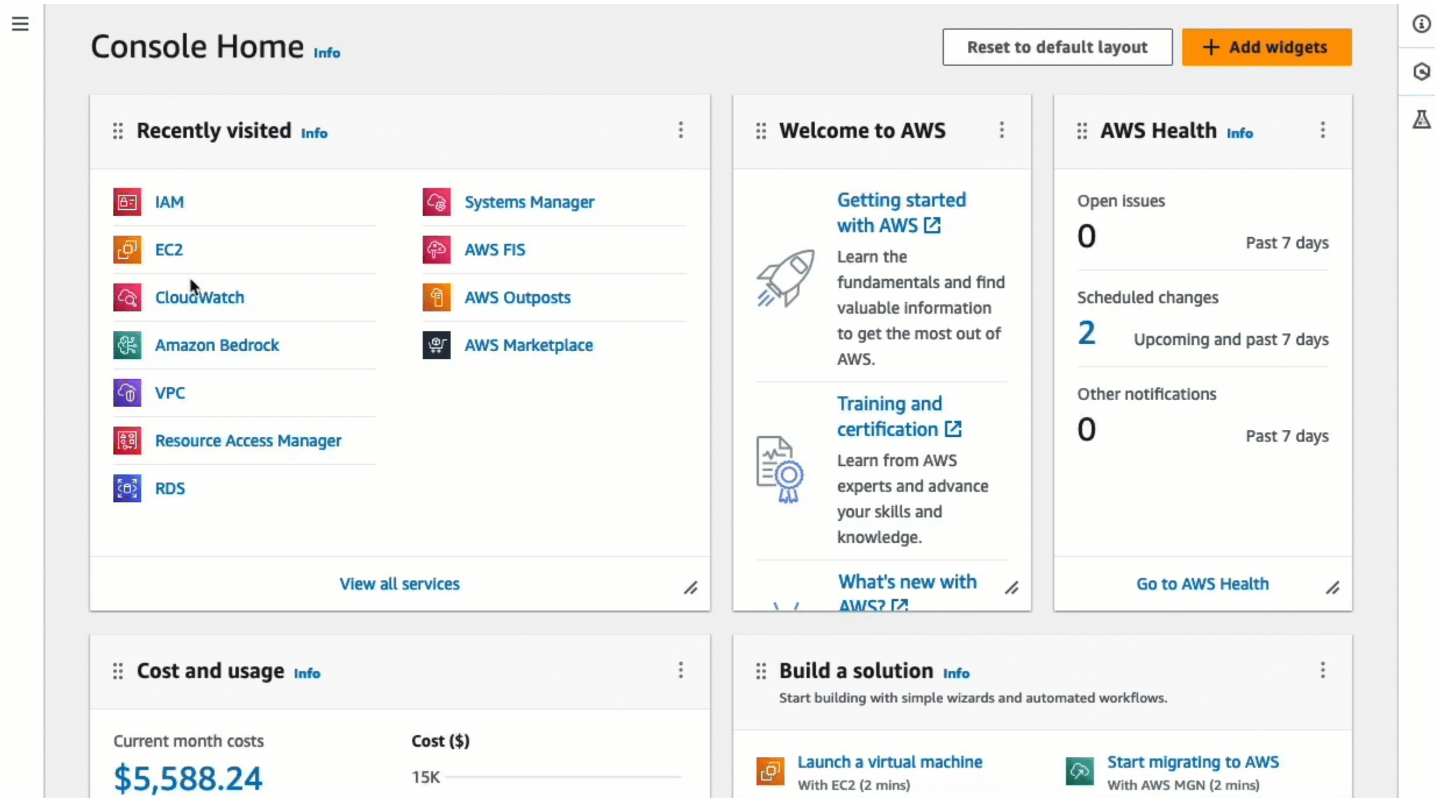
   b. In the list of policies, select the option button next to the name of the policy you created. You can use the search box to filter the list of policies.

   c. Choose **Actions**, **Attach**.

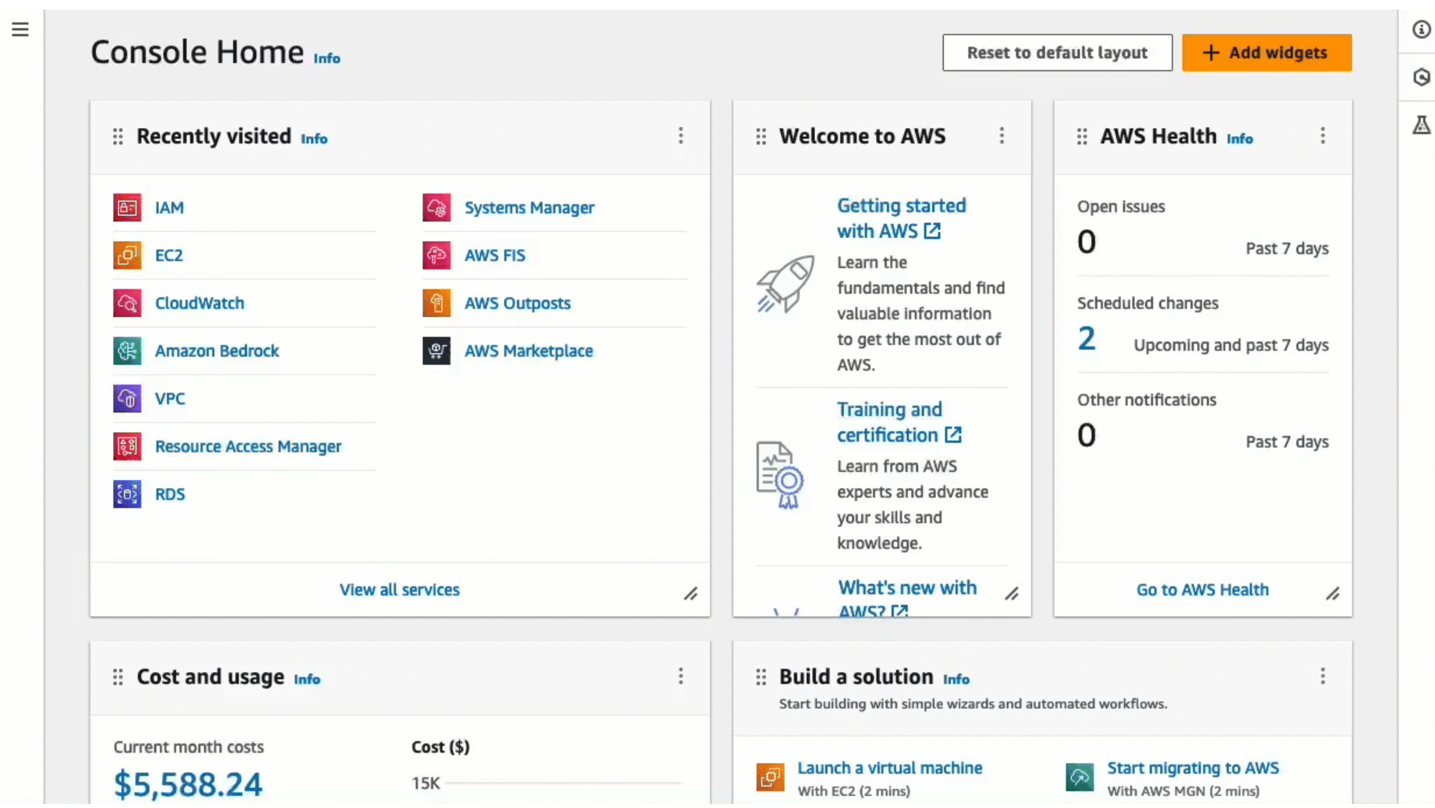
   d. Under **IAM entities**, select the checkbox next to your identity (user, user group, or role). You can use the search box to filter the list of entities.

   e. Choose **Attach policy**.

View an animation: Create an IAM policy



View an animation: Attach an IAM policy



Task 2: Allow inbound traffic from the EC2 Instance Connect service to your instance

When you use EC2 Instance Connect in the Amazon EC2 console to connect to an instance, the traffic that must be allowed to reach the instance is traffic from the EC2 Instance Connect service. This is different to connecting from your local computer to an instance; in that case, you must allow traffic from your local computer to your instance. To allow traffic from the EC2 Instance Connect service, you must create a security group that allows inbound SSH traffic from the IP address range for the EC2 Instance Connect service.

AWS uses prefix lists to manage IP address ranges. The names of the EC2 Instance Connect prefix lists are as follows, with *region* replaced by the Region code:

- IPv4 prefix list name: `com.amazonaws.region.ec2-instance-connect`
- IPv6 prefix list name: `com.amazonaws.region.ipv6.ec2-instance-connect`

Task objective

You'll create a security group that allows inbound SSH traffic on port 22 from the IPv4 prefix list in the Region in which your instance is located.

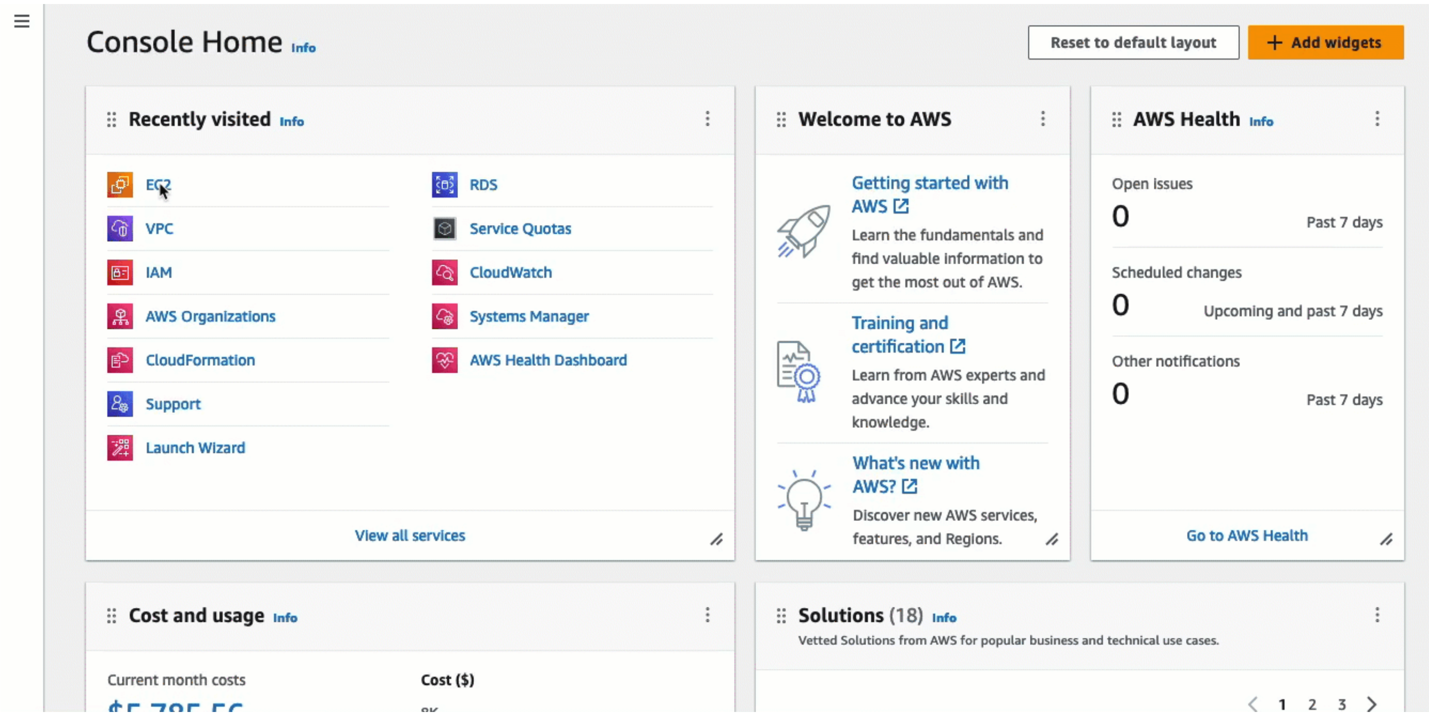
To create a security group that allows inbound traffic from the EC2 Instance Connect service to your instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Security Groups**.
3. Choose **Create security group**.
4. Under **Basic details**, do the following:
   a. For **Security group name**, enter a meaningful name for your security group.
   b. For **Description**, enter a meaningful description for your security group.
5. Under **Inbound rules**, do the following:
   a. Choose **Add rule**.
   b. For **Type**, choose **SSH**.
   c. For **Source**, leave **Custom**.
   d. In the field next to **Source**, select the prefix list for EC2 Instance Connect.

For example, if your instance is located in the US East (N. Virginia) (`us-east-1`) Region and your users will connect to its public IPv4 address, choose the following prefix list: **com.amazonaws.us-east-1.ec2-instance-connect**

6. Choose **Create security group**.

View an animation: Create the security group



Task 3: Launch your instance

When you launch an instance, you must specify an AMI that contains the information required to launch the instance. You can choose to launch an instance with or without EC2 Instance Connect pre-installed. In this task, we specify an AMI that comes pre-installed with EC2 Instance Connect.

If you launch your instance without EC2 Instance Connect pre-installed, and you want to use EC2 Instance Connect to connect to your instance, you'll need to perform additional configuration steps. These steps are outside the scope of this tutorial.

Task objective

You'll launch an instance with the Amazon Linux 2023 AMI, which comes pre-installed with EC2 Instance Connect. You'll also specify the security group that you created earlier so that you can use EC2 Instance Connect in the Amazon EC2 console to connect to your instance. Because you'll use EC2 Instance Connect to connect to your instance, which pushes a public key to your instance's metadata, you won't need to specify an SSH key when you launch your instance.

To launch an instance that can use EC2 Instance Connect in the Amazon EC2 console for connection

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, **Ireland**). Select a Region in which to launch your instance. This choice is important because you created a security group that allows traffic for a specific Region, so you must select the same Region in which to launch your instance.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
5. Under **Application and OS Images (Amazon Machine Image)**, choose **Quick Start**. **Amazon Linux** is selected by default. Under **Amazon Machine Image (AMI)**, **Amazon Linux 2023 AMI** is selected by default. Keep the default selection for this task.
6. Under **Instance type**, for **Instance type**, keep the default selection, or choose a different instance type.
7. Under **Key pair (login)**, for **Key pair name**, choose **Proceed without a key pair (Not recommended)**. When you use EC2 Instance Connect to connect to an instance, EC2 Instance Connect pushes a key pair to the instance's metadata, and it is this key pair that is used for the connection.
8. Under **Network settings**, do the following:

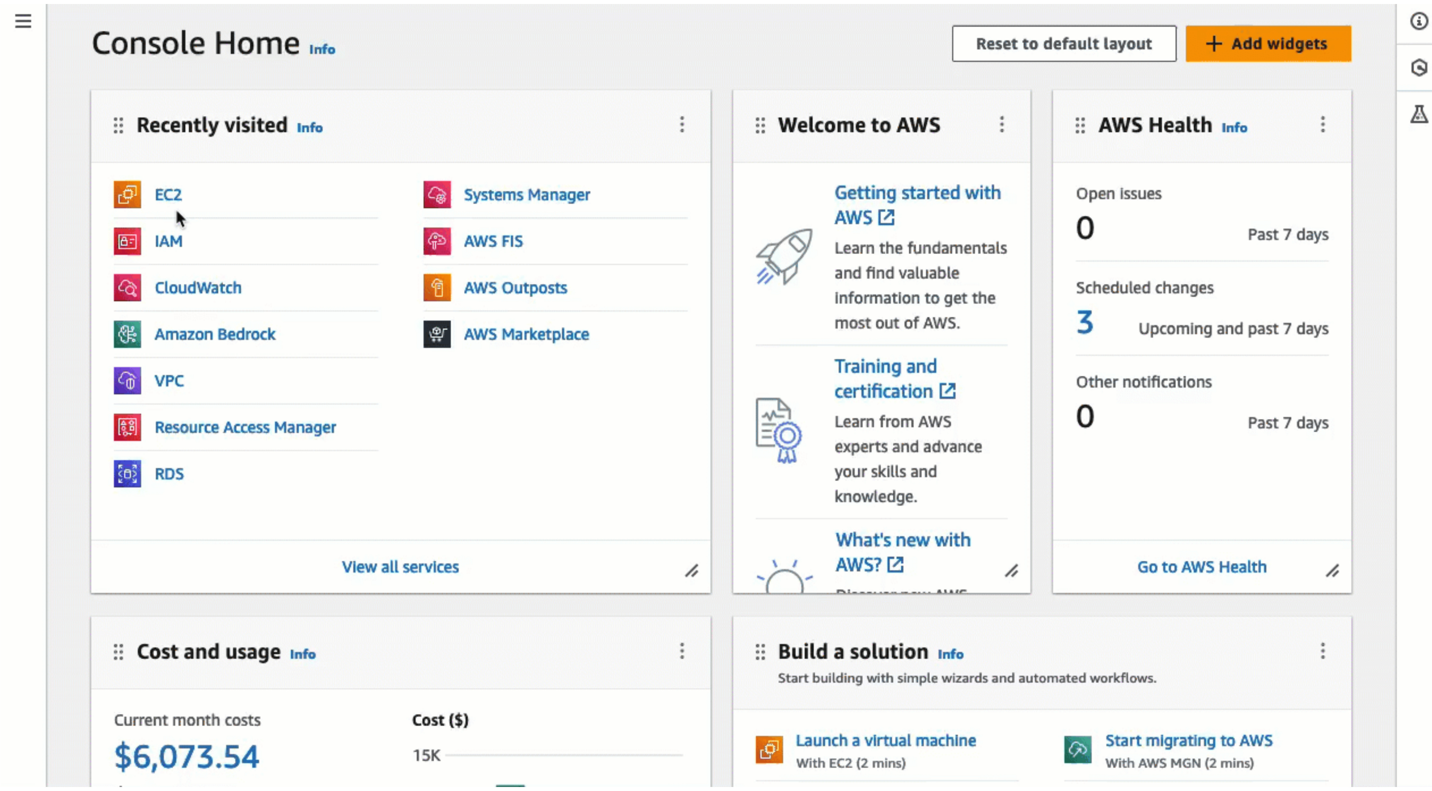
   a. For **Auto-assign public IP**, leave **Enable**.

      > **Note**
      >
      > To use EC2 Instance Connect in the Amazon EC2 console to connect to an instance, the instance must have a public IPv4 or public IPv6 address.

   b. For **Firewall (security groups)**, choose **Select existing security group**.

   c. Under **Common security groups**, choose the security group that you created earlier.
9. In the **Summary** panel, choose **Launch instance**.

View an animation: Launch your instance



Task 4: Connect to your instance

When you connect to an instance using EC2 Instance Connect, the EC2 Instance Connect API pushes an SSH public key to the [instance metadata](#) where it remains for 60 seconds. The SSH daemon uses `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` to look up the public key from the instance metadata for authentication, and connects you to the instance.

Task objective

In this task, you'll connect to your instance using EC2 Instance Connect in the Amazon EC2 console. If you completed the prerequisite Tasks 1, 2, and 3, the connection should be successful.

Steps to connect to your instance

Use the following steps to connect to your instance. To view an animation of the steps, see [View an animation: Connect to your instance](#).

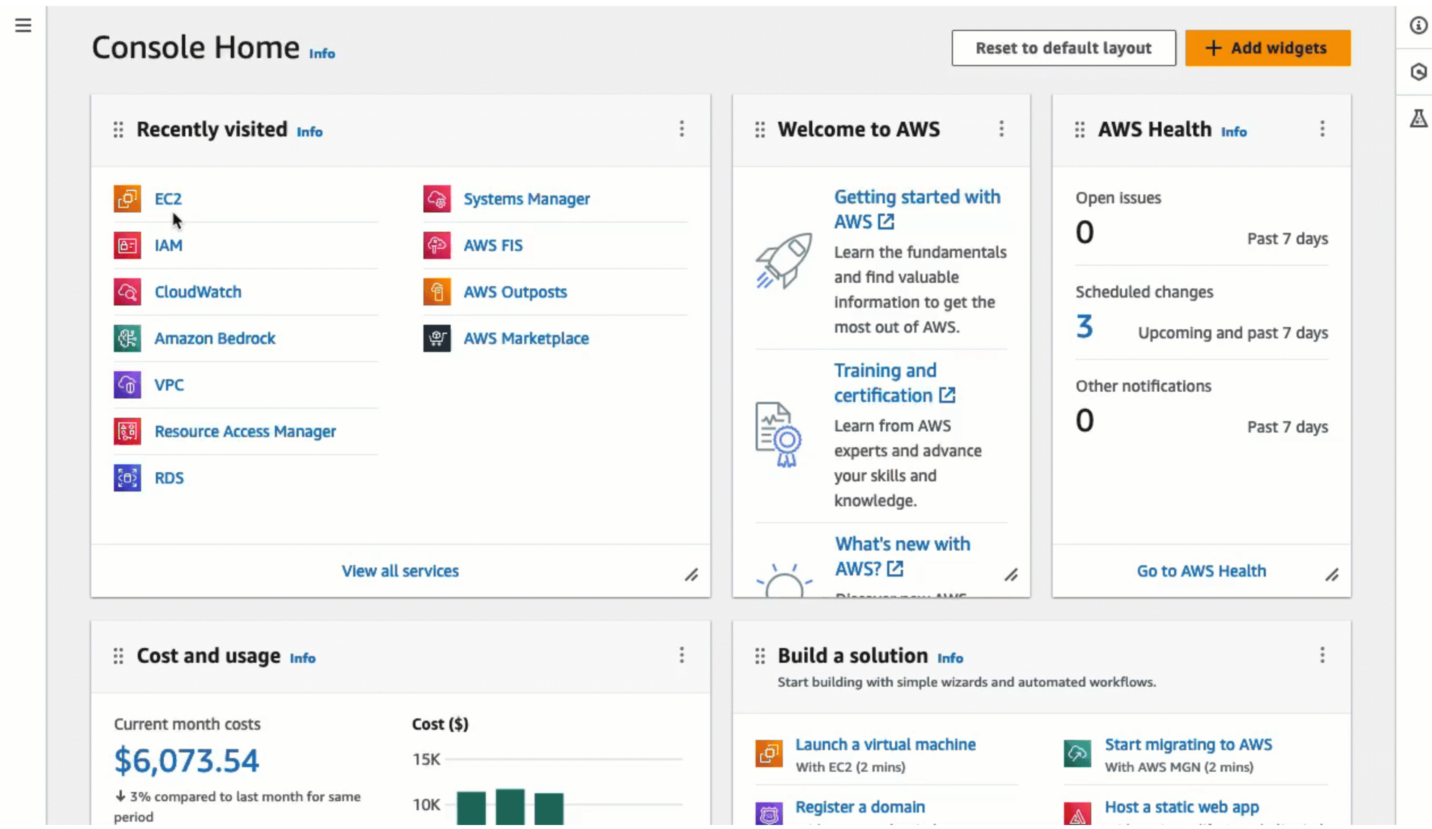
To connect an instance using EC2 Instance Connect in the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, **Ireland**). Select the Region in which your instance is located.
3. In the navigation pane, choose **Instances**.
4. Select your instance and choose **Connect**.
5. Choose the **EC2 Instance Connect** tab.
6. Choose **Connect using a Public IP**.
7. Choose **Connect**.

   A terminal window opens in the browser, and you are connected to your instance.

View an animation: Connect to your instance



Prerequisites for EC2 Instance Connect

The following are the prerequisites for installing and using EC2 Instance Connect:

- Install EC2 Instance Connect
- Ensure network connectivity
- Allow inbound SSH traffic

- Grant permissions
- Install an SSH client on your local computer
- Meet username requirements

Install EC2 Instance Connect

To use EC2 Instance Connect to connect to an instance, the instance must have EC2 Instance Connect installed. You can either launch the instance using an AMI that comes pre-installed with EC2 Instance Connect, or you can install EC2 Instance Connect on instances that are launched with supported AMIs. For more information, see Install EC2 Instance Connect on your EC2 instances.

Ensure network connectivity

Instances can be configured to allow users to connect to your instance over the internet or through the instance's private IP address. Depending on how your users will connect to your instance using EC2 Instance Connect, you must configure the following network access:

- If your users will connect to your instance over the internet, then your instance must have a public IPv4 or public IPv6 address and be in a public subnet with a route to the internet. If you haven't modified your default public subnet, then it contains a route to the internet for IPv4 only, and not for IPv6. For more information, see Enable VPC internet access using internet gateways in the *Amazon VPC User Guide*.
- If your users will connect to your instance through the instance's private IPv4 address, then you must establish private network connectivity to your VPC, such as by using AWS Direct Connect, AWS Site-to-Site VPN, or VPC peering, so that your users can reach the instance's private IP address.

If your instance does not have a public IPv4 or public IPv6 address and you prefer not to configure the network access as described above, you can consider EC2 Instance Connect Endpoint as an alternative to EC2 Instance Connect. With EC2 Instance Connect Endpoint, you can connect to an instance using SSH or RDP even if the instance does not have a public IPv4 or public IPv6 address. For more information, see Connect to your Linux instance using the Amazon EC2 console.

Allow inbound SSH traffic

When using the Amazon EC2 console to connect to an instance

When users connect to an instance using the Amazon EC2 console, the traffic that must be allowed to reach the instance is traffic from the EC2 Instance Connect service. The service is identified by specific IP address ranges, which AWS manages through prefix lists. You must create a security group that allows inbound SSH traffic from the EC2 Instance Connect service. To configure this, for the inbound rule, in the field next to **Source**, select the EC2 Instance Connect prefix list.

AWS provides different managed prefix lists for IPv4 and IPv6 addresses for each Region. The names of the EC2 Instance Connect prefix lists are as follows, with *region* replaced by the Region code:

- IPv4 prefix list name: `com.amazonaws.region.ec2-instance-connect`
- IPv6 prefix list name: `com.amazonaws.region.ipv6.ec2-instance-connect`

For the instructions for creating the security group, see Task 2: Allow inbound traffic from the EC2 Instance Connect service to your instance. For more information, see Available AWS-managed prefix lists in the *Amazon VPC User Guide*.

When using the CLI or SSH to connect to an instance

Ensure that the security group associated with your instance allows inbound SSH traffic on port 22 from your IP address or from your network. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch instance wizard allows incoming SSH traffic by default. For more information, see Rules to connect to instances from your computer.

Grant permissions

You must grant the required permissions to every IAM user who will use EC2 Instance Connect to connect to an instance. For more information, see Grant IAM permissions for EC2 Instance Connect.

Install an SSH client on your local computer

If your users will connect using SSH, they must ensure that their local computer has an SSH client.

A user's local computer most likely has an SSH client installed by default. They can check for an SSH client by typing **ssh** at the command line. If their local computer doesn't recognize the command, they can install an SSH client. For information about installing an SSH client on Linux or macOS X, see http://www.openssh.com. For information about installing an SSH client on Windows 10, see OpenSSH in Windows.

There is no need to install an SSH client on a local computer if your users use only the Amazon EC2 console to connect to an instance.

Meet username requirements

When using EC2 Instance Connect to connect to an instance, the username must meet the following requirements:

- First character: Must be a letter (`A-Z`, `a-z`), a digit (`0-9`), or an underscore (`_`)
- Subsequent characters: Can be letters (`A-Z`, `a-z`), digits (`0-9`), or the following characters: `@ . _ -`
- Minimum length: 1 character
- Maximum length: 31 characters

Grant IAM permissions for EC2 Instance Connect

To connect to an instance using EC2 Instance Connect, you must create an IAM policy that grants your users permissions for the following actions and condition:

- `ec2-instance-connect:SendSSHPublicKey` action – Grants permission to push the public key to an instance.
- `ec2:osuser` condition – Specifies the name of the OS user that can push the public key to an instance. Use the default username for the AMI that you used to launch the instance. The default username for AL2023 and Amazon Linux 2 is `ec2-user`, and for Ubuntu it's `ubuntu`.
- `ec2:DescribeInstances` action – Required when using the EC2 console because the wrapper calls this action. Users might already have permission to call this action from another policy.
- `ec2:DescribeVpcs` action – Required when connecting to an IPv6 address.

Consider restricting access to specific EC2 instances. Otherwise, all IAM principals with permission for the `ec2-instance-connect:SendSSHPublicKey` action can connect to all EC2 instances. You can restrict access by specifying resource ARNs or by using resource tags as condition keys.

For more information, see Actions, resources, and condition keys for Amazon EC2 Instance Connect.

For information about creating IAM policies, see Creating IAM policies in the *IAM User Guide*.

Allow users to connect to specific instances

The following IAM policy grants permission to connect to specific instances, identified by their resource ARNs.

In the following example IAM policy, the following actions and condition are specified:

- The `ec2-instance-connect:SendSSHPublicKey` action grants users permission to connect to two instances, specified by the resource ARNs. To grant users permission to connect to *all* EC2 instances, replace the resource ARNs with the `*` wildcard.
- The `ec2:osuser` condition grants permission to connect to the instances only if the *`ami-username`* is specified when connecting.
- The `ec2:DescribeInstances` action is specified to grant permission to users who will use the console to connect to your instances. If your users will only use an SSH client to connect to your instances, you can omit `ec2:DescribeInstances`. Note that the `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the `Resource` element.
- The `ec2:DescribeVpcs` action is specified to grant permission to users who will use the console to connect to your instances using an IPv6 address. If your users will only use a public IPv4 address, you can omit `ec2:DescribeVpcs`. Note that the `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the `Resource` element.

JSON

```
{
    "Version": "2012-10-17",
    "Statement": [{
            "Effect": "Allow",
            "Action": "ec2-instance-connect:SendSSHPublicKey",
            "Resource": [
                "arn:aws:ec2:us-
east-1:111122223333:instance/i-1234567890abcdef0",
                "arn:aws:ec2:us-east-1:111122223333:instance/i-0598c7d356eba48d7"
            ],
            "Condition": {
                "StringEquals": {
                    "ec2:osuser": "ami-username"
```

```
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeInstances",
                "ec2:DescribeVpcs"
            ],
            "Resource": "*"
        }
    ]
}
```

Allow users to connect to instances with specific tags

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. You can use resource tags to control access to an instance. For more information about using tags to control access to your AWS resources, see Controlling access to AWS resources in the *IAM User Guide*.

In the following example IAM policy, the `ec2-instance-connect:SendSSHPublicKey` action grants users permission to connect to any instance (indicated by the `*` wildcard in the resource ARN) on condition that the instance has a resource tag with key=`tag-key` and value=`tag-value`.

The `ec2:DescribeInstances` action is specified to grant permission to users who will use the console to connect to your instances. If your users will use only an SSH client to connect to your instances, you can omit `ec2:DescribeInstances`. Note that the `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the `Resource` element.

The `ec2:DescribeVpcs` action is specified to grant permission to users who will use the console to connect to your instances using an IPv6 address. If your users will only use a public IPv4 address, you can omit `ec2:DescribeVpcs`. Note that the `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the `Resource` element.

                "ec2:DescribeVpcs"
            ],
            "Resource": "*"
        }
    ]
}
```

Install EC2 Instance Connect on your EC2 instances

To connect to a Linux instance using EC2 Instance Connect, the instance must have EC2 Instance Connect installed. Installing EC2 Instance Connect configures the SSH daemon on the instance.

For more information about the EC2 Instance Connect package, see aws/aws-ec2-instance-connect-config on the GitHub website.

> **Note**
>
> If you configured the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` settings for SSH authentication, the EC2 Instance Connect installation will not update them. As a result, you can't use EC2 Instance Connect.

Install prerequisites

Before you install EC2 Instance Connect, ensure that you meet the following prerequisites.

- **Verify that the instance uses one of the following:**

- Amazon Linux 2 prior to version 2.0.20190618 *
- AL2023 minimal AMI or Amazon ECS-optimized AMI
- CentOS Stream 8 and 9
- macOS Sonoma prior to 14.2.1, Ventura prior to 13.6.3, and Monterey prior to 12.7.2 *
- Red Hat Enterprise Linux (RHEL) 8 and 9
- Ubuntu 16.04 and 18.04 *

> **Tip**
>
> * For Amazon Linux 2, macOS, and Ubuntu: If you launched your instance using a later version than those listed above, EC2 Instance Connect comes preinstalled and no manual installation is required.

- **Verify the general prerequisites for EC2 Instance Connect.**

  For more information, see Prerequisites for EC2 Instance Connect.
- **Verify the prerequisites for connecting to your instance using an SSH client on your local machine.**

  For more information, see Connect to your Linux instance using SSH.
- **Get the ID of the instance.**

  You can get the ID of your instance using the Amazon EC2 console (from the **Instance ID** column). If you prefer, you can use the describe-instances (AWS CLI) or Get-EC2Instance (AWS Tools for Windows PowerShell) command.

Manually install EC2 Instance Connect

> **Note**
>
> If you launched your instance using one of the following AMIs, EC2 Instance Connect is pre-installed and you can skip this procedure:
>
> - AL2023 standard AMI
> - Amazon Linux 2 2.0.20190618 or later
> - macOS Sonoma 14.2.1 or later

- macOS Ventura 13.6.3 or later
- macOS Monterey 12.7.2 or later
- Ubuntu 20.04 or later

Use one of the following procedures for installing EC2 Instance Connect, depending on the operating system of your instance.

Amazon Linux 2

To install EC2 Instance Connect on an instance launched with Amazon Linux 2

1. Connect to your instance using SSH.

   Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For Amazon Linux 2, the default username is `ec2-user`.

   ```
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

   For more information about connecting to your instance, see Connect to your Linux instance using an SSH client.

2. Install the EC2 Instance Connect package on your instance.

   ```
   [ec2-user ~]$ sudo yum install ec2-instance-connect
   ```

   You should see three new scripts in the `/opt/aws/bin/` folder:

   ```
   eic_curl_authorized_keys
   eic_parse_authorized_keys
   eic_run_authorized_keys
   ```

3. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

   ```
   [ec2-user ~]$ sudo less /etc/ssh/sshd_config
   ```

EC2 Instance Connect was successfully installed if the AuthorizedKeysCommand and AuthorizedKeysCommandUser lines contain the following values:

```
AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f
AuthorizedKeysCommandUser ec2-instance-connect
```

- AuthorizedKeysCommand sets the eic_run_authorized_keys script to look up the keys from the instance metadata
- AuthorizedKeysCommandUser sets the system user as ec2-instance-connect

Note

If you previously configured AuthorizedKeysCommand and AuthorizedKeysCommandUser, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

CentOS

To install EC2 Instance Connect on an instance launched with CentOS

1. Connect to your instance using SSH.

   Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For CentOS, the default username is centos or ec2-user.

   ```
   $ ssh -i my_ec2_private_key.pem centos@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

   For more information about connecting to your instance, see Connect to your Linux instance using an SSH client.

2. If you use an HTTP or HTTPS proxy, you must set the http_proxy or https_proxy environment variables in the current shell session.

   If you're not using a proxy, you can skip this step.

- For an HTTP proxy server, run the following commands:

```
$ export http_proxy=http://hostname:port
$ export https_proxy=http://hostname:port
```

- For an HTTPS proxy server, run the following commands:

```
$ export http_proxy=https://hostname:port
$ export https_proxy=https://hostname:port
```

3. Install the EC2 Instance Connect package on your instance by running the following commands.

   The EC2 Instance Connect configuration files for CentOS are provided in a Red Hat Package Manager (RPM) package, with different RPM packages for CentOS 8 and CentOS 9 and for instance types that run on Intel/AMD (x86_64) or ARM (AArch64).

   Use the command block for your operating system and CPU architecture.

   - CentOS 8

     Intel/AMD (x86_64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-
west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-
connect-2.0.0-5.rhel8.x86_64.rpm -o /tmp/ec2-instance-connect/ec2-instance-
connect.rpm
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-
west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-
selinux-2.0.0-5.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-
selinux.rpm
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-
connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

     ARM (AArch64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-
west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-
```

```
connect-2.0.0-5.rhel8.aarch64.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect.rpm
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-connect-selinux-2.0.0-5.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

- CentOS 9

  Intel/AMD (x86_64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-2.0.0-5.rhel9.x86_64.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect.rpm
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-selinux-2.0.0-5.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

  ARM (AArch64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-connect-2.0.0-5.rhel9.aarch64.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect.rpm
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-connect-selinux-2.0.0-5.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

You should see the following new script in the `/opt/aws/bin/` folder:

```
eic_run_authorized_keys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

   - For CentOS 8:

     ```
     [ec2-user ~]$ sudo less /lib/systemd/system/sshd.service.d/ec2-instance-connect.conf
     ```

   - For CentOS 9:

     ```
     [ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
     ```

   EC2 Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines contain the following values:

   ```
   AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f
   AuthorizedKeysCommandUser ec2-instance-connect
   ```

   - `AuthorizedKeysCommand` sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
   - `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

   > **Note**
   >
   > If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

macOS

To install EC2 Instance Connect on an instance launched with macOS

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For macOS instances, the default username is `ec2-user`.

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance using an SSH client.

2. Update Homebrew using the following command. The update will list the software that Homebrew knows about. The EC2 Instance Connect package is provided via Homebrew on macOS instances. For more information, see Update the operating system and software on Amazon EC2 Mac instances.

```
[ec2-user ~]$ brew update
```

3. Install the EC2 Instance Connect package on your instance. This will install the software and configure sshd to use it.

```
[ec2-user ~]$ brew install ec2-instance-connect
```

You should see the following new script in the `/opt/aws/bin/` folder:

```
eic_run_authorized_keys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

```
[ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
```

EC2 Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines contain the following values:

```
AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

> **Note**
>
> If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

RHEL

To install EC2 Instance Connect on an instance launched with Red Hat Enterprise Linux (RHEL)

1. Connect to your instance using SSH.

   Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For RHEL, the default username is `ec2-user` or `root`.

   ```
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

   For more information about connecting to your instance, see Connect to your Linux instance using an SSH client.

2. If you use an HTTP or HTTPS proxy, you must set the `http_proxy` or `https_proxy` environment variables in the current shell session.

   If you're not using a proxy, you can skip this step.

   - For an HTTP proxy server, run the following commands:

     ```
     $ export http_proxy=http://hostname:port
     $ export https_proxy=http://hostname:port
     ```

- For an HTTPS proxy server, run the following commands:

```
$ export http_proxy=https://hostname:port
$ export https_proxy=https://hostname:port
```

3. Install the EC2 Instance Connect package on your instance by running the following commands.

   The EC2 Instance Connect configuration files for RHEL are provided in a Red Hat Package Manager (RPM) package, with different RPM packages for RHEL 8 and RHEL 9 and for instance types that run on Intel/AMD (x86_64) or ARM (AArch64).

   Use the command block for your operating system and CPU architecture.

   - RHEL 8

     Intel/AMD (x86_64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-
west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-
connect-2.0.0-5.rhel8.x86_64.rpm -o /tmp/ec2-instance-connect/ec2-instance-
connect.rpm
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-
west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-
selinux-2.0.0-5.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-
selinux.rpm
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-
connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

     ARM (AArch64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-
west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-
connect-2.0.0-5.rhel8.aarch64.rpm -o /tmp/ec2-instance-connect/ec2-instance-
connect.rpm
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-
west-2.amazonaws.com/latest/linux_arm64/ec2-instance-connect-
selinux-2.0.0-5.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-
selinux.rpm
```

```
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

- RHEL 9

  Intel/AMD (x86_64)

  ```
  [ec2-user ~]$ mkdir /tmp/ec2-instance-connect
  [ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-2.0.0-5.rhel9.x86_64.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect.rpm
  [ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-selinux-2.0.0-5.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
  [ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
  ```

  ARM (AArch64)

  ```
  [ec2-user ~]$ mkdir /tmp/ec2-instance-connect
  [ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-connect-2.0.0-5.rhel9.aarch64.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect.rpm
  [ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-connect-selinux-2.0.0-5.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
  [ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
  ```

You should see the following new script in the `/opt/aws/bin/` folder:

```
eic_run_authorized_keys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

   - For RHEL 8:

```
[ec2-user ~]$ sudo less /lib/systemd/system/sshd.service.d/ec2-instance-connect.conf
```

- For RHEL 9:

```
[ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
```

EC2 Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines contain the following values:

```
AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

> **Note**
>
> If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

Ubuntu

To install EC2 Instance Connect on an instance launched with Ubuntu 16.04 or later

1. Connect to your instance using SSH.

   Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and use the default username of the AMI that you used to launch your instance. For an Ubuntu AMI, the username is `ubuntu`.

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance using an SSH client.

2. (Optional) Ensure your instance has the latest Ubuntu AMI.

   Run the following commands to update all the packages on your instance.

   ```
   ubuntu:~$ sudo apt-get update
   ```

   ```
   ubuntu:~$ sudo apt-get upgrade
   ```

3. Install the EC2 Instance Connect package on your instance.

   ```
   ubuntu:~$ sudo apt-get install ec2-instance-connect
   ```

   You should see three new scripts in the `/usr/share/ec2-instance-connect/` folder:

   ```
   eic_curl_authorized_keys
   eic_parse_authorized_keys
   eic_run_authorized_keys
   ```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

   ```
   ubuntu:~$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
   ```

   EC2 Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines contain the following values:

   ```
   AuthorizedKeysCommand /usr/share/ec2-instance-connect/eic_run_authorized_keys %%u %%f
   AuthorizedKeysCommandUser ec2-instance-connect
   ```

   - `AuthorizedKeysCommand` sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
   - `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

> **Note**
>
> If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

Connect to a Linux instance using EC2 Instance Connect

The following instructions explain how to connect to your Linux instance using EC2 Instance Connect through the Amazon EC2 console, the AWS CLI, or an SSH client.

When you connect to an instance using EC2 Instance Connect through the console or AWS CLI, the EC2 Instance Connect API automatically pushes an SSH public key to the instance metadata where it remains for 60 seconds. An IAM policy attached to your user authorizes this action. If you prefer using your own SSH key, you can use an SSH client and explicitly push your SSH key to the instance using EC2 Instance Connect.

Considerations

After connecting to an instance using EC2 Instance Connect, the connection persists until the SSH session is terminated. The duration of the connection is not determined by the duration of your IAM credentials. If your IAM credentials expire, the connection continues to persist. When using the EC2 Instance Connect console experience, if your IAM credentials expire, terminate the connection by closing the browser page. When using your own SSH client and EC2 Instance Connect to push your key, you can set a SSH timeout value to terminate the SSH session automatically.

Requirements

Before you begin, be sure to review the prerequisites.

Connection options

- Connect using the Amazon EC2 console
- Connect using the AWS CLI
- Connect using your own key and SSH client
- Troubleshoot

Connect using the Amazon EC2 console

You can connect to an instance using EC2 Instance Connect through the Amazon EC2 console.

Requirements

To connect using the Amazon EC2 console, the instance must have either a public IPv4 or a public IPv6 address. If the instance only has a private IPv4 address, you can use the ec2-instance-connect AWS CLI to connect.

To connect to your instance using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. Choose the **EC2 Instance Connect** tab.
5. Choose **Connect using a Public IP**.
6. If there is a choice, select the IP address to connect to. Otherwise, the IP address is selected automatically.
7. For **Username**, verify the username.
8. Choose **Connect** to establish a connection. An in-browser terminal window opens.

Connect using the AWS CLI

You can use the ec2-instance-connect AWS CLI to connect to your instance with an SSH client. EC2 Instance Connect attempts to establish a connection using an available IP address in a predefined order, based on the specified connection type. If an IP address isn't available, it automatically tries the next one in the order.

Connection types

`auto` (default)

EC2 Instance Connect tries to connect using the instance's IP addresses in the following order and with the corresponding connection type:

1. Public IPv4: `direct`
2. Private IPv4: `eice`

3. Public IPv6: `direct`

`direct`

EC2 Instance Connect tries to connect using the instance's IP addresses in the following order:

1. Public IPv4
2. Public IPv6
3. Private IPv4 (it does not connect over an EC2 Instance Connect Endpoint)

`eice`

EC2 Instance Connect tries to connect using the instance's private IPv4 address and an EC2 Instance Connect Endpoint.

> **Note**
>
> In the future, we might change the behavior of the `auto` connection type. To ensure that your desired connection type is used, we recommend that you explicitly set the `--connection-type` to either `direct` or `eice`.
> Connecting to a *private* IPv6 address is not supported when using the ec2-instance-connect AWS CLI.

Requirements

You must use AWS CLI version 2. For more information, see Install or update to the latest version of the AWS CLI.

To connect to an instance using the instance ID

If you only know the instance ID, and want to let EC2 Instance Connect determine the connection type to use when connecting to your instance, use the ec2-instance-connect ssh CLI command with the instance ID.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example
```

To connect to an instance using the instance ID and an EC2 Instance Connect Endpoint

If you want to connect to your instance over an EC2 Instance Connect Endpoint, use the preceding command and also specify the `--connection-type` parameter with the `eice` value.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example --connection-type eice
```

To connect to an instance using the instance ID and your own private key file

If you want to connect to your instance over an EC2 Instance Connect Endpoint using your own private key, specify the instance ID and the path to the private key file. Do not include *file://* in the path; the following example will fail: *file:///path/to/key*.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example --private-key-file /
path/to/key.pem
```

> **Tip**
>
> If you get an error when using these commands, make sure that you're using AWS CLI version 2, because the `ssh` command is only available in this major version. We also recommend regularly updating to the latest minor version of AWS CLI version 2 to access the latest features. For more information, see About AWS CLI version 2 in the *AWS Command Line Interface User Guide*.

Connect using your own key and SSH client

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the EC2 Instance Connect API. This enables you to benefit from the EC2 Instance Connect capability to push a public key to the instance. This connection method works for instances with public and private IP addresses.

Requirements

- Requirements for key pairs
  - Supported types: RSA (OpenSSH and SSH2) and ED25519
  - Supported lengths: 2048 and 4096
  - For more information, see Create a key pair using a third-party tool and import the public key to Amazon EC2.
- When connecting to an instance that has only private IP addresses, the local computer from which you are initiating the SSH session must have connectivity to the EC2 Instance Connect service endpoint (to push your SSH public key to the instance) as well as network connectivity to

the instance's private IP address to establish the SSH session. The EC2 Instance Connect service endpoint is reachable over the internet or over an AWS Direct Connect public virtual interface. To connect to the instance's private IP address, you can leverage services such as AWS Direct Connect, AWS Site-to-Site VPN, or VPC peering.

To connect to your instance using your own key and any SSH client

1. **(Optional) Generate new SSH private and public keys**

   You can generate new SSH private and public keys, `my_key` and `my_key.pub`, using the following command:

   ```
   ssh-keygen -t rsa -f my_key
   ```

2. **Push your SSH public key to the instance**

   Use the send-ssh-public-key command to push your SSH public key to the instance. If you launched your instance using AL2023 or Amazon Linux 2, the default username for the AMI is `ec2-user`. If you launched your instance using Ubuntu, the default username for the AMI is `ubuntu`.

   The following example pushes the public key to the specified instance in the specified Availability Zone, to authenticate `ec2-user`.

   ```
   aws ec2-instance-connect send-ssh-public-key \
       --region us-west-2 \
       --availability-zone us-west-2b \
       --instance-id i-001234a4bf70dec41EXAMPLE \
       --instance-os-user ec2-user \
       --ssh-public-key file://my_key.pub
   ```

3. **Connect to the instance using your private key**

   Use the **ssh** command to connect to the instance using the private key before the public key is removed from the instance metadata (you have 60 seconds before it is removed). Specify the private key that corresponds to the public key, the default username for the AMI that you used to launch your instance, and the instance's public DNS name (if connecting over a private network, specify the private DNS name or IP address). Add the `IdentitiesOnly=yes` option to ensure that only the files in the ssh config and the specified key are used for the connection.

```
ssh -o "IdentitiesOnly=yes" -i my_key ec2-
user@ec2-198-51-100-1.compute-1.amazonaws.com
```

The following example uses `timeout 3600` to set your SSH session to terminate after 1 hour. Processes started during the session may continue running on your instance after the session terminates.

```
timeout 3600 ssh -o “IdentitiesOnly=yes” -i my_key ec2-
user@ec2-198-51-100-1.compute-1.amazonaws.com
```

Troubleshoot

If you receive an error while attempting to connect to your instance, see the following:

- Troubleshoot issues connecting to your Amazon EC2 Linux instance
- How do I troubleshoot issues connecting to my EC2 instance using EC2 Instance Connect?

Uninstall EC2 Instance Connect

To disable EC2 Instance Connect, connect to your Linux instance and uninstall the `ec2-instance-connect` package that is installed on the OS. If the `sshd` configuration matches what it was set to when you installed EC2 Instance Connect, uninstalling `ec2-instance-connect` also removes the `sshd` configuration. If you modified the `sshd` configuration after installing EC2 Instance Connect, you must update it manually.

Amazon Linux

You can uninstall EC2 Instance Connect on AL2023 and Amazon Linux 2 2.0.20190618 or later, where EC2 Instance Connect is preconfigured.

To uninstall EC2 Instance Connect on an instance launched using Amazon Linux

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default username for the AL2023 or Amazon Linux 2 AMI, which is `ec2-user`.

For example, the following **ssh** command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-
west-2.compute.amazonaws.com
```

2. Uninstall the `ec2-instance-connect` package using the **yum** command.

```
[ec2-user ~]$ sudo yum remove ec2-instance-connect
```

Ubuntu

To uninstall EC2 Instance Connect on an instance launched using an Ubuntu AMI

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default username for the Ubuntu AMI, which is `ubuntu`.

   For example, the following **ssh** command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-
west-2.compute.amazonaws.com
```

2. Uninstall the `ec2-instance-connect` package using the **apt-get** command.

```
ubuntu:~$ sudo apt-get remove ec2-instance-connect
```

Connect to your instances using a private IP address and EC2 Instance Connect Endpoint

EC2 Instance Connect Endpoint allows you to connect securely to an instance from the internet, without using a bastion host, or requiring that your virtual private cloud (VPC) has direct internet connectivity.

Benefits

- You can connect to your instances without requiring the instances to have a public IPv4 address. AWS charges for all public IPv4 addresses, including public IPv4 addresses associated with running instances and Elastic IP addresses. For more information, see the **Public IPv4 Address** tab on the Amazon VPC pricing page.
- You can connect to your instances from the internet without requiring that your VPC has direct internet connectivity through an internet gateway.
- You can control access to the creation and use of the EC2 Instance Connect Endpoints to connect to instances using IAM policies and permissions.
- All attempts to connect to your instances, both successful and unsuccessful, are logged to CloudTrail.

Pricing

There is no additional cost for using EC2 Instance Connect Endpoints. If you use an EC2 Instance Connect Endpoint to connect to an instance in a different Availability Zone, there is an additional charge for data transfer across Availability Zones.

Contents

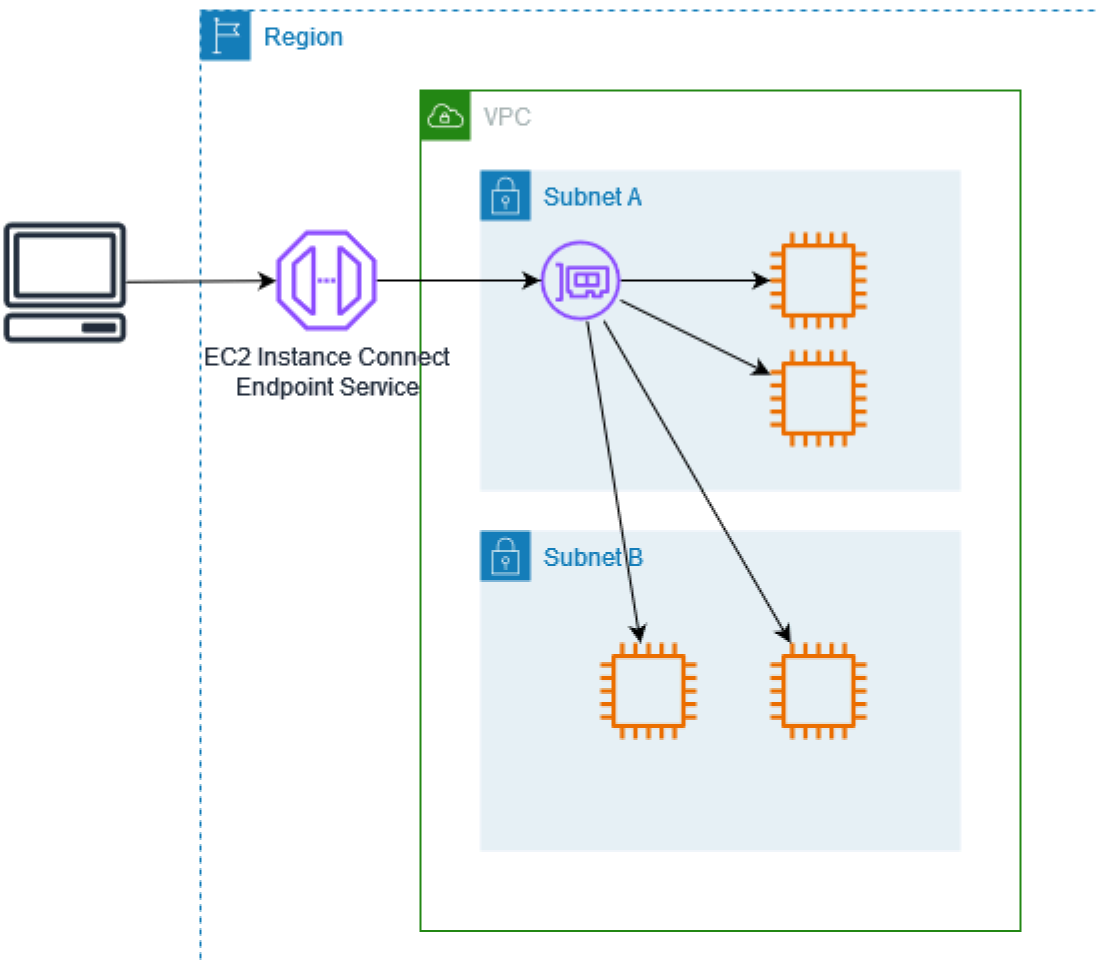
How it works

EC2 Instance Connect Endpoint is an identity-aware TCP proxy. The EC2 Instance Connect Endpoint Service establishes a private tunnel from your computer to the endpoint using the credentials for your IAM entity. Traffic is authenticated and authorized before it reaches your VPC.

You can configure additional security group rules to restrict inbound traffic to your instances. For example, you can use inbound rules to allow traffic on management ports only from the EC2 Instance Connect Endpoint.

You can configure route table rules to allow the endpoint to connect to any instance in any subnet of the VPC.

The following diagram shows how a user can connect to their instances from the internet using an EC2 Instance Connect Endpoint. First, create an **EC2 Instance Connect Endpoint** in subnet A. We create a network interface for the endpoint in the subnet, which serves as the entry point for traffic destined to your instances in the VPC. If the route table for subnet B allows traffic from subnet A, then you can use the endpoint to reach instances in subnet B.



Considerations

Before you begin, consider the following.

- EC2 Instance Connect Endpoint is intended specifically for management traffic use cases, not for high volume data transfers. High volume data transfers are throttled.
- Your instance must have an IPv4 address (either private or public). EC2 Instance Connect Endpoint does not support connecting to instances using IPv6 addresses.
- (Linux instances) If you use your own key pair, you can use any Linux AMI. Otherwise, your instance must have EC2 Instance Connect installed. For information about which AMIs include EC2 Instance Connect and how to install it on other supported AMIs, see Install EC2 Instance Connect.
- You can assign a security group to an EC2 Instance Connect Endpoint when you create it. Otherwise, we use the default security group for the VPC. The security group for an EC2 Instance Connect Endpoint must allow outbound traffic to the destination instances. For more information, see Security groups for EC2 Instance Connect Endpoint.
- You can configure an EC2 Instance Connect Endpoint to preserve the source IP addresses of clients when routing requests to the instances. Otherwise, the IP address of the network interface becomes the client IP address for all incoming traffic.
  - If you turn on client IP preservation, the security groups for the instances must allow traffic from the clients. Also, the instances must be in the same VPC as the EC2 Instance Connect Endpoint.
  - If you turn off client IP preservation, the security groups for the instances must allow traffic from the VPC. This is the default.
  - The following instance types do not support client IP preservation: C1, CG1, CG2, G1, HI1, M1, M2, M3, and T1. If you turn on client IP preservation and attempt to connect to an instance with one of these instance types by using EC2 Instance Connect Endpoint, the connection fails.
  - Client IP preservation is not supported when traffic is routed through a transit gateway.
- When you create an EC2 Instance Connect Endpoint, a service-linked role is automatically created for the Amazon EC2 service in AWS Identity and Access Management (IAM). Amazon EC2 uses the service-linked role to provision network interfaces in your account, which are required when creating EC2 Instance Connect Endpoints. For more information, see Service-linked role for EC2 Instance Connect Endpoint.

- You can create only 1 EC2 Instance Connect Endpoint per VPC and per subnet. For more information, see Quotas for EC2 Instance Connect Endpoint. If you need to create another EC2 Instance Connect Endpoint in a different Availability Zone within the same VPC, you must first delete the existing EC2 Instance Connect Endpoint. Otherwise, you'll receive a quota error.
- Each EC2 Instance Connect Endpoint can support up to 20 concurrent connections.
- The maximum duration for an established TCP connection is 1 hour (3,600 seconds). You can specify the maximum allowed duration in an IAM policy, which can be up to 3,600 seconds. For more information, see Permissions to use EC2 Instance Connect Endpoint to connect to instances.

  The duration of the connection is not determined by the duration of your IAM credentials. If your IAM credentials expire, the connection continues to persist until the specified maximum duration is reached. When you connect to an instance using the EC2 Instance Connect Endpoint console experience, set **Max tunnel duration (seconds)** to a value that is less than the duration of your IAM credentials. If your IAM credentials expire early, terminate the connection to your instance by closing the browser page.

Grant permissions to use EC2 Instance Connect Endpoint

By default, IAM entities don't have permission to create, describe, or modify EC2 Instance Connect Endpoints. An IAM administrator can create IAM policies that grant the permissions required to perform specific actions on the resources that they need.

For information about creating IAM policies, see Creating IAM policies in the *IAM User Guide*.

The following example policies show how you can control the permissions that users have to EC2 Instance Connect Endpoints.

Examples

- Permissions to create, describe, modify, and delete EC2 Instance Connect Endpoints
- Permissions to use EC2 Instance Connect Endpoint to connect to instances
- Permissions to connect only from a specific IP address range

Permissions to create, describe, modify, and delete EC2 Instance Connect Endpoints

To create and modify an EC2 Instance Connect Endpoint, users require permissions for the following actions:

- `ec2:CreateInstanceConnectEndpoint`
- `ec2:CreateNetworkInterface`
- `ec2:CreateTags`
- `ec2:ModifyInstanceConnectEndpoint`
- `iam:CreateServiceLinkedRole`

To describe and delete EC2 Instance Connect Endpoints, users require permissions for the following actions:

- `ec2:DescribeInstanceConnectEndpoints`
- `ec2:DeleteInstanceConnectEndpoint`

You can create a policy that grants permission to create, describe, modify, and delete EC2 Instance Connect Endpoints in all subnets. Alternatively, you can restrict actions for specified subnets only by specifying the subnet ARNs as the allowed `Resource` or by using the `ec2:SubnetID` condition key. You can also use the `aws:ResourceTag` condition key to explicitly allow or deny endpoint creation with certain tags. For more information, see [Policies and permissions in IAM]() in the *IAM User Guide*.

Example IAM policy

In the following example IAM policy, the `Resource` section grants permission to create, modify, and delete endpoints in all subnets, specified by the asterisk (`*`). The `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the `Resource` element.

Permissions to use EC2 Instance Connect Endpoint to connect to instances

The `ec2-instance-connect:OpenTunnel` action grants permission to establish a TCP connection to an instance to connect over the EC2 Instance Connect Endpoint. You can specify the EC2 Instance Connect Endpoint to use. Alternatively, a `Resource` with an asterisk (`*`) allows users to use any available EC2 Instance Connect Endpoint. You can also restrict access to instances based on the presence or absence of resource tags as condition keys.

Conditions

- `ec2-instance-connect:remotePort` – The port on the instance that can be used to establish a TCP connection. When this condition key is used, attempting to connect to an instance on any other port other than the port specified in the policy results in a failure.
- `ec2-instance-connect:privateIpAddress` – The destination private IP address associated with the instance that you want to establish a TCP connection with. You can specify a single IP address, such as `10.0.0.1/32`, or a range of IPs through CIDRs, such as `10.0.1.0/28`. When this condition key is used, attempting to connect to an instance with a different private IP address or outside the CIDR range results in a failure.
- `ec2-instance-connect:maxTunnelDuration` – The maximum duration for an established TCP connection. The unit is seconds and the duration ranges from a minimum of 1 second to a maximum of 3,600 seconds (1 hour). If the condition is not specified, the default duration is set to 3,600 seconds (1 hour). Attempting to connect to an instance for longer than the specified duration in the IAM policy or for longer than the default maximum results in a failure. The connection is disconnected after the specified duration.

  If `maxTunnelDuration` is specified in the IAM policy and the value specified is less than 3,600 seconds (the default), then you must specify `--max-tunnel-duration` in the command when connecting to an instance. For information about how to connect to an instance, see Connect to an Amazon EC2 instance using EC2 Instance Connect Endpoint.

You can also grant a user access to establish connections to instances based on the presence of resource tags on the EC2 Instance Connect Endpoint. For more information, see Policies and permissions in IAM in the *IAM User Guide*.

For Linux instances, the `ec2-instance-connect:SendSSHPublicKey` action grants permission to push the public key to an instance. The `ec2:osuser` condition specifies the name of the OS (operating system) user that can push the public key to an instance. Use the default username for the AMI that you used to launch the instance. For more information, see Grant IAM permissions for EC2 Instance Connect.

Example IAM policy

The following example IAM policies allow an IAM principal to connect to an instance using only the specified EC2 Instance Connect Endpoint, identified by the specified endpoint ID `eice-123456789abcdef`. The connection is successfully established only if all the conditions are satisfied.

> **Note**
>
> The `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the `Resource` element.

Linux

This example evaluates if the connection to the instance is established on —port 22 (SSH), if the private IP address of the instance lies within the range of `10.0.1.0/31` (between `10.0.1.0` and `10.0.1.1`), and the `maxTunnelDuration` is less than or equal to `3600` seconds. The connection is disconnected after `3600` seconds (1 hour).

        ]
}
```

Permissions to connect only from a specific IP address range

The following example IAM policy allows an IAM principal to connect to an instance on condition they are connecting from an IP address within the IP address range specified in the policy. If the IAM principal calls `OpenTunnel` from an IP address not within `192.0.2.0/24` (the example IP address range in this policy), the response is `Access Denied`. For more information, see aws:SourceIp in the *IAM User Guide*.

```

Security groups for EC2 Instance Connect Endpoint

A security group controls the traffic that is allowed to reach and leave the resources that it is associated with. For example, we deny traffic to and from an Amazon EC2 instance unless it is specifically allowed by the security groups associated with the instance.

The following examples show you how to configure the security group rules for the EC2 Instance Connect Endpoint and the target instances.

Examples

- EC2 Instance Connect Endpoint security group rules
- Target instance security group rules

EC2 Instance Connect Endpoint security group rules

The security group rules for an EC2 Instance Connect Endpoint must allow outbound traffic destined for the target instances to leave the endpoint. You can specify either the instance security group or the IPv4 address range of the VPC as the destination.

Traffic to the endpoint originates from the EC2 Instance Connect Endpoint Service, and it is allowed regardless of the inbound rules for the endpoint security group. To control who can use EC2 Instance Connect Endpoint to connect to an instance, use an IAM policy. For more information, see Permissions to use EC2 Instance Connect Endpoint to connect to instances.

Example outbound rule: Security group referencing

The following example uses security group referencing, which means that the destination is a security group associated with the target instances. This rule allows outbound traffic from the endpoint to all instances that use this security group.

Protocol	Destination	Port range	Comment
TCP	*ID of instance security group*	22	Allows outbound SSH traffic to all instances associated with the instance security group

Example outbound rule: IPv4 address range

The following example allows outbound traffic to the specified IPv4 address range. The IPv4 addresses of an instance is assigned from its subnet, so you can use the IPv4 address range of the VPC.

Protocol	Destination	Port range	Comment
TCP	*VPC IPv4 CIDR*	22	Allows outbound SSH traffic to the VPC

Target instance security group rules

The security group rules for target instances must allow inbound traffic from the EC2 Instance Connect Endpoint. You can specify either the endpoint security group or an IPv4 address range as the source. If you specify an IPv4 address range, the source depends on whether client IP preservation is off or on. For more information, see Considerations.

Because security groups are stateful, the response traffic is allowed to leave the VPC regardless of the outbound rules for the instance security group.

Example inbound rule: Security group referencing

The following example uses security group referencing, which means that the source is the security group associated with the endpoint. This rule allows inbound SSH traffic from the endpoint to all instances that use this security group, whether client IP preservation is on or off. If there are no other inbound security group rules for SSH, then the instances accept SSH traffic only from the endpoint.

Protocol	Source	Port range	Comment
TCP	*ID of endpoint security group*	22	Allows inbound SSH traffic from the resources associated with the endpoint security group

Example inbound rule: Client IP preservation off

The following example allows inbound SSH traffic from the specified IPv4 address range. Because client IP preservation is off, the source IPv4 address is the address of the endpoint network interface. The address of the endpoint network interface is assigned from its subnet, so you can use the IPv4 address range of the VPC to allow connections to all instances in the VPC.

Protocol	Source	Port range	Comment
TCP	*VPC IPv4 CIDR*	22	Allows inbound SSH traffic from the VPC

Example inbound rule: Client IP preservation on

The following example allows inbound SSH traffic from the specified IPv4 address range. Because client IP preservation is on, the source IPv4 address is the address of the client.

Protocol	Source	Port range	Comment
TCP	*Public IPv4 address range*	22	Allows inbound traffic from the specified client IPv4 address range

Create an EC2 Instance Connect Endpoint

You can create an EC2 Instance Connect Endpoint to allow secure connection to your instances.

Prerequisites

You must have the required IAM permissions to create an EC2 Instance Connect Endpoint. For more information, see [Permissions to create, describe, modify, and delete EC2 Instance Connect Endpoints].

Shared subnets

You can create an EC2 Instance Connect Endpoint in a subnet that is shared with you. You can't use a EC2 Instance Connect Endpoint that the VPC owner created in a subnet that is shared with you.

Console

To create an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the left navigation pane, choose **Endpoints**.
3. Choose **Create endpoint**, and then specify the endpoint settings as follows:

    a. (Optional) For **Name tag**, enter a name for the endpoint.

    b. For **Type**, choose **EC2 Instance Connect Endpoint**.

    c. Under **Network settings**, for **VPC**, select the VPC that has the target instances.

    d. (Optional) To preserve client IP addresses, expand **Additional settings** and select the **Preserve Client IP** check box. Otherwise, the default is to use the endpoint network interface as the client IP address.

e. (Optional) For **Security groups**, select the security group to associate with the endpoint. Otherwise, the default is to use the default security group for the VPC. For more information, see Security groups for EC2 Instance Connect Endpoint.

f. For **Subnet**, select the subnet in which to create the endpoint.

g. (Optional) To add a tag, choose **Add new tag** and enter the tag key and the tag value.

4. Review your settings and then choose **Create endpoint**.

   The initial status of the endpoint is **Pending**. Before you can connect to an instance using this endpoint, you must wait until the endpoint status is **Available**. This can take a few minutes.

5. To connect to an instance using your endpoint, see Connect to an instance.

AWS CLI

To create an EC2 Instance Connect Endpoint

Use the create-instance-connect-endpoint command.

```
aws ec2 create-instance-connect-endpoint --subnet-id subnet-0123456789example
```

The following is example output.

```
{
        "OwnerId": "111111111111",
        "InstanceConnectEndpointId": "eice-0123456789example",
        "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example",
        "State": "create-complete",
        "StateMessage": "",
        "DnsName": "eice-0123456789example.0123abcd.ec2-instance-connect-endpoint.us-east-1.amazonaws.com",
        "FipsDnsName": "eice-0123456789example.0123abcd.fips.ec2-instance-connect-endpoint.us-east-1.amazonaws.com",
        "NetworkInterfaceIds": [
            "eni-0123abcd"
        ],
        "VpcId": "vpc-0123abcd",
        "AvailabilityZone": "us-east-1a",
        "CreatedAt": "2023-04-07T15:43:53.000Z",
```

```
        "SubnetId": "subnet-0123abcd",
        "PreserveClientIp": false,
        "SecurityGroupIds": [
            "sg-0123abcd"
        ],
        "Tags": []
}
```

To monitor the creation status

The initial value for the `State` field is `create-in-progress`. Before you can connect to an instance using this endpoint, wait until the state is `create-complete`. Use the describe-instance-connect-endpoints command to monitor the status of the EC2 Instance Connect Endpoint. The `--query` parameter filters the results to the `State` field.

```
aws ec2 describe-instance-connect-endpoints --instance-connect-endpoint-
ids eice-0123456789example --query InstanceConnectEndpoints[*].State --output text
```

The following is example output.

```
create-complete
```

PowerShell

To create the EC2 Instance Connect Endpoint

Use the New-EC2InstanceConnectEndpoint cmdlet.

```
New-EC2InstanceConnectEndpoint -SubnetId subnet-0123456789example
```

The following is example output.

```
OwnerId                     : 111111111111
InstanceConnectEndpointId   : eice-0123456789example
InstanceConnectEndpointArn  : arn:aws:ec2:us-east-1:111111111111:instance-connect-
endpoint/eice-0123456789example
State                       : create-complete
StateMessage                :
DnsName                     : eice-0123456789example.0123abcd.ec2-instance-connect-
endpoint.us-east-1.amazonaws.com
```

```
FipsDnsName                  : eice-0123456789example.0123abcd.fips.ec2-instance-
connect-endpoint.us-east-1.amazonaws.com
NetworkInterfaceIds          : {eni-0123abcd}
VpcId                        : vpc-0123abcd
AvailabilityZone             : us-east-1a
CreatedAt                    : 4/7/2023 3:43:53 PM
SubnetId                     : subnet-0123abcd
PreserveClientIp             : False
SecurityGroupIds             : {sg-0123abcd}
Tags                         : {}
```

To monitor the creation status

The initial value for the `State` field is `create-in-progress`. Before you can connect to an instance using this endpoint, wait until the state is `create-complete`. Use the Get-EC2InstanceConnectEndpoint cmdlet to monitor the status of the EC2 Instance Connect Endpoint. `.State.Value` filters the results to the `State` field.

```
(Get-EC2InstanceConnectEndpoint -InstanceConnectEndpointId
 "eice-0123456789example").State.Value
```

The following is example output.

```
create-complete
```

Modify an EC2 Instance Connect Endpoint

You can modify existing EC2 Instance Connect Endpoints using the AWS CLI or an SDK. The Amazon EC2 console doesn't support endpoint modification.

Before you begin, you must have the required IAM permissions. For more information, see Permissions to create, describe, modify, and delete EC2 Instance Connect Endpoints.

Parameters you can modify

You can modify the following EC2 Instance Connect Endpoint parameters:

Security groups

You can specify new security groups for the EC2 Instance Connect Endpoint. The new security groups replace the current security groups.

When modifying the security groups, you must specify:

- At least one security group, even if it's just the default security group in the VPC.
- The IDs of the security groups, not the names.

IP address type

You can specify a new IP address type for the EC2 Instance Connect Endpoint.

Valid values: `ipv4` | `dualstack` | `ipv6`

Preserve client IP setting

You can specify whether to preserve the client IP address as the source.

> **Note**
>
> Preserving the client IP is only supported on IPv4 EC2 Instance Connect Endpoints. When enabling `PreserveClientIp`, either the endpoint's existing IP address type must be `ipv4`, or if modifying the IP address type in the same request, the new value must be `ipv4`.

AWS CLI

To modify an EC2 Instance Connect Endpoint

Use the modify-instance-connect-endpoint command and specify the EC2 Instance Connect Endpoint and the parameters to modify. The following example modifies all the parameters in a single request.

```
aws ec2 modify-instance-connect-endpoint \
    --instance-connect-endpoint-id eice-0123456789example \
    --security-group-ids sg-0123456789example \
    --ip-address-type dualstack \
    --no-preserve-client-ip
```

The following is example output.

```
{
    "Return": true
}
```

To monitor the update status

During modification, the EC2 Instance Connect Endpoint status changes to `update-in-progress`. The update process runs asynchronously and completes with either an `update-complete` or `update-failed` status. The endpoint uses its old configuration until the status changes to `update-complete`.

Use the describe-instance-connect-endpoints command to monitor the update status. The `--query` parameter filters the results to the `State` field.

```
aws ec2 describe-instance-connect-endpoints \
    --instance-connect-endpoint-ids eice-0123456789example \
    --query InstanceConnectEndpoints[*].State --output text
```

The following is example output.

```
update-complete
```

PowerShell

To modify an EC2 Instance Connect Endpoint

Use the Edit-EC2InstanceConnectEndpoint cmdlet and specify the EC2 Instance Connect Endpoint and the parameters to modify. The following example modifies all the parameters in a single request.

```
Edit-EC2InstanceConnectEndpoint `
    -InstanceConnectEndpointId eice-0123456789example `
    -SecurityGroupIds sg-0123456789example `
    -IpAddressType dualstack `
    -PreserveClientIp $false
```

The following is example output.

```
True
```

To monitor the update status

During modification, the EC2 Instance Connect Endpoint status changes to `update-in-progress`. The update process runs asynchronously and completes with either an `update-`

complete or update-failed status. The endpoint uses its old configuration until the status changes to update-complete.

Use the Get-EC2InstanceConnectEndpoint command to monitor the update status. .State.Value filters the results to the State field.

```
(Get-EC2InstanceConnectEndpoint -InstanceConnectEndpointId
 "eice-0123456789example").State.Value
```

The following is example output.

```
update-complete
```

Delete an EC2 Instance Connect Endpoint

When you are finished with an EC2 Instance Connect Endpoint, you can delete it.

You must have the required IAM permissions to create an EC2 Instance Connect Endpoint. For more information, see Permissions to create, describe, modify, and delete EC2 Instance Connect Endpoints.

When you delete an EC2 Instance Connect Endpoint using the console, it enters the **Deleting** state. If deletion is successful, the deleted endpoint no longer appears. If deletion fails, the state is delete-failed and **Status message** provides the failure reason.

When you delete an EC2 Instance Connect Endpoint using the AWS CLI, it enters the delete-in-progress state. If deletion is successful, it enters the delete-complete state. If deletion fails, the state is delete-failed and StateMessage provides the failure reason.

Console

To delete an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the left navigation pane, choose **Endpoints**.
3. Select the endpoint.
4. Choose **Actions**, **Delete VPC endpoints**.
5. When prompted for confirmation, enter **delete**.

6. Choose **Delete**.

AWS CLI

To delete an EC2 Instance Connect Endpoint

Use the delete-instance-connect-endpoint command and specify the ID of the EC2 Instance Connect Endpoint to delete.

```
aws ec2 delete-instance-connect-endpoint --instance-connect-endpoint-
id eice-03f5e49b83924bbc7
```

The following is example output.

```
{
    "InstanceConnectEndpoint": {
        "OwnerId": "111111111111",
        "InstanceConnectEndpointId": "eice-0123456789example",
        "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-
connect-endpoint/eice-0123456789example",
        "State": "delete-in-progress",
        "StateMessage": "",
        "NetworkInterfaceIds": [],
        "VpcId": "vpc-0123abcd",
        "AvailabilityZone": "us-east-1d",
        "CreatedAt": "2023-02-07T12:05:37+00:00",
        "SubnetId": "subnet-0123abcd"
    }
}
```

PowerShell

To delete an EC2 Instance Connect Endpoint

Use the Remove-EC2InstanceConnectEndpoint cmdlet and specify the ID of the EC2 Instance Connect Endpoint to delete.

```
Remove-EC2InstanceConnectEndpoint -InstanceConnectEndpointId eice-03f5e49b83924bbc7
```

The following is example output.

```
@{
    InstanceConnectEndpoint = @{
        OwnerId = "111111111111"
        InstanceConnectEndpointId = "eice-0123456789example"
        InstanceConnectEndpointArn = "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example"
        State = "delete-in-progress"
        StateMessage = ""
        NetworkInterfaceIds = @()
        VpcId = "vpc-0123abcd"
        AvailabilityZone = "us-east-1d"
        CreatedAt = "2023-02-07T12:05:37+00:00"
        SubnetId = "subnet-0123abcd"
    }
}
```

Connect to an Amazon EC2 instance using EC2 Instance Connect Endpoint

You can use EC2 Instance Connect Endpoint to connect to an Amazon EC2 instance that supports SSH or RDP.

Prerequisites

- You must have the required IAM permission to connect to an EC2 Instance Connect Endpoint. For more information, see Permissions to use EC2 Instance Connect Endpoint to connect to instances.
- The EC2 Instance Connect Endpoint must be in the **Available** (console) or `create-complete` (AWS CLI) state. If you do not have an EC2 Instance Connect Endpoint for your VPC, you can create one. For more information, see Create an EC2 Instance Connect Endpoint.
- Your instance must have an IPv4 address (either private or public). EC2 Instance Connect Endpoint does not support connecting to instances using IPv6 addresses.
- (Linux instances) To use the Amazon EC2 console to connect to your instance, or to use the CLI to connect and have EC2 Instance Connect handle the ephemeral key, your instance must have EC2 Instance Connect installed. For more information, see Install EC2 Instance Connect.
- Ensure that the security group of the instance allows inbound SSH traffic from the EC2 Instance Connect Endpoint. For more information, see Target instance security group rules.

Connection options

Connect to your Linux instance using the Amazon EC2 console

You can connect to an instance using the Amazon EC2 console (a browser-based client) as follows.

To connect to your instance using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and then choose **Connect**.
4. Choose the **EC2 Instance Connect** tab.
5. Choose **Connect using a Private IP**.
6. For **EC2 Instance Connect Endpoint**, choose the ID of the EC2 Instance Connect Endpoint.
7. For **Username**, if the AMI that you used to launch the instance uses a username other than `ec2-user`, enter the correct username.
8. For **Max tunnel duration (seconds)**, enter the maximum allowed duration for the SSH connection.

   The duration must comply with any `maxTunnelDuration` condition specified in the IAM policy. If you don't have access to the IAM policy, contact your administrator.
9. Choose **Connect**. This opens a terminal window for your instance.

Connect to your Linux instance using SSH

You can use SSH to connect to your Linux instance, and use the `open-tunnel` command to establish a private tunnel. You can use `open-tunnel` in single connection or multi-connection mode.

For information about using the AWS CLI to connect to your instance using SSH, see Connect using the AWS CLI.

The following examples use OpenSSH. You can use any other SSH client that supports a proxy mode.

Single connection

To allow only a single connection to an instance using SSH and the open-tunnel command

Use `ssh` and the open-tunnel AWS CLI command as follows. The `-o` proxy command encloses the `open-tunnel` command that creates the private tunnel to the instance.

```
ssh -i my-key-pair.pem ec2-user@i-1234567890abcdef0 \
    -o ProxyCommand='aws ec2-instance-connect open-tunnel --instance-id i-1234567890abcdef0'
```

For:

- `-i` – Specify the key pair that was used to launch the instance.
- *`ec2-user`*`@`*`i-1234567890abcdef0`* – Specify the username of the AMI that was used to launch the instance, and the instance ID.
- `--instance-id` – Specify the ID of the instance to connect to. Alternatively, specify `%h`, which extracts the instance ID from the user.

Multi-connection

To allow multiple connections to an instance, first run the open-tunnel AWS CLI command to start listening for new TCP connections, and then use `ssh` to create a new TCP connection and a private tunnel to your instance.

To allow multiple connections to your instance using SSH and the open-tunnel command

1. Run the following command to start listening for new TCP connections on the specified port on your local machine.

   ```
   aws ec2-instance-connect open-tunnel \
       --instance-id i-1234567890abcdef0 \
       --local-port 8888
   ```

   Expected output

```
Listening for connections on port 8888.
```

2. In a *new terminal window*, run the following `ssh` command to create a new TCP connection and a private tunnel to your instance.

   ```
   ssh -i my-key-pair.pem ec2-user@localhost -p 8888
   ```

   Expected output – In the *first* terminal window, you'll see the following:

   ```
   [1] Accepted new tcp connection, opening websocket tunnel.
   ```

   You might also see the following:

   ```
   [1] Closing tcp connection.
   ```

Connect to your Linux instance using the AWS CLI

If you only know your instance ID, you can use the ec2-instance-connect ssh AWS CLI command to connect to your instance using an SSH client. For more information, see Connect using the AWS CLI.

Prerequisites

Install AWS CLI version 2 and configure it using your credentials. For more information, see Install or update to the latest version of the AWS CLI and Configure the AWS CLI in the *AWS Command Line Interface User Guide*. Alternatively, open AWS CloudShell and run AWS CLI commands in its pre-authenticated shell.

To connect to an instance using the instance ID and an EC2 Instance Connect Endpoint

If you only know the instance ID, use the ec2-instance-connect ssh CLI command, and specify the `ssh` command, the instance ID, and the `--connection-type` parameter with the `eice` value.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example --os-user ec2-user --
connection-type eice
```

> **Tip**
>
> If you get an error when using this command, make sure that you're using AWS CLI version 2. The `ssh` parameter is only available in AWS CLI version 2. For more information, see About AWS CLI version 2 in the *AWS Command Line Interface User Guide*.

Connect to your Windows instance using RDP

You can use Remote Desktop Protocol (RDP) over EC2 Instance Connect Endpoint to connect to a Windows instance without a public IPv4 address or public DNS name.

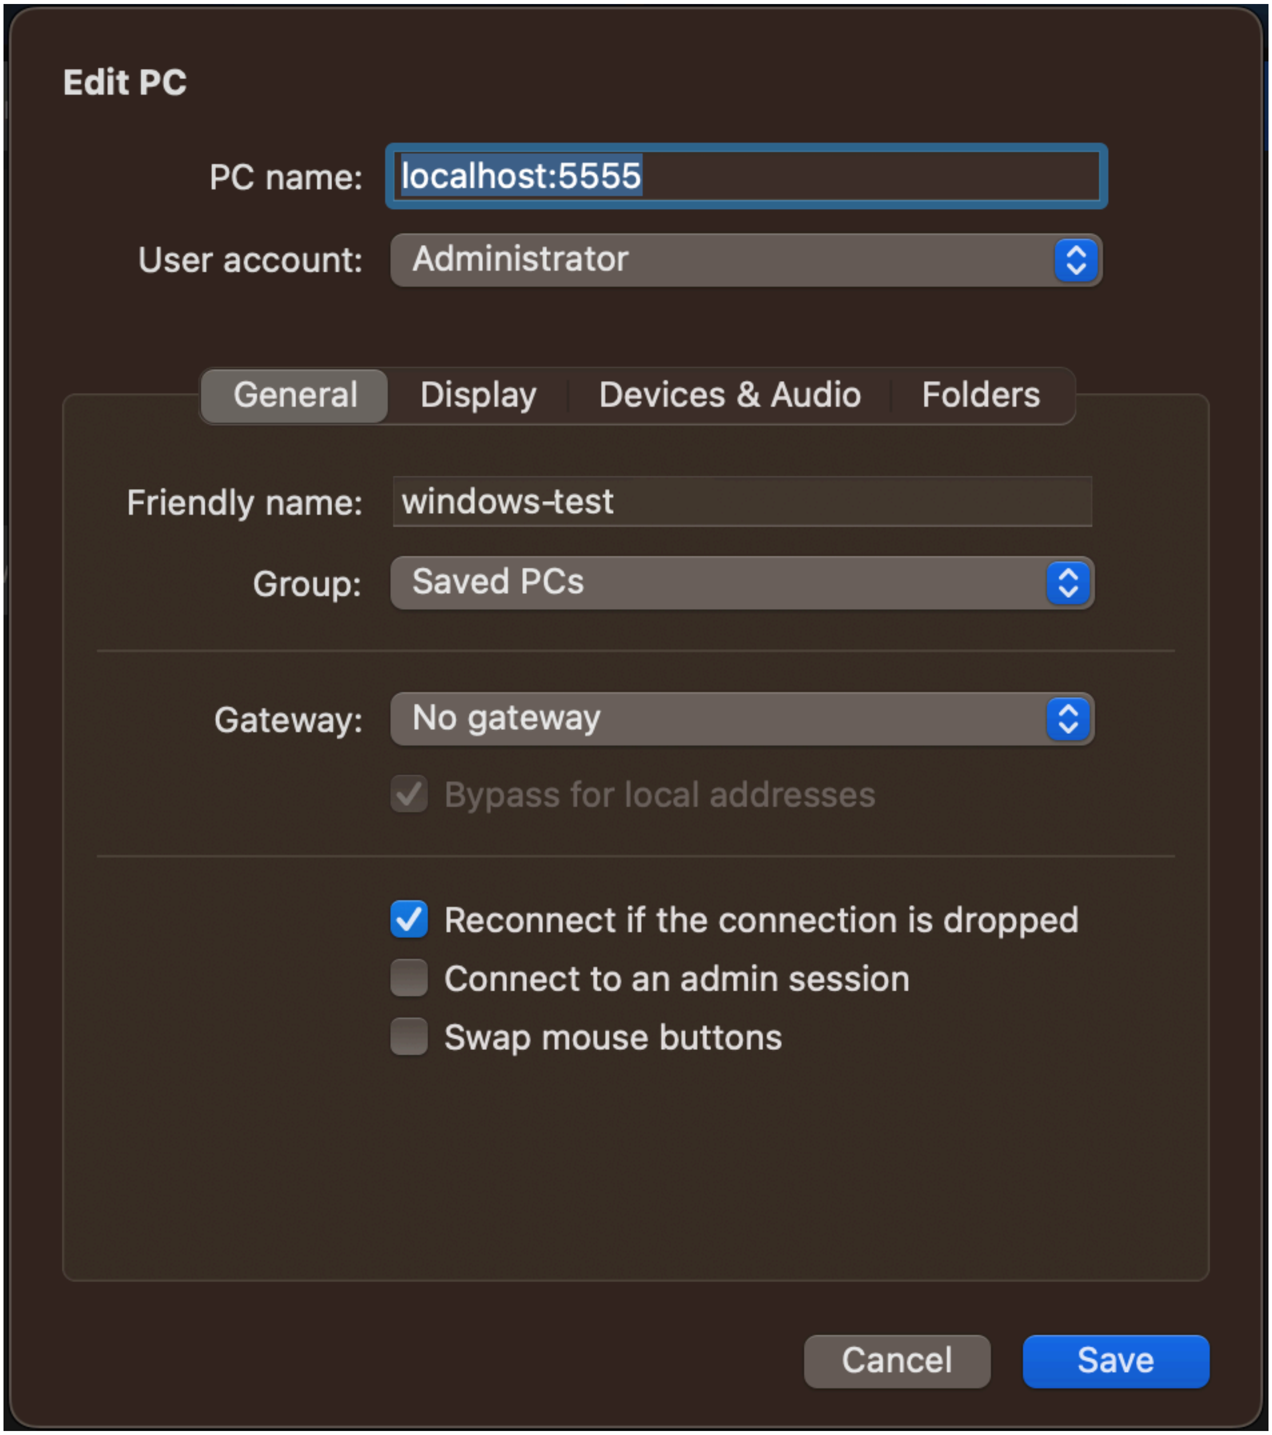
To connect to your Windows instance using an RDP client

1. Complete Steps 1 – 8 in Connect to your Windows instance using RDP. After downloading the RDP desktop file at Step 8, you'll get an **Unable to connect** message, which is to be expected because your instance does not have a public IP address.
2. Run the following command to establish a private tunnel to the VPC in which the instance is located. `--remote-port` must be 3389 because RDP uses port 3389 by default.

```
aws ec2-instance-connect open-tunnel \
    --instance-id i-1234567890abcdef0 \
    --remote-port 3389 \
    --local-port any-port
```

3. In your **Downloads** folder, find the RDP desktop file that you downloaded, and drag it onto the RDP client window.
4. Right-click the RDP desktop file and choose **Edit**.
5. In the **Edit PC** window, for **PC name** (the instance to connect to), enter `localhost:local-port`, where *`local-port`* uses the same value as you specified in Step 2, and then choose **Save**.

   Note that the following screenshot of the **Edit PC** window is from Microsoft Remote Desktop on a Mac. If you are using a Windows client, the window might be different.



6. In the RDP client, right-click the PC (that you just configured) and choose **Connect** to connect to your instance.

7. At the prompt, enter the decrypted password for the administrator account.

Troubleshoot

Use the following information to help diagnose and fix issues that you might encounter when using EC2 Instance Connect Endpoint to connect an instance.

Can't connect to your instance

The following are common reasons why you might not be able to connect to your instance.

- Security groups – Check the security groups assigned to the EC2 Instance Connect Endpoint and your instance. For more information about the required security group rules, see Security groups for EC2 Instance Connect Endpoint.
- Instance state – Verify that your instance is in the `running` state.
- Key pair – If the command you're using to connect requires a private key, verify that your instance has a public key and that you have the corresponding private key.
- IAM permissions – Verify that you have the required IAM permissions. For more information, see Grant permissions to use EC2 Instance Connect Endpoint.

For more troubleshooting tips for Linux instances, see Troubleshoot issues connecting to your Amazon EC2 Linux instance. For troubleshooting tips for Windows instances, see the section called "Windows instance RDP issues".

ErrorCode: AccessDeniedException

If you receive an `AccessDeniedException` error, and the `maxTunnelDuration` condition is specified in the IAM policy, be sure to specify the `--max-tunnel-duration` parameter when connecting to an instance. For more information about this parameter, see open-tunnel in the *AWS CLI Command Reference*.

Log connections established over EC2 Instance Connect Endpoint

You can log resource operations and audit connections established over the EC2 Instance Connect Endpoint with AWS CloudTrail logs.

For more information about using AWS CloudTrail with Amazon EC2, see Log Amazon EC2 API calls using AWS CloudTrail.

Log EC2 Instance Connect Endpoint API calls with AWS CloudTrail

EC2 Instance Connect Endpoint resource operations are logged to CloudTrail as management events. When the following API calls are made, the activity is recorded as a CloudTrail event in **Event history**:

- `CreateInstanceConnectEndpoint`
- `DescribeInstanceConnectEndpoints`
- `DeleteInstanceConnectEndpoint`

You can view, search, and download recent events in your AWS account. For more information, see [Viewing events with CloudTrail Event history] in the *AWS CloudTrail User Guide*.

Use AWS CloudTrail to audit users who connect to an instance using EC2 Instance Connect Endpoint

Connection attempts to instances via EC2 Instance Connect Endpoint are logged in CloudTrail in **Event history**. When a connection to an instance is initiated through an EC2 Instance Connect Endpoint, the connection is logged as a CloudTrail management event with the `eventName` of `OpenTunnel`.

You can create Amazon EventBridge rules that route the CloudTrail event to a target. For more information, see the [Amazon EventBridge User Guide].

The following is an example of an `OpenTunnel` management event that was logged in CloudTrail.

```

Service-linked role for EC2 Instance Connect Endpoint

Amazon EC2 uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EC2. Service-linked roles are predefined by Amazon EC2 and include all the permissions that Amazon EC2 requires to call other AWS services on your behalf. For more information, see Service-linked roles in the *IAM User Guide*.

Service-linked role permissions for EC2 Instance Connect Endpoint

Amazon EC2 uses **AWSServiceRoleForEC2InstanceConnect** to create and manage network interfaces in your account that are required by EC2 Instance Connect Endpoint.

The **AWSServiceRoleForEC2InstanceConnect** service-linked role trusts the following service to assume the role:

- `ec2-instance-connect.amazonaws.com`

The **AWSServiceRoleForEC2InstanceConnect** service-linked role uses the following managed policy:

- **Ec2InstanceConnectEndpoint**

To view the permissions for the managed policy, see Ec2InstanceConnectEndpoint in the *AWS Managed Policy Reference*.

Create a service-linked role for EC2 Instance Connect Endpoint

You don't need to manually create this service-linked role. When you create an EC2 Instance Connect Endpoint, Amazon EC2 creates the service-linked role for you.

Edit a service-linked role for EC2 Instance Connect Endpoint

EC2 Instance Connect Endpoint doesn't allow you to edit the **AWSServiceRoleForEC2InstanceConnect** service-linked role.

Delete a service-linked role for EC2 Instance Connect Endpoint

If you no longer need to use EC2 Instance Connect Endpoint, we recommend that you delete the **AWSServiceRoleForEC2InstanceConnect** service-linked role.

You must delete all EC2 Instance Connect Endpoint resources before you can delete the service-linked role.

To delete the service-linked role, see Delete a service-linked role in the *IAM User Guide*.

You must configure permissions to allow an IAM entity (a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the *IAM User Guide*.

Quotas for EC2 Instance Connect Endpoint

Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Unless otherwise noted, each quota is Region-specific.

Your AWS account has the following quotas related to EC2 Instance Connect Endpoint.

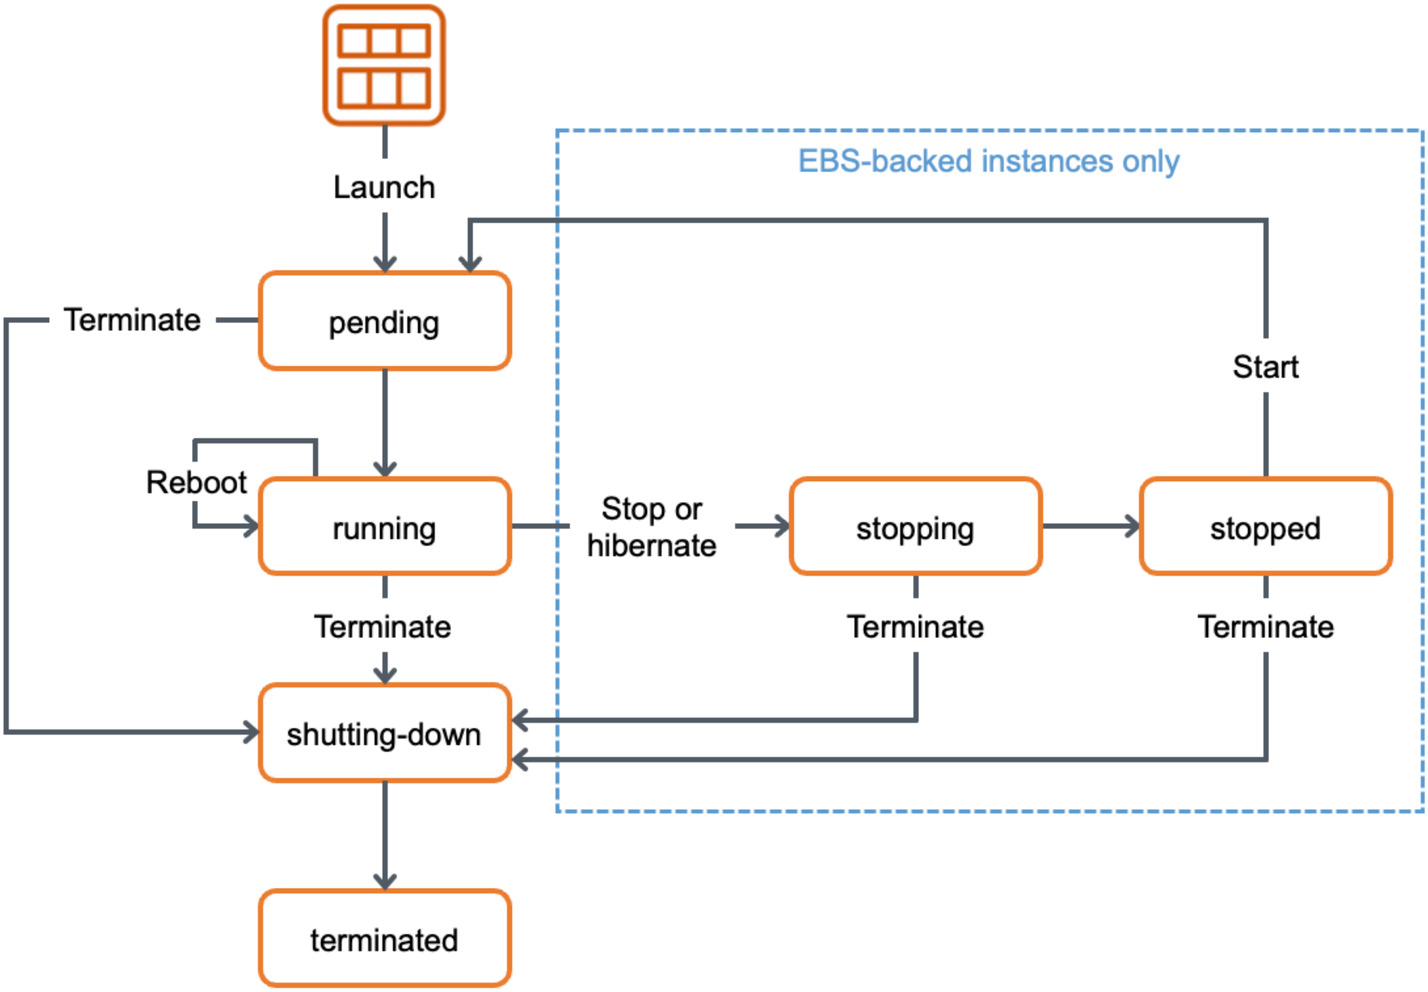
Name	Default	Adjustable
Maximum number of EC2 Instance Connect Endpoints per AWS account per AWS Region	5	No

Name	Default	Adjustable
Maximum number of EC2 Instance Connect Endpoints per VPC	1	No
Maximum number of EC2 Instance Connect Endpoints per subnet	1	No
Maximum number of concurrent connections per EC2 Instance Connect Endpoint	20	No

Amazon EC2 instance state changes

An Amazon EC2 instance transitions through different states from the moment you launch it through to its termination.

The following illustration represents the transitions between instance states.



You can receive notifications when your instances change states. For more information, see [the section called “State change events”](#).

Billing by instance state

The following table provides a brief description of each instance state and indicates whether instance usage is billed. Some AWS resources, such as Amazon EBS volumes and Elastic IP addresses, incur charges regardless of the instance's state. For more information, see [Avoiding Unexpected Charges](#) in the *AWS Billing User Guide*.

Instance state	Description	Instance usage billing
`pending`	The instance is preparing to enter the `running`	Not billed

Instance state	Description	Instance usage billing
	state. An instance enters the `pending` state when it is launched or when it is started after being in the `stopped` state.	
`running`	The instance is running and ready for use.	Billed
`stopping`	The instance is preparing to be stopped.	Not billed **Note** If you hibernate an instance, you're billed while the instance is in the `stopping` state.
`stopped`	The instance is shut down and cannot be used. The instance can be started at any time.	Not billed
`shutting-down`	The instance is preparing to be terminated.	Not billed
`terminated`	The instance has been permanently deleted and cannot be started.	Not billed **Note** Reserved Instances that applied to terminated instances are billed until the end of their term according to their payment option. For more information, see [Reserved Instances for Amazon EC2 overview](#)

Pending instances

When you launch an instance, it enters the `pending` state. The instance type that you specified at launch determines the hardware of the host computer for your instance. We use the Amazon Machine Image (AMI) you specified at launch to boot the instance. After the instance is ready for you, it enters the `running` state. You can connect to your running instance and use it the way that you'd use a computer sitting in front of you.

As soon as your instance transitions to the `running` state, you're billed for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don't connect to it.

Stopped instances

If your instance fails a status check or is not running your applications as expected, and if the root volume of your instance is an Amazon EBS volume, you can stop and start your instance to try to fix the problem.

When you stop your instance, it enters the `stopping` state, and then the `stopped` state. You are not charged for usage or data transfer fees for your instance when it is `stopped`. Charges are incurred for the storage of any Amazon EBS volumes. While your instance is in the `stopped` state, you can modify certain attributes of the instance, including the instance type.

When you start your instance, it enters the `pending` state, and the instance is moved to a new host computer (though in some cases, it remains on the current host). When you stop and start your instance, you lose any data on the instance store volumes attached to the previous host computer.

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface remains associated with your instance. If your instance has an IPv6 address, it retains the IPv6 address.

Each time you transition an instance from `stopped` to `running`, you are charged per second when the instance is running, with a minimum of one minute per instance start.

For more details about stopping and starting an instance, see Stop and start Amazon EC2 instances.

Hibernated instances

When you hibernate an instance, we signal the operating system to perform hibernation (suspend-to-disk), which saves the contents from the instance memory (RAM) to your Amazon EBS root volume. We persist the instance's Amazon EBS root volume and any attached Amazon EBS data volumes. When you start your instance, the Amazon EBS root volume is restored to its previous state and the RAM contents are reloaded. Previously attached data volumes are reattached and the instance retains its instance ID.

When you hibernate your instance, it enters the `stopping` state, and then the `stopped` state. We don't charge usage for a hibernated instance when it is in the `stopped` state, but we do charge while it is in the `stopping` state, unlike when you stop an instance without hibernating it. We don't charge usage for data transfer fees, but we do charge for the storage for any Amazon EBS volumes, including storage for the RAM data.

When you start your hibernated instance, it enters the `pending` state, and we move the instance to a new host computer (though in some cases, it remains on the current host).

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface is still associated with your instance. If your instance has an IPv6 address, it retains its IPv6 address.

For more information, see Hibernate your Amazon EC2 instance.

Rebooting instances

You can reboot your instance using the Amazon EC2 console, a command line tool, and the Amazon EC2 API. We recommend that you use Amazon EC2 to reboot your instance instead of running the operating system reboot command from your instance.

Rebooting an instance is equivalent to rebooting an operating system. The instance remains on the same host computer and maintains its public DNS name, private IP address, and any data on its instance store volumes. It typically takes a few minutes for the reboot to complete, but the time it takes to reboot depends on the instance configuration.

Rebooting an instance doesn't start a new instance billing period; per second billing continues without a further one-minute minimum charge.

For more information, see Reboot your Amazon EC2 instance.

Terminated instances

When you've decided that you no longer need an instance, you can terminate it. As soon as the status of an instance changes to `shutting-down` or `terminated`, you stop incurring charges for that instance.

If you enable termination protection, you can't terminate the instance using the console, CLI, or API.

After you terminate an instance, it remains visible in the console for a short while, and then the entry is automatically deleted. You can also describe a terminated instance using the CLI and API. Resources (such as tags) are gradually disassociated from the terminated instance, therefore may no longer be visible on the terminated instance after a short while. You can't connect to or recover a terminated instance.

Each Amazon EBS-backed instance supports the `InstanceInitiatedShutdownBehavior` attribute, which controls whether the instance stops or terminates when you initiate shutdown from within the instance itself (for example, by using the **shutdown** command on Linux). The default behavior is to stop the instance. You can modify the setting of this attribute while the instance is running or stopped.

Each Amazon EBS volume supports the `DeleteOnTermination` attribute, which controls whether the volume is deleted or preserved when you terminate the instance it is attached to. The default is to delete the root device volume and preserve any other EBS volumes.

For more information, see Terminate Amazon EC2 instances.

Differences between instance states

The following table summarizes the key differences between rebooting, stopping, hibernating, and terminating your instance.

Characteristic	Reboot	Stop/start (Amazon EBS-backed instances only)	Hibernate (Amazon EBS-backed instances only)	Terminate
Host computer	The instance stays on the same host computer.	We move the instance to a new host computer (though in some cases, it remains on the current host).	We move the instance to a new host computer (though in some cases, it remains on the current host).	None

Characteristic	Reboot	Stop/start (Amazon EBS-backed instances only)	Hibernate (Amazon EBS-backed instances only)	Terminate
Private IPv4 address	The instance keeps its private IPv4 address.	The instance keeps its private IPv4 address.	The instance keeps its private IPv4 address.	None
Public IPv4 address	The instance keeps its public IPv4 address.	The instance gets a new public IPv4 address, unless it has a secondary network interface or a secondary private IPv4 address that is associated with an Elastic IP address.	The instance gets a new public IPv4 address, unless it has a secondary network interface or a secondary private IPv4 address that is associated with an Elastic IP address.	None
Elastic IP address (IPv4)	The Elastic IP address remains associated with the instance	The Elastic IP address remains associated with the instance	The Elastic IP address remains associated with the instance	The Elastic IP address is disassociated from the instance
IPv6 address	The instance keeps its IPv6 address	The instance keeps its IPv6 address	The instance keeps its IPv6 address	None
Instance store volumes	The data is preserved	The data is erased	The data is erased	The data is erased
Root device volume	The volume is preserved	The volume is preserved	The volume is preserved	The volume is deleted by default

Characteristic	Reboot	Stop/start (Amazon EBS-backed instances only)	Hibernate (Amazon EBS-backed instances only)	Terminate
RAM (contents of memory)	The RAM is erased	The RAM is erased	The RAM is saved to a file on the root volume	The RAM is erased
Billing	The instance billing hour doesn't change	You stop incurring charges for an instance as soon as its state changes to `stopping`. Each time an instance transitions from `stopped` to `running`, we start a new instance billing period, billing a minimum of one minute every time you start your instance.	You incur charges while the instance is in the `stopping` state, but stop incurring charges when the instance is in the `stopped` state. Each time an instance transitions from `stopped` to `running`, we start a new instance billing period, billing a minimum of one minute every time you start your instance.	You stop incurring charges for an instance as soon as its state changes to `shutting-down`

Operating system shutdown commands always terminate an instance store-backed instance. You can control whether operating system shutdown commands stop or terminate an Amazon EBS-backed instance. For more information, see Change instance initiated shutdown behavior.

Stop and start Amazon EC2 instances

You can stop and start your instance if it has an Amazon EBS volume as its root device. When you stop an instance, it shuts down. When you start an instance, it is typically migrated to a new underlying host computer and assigned a new public IPv4 address.

An instance stop can be user-initiated (where you manually stop the instance) or initiated by AWS (in response to a scheduled stop event when AWS detects irreparable failure of the underlying host for your instance).

For user-initiated stops, we recommend using the Amazon EC2 console, CLI, or API instead of running the operating system stop command from your instance. When using Amazon EC2, if the instance does not cleanly shut down within a few minutes, Amazon EC2 performs a hard shut down. Furthermore, AWS CloudTrail creates an API record of when your instance was stopped.

This topic describes how to perform a user-initiated stop. For information about a stop performed by AWS, see Manage Amazon EC2 instances scheduled to stop or retire.

When you stop an instance, it is not deleted. If you decide that you no longer need an instance, you can terminate it. For more information, see Terminate Amazon EC2 instances. If you want to hibernate an instance to save the contents from the instance memory (RAM), see Hibernate your Amazon EC2 instance. For distinctions between instance lifecycle actions, see Differences between instance states.

Contents

How EC2 instance stop and start works

When you stop an Amazon EC2 instance, changes are registered at the operating system (OS) level of the instance, some resources are lost, and some resources persist. When you start an instance, changes are registered at the instance level.

Topics

- Test application response to stop and start
- Costs related to instance stop and start

What happens when you stop an instance

The following describes what typically happens when you stop an instance using the default stop method. Note that some aspects might vary depending on which stop method you use.

Changes registered at the OS level

- The API request sends a button press event to the guest.
- Various system services are stopped as a result of the button press event. Graceful OS shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown is initiated.
- The instance shuts down when the graceful OS shutdown process exits. There is no configurable OS shutdown time.
- If the instance OS does not cleanly shut down within a few minutes, a hard shutdown is performed.
- The instance stops running.
- The instance state changes to `stopping` and then `stopped`.
- [Auto Scaling] If your instance is in an Auto Scaling group, when the instance is in any Amazon EC2 state other than `running`, or if its status for the status checks becomes `impaired`, Amazon EC2 Auto Scaling considers the instance to be unhealthy and replaces it. For more information, see Health checks for instances in an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.
- [Windows instances] When you stop and start a Windows instance, the launch agent performs tasks on the instance, such as changing the drive letters for any attached Amazon EBS volumes. For more information about these defaults and how you can change them, see the section called "EC2Launch v2".

Resources lost

- Data stored on the RAM.
- Data stored on the instance store volumes.

- The public IPv4 address that Amazon EC2 automatically assigned to the instance upon launch or start. To retain a public IPv4 address that never changes, you can associate an Elastic IP address with your instance.

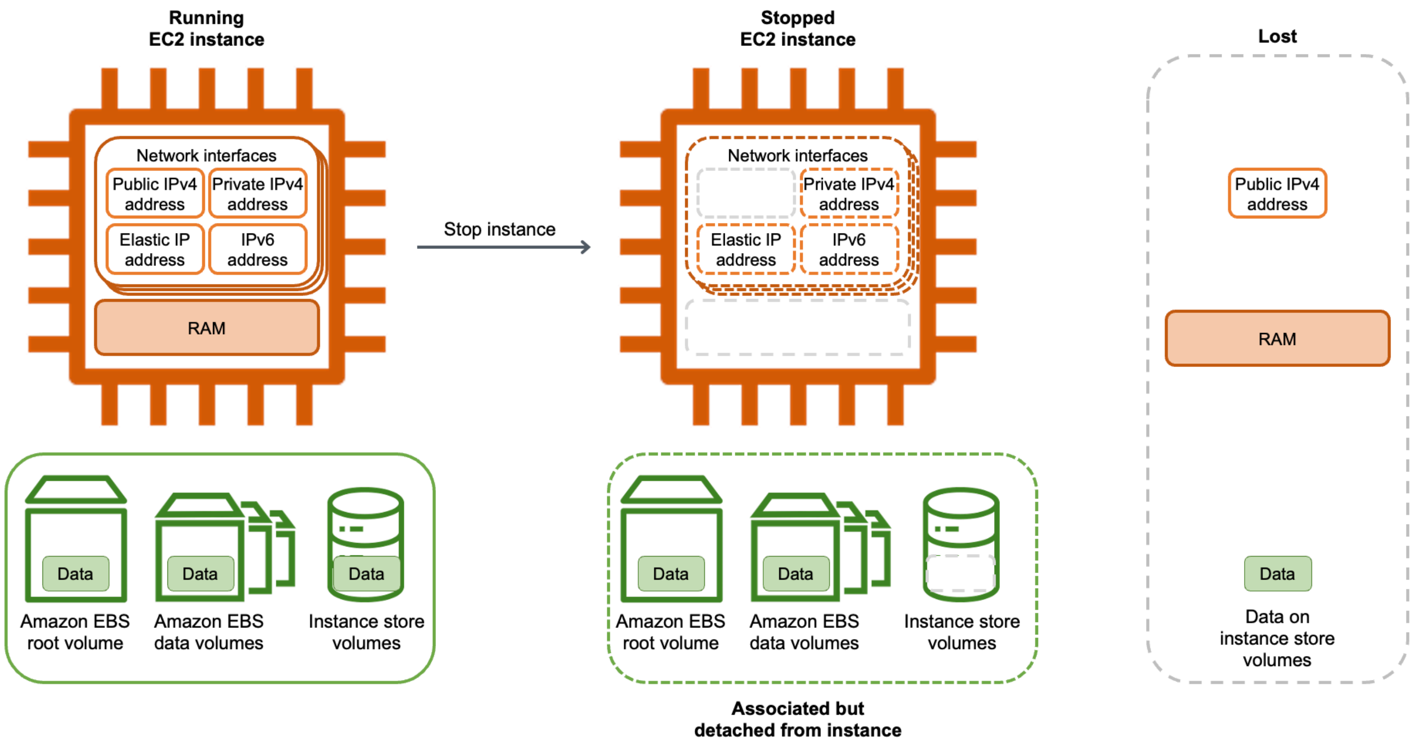
Resources that persist

- Any attached Amazon EBS root and data volumes.
- Data stored on the Amazon EBS volumes.
- Any attached network interfaces.

  A network interface includes the following resources, which also persist:

  - Private IPv4 addresses.
  - IPv6 addresses.
  - Elastic IP addresses associated with the instance. Note that when the instance is stopped, you are charged for the associated Elastic IP addresses.

The following diagram illustrates what persists and what is lost when an EC2 instance is stopped. The diagram is divided into three parts: the first part, labeled **Running EC2 instance**, shows the instance in the `running` state with its resources. The second part, labeled **Stopped EC2 instance**, shows the instance in the `stopped` state with the resources that persist. The third part, labeled **Lost**, shows the resources that are lost when the instance is stopped.



For information about what happens when you stop a Mac instance, see [Stop or terminate your Amazon EC2 Mac instance](#).

What happens when you start an instance

- In most cases, the instance is migrated to a new underlying host computer (though in some cases, such as when an instance is allocated to a host in a [Dedicated Host](#) configuration, it remains on the current host).
- The associated EBS volumes and network interfaces are reattached to the instance.
- Amazon EC2 assigns a new public IPv4 address to the instance if the instance is configured to receive a public IPv4 address, unless it has a secondary network interface or a secondary private IPv4 address that is associated with an Elastic IP address.

Test application response to stop and start

You can use AWS Fault Injection Service to test how your application responds when your instance is stopped and started. For more information, see the [AWS Fault Injection Service User Guide](#).

Costs related to instance stop and start

The following costs are associated with stopping and starting an instance.

Stopping – As soon as the state of an instance changes to `shutting-down` or `terminated`, charges are no longer incurred for the instance. You are not charged for usage or data transfer fees for a stopped instance. Charges are incurred to store Amazon EBS storage volumes.

Starting – Each time you start a stopped instance, you are charged for a minimum of one minute of usage. After one minute, you are charged for only the seconds you use. For example, if you run an instance for 20 seconds and then stop it, you are charged for a minute of usage. If you run an instance for 3 minutes and 40 seconds, you are charged for 3 minutes and 40 seconds of usage.

Methods for stopping an instance

There are four ways to perform a user-initiated stop: default stop, stop with skip OS shutdown, force stop, and force stop with skip OS shutdown. The following table compares the key differences between the stop methods:

Stop method	Key purpose	Use case	CLI command
Default stop	Normal instance shutdown with attempted graceful OS shutdown.	Typical instance stop.	`aws ec2 stop-instances \ --instance-id i-1234567890abcdef0`
Stop with skip OS shutdow	Bypasses the graceful OS shutdown when stopping an instance.	When bypassing graceful OS shutdown is required.	`aws ec2 stop-instances \ --instance-id i-1234567890abcdef0 \ --skip-os-shutdown`
Force stop	Handles stuck instances. Attempts a default stop first; if instance fails to stop, then forcibly stops the instance.	When instance is stuck in `stopping` state.	`aws ec2 stop-instances \ --instance-id i-1234567890abcdef0 \`

Stop method	Key purpose	Use case	CLI command
			`--force`
Force stop with skip OS shutdown	Force stops and bypasses the graceful OS shutdown when stopping an instance.	When force stop and bypassing graceful OS shutdown is required.	`aws ec2 stop-instances \ --instance-id i-1234567890abcdef0 \ --force \ --skip-os-shutdown`

For instructions on how to use each method, see the following:

- Stop an instance with a graceful OS shutdown
- Stop an instance and bypass the graceful OS shutdown
- Force stop an instance

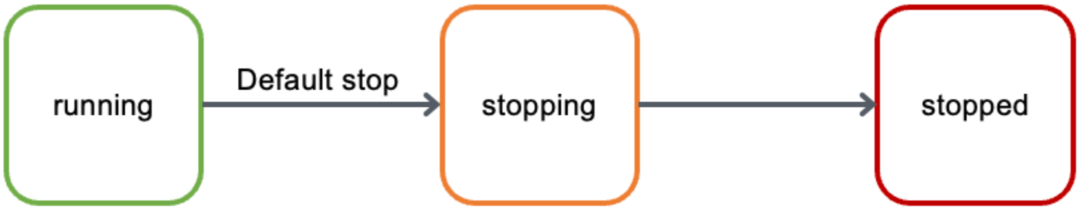
Stop methods:

- Default stop
- Stop with skip OS shutdown
- Force stop
- Force stop with skip OS shutdown

The following sections provide more detailed information about the four different user-initiated stop methods.

Default stop

The default stop method is the standard way to stop an instance. When you issue the StopInstances command, the instance transitions from the `running` state, to `stopping`, and finally to `stopped`, as illustrated by the following diagram:



Purpose: Normal instance shutdown with attempted graceful OS shutdown.

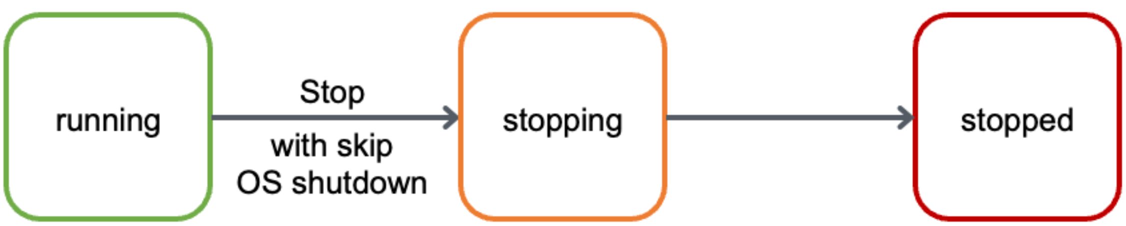
Data impact: Preserves data on the EBS root volume and data volumes. Loses data on the instance store volume.

When to use: First stop attempt for typical stops.

> **Note**
>
> If you've already attempted a stop with skip OS shutdown, a subsequent default stop attempt during the same state transition session will not perform a graceful OS shutdown. Bypassing the graceful OS shutdown is irreversible for the instance's current session.

Stop with skip OS shutdown

When bypassing the graceful OS shutdown is required, the stop with skip OS shutdown method can be used to stop an instance and bypass the graceful OS shutdown, as illustrated by the following diagram:



> **Warning**
>
> Bypassing the graceful OS shutdown might result in data loss or corruption (for example, memory contents not flushed to disk or loss of in-flight IOs) or skipped shutdown scripts.

Purpose: Bypass the graceful OS shutdown when stopping an instance.

Data impact: Might result in data loss or corruption. Contents of memory might not be flushed to disk and in-flight IOs might be lost. Might skip shutdown scripts.

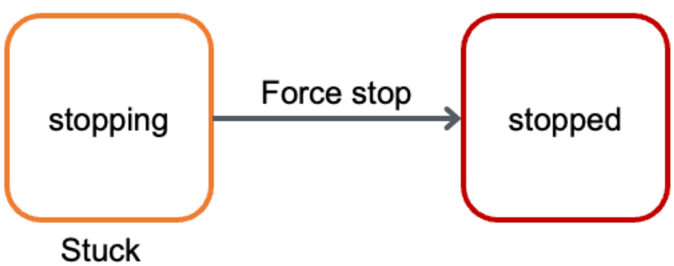
When to use: When bypassing the graceful OS shutdown is required. If used while a default stop with graceful OS shutdown is in progress, the graceful OS shutdown will be bypassed.

> **Note**
>
> Bypassing the graceful OS shutdown is irreversible for the instance's current state transition session. A subsequent default stop attempt during this session will not attempt a graceful OS shutdown.

Force stop

The force stop method is used to handle instances that are stuck in the `stopping` state. An instance typically becomes stuck due to an underlying hardware issue (indicated by a failed [system status check](#)).

The force stop method first attempts a default stop. If the instance remains stuck in the `stopping` state, the `force` parameter forcibly shuts down the instance and transitions the instance to the `stopped` state, as indicated by the following diagram:



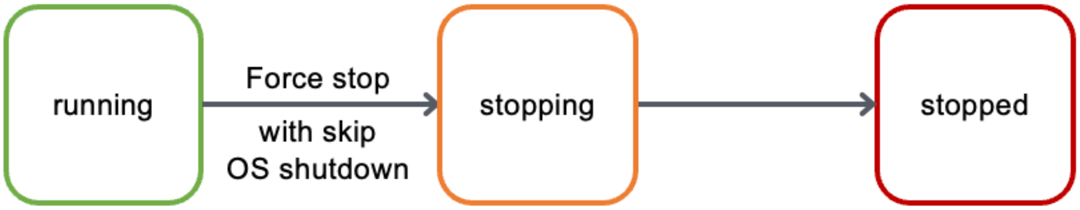
Purpose: Handles instances stuck in the `stopping` state. Attempts a default stop first. If the instance fails to stop, then forcibly shuts down the instance.

Data impact: Attempts a default stop first, but if force stop goes ahead, then might cause data loss or corruption. In rare cases, results in post-stop writes to EBS volumes or other shared resources.

When to use: Second stop attempt when an instance remains stuck after a default stop. For more information, see [Troubleshoot Amazon EC2 instance stop issues](#).

Force stop with skip OS shutdown

When force stopping and bypassing the graceful OS shutdown is required, the force stop with skip OS shutdown method can be used to bring an instance to the `stopped` state, as illustrated in the following diagram:



Purpose: Combines force stop with bypassing a graceful OS shutdown when stopping an instance.

Data impact: Skip OS shutdown might result in data loss or corruption. Contents of memory might not be flushed to disk and in-flight IOs might be lost. Might skip shutdown scripts. If force stop goes ahead, then might cause additional data loss or corruption. In rare cases, results in post-stop writes to the EBS volumes or other shared resources.

When to use: When you want to be sure that your instance will stop and you want to bypass the graceful OS shutdown. If used while a default stop with graceful OS shutdown is in progress, the graceful OS shutdown will be bypassed.

Manually stop and start your instances

You can stop and start your Amazon EBS-backed instances (instances with EBS root volumes). You can't stop and start instances with an instance store root volume.

When using the default method to stop an instance, a graceful operating system (OS) shutdown is attempted. You can bypass the graceful OS shutdown; however, this might risk data integrity.

> **Warning**
>
> When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from the instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

[Linux instances] Using the OS **halt** command from an instance does not initiate a shutdown. If you use the **halt** command, the instance does not terminate; instead, it places the CPU into HLT, which suspends CPU operation. The instance remains running.

You can initiate a shutdown using the OS **shutdown** or **poweroff** commands. When you use an OS command, the instance stops by default. You can change this behavior. For more information, see Change instance initiated shutdown behavior.

> **Note**
>
> If you stopped an Amazon EBS-backed instance and it appears "stuck" in the `stopping` state, you can forcibly stop it. For more information, see Troubleshoot Amazon EC2 instance stop issues.

Stop and start methods

- Stop an instance with a graceful OS shutdown
- Stop an instance and bypass the graceful OS shutdown
- Start an instance

Stop an instance with a graceful OS shutdown

You can stop an instance using the default stop method, which includes an attempt at a graceful OS shutdown. For more information, see Default stop.

Console

To stop an instance using the default stop method

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**, and then select the instance.
3. Choose **Instance state**, **Stop instance**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.

AWS CLI

To stop an instance using the default stop method

Use the stop-instances command.

```
aws ec2 stop-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To stop an instance using the default stop method

Use the Stop-EC2Instance cmdlet

```
Stop-EC2Instance -InstanceId i-1234567890abcdef0
```

Stop an instance and bypass the graceful OS shutdown

You can bypass the graceful OS shutdown when stopping an instance. For more information, see Stop with skip OS shutdown.

Warning

Bypassing the graceful OS shutdown might result in data loss or corruption (for example, memory contents not flushed to disk or loss of in-flight IOs) or skipped shutdown scripts.

Console

To stop an instance and bypass the graceful OS shutdown

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances** and select the instance.
3. Choose **Instance state**, **Stop instance**.
4. Under **Skip OS shutdown**, select the **Skip OS shutdown** checkbox. If you don't see this option in the console, it's not yet available in the console in the current Region. You can, however, access this feature using the AWS CLI or SDK, or try another Region in the console.
5. Choose **Stop**.

AWS CLI

To stop an instance and bypass the graceful OS shutdown

Use the stop-instances command with `--skip-os-shutdown`.

```
aws ec2 stop-instances \
    --instance-ids i-1234567890abcdef0 \
    --skip-os-shutdown
```

PowerShell

To stop an instance and bypass the graceful OS shutdown

Use the [Stop-EC2Instance](#) cmdlet with `-SkipOsShutdown $true`.

```
Stop-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -SkipOsShutdown $true
```

Start an instance

You can start a stopped instance.

Console

To start an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**.
3. Select the instance, and choose **Instance state**, **Start instance**.

   It can take a few minutes for the instance to enter the `running` state.

AWS CLI

To start an instance

Use the start-instances command.

```
aws ec2 start-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To start an instance

Use the Start-EC2Instance cmdlet.

```
Start-EC2Instance -InstanceId i-1234567890abcdef0
```

Automatically stop and start your instances

You can automate stopping and starting instances with the following services:

Instance Scheduler on AWS

You can use Instance Scheduler on AWS to automate the starting and stopping of EC2 instances. For more information, see How do I use Instance Scheduler with CloudFormation to schedule EC2 instances? Note that additional charges apply.

AWS Lambda and an Amazon EventBridge rule

You can use Lambda and an EventBridge rule to stop and start your instances on a schedule. For more information, see How do I use Lambda to stop and start Amazon EC2 instances at regular intervals?

Amazon EC2 Auto Scaling

To ensure you have the correct number of Amazon EC2 instances available to handle the load for an application, create Auto Scaling groups. Amazon EC2 Auto Scaling ensures that your application always has the right capacity to handle the traffic demand, and saves costs by launching instances only when they are needed. Note that Amazon EC2 Auto Scaling terminates, rather than stops, unneeded instances. To set up Auto Scaling groups, see Get started with Amazon EC2 Auto Scaling.

Find all running and stopped instances

You can find all of your running and stopped instances across all AWS Regions on a single page using Amazon EC2 Global View. This capability is especially useful for taking inventory and finding forgotten instances. For information about how to use Global View, see View resources across Regions using AWS Global View.

Alternatively, you can run a command or cmdlet in each Region where you have instances.

AWS CLI

To get the number of EC2 instances in a Region

Use the following describe-instances command to count the instances in the current Region. You must run this command in each Region where you have instances.

```
aws ec2 describe-instances \
    --region us-east-2 \
    --query "length(Reservations[].Instances[])"
```

The following is example output.

```
27
```

To get summary info about your EC2 instances in a Region

Use the following describe-instances command. You must run this command in each Region where you have instances.

```
aws ec2 describe-instances \
    --region us-east-2 \
    --query "Reservations[].Instances[].[InstanceId,InstanceType,PrivateIpAddress]"
 \
    --output table
```

The following is example output.

```
---------------------------------------------------------
|                    DescribeInstances                  |
+----------------------+----------------+-----------------+
|  i-0e3e777f4362f1bf7|  t2.micro     |  10.0.12.9      |
|  i-09453945dcf1529e9|  t2.micro     |  10.0.143.213   |
|  i-08fd74f3f1595fdbd|  m7i.4xlarge  |  10.0.1.103     |
+----------------------+----------------+-----------------+
```

PowerShell

To get the number of EC2 instances in a Region

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -Region us-east-2).Instances.Length
```

The following is example output.

```
27
```

To get summary info about your EC2 instances in a Region

Use the Get-EC2Instance cmdlet. You must run this command in each Region where you have instances.

```
(Get-EC2Instance).Instances | Select InstanceId, InstanceType, PrivateIpAddress
```

The following is example output.

```
InstanceId          InstanceType PrivateIpAddress
----------          ------------ ----------------
i-0e3e777f4362f1bf7 t2.micro     10.0.12.9
i-09453945dcf1529e9 t2.micro     10.0.143.213
i-08fd74f3f1595fdbd m7i.4xlarge  10.0.1.103
```

Find the initial and most recent launch times

When you describe an instance, the launch time for the instance is its most recent launch time. After you stop and start an instance, the launch time reflects the new instance start time. To find the initial launch time for an instance, even after stopping and starting it, view the time at which the primary network interface was attached to the instance.

Console

To find the most recent launch time

Select the instance and find **Launch time** under **Instance details** on the **Details** tab.

To find the initial launch time

Select the instance and find the primary network interface (device index is 0) under **Network interfaces** on the **Networking** tab.

AWS CLI

To find the initial and most recent launch times

Use the following [describe-instances](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-instances.html) command to display both the initial launch time and the most recent launch time for the specified instance.

```
aws ec2 describe-instances \
    --instance-id i-1234567890abcdef0 \
    --query 'Reservations[].Instances[].
{InstanceID:InstanceId,InitialLaunch:NetworkInterfaces[0].Attachment.AttachTime,LastLaunch:L
```

The following is example output.

```
[
    {
        "InstanceID": "i-1234567890abcdef0",
        "InitialLaunch": "2024-04-19T00:47:08+00:00",
        "LastLaunch": "2024-05-27T06:24:06+00:00"
    }
]
```

PowerShell

To find the most recent launch time

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -InstanceId i-1234567890abcdef0).Instances.LaunchTime
```

The following is example output.

```
Monday, May 27, 2024 6:24:06 AM
```

To find the initial launch time

Use the Get-EC2Instance cmdlet.

```
(Get-EC2Instance -
InstanceId i-1234567890abcdef0).Instances.NetworkInterfaces.Attachment.AttachTime
```

The following is example output.

```
Friday, April 19, 2024 12:47:08 AM
```

Enable stop protection for your EC2 instances

To prevent an instance from being accidentally stopped, you can enable stop protection for the instance. Stop protection also protects your instance from accidental termination.

The `DisableApiStop` attribute of the Amazon EC2 [`ModifyInstanceAttribute`] API controls whether the instance can be stopped by using the Amazon EC2 console, the AWS CLI, or the Amazon EC2 API. You can set the value of this attribute when you launch the instance, while the instance is running, or while the instance is stopped.

Considerations

- Enabling stop protection does not prevent you from accidentally stopping an instance by initiating a shutdown from the instance using an operating system command such as **shutdown** or **poweroff**.
- Enabling stop protection does not prevent AWS from stopping the instance when there is a scheduled event to stop the instance.
- Enabling stop protection does not prevent Amazon EC2 Auto Scaling from terminating an instance when the instance is unhealthy or during scale-in events. You can control whether an Auto Scaling group can terminate a particular instance when scaling in by using instance scale-in protection.
- Stop protection not only prevents your instance from being accidentally stopped, but also from accidental termination when using the console, AWS CLI, or API. However, it does not automatically set the `DisableApiTermination` attribute. Note that when the `DisableApiStop` attribute is set to `false`, the `DisableApiTermination` attribute setting determines whether the instance can be terminated using the console, AWS CLI, or API. For more information see Terminate Amazon EC2 instances.
- You can't enable stop protection for instance store-backed instances.
- You can't enable stop protection for Spot Instances.
- The Amazon EC2 API follows an eventual consistency model when you enable or disable stop protection. This means that the result of running commands to set the stop protection attribute might not be immediately visible to all subsequent commands you run. For more information, see Eventual consistency in the *Amazon EC2 Developer Guide*.

Stop protection tasks

- Enable stop protection for an instance at launch

- Enable stop protection for a running or stopped instance
- Disable stop protection for a running or stopped instance

Enable stop protection for an instance at launch

You can enable stop protection for an instance when launching the instance.

Console

To enable stop protection for an instance at launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the dashboard, choose **Launch instance**.
3. Configure your instance in the new launch instance wizard.
4. In the wizard, enable stop protection by choosing **Enable** for **Stop protection** under **Advanced details**.

AWS CLI

To enable stop protection for an instance at launch

Use the run-instances command to launch the instance. Add the following parameter.

```
--disable-api-stop
```

PowerShell

To enable stop protection for an instance at launch

Use the New-EC2Instance cmdlet to launch the instance. Add the following parameter.

```
-DisableApiStop $true
```

Enable stop protection for a running or stopped instance

You can enable stop protection for an instance while the instance is running or stopped.

Console

To enable stop protection for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions**>**Instance settings**>**Change stop protection**.
4. Select the **Enable** checkbox, and then choose **Save**.

AWS CLI

To enable stop protection for an instance

Use the modify-instance-attribute command.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --disable-api-stop
```

PowerShell

To enable stop protection for an instance

Use the Edit-EC2InstanceAttribute cmdlet.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -DisableApiStop $true
```

Disable stop protection for a running or stopped instance

You can disable stop protection for a running or stopped instance using one of the following methods.

Console

To disable stop protection for a running or stopped instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**.

3. Select the instance, and then choose **Actions**, **Instance settings**, **Change stop protection**.
4. Clear the **Enable** checkbox, and then choose **Save**.

AWS CLI

To disable stop protection for a running or stopped instance

Use the modify-instance-attribute command.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --no-disable-api-stop
```

PowerShell

To disable stop protection for an instance

Use the Edit-EC2InstanceAttribute cmdlet.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -DisableApiStop $false
```

Hibernate your Amazon EC2 instance

When you hibernate an instance, Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). Hibernation saves the contents from the instance memory (RAM) to your Amazon Elastic Block Store (Amazon EBS) root volume. Amazon EC2 persists the instance's EBS root volume and any attached EBS data volumes. When your instance is started:

- The EBS root volume is restored to its previous state
- The RAM contents are reloaded
- The processes that were previously running on the instance are resumed
- Previously attached data volumes are reattached and the instance retains its instance ID

You can hibernate an instance only if it's enabled for hibernation and it meets the hibernation prerequisites.

If an instance or application takes a long time to bootstrap and build a memory footprint in order to become fully productive, you can use hibernation to pre-warm the instance. To pre-warm the instance, you:

1. Launch it with hibernation enabled.
2. Bring it to a desired state.
3. Hibernate it so that it's ready to be resumed to the desired state whenever needed.

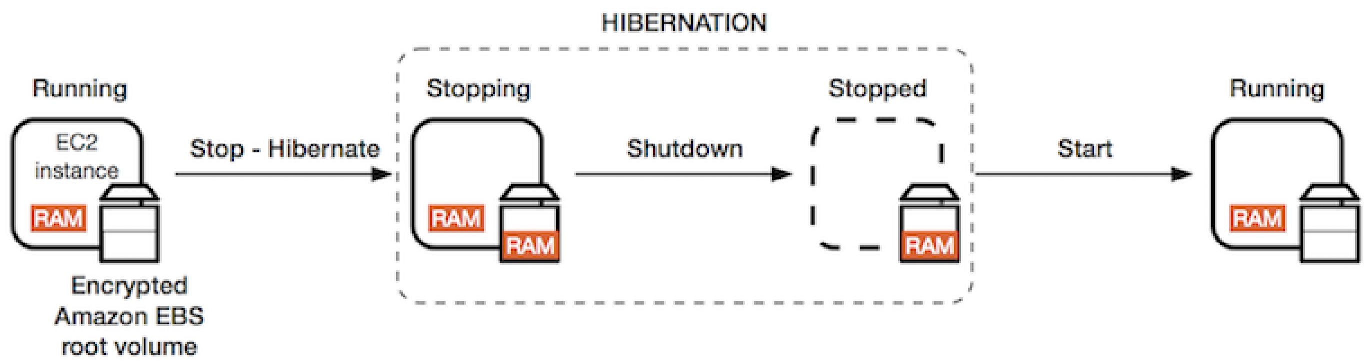
You're not charged for instance usage for a hibernated instance when it is in the `stopped` state or for data transfer when the contents of the RAM are transferred to the EBS root volume. You are charged for storage of any EBS volumes, including storage for the RAM contents.

If you no longer need an instance, you can terminate it at any time, including when it is in a `stopped` (hibernated) state. For more information, see Terminate Amazon EC2 instances.

Contents

How Amazon EC2 instance hibernation works

The following diagram shows a basic overview of the hibernation process for EC2 instances.



What happens when you hibernate an instance

When you hibernate an instance, the following happens:

- The instance moves to the `stopping` state. Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). The hibernation freezes all of the processes, saves the contents of the RAM to the EBS root volume, and then performs a regular shutdown.
- After the shutdown is complete, the instance moves to the `stopped` state.
- Any EBS volumes remain attached to the instance, and their data persists, including the saved contents of the RAM.
- Any Amazon EC2 instance store volumes remain attached to the instance, but the data on the instance store volumes is lost.
- In most cases, the instance is migrated to a new underlying host computer when it's started. This is also what happens when you stop and start an instance.
- When the instance is started, the instance boots up and the operating system reads in the contents of the RAM from the EBS root volume, before unfreezing processes to resume its state.
- The instance retains its private IPv4 addresses and any IPv6 addresses. When the instance is started, the instance continues to retain its private IPv4 addresses and any IPv6 addresses.
- Amazon EC2 releases the public IPv4 address. When the instance is started, Amazon EC2 assigns a new public IPv4 address to the instance.
- The instance retains its associated Elastic IP addresses. You're charged for any Elastic IP addresses that are associated with a hibernated instance.

For information about how hibernation differs from reboot, stop, and terminate, see [Differences between instance states](#).

Limitations

- When you hibernate an instance, the data on any instance store volumes is lost.
- (Linux instances) You can't hibernate a Linux instance that has more than 150 GiB of RAM.
- (Windows instances) You can't hibernate a Windows instance that has more than 16 GiB of RAM.
- While your instance is hibernated, you can't modify it. This is different to a stopped instance that isn't hibernated, where you can modify certain attributes, such as the instance type or size.
- If you create a snapshot or AMI from an instance that is hibernated or has hibernation enabled, you might not be able to connect to a new instance that is launched from the AMI or from an AMI that was created from the snapshot.
- (Spot Instances only) If Amazon EC2 hibernates your Spot Instance, only Amazon EC2 can resume your instance. If you hibernate your Spot Instance (user-initiated hibernation), you can resume your instance. A hibernated Spot Instance can only be resumed if capacity is available and the Spot price is less than or equal to your specified maximum price.
- You can't hibernate an instance that is in an Auto Scaling group or used by Amazon ECS. If your instance is in an Auto Scaling group and you try to hibernate it, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and might terminate it and launch a replacement instance. For more information, see Health checks for instances in an Auto Scaling group in the *Amazon EC2 Auto Scaling User Guide*.
- You can't hibernate an instance that is configured to boot in UEFI mode with UEFI Secure Boot enabled.
- If you hibernate an instance that was launched into a Capacity Reservation, the Capacity Reservation does not ensure that the hibernated instance can resume after you try to start it.
- You can’t hibernate an instance that uses a kernel below 5.10 if Federal Information Processing Standard (FIPS) mode is enabled.
- We do not support keeping an instance hibernated for more than 60 days. To keep the instance for longer than 60 days, you must start the hibernated instance, stop the instance, and start it.
- We constantly update our platform with upgrades and security patches, which can conflict with existing hibernated instances. We notify you about critical updates that require a start for hibernated instances so that we can perform a shutdown or a reboot to apply the necessary upgrades and security patches.

Considerations for hibernating a Spot Instance

- If *you* hibernate your Spot Instance, you can restart it provided capacity is available and the Spot price is less than or equal to your specified maximum price.
- If *Amazon EC2* hibernates your Spot Instance:
  - Only Amazon EC2 can resume your instance.
  - Amazon EC2 resumes the hibernated Spot Instance when capacity becomes available with a Spot price that is less than or equal to your specified maximum price.
  - Before Amazon EC2 hibernates your Spot Instance, you'll receive an interruption notice two minutes before hibernation starts.

  For more information, see Spot Instance interruptions.

Prerequisites for EC2 instance hibernation

You can enable hibernation support for an On-Demand Instance or a Spot Instance when you launch it. You can't enable hibernation on an existing instance, whether it is running or stopped. For more information, see Enable instance hibernation.

Requirements to hibernate an instance

- AWS Regions
- AMIs
- Instance families
- Instance RAM size
- Root volume type
- Root volume size
- Root volume encryption
- EBS volume type
- Spot Instance requests

AWS Regions

You can use hibernation with instances in all AWS Regions.

AMIs

You must use an HVM AMI that supports hibernation. The following AMIs support hibernation:

Linux AMIs

AMIs for Intel and AMD instance types

- AL2023 AMI released 2023.09.20 or later [1]
- Amazon Linux 2 AMI released 2019.08.29 or later
- Amazon Linux AMI 2018.03 released 2018.11.16 or later
- CentOS version 8 AMI [2] (Additional configuration is required)
- Fedora version 34 or later AMI [2] (Additional configuration is required)
- Red Hat Enterprise Linux (RHEL) 9 AMI [2] (Additional configuration is required)
- Red Hat Enterprise Linux (RHEL) 8 AMI [2] (Additional configuration is required)
- Ubuntu 22.04.2 LTS (Jammy Jellyfish) AMI released with serial number 20230303 or later [3]
- Ubuntu 20.04 LTS (Focal Fossa) AMI released with serial number 20210820 or later [3]
- Ubuntu 18.04 LTS (Bionic Beaver) AMI released with serial number 20190722.1 or later [3] [5]
- Ubuntu 16.04 LTS (Xenial Xerus) AMI [3] [4] [5] (Additional configuration is required)

AMIs for Graviton instance types

- AL2023 AMI (64-bit Arm) released 2024.07.01 or later [1]
- Amazon Linux 2 AMI (64-bit Arm) released 2024.06.20 or later
- Ubuntu 22.04.2 LTS (64-bit Arm) (Jammy Jellyfish) AMI released with serial number 20240701 or later [3]
- Ubuntu 20.04 LTS (64-bit Arm) (Focal Fossa) AMI released with serial number 20240701 or later [3]

[1] For AL2023 minimal AMI, additional configuration is required.

[2] For CentOS, Fedora, and Red Hat Enterprise Linux, hibernation is supported on Nitro-based instances only.

[3] We recommend disabling KASLR on instances with Ubuntu 22.04.2 LTS (Jammy Jellyfish), Ubuntu 20.04 LTS (Focal Fossa), Ubuntu 18.04 LTS (Bionic Beaver), and Ubuntu 16.04 LTS (Xenial Xerus). For more information, see Disable KASLR on an instance (Ubuntu only).

[4] For the Ubuntu 16.04 LTS (Xenial Xerus) AMI, hibernation is not supported on `t3.nano` instance types. No patch will be made available because Ubuntu (Xenial Xerus) ended support in April 2021. If you want to use `t3.nano` instance types, we recommend that you upgrade to the Ubuntu 22.04.2 LTS (Jammy Jellyfish), Ubuntu 20.04 LTS (Focal Fossa) AMI, or the Ubuntu 18.04 LTS (Bionic Beaver) AMI.

[5] Support for Ubuntu 18.04 LTS (Bionic Beaver) and Ubuntu 16.04 LTS (Xenial Xerus) has reached end of life.

To configure your own AMI to support hibernation, see Configure a Linux AMI to support hibernation.

Support for other versions of Ubuntu and other operating systems is coming soon.

Windows AMIs

- Windows Server 2022 AMI released 2023.09.13 or later
- Windows Server 2019 AMI released 2019.09.11 or later
- Windows Server 2016 AMI released 2019.09.11 or later
- Windows Server 2012 R2 AMI released 2019.09.11 or later
- Windows Server 2012 AMI released 2019.09.11 or later

Instance families

You must use an instance family that supports hibernation. However, bare metal instances are not supported.

- General purpose: M3, M4, M5, M5a, M5ad, M5d, M6a, M6g, M6gd, M6i, M6id, M6idn, M6in, M7a, M7g, M7gd, M7i, M7i-flex, M8g, M8gd, M8i, M8i-flex, T2, T3, T3a, T4g
- Compute optimized: C3, C4, C5, C5d, C6a, C6g, C6gd, C6gn, C6i, C6id, C6in, C7a, C7g, C7gd, C7gn, C7i, C7i-flex, C8g, C8gd, C8gn
- Memory optimized: R3, R4, R5, R5a, R5ad, R5d, R6a, R6g, R6gd, R6idn, R6in, R7a, R7g, R7gd, R7i, R7iz, R8g, R8gd, R8i, R8i-flex, X2gd
- Storage optimized: I3, I3en, I4g, I7i, I7ie, I8g, I8ge, Im4gn, Is4gen

Console

To get the instance types that support hibernation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instance Types**.
3. Add the filter **On-Demand Hibernation support = true**.
4. (Optional) Add filters to further scope to specific instance types of interest.

AWS CLI

To get the instance types that support hibernation

Use the describe-instance-types command. Note that the available instance types vary by Region.

```
aws ec2 describe-instance-types \
    --filters Name=hibernation-supported,Values=true \
    --query "InstanceTypes[*].[InstanceType]" \
    --output text | sort
```

PowerShell

To get the instance types that support hibernation

Use the Get-EC2InstanceType cmdlet. Note that the available instance types vary by Region.

```
(Get-EC2InstanceType `
    -Filter @{Name="hibernation-supported"; Values="true"}).InstanceType | Sort-
Object
```

Instance RAM size

Linux instances – Must be less than 150 GiB.

Windows instances – Must be less than or equal to 16 GiB. For hibernating a T3 or T3a Windows instance, we recommend at least 1 GiB of RAM.

Root volume type

The root volume must be an EBS volume, not an instance store volume.

Root volume size

The root volume must be large enough to store the RAM contents and accommodate your expected usage, for example, OS or applications. If you enable hibernation, space is allocated on the root volume at launch to store the RAM.

Root volume encryption

The root volume must be encrypted to ensure the protection of sensitive content that is in memory at the time of hibernation. When RAM data is moved to the EBS root volume, it is always encrypted. Encryption of the root volume is enforced at instance launch.

Use one of the following three options to ensure that the root volume is an encrypted EBS volume:

- **EBS encryption by default** – You can enable EBS encryption by default to ensure that all new EBS volumes created in your AWS account are encrypted. This way, you can enable hibernation for your instances without specifying encryption intent at instance launch. For more information, see Enable encryption by default.
- **EBS "single-step" encryption** – You can launch encrypted EBS-backed EC2 instances from an unencrypted AMI and also enable hibernation at the same time. For more information, see Use encryption with EBS-backed AMIs.
- **Encrypted AMI** – You can enable EBS encryption by using an encrypted AMI to launch your instance. If your AMI does not have an encrypted root snapshot, you can copy it to a new AMI and request encryption. For more information, see Encrypt an unencrypted image during copy and Copy an AMI.

EBS volume type

The EBS volumes must use one of the following EBS volume types:

- General Purpose SSD (`gp2` and `gp3`)
- Provisioned IOPS SSD (`io1` and `io2`)

If you choose a Provisioned IOPS SSD volume type, you must provision the EBS volume with the appropriate IOPS to achieve optimum performance for hibernation. For more information, see Amazon EBS volume types in the *Amazon EBS User Guide*.

Spot Instance requests

For Spot Instances, the following requirements apply:

- The Spot Instance request type must be `persistent`.
- You can't specify a launch group in the Spot Instance request.

Configure a Linux AMI to support hibernation

The following Linux AMIs can support hibernating an Amazon EC2 instance, provided you complete the additional configuration steps described in this section.

Additional configuration required for:

- AL2023 minimal AMI released 2023.09.20 or later
- Amazon Linux 2 minimal AMI released 2019.08.29 or later
- Amazon Linux 2 released before 2019.08.29
- Amazon Linux released before 2018.11.16
- CentOS version 8 or later
- Fedora version 34 or later
- Red Hat Enterprise Linux version 8 or 9
- Ubuntu 20.04 LTS (Focal Fossa) released before serial number 20210820
- Ubuntu 18.04 (Bionic Beaver) released before serial number 20190722.1
- Ubuntu 16.04 (Xenial Xerus)

For the Linux and Windows AMIs that support hibernation and for which *no additional* configuration is required, see AMIs.

For more information, see Update instance software on your Amazon Linux 2 instance.

AL2023 minimal AMI released 2023.09.20 or later

To configure an AL2023 minimal AMI released 2023.09.20 or later to support hibernation

1. Install the `ec2-hibinit-agent` package from the repositories.

   ```
   [ec2-user ~]$ sudo dnf install ec2-hibinit-agent
   ```

2. Restart the service.

```
[ec2-user ~]$ sudo systemctl start hibinit-agent
```

Amazon Linux 2 minimal AMI released 2019.08.29 or later

To configure an Amazon Linux 2 minimal AMI released 2019.08.29 or later to support hibernation

1. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

2. Restart the service.

```
[ec2-user ~]$ sudo systemctl start hibinit-agent
```

Amazon Linux 2 released before 2019.08.29

To configure an Amazon Linux 2 AMI released before 2019.08.29 to support hibernation

1. Update the kernel to `4.14.138-114.102` or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to `4.14.138-114.102` or later.

```
[ec2-user ~]$ uname -a
```

5. Stop the instance and create an AMI. For more information, see Create an Amazon EBS-backed AMI.

Amazon Linux released before 2018.11.16

To configure an Amazon Linux AMI released before 2018.11.16 to support hibernation

1. Update the kernel to `4.14.77-70.59` or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to `4.14.77-70.59` or greater.

```
[ec2-user ~]$ uname -a
```

5. Stop the instance and create an AMI. For more information, see Create an Amazon EBS-backed AMI.

CentOS version 8 or later

To configure a CentOS version 8 or later AMI to support hibernation

1. Update the kernel to `4.18.0-305.7.1.el8_4.x86_64` or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-8.noarch.rpm
```

3. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

4. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibinit-agent.service
```

5. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

6. Confirm that the kernel version is updated to `4.18.0-305.7.1.el8_4.x86_64` or later.

```
[ec2-user ~]$ uname -a
```

Fedora version 34 or later

To configure a Fedora version 34 or later AMI to support hibernation

1. Update the kernel to `5.12.10-300.fc34.x86_64` or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo dnf install ec2-hibinit-agent
```

3. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibinit-agent.service
```

4. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

5. Confirm that the kernel version is updated to `5.12.10-300.fc34.x86_64` or later.

```
[ec2-user ~]$ uname -a
```

Red Hat Enterprise Linux version 8 or 9

To configure a Red Hat Enterprise Linux 8 or 9 AMI to support hibernation

1. Update the kernel to `4.18.0-305.7.1.el8_4.x86_64` or later.

   ```
   [ec2-user ~]$ sudo yum update kernel
   ```

2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

   RHEL version 8:

   ```
   [ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-8.noarch.rpm
   ```

   RHEL version 9:

   ```
   [ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-9.noarch.rpm
   ```

3. Install the `ec2-hibinit-agent` package from the repositories.

   ```
   [ec2-user ~]$ sudo yum install ec2-hibinit-agent
   ```

4. Enable the hibernate agent to start on boot.

   ```
   [ec2-user ~]$ sudo systemctl enable hibinit-agent.service
   ```

5. Reboot the instance.

   ```
   [ec2-user ~]$ sudo reboot
   ```

6. Confirm that the kernel version is updated to `4.18.0-305.7.1.el8_4.x86_64` or later.

   ```
   [ec2-user ~]$ uname -a
   ```

Ubuntu 20.04 LTS (Focal Fossa) released before serial number 20210820

To configure an Ubuntu 20.04 LTS (Focal Fossa) AMI released before serial number 20210820 to support hibernation

1. Update the linux-aws-kernel to `5.8.0-1038.40` or later, and grub2 to `2.04-1ubuntu26.13` or later.

```
[ec2-user ~]$ sudo apt update
[ec2-user ~]$ sudo apt dist-upgrade
```

2. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

3. Confirm that the kernel version is updated to `5.8.0-1038.40` or later.

```
[ec2-user ~]$ uname -a
```

4. Confirm that the grub2 version is updated to `2.04-1ubuntu26.13` or later.

```
[ec2-user ~]$ dpkg --list | grep grub2-common
```

Ubuntu 18.04 (Bionic Beaver) released before serial number 20190722.1

To configure an Ubuntu 18.04 LTS AMI released before serial number 20190722.1 to support hibernation

1. Update the kernel to `4.15.0-1044` or later.

```
[ec2-user ~]$ sudo apt update
[ec2-user ~]$ sudo apt dist-upgrade
```

2. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo apt install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to `4.15.0-1044` or later.

```
[ec2-user ~]$ uname -a
```

Ubuntu 16.04 (Xenial Xerus)

To configure Ubuntu 16.04 LTS to support hibernation, you need to install the linux-aws-hwe kernel package version 4.15.0-1058-aws or later and the ec2-hibinit-agent.

> **Important**
>
> The `linux-aws-hwe` kernel package is supported by Canonical. The standard support for Ubuntu 16.04 LTS ended in April 2021, and the package no longer receives regular updates. However, it will receive additional security updates until the Extended Security Maintenance support ends in 2024. For more information, see [Amazon EC2 Hibernation for Ubuntu 16.04 LTS now available](#) on the Canonical Ubuntu Blog.
> We recommend that you upgrade to the Ubuntu 20.04 LTS (Focal Fossa) AMI or the Ubuntu 18.04 LTS (Bionic Beaver) AMI.

To configure an Ubuntu 16.04 LTS AMI to support hibernation

1. Update the kernel to `4.15.0-1058-aws` or later.

```
[ec2-user ~]$ sudo apt update
[ec2-user ~]$ sudo apt install linux-aws-hwe
```

2. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo apt install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to `4.15.0-1058-aws` or later.

```
[ec2-user ~]$ uname -a
```

Enable hibernation for an Amazon EC2 instance

To hibernate an instance, you must first enable it for hibernation while launching the instance.

> **Important**
>
> You can't enable or disable hibernation for an instance after you launch it.

Tasks

Enable hibernation for On-Demand Instances

You can enable hibernation for your On-Demand Instances.

Console

To enable hibernation for an On-Demand Instance

1. Follow the procedure to launch an instance, but don't launch the instance until you've completed the following steps to enable hibernation.
2. To enable hibernation, configure the following fields in the launch instance wizard:

   a. Under **Application and OS Images (Amazon Machine Image)**, select an AMI that supports hibernation. For more information, see AMIs.

   b. Under **Instance type**, select a supported instance type. For more information, see Instance families.

   c. Under **Configure storage**, choose **Advanced** (at the right), and specify the following information for the root volume:

      - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
      - For **Volume type**, select a supported EBS volume type: General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (`io1` and `io2`).

- For **Encrypted**, choose **Yes**. If you enabled encryption by default in this AWS Region, **Yes** is selected.
- For **KMS key**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

For more information about the prerequisites for the root volume, see [Prerequisites for EC2 instance hibernation](#).

d. Expand **Advanced details**, and for **Stop - Hibernate behavior**, choose **Enable**.

3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an EC2 instance using the launch instance wizard in the console](#).

AWS CLI

To enable hibernation for an On-Demand Instance

Use the [run-instances](#) command to launch an instance. Specify the EBS root volume parameters using the `--block-device-mappings file://mapping.json` parameter, and enable hibernation using the `--hibernation-options Configured=true` parameter.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type m5.large \
    --block-device-mappings file://mapping.json \
    --hibernation-options Configured=true \
    --count 1 \
    --key-name MyKeyPair
```

Specify the following in `mapping.json`.

```
[
    {
        "DeviceName": "/dev/xvda",
        "Ebs": {
            "VolumeSize": 30,
            "VolumeType": "gp2",
            "Encrypted": true
        }
    }
```

```
]
```

The value for `DeviceName` must match the root device name that's associated with the AMI. To find the root device name, use the describe-images command.

```
aws ec2 describe-images --image-id ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit `"Encrypted": true`.

PowerShell

To enable hibernation for an On-Demand Instance

Use the New-EC2Instance command to launch an instance. Specify the EBS root volume by first defining the block device mapping, and then adding it to the command using the `-BlockDeviceMappings` parameter. Enable hibernation using the `-HibernationOptions_Configured $true` parameter.

```
$ebs_encrypt = New-Object Amazon.EC2.Model.BlockDeviceMapping
$ebs_encrypt.DeviceName = "/dev/xvda"
$ebs_encrypt.Ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
$ebs_encrypt.Ebs.VolumeSize = 30
$ebs_encrypt.Ebs.VolumeType = "gp2"
$ebs_encrypt.Ebs.Encrypted = $true

New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType m5.large `
    -BlockDeviceMappings $ebs_encrypt `
    -HibernationOptions_Configured $true `
    -MinCount 1 `
    -MaxCount 1 `
    -KeyName MyKeyPair
```

The value for `DeviceName` must match the root device name associated with the AMI. To find the root device name, use the Get-EC2Image command.

```
Get-EC2Image -ImageId ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit `Encrypted = $true` from the block device mapping.

Enable hibernation for Spot Instances

You can enable hibernation for your Spot Instances. For more information about hibernating a Spot Instance on interruption, see Spot Instance interruptions.

Console

To enable hibernation for a Spot Instance

1. Follow the procedure to request a Spot Instance using the launch instance wizard, but don't launch the instance until you've completed the following steps to enable hibernation.
2. To enable hibernation, configure the following fields in the launch instance wizard:
   a. Under **Application and OS Images (Amazon Machine Image)**, select an AMI that supports hibernation. For more information, see AMIs.
   b. Under **Instance type**, select a supported instance type. For more information, see Instance families.
   c. Under **Configure storage**, choose **Advanced** (at the right), and specify the following information for the root volume:
      - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
      - For **Volume type**, select a supported EBS volume type: General Purpose SSD (`gp2` and `gp3`) or Provisioned IOPS SSD (`io1` and `io2`).
      - For **Encrypted**, choose **Yes**. If you enabled encryption by default in this AWS Region, **Yes** is selected.
      - For **KMS key**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

      For more information about the prerequisites for the root volume, see Prerequisites for EC2 instance hibernation.
   d. Expand **Advanced details**, and, in addition to the fields for configuring a Spot Instance, do the following:
      i. For **Request type**, choose **Persistent**.

ii. For **Interruption behavior**, choose **Hibernate**. Alternatively, for **Stop - Hibernate behavior**, choose **Enable**. Both fields enable hibernation on your Spot Instance. You need only configure one of them.

3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

AWS CLI

To enable hibernation for a Spot Instance

Use the run-instances command to request a Spot Instance. Specify the EBS root volume parameters using the `--block-device-mappings file://mapping.json` parameter, and enable hibernation using the `--hibernation-options Configured=true` parameter. The Spot request type (`SpotInstanceType`) must be `persistent`.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type c4.xlarge \
    --block-device-mappings file://mapping.json \
    --hibernation-options Configured=true \
    --count 1 \
    --key-name MyKeyPair
    --instance-market-options
        {
           "MarketType":"spot",
           "SpotOptions":{
              "MaxPrice":"1",
              "SpotInstanceType":"persistent"
            }
        }
```

Specify the EBS root volume parameters in `mapping.json` as follows.

```
[
    {
        "DeviceName": "/dev/xvda",
        "Ebs": {
            "VolumeSize": 30,
            "VolumeType": "gp2",
```

```
                "Encrypted": true
            }
        }
]
```

The value for DeviceName must match the root device name that's associated with the AMI. To find the root device name, use the describe-images command.

```
aws ec2 describe-images --image-id ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit "Encrypted": true.

PowerShell

To enable hibernation for a Spot Instance

Use the New-EC2Instance command to request a Spot Instance. Specify the EBS root volume by first defining the block device mapping, and then adding it to the command using the -BlockDeviceMappings parameter. Enable hibernation using the -HibernationOptions_Configured $true parameter.

```
$ebs_encrypt = New-Object Amazon.EC2.Model.BlockDeviceMapping
$ebs_encrypt.DeviceName = "/dev/xvda"
$ebs_encrypt.Ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
$ebs_encrypt.Ebs.VolumeSize = 30
$ebs_encrypt.Ebs.VolumeType = "gp2"
$ebs_encrypt.Ebs.Encrypted = $true

New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType m5.large `
    -BlockDeviceMappings $ebs_encrypt `
    -HibernationOptions_Configured $true `
    -MinCount 1 `
    -MaxCount 1 `
    -KeyName MyKeyPair `
    -InstanceMarketOption @(
        MarketType = spot;
        SpotOptions @{
        MaxPrice = 1;
        SpotInstanceType = persistent}
    )
```

The value for `DeviceName` must match the root device name associated with the AMI. To find the root device name, use the [Get-EC2Image](https://docs.aws.amazon.com/powershell/latest/reference/items/Get-EC2Image.html) command.

```
Get-EC2Image -ImageId ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit `Encrypted = $true` from the block device mapping.

View if an instance is enabled for hibernation

You can check whether an instance is enabled for hibernation.

Console

To view if an instance is enabled for hibernation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the **Details** tab, in the **Instance details** section, inspect **Stop-hibernate behavior**. **Enabled** indicates that the instance is enabled for hibernation.

AWS CLI

To view if an instance is enabled for hibernation

Use the describe-instances command and specify the `--filters "Name=hibernation-options.configured,Values=true"` parameter to filter instances that are enabled for hibernation.

```
aws ec2 describe-instances \
    --filters "Name=hibernation-options.configured,Values=true"
```

The following field in the output indicates that the instance is enabled for hibernation.

```
"HibernationOptions": {
    "Configured": true
}
```

PowerShell

To view if an instance is enabled for hibernation

Use the Get-EC2Instance cmdlet and filter instances that are enabled for hibernation.

```
(Get-EC2Instance `
    -Filter @{Name="hibernation-options.configured"; Values="true"}).Instances
```

Disable KASLR on an instance (Ubuntu only)

To run hibernation on a newly launched instance with Ubuntu 16.04 LTS (Xenial Xerus), Ubuntu 18.04 LTS (Bionic Beaver) released with serial number 20190722.1 or later, or Ubuntu 20.04 LTS (Focal Fossa) released with serial number 20210820 or later, we recommend disabling KASLR (Kernel Address Space Layout Randomization). On Ubuntu 16.04 LTS, Ubuntu 18.04 LTS, or Ubuntu 20.04 LTS, KASLR is enabled by default.

KASLR is a standard Linux kernel security feature that helps to mitigate exposure to and ramifications of yet-undiscovered memory access vulnerabilities by randomizing the base address value of the kernel. With KASLR enabled, there is a possibility that the instance might not resume after it has been hibernated.

To learn more about KASLR, see Ubuntu Features.

To disable KASLR on an instance launched with Ubuntu

1. Connect to your instance using SSH. For more information, see Connect to your Linux instance using SSH.
2. Open the `/etc/default/grub.d/50-cloudimg-settings.cfg` file in your editor of choice. Edit the `GRUB_CMDLINE_LINUX_DEFAULT` line to append the `nokaslr` option to its end, as shown in the following example.

   ```
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0
    nvme_core.io_timeout=4294967295 nokaslr"
   ```
3. Save the file and exit your editor.
4. Run the following command to rebuild the grub configuration.

   ```
   sudo update-grub
   ```

5. Reboot the instance.

```
sudo reboot
```

6. Run the following command to confirm that `nokaslr` has been added.

```
cat /proc/cmdline
```

The output of the command should include the `nokaslr` option.

Hibernate an Amazon EC2 instance

You can initiate hibernation on an On-Demand Instance or Spot Instance if the instance is an EBS-backed instance, is enabled for hibernation, and meets the hibernation prerequisites. If an instance cannot hibernate successfully, a normal shutdown occurs.

Console

To hibernate an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and choose **Instance state**, **Hibernate instance**. If **Hibernate instance** is disabled, the instance is already hibernated or stopped, or it can't be hibernated. For more information, see Prerequisites for EC2 instance hibernation.
4. When prompted for confirmation, choose **Hibernate**. It can take a few minutes for the instance to hibernate. The instance state first changes to **Stopping**, and then changes to **Stopped** when the instance has hibernated.

AWS CLI

To hibernate an instance

Use the stop-instances command and specify the `--hibernate` parameter.

```
aws ec2 stop-instances \
    --instance-ids i-1234567890abcdef0 \
    --hibernate
```

PowerShell

To hibernate an instance

Use the Stop-EC2Instance cmdlet.

```
Stop-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
    -Hibernate $true
```

You can check whether hibernation was initiated on an instance.

Console

To view if hibernation was initiated on an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the **Details** tab, in the **Instance details** section, check the value for **State transition message**.

   Client.UserInitiatedHibernate: User initiated hibernate indicates that you initiated hibernation on the On-Demand Instance or Spot Instance.

AWS CLI

To view if hibernation was initiated on an instance

Use the describe-instances command and specify the `state-reason-code` filter to see the instances on which hibernation was initiated.

```
aws ec2 describe-instances \
    --filters "Name=state-reason-code,Values=Client.UserInitiatedHibernate"
```

The following field in the output indicates that hibernation was initiated on the On-Demand Instance or Spot Instance.

```
"StateReason": {
    "Code": "Client.UserInitiatedHibernate"
```

```
}
```

PowerShell

To view if hibernation was initiated on an instance

Use the Get-EC2Instance cmdlet and specify the `state-reason-code` filter to see the instances on which hibernation was initiated.

```
Get-EC2Instance `
    -Filter @{Name="state-reason-code";Value="Client.UserInitiatedHibernate"}
```

Start a hibernated Amazon EC2 instance

Start a hibernated instance by starting it in the same way that you would start a stopped instance.

For Spot Instances, if Amazon EC2 hibernated the instance, then only Amazon EC2 can resume it. You can only resume a hibernated Spot Instance if *you* hibernated it. Spot Instances can only be resumed if capacity is available and the Spot price is less than or equal to your specified maximum price.

Console

To start a hibernated instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select a hibernated instance, and choose **Instance state**, **Start instance**. It can take a few minutes for the instance to enter the `running` state. During this time, the instance status checks show the instance in a failed state until the instance has started.

AWS CLI

To start a hibernated instance

Use the start-instances command.

```
aws ec2 start-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To start a hibernated instance

Use the Start-EC2Instance cmdlet.

```
Start-EC2Instance -InstanceId i-1234567890abcdef0
```

Troubleshoot Amazon EC2 instance hibernation

Use this information to help diagnose and fix issues that you might encounter when hibernating an instance.

Hibernation issues

- Can't hibernate immediately after launch
- Takes too long to transition from stopping to stopped, and memory state not restored after start
- Instance "stuck" in the stopping state
- Can’t start Spot Instance immediately after hibernate
- Resume Spot Instances failed

Can't hibernate immediately after launch

If you try to hibernate an instance too quickly after you've launched it, you get an error.

You must wait for about two minutes for Linux instances and about five minutes for Windows instances after launch before hibernating.

Takes too long to transition from stopping to stopped, and memory state not restored after start

If it takes a long time for your hibernating instance to transition from the `stopping` state to `stopped`, and if the memory state is not restored after you start, this could indicate that hibernation was not properly configured.

Linux instances

Check the instance system log and look for messages that are related to hibernation. To access the system log, connect to the instance or use the get-console-output command. Find the log lines from the `hibinit-agent`. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that the instance root volume is not large enough: `hibinit-agent: Insufficient disk space. Cannot create setup for hibernation. Please allocate a larger root device.`

If the last log line from the `hibinit-agent` is `hibinit-agent: Running: swapoff /swap`, hibernation was successfully configured.

If you do not see any logs from these processes, your AMI might not support hibernation. For information about supported AMIs, see Prerequisites for EC2 instance hibernation. If you used your own Linux AMI, make sure that you followed the instructions for Configure a Linux AMI to support hibernation.

Windows Server 2016 and later

Check the EC2 launch log and look for messages that are related to hibernation. To access the EC2 launch log, connect to the instance and open the `C:\ProgramData\Amazon\EC2-Windows\Launch\Log\Ec2Launch.log` file in a text editor. If you're using EC2Launch v2, open `C:\ProgramData\Amazon\EC2Launch\log\agent.log`.

Note

By default, Windows hides files and folders under `C:\ProgramData`. To view EC2 Launch directories and files, enter the path in Windows Explorer or change the folder properties to show hidden files and folders.

Find the log lines for hibernation. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that hibernation failed to configure: `Message: Failed to enable hibernation.` If the error message includes decimal ASCII values, you can convert the ASCII values to plain text in order to read the full error message.

If the log line contains `HibernationEnabled: true`, hibernation was successfully configured.

Windows Server 2012 R2 and earlier

Check the EC2 config log and look for messages that are related to hibernation. To access the EC2 config log, connect to the instance and open the `C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2ConfigLog.txt` file in a text editor. Find the log lines for `SetHibernateOnSleep`. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that the instance root volume is not large enough: `SetHibernateOnSleep: Failed to enable hibernation: Hibernation failed with the following error: There is not enough space on the disk.`

If the log line is `SetHibernateOnSleep: HibernationEnabled: true`, hibernation was successfully configured.

Windows instance size

If you're using a T3 or T3a Windows instance with less than 1 GiB of RAM, try increasing the size of the instance to one that has at least 1 GiB of RAM.

Instance "stuck" in the stopping state

If you hibernated your instance and it appears "stuck" in the `stopping` state, you can forcibly stop it. For more information, see Troubleshoot Amazon EC2 instance stop issues.

Can't start Spot Instance immediately after hibernate

If you try to start a Spot Instance within two minutes of hibernating it, you might get the following error:

`You failed to start the Spot Instance because the associated Spot Instance request is not in an appropriate state to support start.`

Wait for about two minutes for Linux instances and about five minutes for Windows instances and then retry starting the instance.

Resume Spot Instances failed

If your Spot Instance was hibernated successfully but failed to resume, and instead rebooted (a fresh restart where the hibernated state is not retained), it might be because the user data contained the following script:

```
/usr/bin/enable-ec2-spot-hibernation
```

Remove this script from the **User data** field in the launch template, and then request a new Spot Instance.

Note that even if the instance failed to resume, without the hibernated state preserved, the instance can still be started in the same way as starting from the `stopped` state.

Reboot your Amazon EC2 instance

An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance.

When you reboot an instance, it keeps the following:

- Public DNS name (IPv4)
- Private IPv4 address
- Public IPv4 address
- IPv6 address (if applicable)
- Any data on its instance store volumes

Rebooting an instance doesn't start a new instance billing period, unlike stopping and starting an instance (which starts a new billing period with a one-minute minimum charge).

An instance reboot can be user-initiated (where you manually reboot the instance) or initiated by AWS (for automatic instance recovery, or in response to a scheduled reboot event for necessary maintenance, such as to apply updates that require a reboot).

For user-initiated reboots, we recommend using the Amazon EC2 console, CLI, or API instead of running the operating system reboot command from your instance. When using Amazon EC2, if the instance does not cleanly shut down within a few minutes, Amazon EC2 performs a hard reboot. Furthermore, AWS CloudTrail creates an API record of when your instance was rebooted.

This topic describes how to perform a user-initiated reboot. For information about reboots performed by AWS, see Automatic instance recovery and Manage Amazon EC2 instances scheduled for reboot.

> **Important**
>
> If updates are installing on your instance, we recommend that you do not reboot or shut down your instance using the Amazon EC2 console or the command line until all the

updates are installed. When you use the Amazon EC2 console or the command line to reboot or shut down your instance, there is a risk that your instance will be hard rebooted. A hard reboot while updates are being installed could throw your instance into an unstable state.

Console

To reboot an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state**, **Reboot instance**.
4. Choose **Reboot** when prompted for confirmation.

   The instance remains in the `running` state.

AWS CLI

To reboot an instance

Use the reboot-instances command.

```
aws ec2 reboot-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To reboot an instance

Use the Restart-EC2Instance cmdlet.

```
Restart-EC2Instance -InstanceId i-1234567890abcdef0
```

To run a controlled fault injection experiment

You can use AWS Fault Injection Service to test how your application responds when your instance is rebooted. For more information, see the AWS Fault Injection Service User Guide.

Terminate Amazon EC2 instances

You can delete your instance when you no longer need it. This is referred to as *terminating* your instance. As soon as the state of an instance changes to `shutting-down` or `terminated`, you stop incurring charges for that instance.

You can't connect to or start an instance after you've terminated it. However, you can launch new instances using the same AMI.

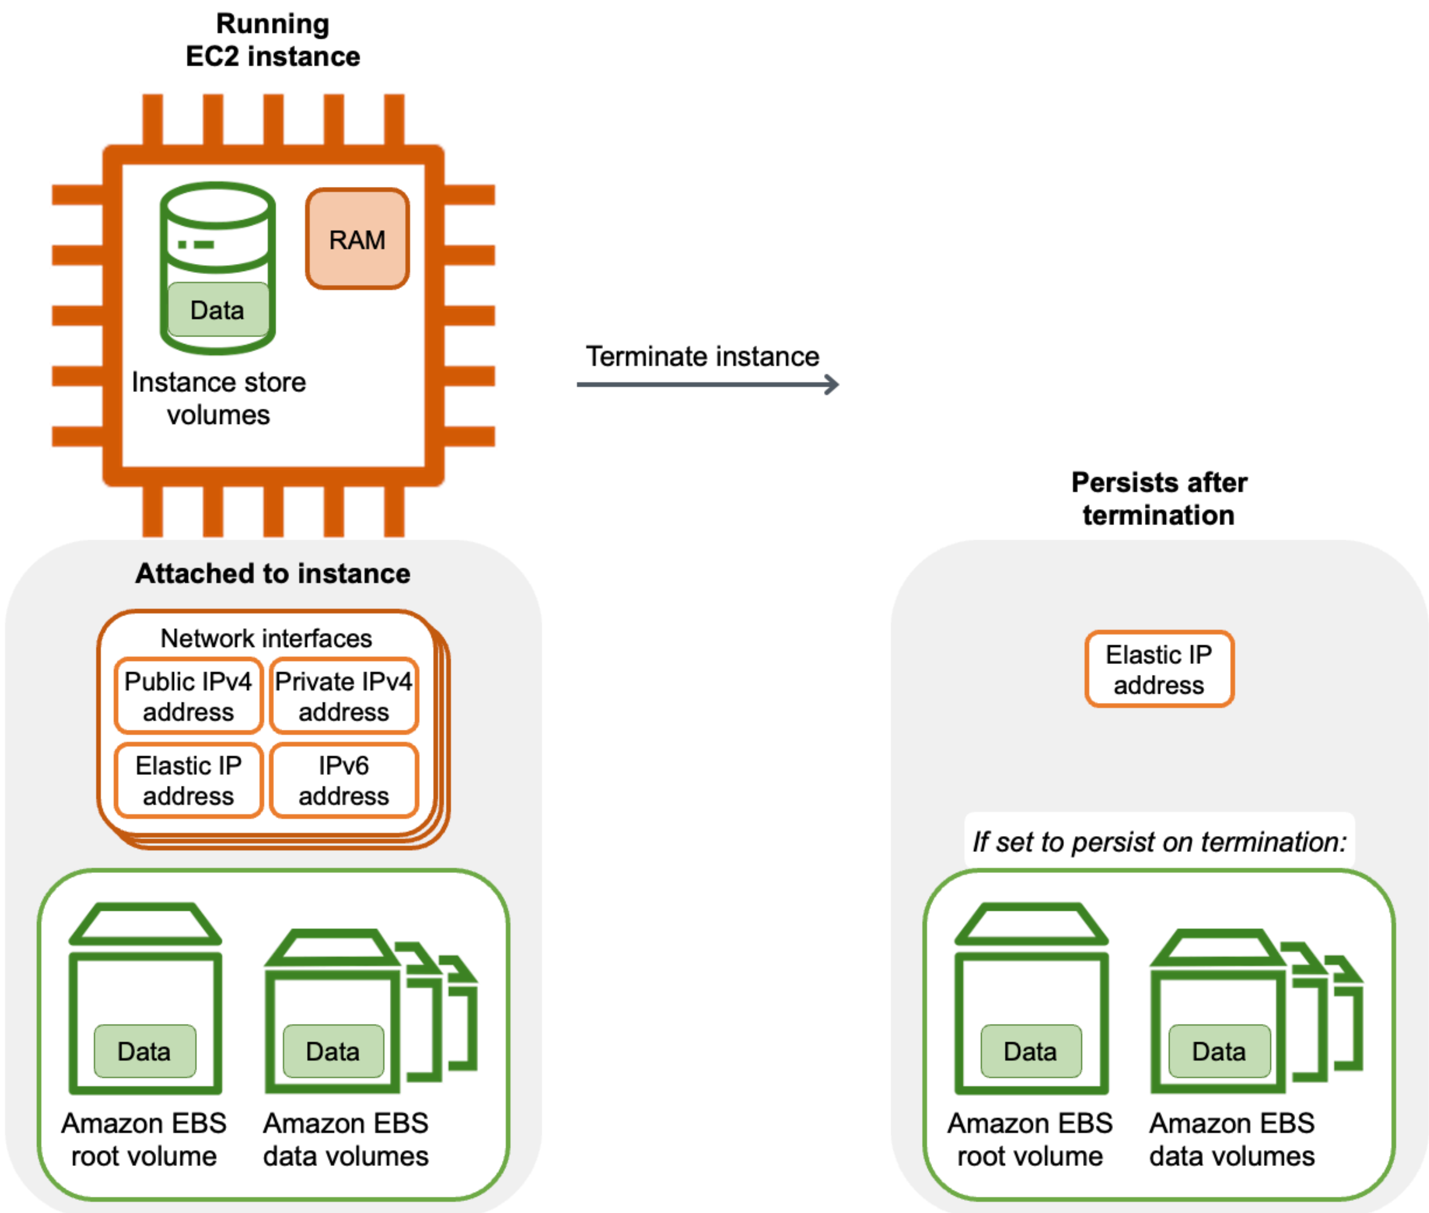
If you'd rather stop or hibernate your instance, see Stop and start Amazon EC2 instances or Hibernate your Amazon EC2 instance. For more information, see Differences between instance states.

Contents

How instance termination works

When you terminate an instance, changes are registered at the operating system (OS) level of the instance, some resources are lost, and some resources persist.

The following diagram shows what is lost and what persists when an Amazon EC2 instance is terminated. When an instance terminates, the data on any instance store volumes and the data stored in the instance RAM is erased. Any Elastic IP addresses associated with the instance are detached. For Amazon EBS root volumes and data volumes, the outcome depends on the **Delete on termination** setting of each volume.



Considerations

- **Data persistence**
  - Instance store volumes: All data is permanently deleted when the instance terminates.
  - EBS root volume:
    - When attached at launch, deleted by default when the instance terminates.
    - When attached after launch, persists by default when the instance terminates.
  - EBS data volumes:

  - When attached at launch using the console: Persists by default when the instance terminates.
  - When attached at launch using the CLI: Deleted by default when the instance terminates.
  - When attached after launch using the console or CLI: Persists by default when the instance terminates.

> **Note**
>
> Any volumes that are not deleted on instance termination continue to incur charges. You can change the setting so that a volume is deleted or persists on instance termination. For more information, see Preserve data when an instance is terminated.

- **Protection against accidental termination**
  - To prevent an instance from being accidentally terminated by someone, enable termination protection.
  - To control whether an instance stops or terminates when shutdown is initiated from the instance, change the instance initiated shutdown behavior.
- **Shutdown scripts** – If you run a script on instance termination, your instance might have an abnormal termination because we have no way of ensuring that shutdown scripts run. Amazon EC2 attempts to cleanly shut down an instance and run any system shutdown scripts; however, certain events (such as hardware failure) may prevent these system shutdown scripts from running.
- **Bare metal instances** – x86 bare metal instances don't support cooperative shutdown.

What happens when you terminate an instance

Changes registered at the OS level

- The API request sends a button press event to the guest.
- Various system services are stopped as a result of the button press event. Graceful shutdown of the system is provided by **systemd** (Linux) or the System process (Windows). Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown is initiated.

- The instance shuts down after the graceful shutdown process exits. There is no configurable OS shutdown time. The instance remains visible in the console for a short time, then the entry is automatically deleted.

Resources lost

- Data stored on the instance store volumes.
- EBS root volume if the `DeleteOnTermination` attribute is set to `true`.
- EBS data volumes (attached at launch or after) if the `DeleteOnTermination` attribute is set to `true`.

Resources that persist

- EBS root volume if the `DeleteOnTermination` attribute is set to `false`.
- EBS data volumes (attached at launch or after) if the `DeleteOnTermination` attribute is set to `false`.

Test application response to instance termination

You can use AWS Fault Injection Service to test how your application responds when your instance is terminated. For more information, see the AWS Fault Injection Service User Guide.

Methods for terminating an instance

There are four ways to perform a user-initiated instance termination: default terminate, terminate with skip OS shutdown, force terminate, and force terminate with skip OS shutdown. The following table compares the key differences between the termination methods:

Termination method	Key purpose	Use case	CLI command
Default terminat	Normal instance shutdown with attempted graceful OS shutdown.	Typical instance termination.	`aws ec2 terminate-instances \`

Termination method	Key purpose	Use case	CLI command
			`--instance-id i-1234567890abcdef0`
Terminate with skip OS shutdown	Bypasses the graceful OS shutdown when terminating an instance.	When bypassing graceful OS shutdown is required.	`aws ec2 terminate-instances \ --instance-id i-1234567890abcdef0 \ --skip-os-shutdown`
Force terminate	Handles stuck instances. Attempts a default termination first; if instance fails to terminate, then forcibly terminates the instance.	When instance is stuck in `shutting-down` state.	`aws ec2 terminate-instances \ --instance-id i-1234567890abcdef0 \ --force`
Force terminate with skip OS shutdown	Force terminates and bypasses the graceful OS shutdown when terminating an instance.	When force termination and bypassing graceful OS shutdown is required.	`aws ec2 terminate-instances \ --instance-id i-1234567890abcdef0 \ --force \ --skip-os-shutdown`

For instructions on how to use each method, see the following:

- Terminate an instance with a graceful OS shutdown
- Terminate an instance and bypass the graceful OS shutdown
- Force terminate an instance

Terminate an instance with a graceful OS shutdown

You can terminate an instance using the default terminate method, which includes an attempt at a graceful OS shutdown. For more information, see Methods for terminating an instance.

Console

To terminate an instance using the default terminate method

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and choose **Instance state**, **Terminate (delete) instance**.
4. Choose **Terminate (delete)** when prompted for confirmation.
5. After you terminate an instance, it remains visible for a short while, with a state of `terminated`.

   If termination fails or if a terminated instance is visible for more than a few hours, see Terminated instance still displayed.

AWS CLI

To terminate an instance using the default terminate method

Use the terminate-instances command.

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0
```

PowerShell

To terminate an instance using the default terminate method

Use the Remove-EC2Instance cmdlet.

```
Remove-EC2Instance -InstanceId i-1234567890abcdef0
```

Terminate an instance and bypass the graceful OS shutdown

You can bypass the graceful OS shutdown when terminating an instance. For more information, see Methods for terminating an instance.

Console

To terminate an instance and bypass the graceful OS shutdown

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and choose **Instance state**, **Terminate (delete) instance**.
4. Under **Skip OS shutdown**, select the **Skip OS shutdown** checkbox. If you don't see this option in the console, it's not yet available in the console in the current Region. You can, however, access this feature using the AWS CLI or SDK, or try another Region in the console.
5. Choose **Terminate (delete)**.
6. After you terminate an instance, it remains visible for a short while, with a state of `terminated`.

   If termination fails or if a terminated instance is visible for more than a few hours, see Terminated instance still displayed.

AWS CLI

To terminate an instance and bypass the graceful OS shutdown

Use the terminate-instances command with `--skip-os-shutdown`..

```
aws ec2 terminate-instances \
    --instance-ids i-1234567890abcdef0 \
    --skip-os-shutdown
```

PowerShell

To terminate an instance and bypass the graceful OS shutdown

Use the Remove-EC2Instance cmdlet with `-SkipOsShutdown $true`..

```
Remove-EC2Instance `
    -InstanceId i-1234567890abcdef0 `
```

```
    -SkipOsShutdown $true
```

Troubleshoot instance termination

The requester must have permission to call `ec2:TerminateInstances`. For more information, see [Example policies to work with instances].

If you terminate your instance and another instance starts, most likely you have configured automatic scaling through a feature like EC2 Fleet or Amazon EC2 Auto Scaling. For more information, see [Instances automatically launched or terminated].

You can't terminate an instance if termination protection is turned on. For more information, see [termination protection].

If your instance is in the `shutting-down` state for longer than usual, you can attempt to force terminate it. If it remains in the `shutting-down` state, it should be cleaned up (terminated) by automated processes within the Amazon EC2 service. For more information, see [Delayed instance termination].

Change instance termination protection

To prevent your instance from being accidentally terminated using the Amazon EC2 API, whether you call `TerminateInstances` directly or using another interface such as the Amazon EC2 console, enable *termination protection* for the instance. The `DisableApiTermination` attribute controls whether the instance can be terminated. By default, termination protection is disabled for your instance. You can set the value of this attribute when you launch an instance, or while the instance is running or stopped.

The `DisableApiTermination` attribute doesn't prevent you from terminating an instance by initiating shutdown from the instance (for example, by using an operating system command for system shutdown) when the `InstanceInitiatedShutdownBehavior` attribute is set to `terminate`. For more information, see [Change instance initiated shutdown behavior].

Considerations

- Enabling termination protection does not prevent AWS from terminating the instance when there is a [scheduled event] to terminate the instance.
- Enabling termination protection does not prevent Amazon EC2 Auto Scaling from terminating an instance when the instance is unhealthy or during scale-in events. You can control whether

an Auto Scaling group can terminate a particular instance when scaling using instance scale-in protection. You can control whether an Auto Scaling group can terminate unhealthy instances by suspending the ReplaceUnhealthy scaling process.

- You can't enable termination protection for Spot Instances.

Console

To enable termination protection for an instance at launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the dashboard, choose **Launch instance**.
3. Expand **Advanced details**. For **Termination protection**, select **Enable**.
4. When you are finishing specifying the details for your instance, choose **Launch instance**.

To change termination protection for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, select **Instances**.
3. Select the instance.
4. Choose **Actions**, **Instance settings**, **Change termination protection**.
5. For **Termination protection** select or clear **Enable**.
6. Choose **Save**.

AWS CLI

To enable termination protection for an instance

Use the modify-instance-attribute command.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --disable-api-termination
```

To disable termination protection for an instance

Use the modify-instance-attribute command.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --no-disable-api-termination
```

PowerShell

To enable termination protection for an instance

Use the Edit-EC2InstanceAttribute cmdlet.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -DisableApiTermination $true
```

To disable termination protection for an instance

Use the Edit-EC2InstanceAttribute cmdlet.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -DisableApiTermination $false
```

Terminate multiple instances with termination protection

If you terminate multiple instances across multiple Availability Zones in the same request, and one or more of the specified instances are enabled for termination protection, the request fails with the following results:

- The specified instances that are in the same Availability Zone as the protected instance are not terminated.
- The specified instances that are in different Availability Zones, where no other specified instances are protected, are successfully terminated.

Example

Suppose that you have the following four instances across two Availability Zones.

Instance	Availability Zone	Terminate protection
Instance 1	AZ A	`Disabled`
Instance 2		`Disabled`
Instance 3	AZ B	`Enabled`
Instance 4		`Disabled`

If you attempt to terminate all of these instances in the same request, the request reports failure with the following results:

- **Instance 1** and **Instance 2** are successfully terminated because neither instance is enabled for termination protection.
- **Instance 3** and **Instance 4** fail to terminate because **Instance 3** is enabled for termination protection.

Change instance initiated shutdown behavior

By default, when you initiate a shutdown from an Amazon EBS backed instance (using a command such as **shutdown** or **poweroff**), the instance stops. You can change this behavior so that the instance terminates instead by changing the `InstanceInitiatedShutdownBehavior` attribute for the instance. You can change this attribute while the instance is running or stopped.

The **halt** command doesn't initiate a shutdown. If used, the instance doesn't terminate; instead, it places the CPU into HLT and the instance continues to run.

> **Note**
>
> The `InstanceInitiatedShutdownBehavior` attribute only applies when you perform a shutdown from the operating system of the instance itself. It doesn't apply when you stop an instance using the `StopInstances` API or the Amazon EC2 console.

Console

To change the instance initiated shutdown behavior

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions**, **Instance settings**, **Change shutdown behavior**.

   Shutdown behavior displays the current behavior.
5. To change the behavior, for **Shutdown behavior**, choose **Stop** or **Terminate**.
6. Choose **Save**.

AWS CLI

To change the instance initiated shutdown behavior

Use the modify-instance-attribute command.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0 \
    --instance-initiated-shutdown-behavior terminate
```

PowerShell

To change the instance initiated shutdown behavior

Use the Edit-EC2InstanceAttribute cmdlet.

```
Edit-EC2InstanceAttribute `
    -InstanceId i-1234567890abcdef0 `
    -InstanceInitiatedShutdownBehavior terminate
```

Preserve data when an instance is terminated

When an Amazon EC2 instance is terminated, you can preserve the data on your instance store volumes or Amazon EBS volumes. This topic explains how to ensure your data persists beyond instance termination.

How instance termination affects root and data volumes

Instance store volumes

When an instance is terminated, the instance store volumes are automatically deleted and the data is lost. To preserve this data beyond the lifetime of the instance, before terminating the instance, manually copy the data to persistent storage, such as an Amazon EBS volume, an Amazon S3 bucket, or an Amazon EFS file system. For more information, see Storage options for your Amazon EC2 instances.

Amazon EBS volumes

When an instance is terminated, the EBS volumes are either deleted or preserved, depending on the value of the `DeleteOnTermination` attribute for each volume:

- **Yes** (console) / `true` (CLI) – The volume is deleted when the instance is terminated.
- **No** (console) / `false` (CLI) – The volume is preserved when the instance is terminated. Preserved volumes continue to incur charges.

> **Note**
>
> After an instance terminates, you can take a snapshot of the preserved volume or attach it to another instance. To avoid incurring charges, you must delete the volume.

Default deletion behavior for EBS volumes

The default `DeleteOnTermination` value differs depending on the volume type, whether the volume was attached at launch or after, and the method (console or CLI) used to attach the volume:

Volume type	Attached when	Method for attaching	Default behavior on instance termination
Root volume	At launch	Console or CLI	Delete
Root volume	After launch	Console or CLI	Preserve
Data volume	At launch	Console	Preserve

Volume type	Attached when	Method for attaching	Default behavior on instance termination
Data volume	At launch	CLI	Delete
Data volume	After launch	Console and CLI	Preserve

Check volume persistence settings

The default value at launch for an EBS volume is determined by the `DeleteOnTermination` attribute set on the AMI. You can change the value at instance launch, overriding the AMI setting. We recommend that you verify the default setting for the `DeleteOnTermination` attribute after you launch an instance.

To check if an Amazon EBS volume will be deleted on instance termination

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose the **Storage** tab.
5. Under **Block devices**, scroll right to check the **Delete on termination** column.
   - If **Yes**, the volume is deleted when the instance is terminated.
   - If **No**, the volume is not be deleted when the instance is terminated. Any volumes not deleted continue to incur charges.

Change the root volume to persist at launch

You can change the `DeleteOnTermination` attribute of an EBS root volume when you launch an instance. You can also use the following procedure for a data volume.

Console

To change the root volume of an instance to persist at launch

1. Follow the procedure to launch an instance, but don't launch the instance until you've completed the following steps to change the root volume to persist.

2. On the **Configure storage** pane, choose **Advanced**.
3. Under **EBS volumes**, expand the root volume information.
4. For **Delete on termination**, choose **No**.
5. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an EC2 instance using the launch instance wizard in the console.

AWS CLI

To change the root volume of an instance to persist at launch

Use the run-instances command to change the value of `DeleteOnTermination` in the block device mapping.

Add the `--block-device-mappings` option:

```
--block-device-mappings file://mapping.json
```

In `mapping.json`, specify the device name, for example `/dev/sda1` or `/dev/xvda`, and for `DeleteOnTermination`, specify `false`.

```
[
  {
    "DeviceName": "device_name",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

PowerShell

To change the root volume of an instance to persist at launch

Use the New-EC2Instance cmdlet to change the value of `DeleteOnTermination` in the block device mapping.

Add the `-BlockDeviceMapping` option:

```
-BlockDeviceMapping $bdm
```

In bdm, specify the device name, for example /dev/sda1 or /dev/xvda, and for DeleteOnTermination, specify false.

```
$ebd = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebd.DeleteOnTermination = false
$bdm = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$bdm.DeviceName = "/dev/sda1"
$bdm.Ebs = $ebd
```

Change the root volume of a running instance to persist

You can change the EBS root volume of a running instance to persist. You can also use the following procedure for a data volume.

AWS CLI

To change the root volume to persist

Use the modify-instance-attribute command.

```
aws ec2 modify-instance-attribute \
    --instance-id i-1234567890abcdef0  \
    --block-device-mappings file://mapping.json
```

In mapping.json, specify the device name, for example /dev/sda1 or /dev/xvda, and for --DeleteOnTermination, specify false.

```
[
  {
    "DeviceName": "device_name",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

PowerShell

To change the root volume to persist

Use the Edit-EC2InstanceAttribute cmdlet.

Add the `-BlockDeviceMapping` option:

```
-BlockDeviceMapping $bdm
```

In bdm, specify the device name, for example `/dev/sda1` or `/dev/xvda`, and for `DeleteOnTermination`, specify `false`.

```
$ebd = New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice
$ebd.DeleteOnTermination = false
$bdm = New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping
$bdm.DeviceName = "/dev/sda1"
$bdm.Ebs = $ebd
```

Instance retirement

An instance is scheduled to be retired when AWS detects irreparable failure of the underlying hardware that hosts the instance. The instance root device determines the behavior of instance retirement:

- If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. Starting the stopped instance migrates it to new hardware.
- If your instance root device is an instance store volume, the instance is terminated, and can't be used again.

For more information about the types of instance events, see [Scheduled events for Amazon EC2 instances](#).

Contents

Identify instances scheduled for retirement

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date. You can also check for instances that are scheduled for retirement.

> **Important**
>
> If an instance is scheduled for retirement, we recommend that you take action as soon as possible, because the instance might already be unreachable. For more information, see Check if your instance is reachable.

Options to identify instances scheduled for retirement

- Monitor the email for the account contacts
- Check your instances

Monitor the email for the account contacts

If an instance is scheduled for retirement, the primary contact for the account and the operations contact receive an email prior to the event. This email includes the instance ID and scheduled retirement date. For more information, see Update the primary contact for your AWS account and Update the alternate contacts for your AWS account in the *AWS Account Management Reference Guide*.

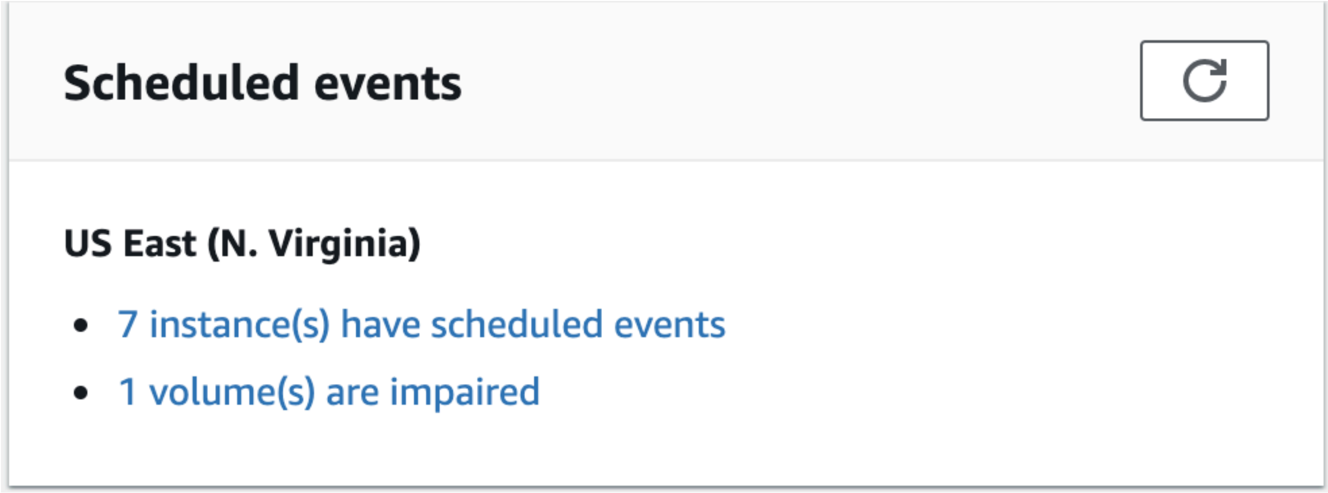
Check your instances

If you use an email account that you do not check regularly, you might miss an instance retirement notification. You can check whether any of your instances are scheduled for retirement at any time.

Console

To identify instances scheduled for retirement

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **EC2 Dashboard**. Under **Scheduled events**, you can see the events that are associated with your Amazon EC2 instances and volumes, organized by Region.



3. If you have an instance with a scheduled event listed, select its link below the Region name to go to the **Events** page.
4. The **Events** page lists all resources that have events associated with them. To view instances that are scheduled for retirement, select **Instance resources** from the first filter list, and then **Instance stop or retirement** from the second filter list.
5. If the filter results show that an instance is scheduled for retirement, select it, and note the date and time in the **Start time** field in the details pane. This is your instance retirement date.

AWS CLI

To find instances scheduled for retirement

Use the following describe-instance-status command. Repeat in each Region where you have running instances.

```
aws ec2 describe-instance-status --filters Name=event.code,Values=instance-
retirement
```

PowerShell

To find instances scheduled for retirement

Use the Get-EC2InstanceStatus cmdlet. Repeat in each Region where you have running instances.

```
Get-EC2InstanceStatus -Filter @{Name="event.code"; Values="instance-retirement"}
```

Actions to take for EBS-backed instances scheduled for retirement

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

For Linux instances, if you are not sure whether your instance is backed by EBS or instance store, see Root volumes for your Amazon EC2 instances.

Check if your instance is reachable

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either connecting to or pinging your instance.
- If your instance is reachable, you should plan to stop/start your instance at an appropriate time before the scheduled retirement date, when the impact is minimal. For more information about stopping and starting your instance, and what to expect when your instance is stopped, such as the effect on public, private, and Elastic IP addresses that are associated with your instance, see Stop and start Amazon EC2 instances. Note that data on instance store volumes is lost when you stop and start your instance.
- If your instance is unreachable, you should take immediate action and perform a stop/start to recover your instance.
- Alternatively, if you want to terminate your instance, plan to do so as soon as possible so that you stop incurring charges for the instance.

Create a backup of your instance

Create an EBS-backed AMI from your instance so that you have a backup. To ensure data integrity, stop the instance before you create the AMI. You can wait for the scheduled retirement date when the instance is stopped, or stop the instance yourself before the retirement date. You can start the instance again at any time. For more information, see Create an Amazon EBS-backed AMI.

Launch a replacement instance

After you create an AMI from your instance, you can use the AMI to launch a replacement instance. From the Amazon EC2 console, select your new AMI and then choose **Launch instance from AMI**. Configure the parameters for your instance and then choose **Launch instance**. For more information about each field, see Launch an EC2 instance using the launch instance wizard in the console.

Actions to take for instance-store backed instances scheduled for retirement

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

> **Warning**
>
> If your instance store-backed instance passes its retirement date, it is terminated and you cannot recover the instance or any data that was stored on it. Regardless of the root device of your instance, the data on instance store volumes is lost when the instance is retired, even if the volumes are attached to an EBS-backed instance.

Check if your instance is reachable

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either connecting to or pinging your instance.
- If your instance is unreachable, there is likely very little that can be done to recover your instance. For more information, see Troubleshoot an unreachable Amazon EC2 instance. AWS will terminate your instance on the scheduled retirement date, so, for an unreachable instance, you can immediately terminate the instance yourself.

Launch a replacement instance

Create an instance store-backed AMI from your instance using the AMI tools, as described in Create an instance store-backed AMI. From the Amazon EC2 console, select your new AMI and then choose **Launch instance from AMI**. Configure the parameters for your instance and then choose **Launch instance**. For more information about each field, see Launch an EC2 instance using the launch instance wizard in the console.

Convert your instance to an EBS-backed instance

Transfer your data to an EBS volume, take a snapshot of the volume, and then create AMI from the snapshot. You can launch a replacement instance from your new AMI. For more information, see Convert your instance store-backed AMI to an EBS-backed AMI.

Automatic instance recovery

> **Important**
>
> This section describes how to proactively configure recovery mechanisms on an EC2 instance. These recovery mechanisms are designed to restore instance availability when AWS detects an underlying hardware or software issue that causes a system status check to fail. If you are currently experiencing problems accessing your instance, see Troubleshoot EC2 instances.

If AWS detects that an instance is unavailable due to an underlying hardware or software issue, there are two mechanisms that can automatically restore instance availability—simplified automatic recovery and Amazon CloudWatch action based recovery. Restoring instance availability is also known as *instance recovery*.

During the instance recovery process, AWS will attempt to move your instance from the host with the underlying hardware or software issue to a different host. If successful, the instance recovery process will appear to the instance as an unplanned reboot. You can verify if instance recovery occurred.

If the recovery process is unsuccessful, the instance might continue running on the host with the underlying hardware or software issue. In this case, manual intervention is required. If the instance becomes unreachable or the system status check continues to fail, we recommend that you manually stop and start the instance. When you start an instance, it is typically migrated to a new underlying host computer. However, unlike automatic instance recovery, where the instance retains its public IPv4 address, a restarted instance receives a new public IPv4 address unless it has an Elastic IP address.

To benefit from the automatic recovery mechanisms, they must be configured in advance on an instance before a system status check fails. By default, simplified automatic recovery is enabled during instance launch. You can optionally configure Amazon CloudWatch action based recovery after launch. Having one of these mechanisms configured makes your instance more resilient.

Simplified automatic recovery and Amazon CloudWatch action based recovery are only available on supported instances. For more information, see Requirements for enabling simplified automatic recovery and Requirements for enabling CloudWatch action based recovery.

> **Warning**
>
> When AWS recovers your instance due to an underlying hardware or software issue, be aware of the following consequences: data stored in volatile memory (RAM) will be lost and the operating system's uptime will start over from zero. Furthermore, with CloudWatch action based recovery, data on instance store volumes will also be lost. To help protect against data loss, we recommend that you regularly create backups of valuable data. For more information about backup and recovery best practices for EC2 instances, see Best practices for Amazon EC2.
> Automatic instance recovery mechanisms are designed for *individual instances*. For guidance on building a resilient *system*, see Build a resilient system.

Topics

Key concepts of automatic instance recovery

Automatic instance recovery is an Amazon EC2 feature that automatically restores instance availability when underlying hardware or software failures occur, enhancing the resilience and reliability of your EC2 instances.

The following are key concepts of automatic instance recovery:

Configuration options

Two mechanisms can be configured to support automatic instance recovery:

- Simplified automatic recovery: Enabled by default on supported instances.
- CloudWatch action based recovery: Requires manual configuration on supported instances.

System status checks

System status checks automatically monitor the AWS infrastructure on which your EC2 instance runs.

- If a system status check fails, AWS initiates automatic instance recovery, which attempts to migrate the affected instance to different hardware.
- A failed system status check indicates a problem with the host's hardware or software, and not a problem with the instance itself. Automatic instance recovery can recover an instance that fails a system status check. However, automatic instance recovery does not operate if only the instance status check fails.
- For the differences between instance and system status checks, see Types of status checks.

Examples of underlying hardware or software problems

Hardware or software issues that can cause a system status check to fail include loss of network connectivity, loss of system power, software issues on the physical host, and hardware issues on the physical host that impact network reachability.

Characteristics of recovered instances

A recovered instance is identical to the original instance, except for the elements that are lost.

Preserved elements:

- Instance ID
- Public, private, and Elastic IP addresses
- Instance metadata
- Placement group
- Attached EBS volumes
- Availability Zone

Lost elements:

- Data stored in volatile memory (RAM)
- Data stored on instance store volumes (applicable to CloudWatch action based recovery only)
- Operating system uptime resets to zero

Monitoring system status checks with CloudWatch

The StatusCheckFailed_System metric in CloudWatch indicates whether a system status check passed or failed.

Metric values:

- **0 –** The system status check passed.
- **1 –** The system status check failed.

Events in AWS Health Dashboard

During automatic instance recovery attempts, AWS sends events to your AWS Health Dashboard based on the configured recovery mechanism and its outcome:

- Simplified automatic recovery
  - Success event: `AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_SUCCESS`
  - Failure event: `AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_FAILURE`
- CloudWatch action based recovery
  - Success event: `AWS_EC2_INSTANCE_AUTO_RECOVERY_SUCCESS`
  - Failure event: `AWS_EC2_INSTANCE_AUTO_RECOVERY_FAILURE`

Differences between simplified automatic recovery and CloudWatch action based recovery

The following table compares the key differences between simplified automatic recovery and CloudWatch action based recovery.

Comparison point	Simplified automatic recovery	CloudWatch action based recovery
Configuration	Enabled by default on supported instances	Requires manual configura tion of CloudWatch alarms and actions
Flexibility	Fixed recovery behavior managed by AWS	Customizable actions and conditions

Comparison point	Simplified automatic recovery	CloudWatch action based recovery
Notification	Basic notifications through AWS Health Dashboard	Customizable notifications through SNS
Metal instance size	Excluded	Included
Instance store volumes attached at launch	Not supported for instances that attach instance store volumes at launch	Supported on selected instance types. Note that data on instance store volumes is lost during instance recovery.
Recovery time	Standard recovery attempt	Faster recovery attempts than simplified automatic recovery
Host problem resolves during migration	Migration might be canceled and the instance stays on the original host	Migration continues to a new host
Cost	No additional cost	Might incur CloudWatch charges

Build a resilient system

While simplified automatic recovery and CloudWatch action based recovery are effective for maintaining individual instance availability, AWS recommends implementing a high-availability architecture that allows failover of traffic to healthy instances.

To achieve this, consider using AWS services such as Elastic Load Balancing (which distributes incoming traffic across multiple EC2 instances) and Amazon EC2 Auto Scaling (which automatically adjusts the number of instances based on demand and health).

For more information about building a resilient, fault-tolerant system with EC2 instances, see the following resources:

- Back to Basics: Designing for Failure with EC2 on the *AWS YouTube channel*

- Disaster Recovery (DR) Architecture on AWS, Part I: Strategies for Recovery in the Cloud on the *AWS Architecture Blog* site
- Application Load Balancers User Guide
- Amazon EC2 Auto Scaling User Guide
- REL11-BP02 Fail over to healthy resources in the *Reliability Pillar AWS Well-Architected Framework*

Verify if automatic instance recovery occurred

If your instance appears to have been offline and then unexpectedly rebooted, it might have undergone automatic instance recovery in response to an underlying hardware or software issue. You can verify this by checking for automatic instance recovery events in your AWS Health Dashboard. You can also check whether an underlying hardware or software issue was detected for your instance by checking the **StatusCheckFailed_System** Amazon CloudWatch metric.

Check for events in AWS Health Dashboard

When an automatic instance recovery attempt occurs, AWS sends events to your AWS Health Dashboard. The specific event depends on the configured recovery mechanism and whether the attempt succeeded or failed.

To check for automatic instance recovery events in the AWS Health Dashboard

1. Open the AWS Health Dashboard at https://phd.aws.amazon.com/phd/home#/.
2. Look for the events associated with automatic instance recovery. The presence of these events can confirm whether an attempt at automatic instance recovery occurred and its outcome.
   - Simplified automatic recovery
     - Success event: `AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_SUCCESS`
     - Failure event: `AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_FAILURE`
   - CloudWatch action based recovery
     - Success event: `AWS_EC2_INSTANCE_AUTO_RECOVERY_SUCCESS`
     - Failure event: `AWS_EC2_INSTANCE_AUTO_RECOVERY_FAILURE`

Monitor system status checks with CloudWatch

You can verify if an underlying hardware or software issue was detected for your instance by checking the StatusCheckFailed_System metric in CloudWatch. The metric value indicates whether a system status check passed (no hardware or software issue) or failed (hardware or software issue).

To verify if an underlying hardware or software issue was detected

1. Open the CloudWatch console **Metrics** page at https://console.aws.amazon.com/cloudwatch/home?#metricsV2.
2. Verify that you're in the same Region as your EC2 instance.
3. Paste the following metric in the **Metrics** search field, and press Enter.

```
StatusCheckFailed_System
```

4. Choose **EC2 > Per-Instance Metrics**.
5. In the table, select the check box next to the instance that you want to check.
6. Change the query period to the time that you suspect the recovery event occurred.
7. Choose the **Graphed metrics** tab, and for **StatusCheckFailed_System**, do the following:
   a. For **Statistic**, choose either **Average**, **Maximum**, or **Minimum**.
   b. For **Period**, choose **1 minute**.
8. Check the value for **StatusCheckFailed_System**.
   - Value of **0**: The system status check passed, indicating no underlying hardware or software issue.
   - Value of **1**: The system status check failed, indicating an underlying hardware or software issue.

For more information, see Automatic instance recovery.

Configure simplified automatic recovery on an Amazon EC2 instance

> **Important**
>
> This section describes how to proactively configure recovery mechanisms on an EC2 instance. These recovery mechanisms are designed to restore instance availability when AWS detects an underlying hardware or software issue that causes a system status check to fail. If you are currently experiencing problems accessing your instance, see Troubleshoot EC2 instances.

If AWS detects that an instance is unavailable due to an underlying hardware or software issue, *simplified automatic recovery* can automatically restore instance availability by moving the instance from the host with the underlying issue to a different host.

If simplified automatic recovery occurs, AWS sends one of the following events to your AWS Health Dashboard, depending on the outcome:

- Success event: `AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_SUCCESS`
- Failure event: `AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_FAILURE`

To be notified of these events, you can configure notifications. For more information, see Creating your first notification configuration in AWS User Notifications in the *AWS User Notifications User Guide*. You can also use Amazon EventBridge rules to monitor simplified automatic recovery events.

Simplified automatic recovery is enabled by default on all supported instances during instance launch. However, it can only operate if an instance is in the `running` state, there are no service events listed in the AWS Health Dashboard, and there is available capacity for the instance type. In some situations, such as significant outages, capacity constraints might cause recovery attempts to fail. For more information, see the section called "Troubleshoot simplified automatic recovery failures".

You can disable simplified automatic recovery during or after launch, and re-enable it later if required.

> **Warning**
>
> When AWS recovers your instance due to an underlying hardware or software issue, be aware of the following consequences: data stored in volatile memory (RAM) will be lost and the operating system's uptime will start over from zero. To help protect against data loss, we recommend that you regularly create backups of valuable data. For more information about backup and recovery best practices for EC2 instances, see Best practices for Amazon EC2.
> Automatic instance recovery mechanisms are designed for *individual instances*. For guidance on building a resilient *system*, see Build a resilient system.

Contents

Requirements for enabling simplified automatic recovery

Simplified automatic recovery can be enabled on instances that meet the following criteria:

Instance types

- **General purpose:** A1, M3, M4, M5, M5a, M5n, M5zn, M6a, M6g, M6i, M6in, M7a, M7g, M7i, M7i-flex, M8g, M8i, M8i-flex, T1, T2, T3, T3a, T4g
- **Compute optimized:** C3, C4, C5, C5a, C5n, C6a, C6g, C6gn, C6i, C6in, C7a, C7g, C7gn, C7i, C7i-flex, C8g, C8gn
- **Memory optimized:** R3, R4, R5, R5a, R5b, R5n, R6a, R6g, R6i, R6in, R7a, R7g, R7i, R7iz, R8g, R8i, R8i-flex, U-3tb1, U-6tb1, U-9tb1, U-12tb1, U-18tb1, U-24tb1, U7i-6tb, U7i-8tb, U7i-12tb, U7in-16tb, U7in-24tb, U7in-32tb, U7inh-32tb, X1, X1e, X2iezn, X8g
- **Accelerated computing:** G3, G5g, Inf1, P3, VT1
- **High-performance computing:** Hpc6a, Hpc7a, Hpc7g

Tenancy

- Shared
- Dedicated Instance

For more information, see Amazon EC2 Dedicated Instances.

Limitations

Simplified automatic recovery is not supported for instances with the following characteristics:

- Instance size: `metal` instances
- Tenancy: Dedicated Host. For Dedicated Hosts, use Dedicated Host Auto Recovery instead.
- Storage: Instances with instance store volumes
- Networking: Instances using an Elastic Fabric Adapter
- Auto Scaling: Instances that are part of an Auto Scaling group
- Maintenance: Instances currently undergoing a scheduled maintenance event

Configure simplified automatic recovery

Simplified automatic recovery is enabled by default when you launch a supported instance. You can set the automatic recovery behavior to `disabled` during or after launching the instance.

The `default` configuration doesn't enable simplified automatic recovery for an unsupported instance.

Console

To disable simplified automatic recovery at launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then choose **Launch instance**.
3. In the **Advanced details** section, for **Instance auto-recovery**, choose **Disabled**.
4. Configure the remaining instance launch settings as needed and then launch the instance.

To disable simplified automatic recovery after launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions**, **Instance settings**, **Change auto-recovery behavior**.

4. Choose **Off**, and then choose **Save**.

To enable simplified automatic recovery after launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions**, **Instance settings**, **Change auto-recovery behavior**.
4. Choose **Default (On)**, and then choose **Save**.

AWS CLI

To disable simplified automatic recovery at launch

Use the run-instances command with the `--maintenance-options` option.

```
--maintenance-options AutoRecovery=Disabled
```

To disable simplified automatic recovery after launch

Use the modify-instance-maintenance-options command.

```
aws ec2 modify-instance-maintenance-options \
    --instance-id i-1234567890abcdef0 \
    --auto-recovery disabled
```

To enable simplified automatic recovery after launch

Use the modify-instance-maintenance-options command.

```
aws ec2 modify-instance-maintenance-options \
    --instance-id i-1234567890abcdef0 \
    --auto-recovery default
```

PowerShell

To disable simplified automatic recovery at launch

Use the New-EC2Instance cmdlet.

```
-MaintenanceOptions_AutoRecovery Disabled
```

To disable simplified automatic recovery after launch

Use the Edit-EC2InstanceMaintenanceOption cmdlet.

```
Edit-EC2InstanceMaintenanceOption `
    -InstanceId i-1234567890abcdef0 `
    -AutoRecovery Disabled
```

To enable simplified automatic recovery after launch

Use the Edit-EC2InstanceMaintenanceOption cmdlet.

```
Edit-EC2InstanceMaintenanceOption `
    -InstanceId i-1234567890abcdef0 `
    -AutoRecovery Enabled
```

Troubleshoot simplified automatic recovery failures

If simplified automatic recovery fails to recover your instance, consider the following issues:

- AWS service events are running

  Simplified automatic recovery does not operate during service events in the AWS Health Dashboard. You might not receive recovery failure notifications for such events. For the latest service availability information, see the Service health status page.
- Insufficient capacity

  There is temporarily insufficient replacement hardware to migrate the instance.
- Maximum daily recovery attempts reached

  The instance has reached the maximum daily allowance for recovery attempts. Your instance might subsequently be retired if automatic recovery fails and a hardware degradation is determined to be the root cause of the original failed system status check.

If the instance's system status check failure persists despite multiple recovery attempts, see Troubleshoot instances with failed status checks for additional guidance.

Configure CloudWatch action based recovery on an EC2 instance

> **Important**
>
> This section describes how to proactively configure recovery mechanisms on an EC2 instance. These recovery mechanisms are designed to restore instance availability when AWS detects an underlying hardware or software issue that causes a system status check to fail. If you are currently experiencing problems accessing your instance, see Troubleshoot EC2 instances.

If AWS detects that an instance is unavailable due to an underlying hardware or software issue, *CloudWatch action based recovery* can automatically restore instance availability by moving the instance from the host with the underlying issue to a different host.

If CloudWatch action based recovery occurs, AWS sends one of the following events to your AWS Health Dashboard, depending on the outcome:

- Success event: `AWS_EC2_INSTANCE_AUTO_RECOVERY_SUCCESS`
- Failure event: `AWS_EC2_INSTANCE_AUTO_RECOVERY_FAILURE`

You can configure CloudWatch action based recovery to add recovery actions to Amazon CloudWatch alarms. CloudWatch action based recovery works with the `StatusCheckFailed_System` metric. CloudWatch action based recovery provides to-the-minute recovery response time granularity and Amazon Simple Notification Service (Amazon SNS) notifications of recovery actions and outcomes. These configuration options allow for faster recovery attempts with more granular control over the system status check failure event response compared to simplified automatic recovery. For more information about available CloudWatch options, see Status checks for your instances.

However, CloudWatch action based recovery can only operate if an instance is in the `running` state, there are no service events listed in the AWS Health Dashboard, and there is available capacity for the instance type. In some situations, such as significant outages, capacity constraints might cause recovery attempts to fail. For more information, see the section called “Troubleshoot”.

> **Warning**
>
> When AWS recovers your instance due to an underlying hardware or software issue, be aware of the following consequences: data stored in volatile memory (RAM) and on instance store volumes will be lost, and the operating system's uptime will start over from zero. To help protect against data loss, we recommend that you regularly create backups of valuable data. For more information about backup and recovery best practices for EC2 instances, see Best practices for Amazon EC2.
> Automatic instance recovery mechanisms are designed for *individual instances*. For guidance on building a resilient *system*, see Build a resilient system.

Requirements for enabling CloudWatch action based recovery

CloudWatch action based recovery can be enabled on instances that meet the following criteria:

Instance types

- **General purpose:** A1, M3, M4, M5, M5a, M5n, M5zn, M6a, M6g, M6i, M6in, M7a, M7g, M7i, M7i-flex, M8g, M8i, M8i-flex, T1, T2, T3, T3a, T4g
- **Compute optimized:** C3, C4, C5, C5a, C5n, C6a, C6g, C6gn, C6i, C6in, C7a, C7g, C7gn, C7i, C7i-flex, C8g, C8gn
- **Memory optimized:** R3, R4, R5, R5a, R5b, R5n, R6a, R6g, R6i, R6in, R7a, R7g, R7i, R7iz, R8g, R8i, R8i-flex, U-3tb1, U-6tb1, U-9tb1, U-12tb1, U-18tb1, U-24tb1, U7i-6tb, U7i-8tb, U7i-12tb, U7in-16tb, U7in-24tb, U7in-32tb, U7inh-32tb, X1, X1e, X2idn, X2iedn, X2iezn, X8g
- **Accelerated computing:** G3, G5g, Inf1, P3, VT1
- **High-performance computing:** Hpc6a, Hpc7a, Hpc7g
- **Metal instances:** Any of the above instance types with the metal instance size.
- **If instance store volumes are added at launch:** Then only the following instance types are supported: M3, C3, R3, X1, X1e, X2idn, X2iedn

Tenancy

- Shared
- Dedicated Instance

For more information, see [Amazon EC2 Dedicated Instances](#).

Limitations

CloudWatch action based recovery is not supported for instances with the following characteristics:

- Tenancy: Dedicated Host. For Dedicated Hosts, use Dedicated Host Auto Recovery instead.
- Networking: Instances using an Elastic Fabric Adapter
- Auto Scaling: Instances that are part of an Auto Scaling group
- Maintenance: Instances currently undergoing a scheduled maintenance event

Find a supported instance type

You can view the instance types that support CloudWatch action based recovery.

Console

To view the instance types that support CloudWatch action based recovery

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instance Types**.
3. In the filter bar, add the filter **Auto Recovery support = true**. The **Instance types** table displays all the instance types that support CloudWatch action based recovery.
4. (Optional) Add filters to further scope to specific instance types of interest.

AWS CLI

To view the instance types that support CloudWatch action based recovery

Use the describe-instance-types command with the `auto-recovery-supported` filter.

```
aws ec2 describe-instance-types \
    --filters Name=auto-recovery-supported,Values=true \
    --query "InstanceTypes[*].[InstanceType]" \
```

```
    --output text | sort
```

PowerShell

To view the instance types that support CloudWatch action based recovery

Use the Get-EC2InstanceType cmdlet with the `auto-recovery-supported` filter.

```
Get-EC2InstanceType `
    -Filter @{Name="auto-recovery-supported";Values="true"} | `
    Select InstanceType | Sort-Object InstanceType
```

Configure CloudWatch action based recovery

To configure CloudWatch action based recovery for an EC2 instance, create a CloudWatch alarm that monitors the `StatusCheckFailed_System` metric for the specified instance. Set the alarm to trigger when the metric value is **1**, indicating a failed system status check. Configure the alarm action to automatically recover the instance when triggered.

You can configure the alarm using either the Amazon EC2 console or the CloudWatch console. For the instructions, see Add recover actions to Amazon CloudWatch alarms in this user guide, or Adding recover actions to Amazon CloudWatch alarms in the *Amazon CloudWatch User Guide*.

Troubleshoot CloudWatch action based recovery failures

If CloudWatch action based recovery fails to recover your instance, consider the following issues:

- AWS service events are running

  CloudWatch action based recovery does not operate during service events in the AWS Health Dashboard. You might not receive recovery failure notifications for such events. For the latest service availability information, see the Service health status page.
- Insufficient capacity

  There is temporarily insufficient replacement hardware to migrate the instance.
- Maximum daily recovery attempts reached

  The instance has reached the maximum daily allowance for recovery attempts. Your instance might subsequently be retired if automatic recovery fails and a hardware degradation is determined to be the root cause of the original failed system status check.

If the instance's system status check failure persists despite multiple recovery attempts, see Troubleshoot instances with failed status checks for additional guidance.

Use instance metadata to manage your EC2 instance

Instance metadata is data about your instance that you can use to configure or manage the running instance. Instance metadata includes the following:

Instance metadata properties

Instance metadata properties are divided into categories, for example, host name, events, and security groups.

Dynamic data

Dynamic data is metadata that's generated when the instance is launched, such as an instance identity document. For more information, see Dynamic data categories.

User data

You can also use instance metadata to access *user data* that you specified when you launched your instance. For example, you can specify parameters for configuring your instance, or include a simple script. You can also build generic AMIs and use user data to modify the configuration files supplied at launch time. For example, if you run web servers for various small businesses, they can all use the same generic AMI and retrieve their content from an Amazon S3 bucket that you specify in the user data at launch. To add a new customer at any time, create a bucket for the customer, add their content, and launch your AMI with the unique bucket name provided to your code in the user data. If you launch multiple instances using the same `RunInstances` call, the user data is available to all instances in that reservation. Each instance that is part of the same reservation has a unique `ami-launch-index` number, so that you can write code that controls what the instances do. For example, the first host might elect itself as the original node in a cluster. For a detailed AMI launch example, see Identify each instance launched in a single request.

> **Important**
>
> Although you can only access instance metadata and user data from within the instance itself, the data is not protected by authentication or cryptographic methods. Anyone who has direct access to the instance, and potentially any software running on the instance,

can view its metadata. Therefore, you should not store sensitive data, such as passwords or long-lived encryption keys, as user data.

Contents

Instance metadata categories

Instance metadata properties are divided into categories. To retrieve instance metadata properties, you specify the category in the request, and the metadata is returned in the response.

When new categories are released, a new instance metadata build is created with a new version number. In the following table, the **Version when category was released** column specifies the build version when an instance metadata category was released. To avoid having to update your code every time Amazon EC2 releases a new instance metadata build, use `latest` instead of the version number in your metadata requests. For more information, see Get the available versions of the instance metadata.

When Amazon EC2 releases a new instance metadata category, the instance metadata for the new category might not be available for existing instances. With Nitro-based instances, you can retrieve instance metadata only for the categories that were available at launch. For instances with the Xen hypervisor, you can stop and then start the instance to update the categories that are available for the instance.

The following table lists the categories of instance metadata. Some of the category names include placeholders for data that is unique to your instance. For example, *mac* represents the MAC address for the network interface. You must replace the placeholders with actual values when you retrieve the instance metadata.

Category	Description	Version when category was released
ami-id	The AMI ID used to launch the instance.	1.0
ami-launch-index	If you launch multiple instances using the same RunInstances call, this value indicates the launch order for each instance. The value of the first instance launched is 0. If you launch instances using Auto Scaling or EC2 fleet, this value is always 0.	1.0
ami-manifest-path	The path to the AMI manifest file in Amazon S3. If you used an Amazon EBS-backed AMI to launch the instance, the returned result is unknown.	1.0
ancestor-ami-ids	The AMI IDs of any instances that were rebundled to create this AMI. This value will only exist if the AMI manifest file contained an ancestor-amis key.	2007-10-10
autoscaling/target-lifecycle-state	Value showing the target Auto Scaling lifecycle state that an Auto Scaling instance is transitioning to. Present when the instance transitions to one of the target lifecycle states after March 10, 2022. Possible values: Detached | InService | Standby | Terminated | Warmed:Hi	2021-07-15

Category	Description	Version when category was released
	`bernated` | `Warmed:Running` | `Warmed:Stopped` | `Warmed:Terminated` . See [Retrieve the target lifecycle state through instance metadata]() in the *Amazon EC2 Auto Scaling User Guide*.	
`block-device-mapping/ami`	The virtual device that contains the root/boot file system.	2007-12-15
`block-device-mapping/ebs`*N*	The virtual devices associated with any Amazon EBS volumes. Amazon EBS volumes are only available in metadata if they were present at launch time or when the instance was last started. The *N* indicates the index of the Amazon EBS volume (such as `ebs1` or `ebs2`).	2007-12-15

Category	Description	Version when category was released
`block-device-mapping/ephemeral N`	The virtual devices for any non-NVMe instance store volumes. The *N* indicates the index of each volume. The number of instance store volumes in the block device mapping might not match the actual number of instance store volumes for the instance. The instance type determines the number of instance store volumes that are available to an instance. If the number of instance store volumes in a block device mapping exceeds the number available to an instance, the additional instance store volumes are ignored.	2007-12-15
`block-device-mapping/root`	The virtual devices or partitions associated with the root devices or partitions on the virtual device, where the root (/ or C:) file system is associated with the given instance.	2007-12-15
`block-device-mapping/swap`	The virtual devices associated with `swap`. Not always present.	2007-12-15
`events/maintenance/history`	If there are completed or canceled maintenance events for the instance, contains a JSON string with information about the events.	2018-08-17

Category	Description	Version when category was released
`events/maintenance/scheduled`	If there are active maintenance events for the instance, contains a JSON string with information about the events. For more information, see [View scheduled events that affect your Amazon EC2 instances]().	2018-08-17
`events/recommendations/rebalance`	The approximate time, in UTC, when the EC2 instance rebalance recommendation notification is emitted for the instance. The following is an example of the metadata for this category: `{"noticeTime": "2020-11-05T08:22:00Z"}`. This category is available only after the notification is emitted. For more information, see [EC2 instance rebalance recommendations]().	2020-10-27

Category	Description	Version when category was released
`hostname`	If the EC2 instance is using IP-based naming (IPBN), this is the private IPv4 DNS hostname of the instance. If the EC2 instance is using Resource-based naming (RBN), this is the RBN. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0). For more information about IPBN and RBN, see [EC2 instance hostnames and domains]().	1.0
`iam/info`	If there is an IAM role associated with the instance, contains information about the last time the instance profile was updated, including the instance's LastUpdated date, InstanceProfileArn, and InstanceProfileId. Otherwise, not present.	2012-01-12
`iam/security-credentials/role-name`	If there is an IAM role associated with the instance, *role-name* is the name of the role, and *role-name* contains the temporary security credentials associated with the role (for more information, see [Retrieve security credentials from instance metadata]()). Otherwise, not present.	2012-01-12

Category	Description	Version when category was released
`identity-credentials/ec2/info`	Information about the credentials in `identity-credentials/ec2/security-credentials/ec2-instance`.	2018-05-23
`identity-credentials/ec2/security-credentials/ec2-instance`	Credentials for the instance identity role that allow on-instance software to identify itself to AWS to support features such as EC2 Instance Connect and AWS Systems Manager Default Host Management Configuration. These credentials have no policies attached, so they have no additional AWS API permissions beyond identifying the instance to the AWS feature. For more information, see Instance identity roles for Amazon EC2 instances.	2018-05-23
`instance-action`	Notifies the instance that it should reboot in preparation for bundling. Valid values: `none` | `shutdown` | `bundle-pending`.	2008-09-01
`instance-id`	The ID of this instance.	1.0
`instance-life-cycle`	The purchasing option of this instance. For more information, see Amazon EC2 billing and purchasing options.	2019-10-01
`instance-type`	The type of instance. For more information, see Amazon EC2 instance types.	2007-08-29

Category	Description	Version when category was released
`ipv6`	The IPv6 address of the instance. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0) network interface and the first IPv6 address assigned. If no IPv6 address exists on network interface[0], this item is not set and results in an HTTP 404 response.	2021-01-03
`kernel-id`	The ID of the kernel launched with this instance, if applicable.	2008-02-01
`local-hostname`	In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0). If the EC2 instance is using IP-based naming (IPBN), this is the private IPv4 DNS hostname of the instance. If the EC2 instance is using Resource-based naming (RBN), this is the RBN. For more information about IPBN, RBN, and EC2 instance naming, see [EC2 instance hostnames and domains]().	2007-01-19

Category	Description	Version when category was released
`local-ipv4`	The private IPv4 address of the instance. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0). If this is an IPv6-only instance, this item is not set and results in an HTTP 404 response.	1.0
`mac`	The instance's media access control (MAC) address. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0).	2011-01-01
`metrics/vhostmd`	No longer available.	2011-05-01
`network/interfaces/macs/mac/device-number`	The unique device number associated with that interface. The device number corresponds to the device name; for example, a `device-number` of 2 is for the eth2 device. This category corresponds to the `DeviceIndex` and `device-index` fields that are used by the Amazon EC2 API and the EC2 commands for the AWS CLI.	2011-01-01
`network/interfaces/macs/mac/interface-id`	The ID of the network interface.	2011-01-01

Category	Description	Version when category was released
network/interfaces/macs/mac/ipv4-associations/public-ip	The private IPv4 addresses that are associated with each public IP address and assigned to that interface.	2011-01-01
network/interfaces/macs/mac/ipv6s	The IPv6 addresses assigned to the interface.	2016-06-30
network/interfaces/macs/mac/ipv6-prefix	The IPv6 prefix assigned to the network interface.	
network/interfaces/macs/mac/local-hostname	The private IPv4 DNS hostname of the instance. In cases where multiple network interfaces are present, this refers to the eth0 device (the device for which the device number is 0). If this is a IPv6-only instance, this is the resource-based name. For more information about IPBN and RBN, see EC2 instance hostnames and domains.	2007-01-19
network/interfaces/macs/mac/local-ipv4s	The private IPv4 addresses associated with the interface. If this is an IPv6-only network interface, this item is not set and results in an HTTP 404 response.	2011-01-01
network/interfaces/macs/mac/mac	The instance's MAC address.	2011-01-01
network/interfaces/macs/*mac*/network-card	The index of the network card. Some instance types support multiple network cards.	2020-11-01

Category	Description	Version when category was released
`network/interfaces/macs/mac/owner-id`	The ID of the owner of the network interface. In multiple-interface environments, an interface can be attached by a third party, such as Elastic Load Balancing. Traffic on an interface is always billed to the interface o wner.	2011-01-01
`network/interfaces/macs/mac/public-hostname`	The interface's public DNS (IPv4). This category is only returned if the `enableDnsHostnames` attribute is set to `true`. For more information, see DNS attributes for your VPC in the *Amazon VPC User Guide*. If the instance only has a public-IPv6 address and no public-IPv4 address, this item is not set and results in an HTTP 404 response.	2011-01-01
`network/interfaces/macs/mac/public-ipv4s`	The public IP address or Elastic IP addresses associated with the interface. There may be multiple IPv4 addresses on an instance.	2011-01-01
`network/interfaces/macs/mac/security-groups`	Security groups to which the network interface belongs.	2011-01-01
`network/interfaces/macs/mac/security-group-ids`	The IDs of the security groups to which the network interface b elongs.	2011-01-01

Category	Description	Version when category was released
network/interfaces/macs/mac/subnet-id	The ID of the subnet in which the interface resides.	2011-01-01
network/interfaces/macs/mac/subnet-ipv4-cidr-block	The IPv4 CIDR block of the subnet in which the interface resides.	2011-01-01
network/interfaces/macs/mac/subnet-ipv6-cidr-blocks	The IPv6 CIDR block of the subnet in which the interface resides.	2016-06-30
network/interfaces/macs/mac/vpc-id	The ID of the VPC in which the interface resides.	2011-01-01
network/interfaces/macs/mac/vpc-ipv4-cidr-block	The primary IPv4 CIDR block of the VPC.	2011-01-01
network/interfaces/macs/mac/vpc-ipv4-cidr-blocks	The IPv4 CIDR blocks for the VPC.	2016-06-30
network/interfaces/macs/mac/vpc-ipv6-cidr-blocks	The IPv6 CIDR block of the VPC in which the interface resides.	2016-06-30
placement/availability-zone	The Availability Zone in which the instance launched.	2008-02-01
placement/availability-zone-id	The static Availability Zone ID in which the instance is launched. T he Availability Zone ID is consisten t across accounts. However, it might be different from the Availability Zone, which can vary by account.	2019-10-01

Category	Description	Version when category was released
`placement/group-name`	The name of the placement group in which the instance is launched.	2020-08-24
`placement/host-id`	The ID of the host on which the instance is launched. Applicable only to Dedicated Hosts.	2020-08-24
`placement/partition-number`	The number of the partition in which the instance is launched.	2020-08-24
`placement/region`	The AWS Region in which the instance is launched.	2020-08-24
`product-codes`	AWS Marketplace product codes associated with the instance, if any.	2007-03-01
`public-hostname`	The instance's public DNS (IPv4). This category is only returned if the `enableDnsHostnames` attribute is set to `true`. For more information, see DNS attributes for your VPC in the *Amazon VPC User Guide*. If the instance only has a public-IPv6 address and no public-IPv4 address, this item is not set and results in an HTTP 404 response.	2007-01-19
`public-ipv4`	The public IPv4 address. If an Elastic IP address is associated with the instance, the value returned is the Elastic IP address.	2007-01-19

Category	Description	Version when category was released
public-keys/0/openssh-key	Public key. Only available if supplied at instance launch time.	1.0
ramdisk-id	The ID of the RAM disk specified at launch time, if applicable.	2007-10-10
reservation-id	The ID of the reservation.	1.0
security-groups	The names of the security groups applied to the instance. After launch, you can change the security groups of the instances. Such changes are reflected here and in network/interfaces/macs/*mac*/security-groups.	1.0
services/domain	The domain for AWS resources for the Region.	2014-02-25
services/partition	The partition that the resource is in. For standard AWS Regions, the partition is aws. If you have resources in other partitions, the partition is aws-*partition name* . For example, the partition for resources in the China (Beijing) Region is aws-cn.	2015-10-20

Category	Description	Version when category was released
`spot/instance-action`	The action (hibernate, stop, or terminate) and the approximate time, in UTC, when the action will occur. This item is present only if the Spot Instance has been marked for hibernate, stop, or terminate. For more information, see instance-action.	2016-11-15
`spot/termination-time`	The approximate time, in UTC, that the operating system for your Spot Instance will receive the shutdown signal. This item is present and contains a time value (for example, 2015-01-05T18:02:00Z) only if the Spot Instance has been marked for termination by Amazon EC2. The termination-time item is not set to a time if you terminated the Spot Instance yourself. For more information, see termination-time.	2014-11-05
`tags/instance`	The instance tags associated with the instance. Only available if you explicitly allow access to tags in instance metadata. For more information, see Enable access to tags in instance metadata.	2021-03-23

Dynamic data categories

The following table lists the categories of dynamic data.

Category	Description	Version when category was released
fws/instance-monitoring	Value showing whether the customer has enabled detailed one-minute monitoring in CloudWatch. Valid values: enabled | disabled	2009-04-04
instance-identity/document	JSON containing instance attributes, such as instance-id, private IP address, etc. See Instance identity documents for Amazon EC2 instances.	2009-04-04
instance-identity/pkcs7	Used to verify the document's authenticity and content against the signature. See Instance identity documents for Amazon EC2 instances.	2009-04-04
instance-identity/signature	Data that can be used by other parties to verify its origin and authenticity. See Instance identity documents for Amazon EC2 instances.	2009-04-04

Access instance metadata for an EC2 instance

You can access EC2 instance metadata from inside of the instance itself or from the EC2 console, API, SDKs, or the AWS CLI. To get the current instance metadata settings for an instance from the console or command line, see Query instance metadata options for existing instances.

You can also modify user data for instances with an EBS root volume. The instance must be in the stopped state. For console directions, see Update the instance user data. For a Linux example that uses the AWS CLI, see modify-instance-attribute. For a Windows example that uses the Tools for Windows PowerShell, see the section called “User data and the Tools for Windows PowerShell”.

> **Note**
>
> You are not billed for HTTP requests used to retrieve instance metadata and user data.

Instance metadata access considerations

To avoid problems with instance metadata retrieval, consider the following.

Command format

The command format is different, depending on whether you use Instance Metadata Service Version 1 (IMDSv1) or Instance Metadata Service Version 2 (IMDSv2). By default, you can use both versions of the Instance Metadata Service. To require the use of IMDSv2, see Use the Instance Metadata Service to access instance metadata.

If IMDSv2 is required, IMDSv1 does not work

If you use IMDSv1 and receive no response, it's likely that IMDSv2 is required. To check whether IMDSv2 is required, select the instance to view its details. The **IMDSv2** value indicates either **Required** (you must use IMDSv2) or **Optional** (you can use either IMDSv2 or IMDSv1).

(IMDSv2) Use /latest/api/token to retrieve the token

Issuing PUT requests to any version-specific path, for example `/2021-03-23/api/token`, results in the metadata service returning 403 Forbidden errors. This behavior is intended.

Metadata version

To avoid having to update your code every time Amazon EC2 releases a new instance metadata build, we recommend that you use `latest` in the path, and not the version number.

IPv6 support

To retrieve instance metadata using an IPv6 address, ensure that you enable and use the IPv6 address of the IMDS `[fd00:ec2::254]` instead of the IPv4 address `169.254.169.254`. The instance must be a Nitro-based instance launched in a subnet that supports IPv6.

(Windows) Create custom AMIs using Windows Sysprep

To ensure that IMDS works when you launch an instance from a custom Windows AMI, the AMI must be a standardized image created with Windows Sysprep. Otherwise, the IMDS won't work. For more information, see Create an Amazon EC2 AMI using Windows Sysprep.

In a container environment, consider reconfiguration or increasing the hop limit to 2

The AWS SDKs use IMDSv2 calls by default. If the IMDSv2 call receives no response, some AWS SDKs retry the call and, if still unsuccessful, use IMDSv1. This can result in a delay, especially in a container environment. For those AWS SDKs that *require* IMDSv2, if the hop limit is 1 in a container environment, the call might not receive a response at all because going to the container is considered an additional network hop.

To mitigate these issues in a container environment, consider changing the configuration to pass settings (such as the AWS Region) directly to the container, or consider increasing the hop limit to 2. For information about the hop limit impact, see Add defense in depth against open firewalls, reverse proxies, and SSRF vulnerabilities with enhancements to the EC2 Instance Metadata Service. For information about changing the hop limit, see Change the PUT response hop limit.

Packets per second (PPS) limit

There is a 1024 packet per second (PPS) limit to services that use link-local addresses. This limit includes the aggregate of Route 53 Resolver DNS Queries, Instance Metadata Service (IMDS) requests, Amazon Time Service Network Time Protocol (NTP) requests, and Windows Licensing Service (for Microsoft Windows based instances) requests.

Additional considerations for user data access

- User data is treated as opaque data: what you specify is what you get back upon retrieval. It is up to the instance to interpret and act on user data.
- User data must be base64-encoded. Depending on the tool or SDK that you're using, the base64-encoding might be performed for you. For example:
  - The Amazon EC2 console can perform the base64-encoding for you or accept base64-encoded input.
  - AWS CLI version 2 performs base64-encoding of binary parameters for you by default. AWS CLI version 1 performs the base64-encoding of the `--user-data` parameter for you.
  - The AWS SDK for Python (Boto3) performs base64-encoding of the `UserData` parameter for you.
- User data is limited to 16 KB, in raw form, before it is base64-encoded. The size of a string of length *n* after base64-encoding is ceil(*n*/3)*4.

- User data must be base64-decoded when you retrieve it. If you retrieve the data using instance metadata or the console, it's decoded for you automatically.
- If you stop an instance, modify its user data, and start the instance, the updated user data is not run automatically when you start the instance. With Windows instances, you can configure settings so that updated user data scripts are run one time when you start the instance or every time you reboot or start the instance.
- User data is an instance attribute. If you create an AMI from an instance, the instance user data is not included in the AMI.

Access instance metadata from within an EC2 instance

Because your instance metadata is available from your running instance, you do not need to use the Amazon EC2 console or the AWS CLI. This can be helpful when you're writing scripts to run from your instance. For example, you can access the local IP address of your instance from instance metadata to manage a connection to an external application.

All of the following are considered instance metadata, but they are accessed in different ways. Select the tab that represents the type of instance metadata you want to access to see more information.

Metadata

Instance metadata properties are divided into categories. For a description of each instance metadata category, see Instance metadata categories.

To access instance metadata properties from within a running instance, get the data from the following IPv4 or IPv6 URIs. These IP addresses are link-local addresses and are valid only from the instance. For more information, see Link-local addresses.

IPv4

```
http://169.254.169.254/latest/meta-data/
```

IPv6

```
http://[fd00:ec2::254]/latest/meta-data/
```

Dynamic data

To retrieve dynamic data from within a running instance, use one of the following URIs.

IPv4

```
http://169.254.169.254/latest/dynamic/
```

IPv6

```
http://[fd00:ec2::254]/latest/dynamic/
```

Examples: Access with cURL

The following examples use cURL to retrieve the high-level instance identity categories.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/dynamic/instance-identity/
rsa2048
pkcs7
document
signature
dsa2048
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/dynamic/instance-identity/
rsa2048
pkcs7
document
signature
dsa2048
```

Examples: Access with PowerShell

The following examples use PowerShell to retrieve the high-level instance identity categories.

IMDSv2

```
PS C:\> [string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
PS C:\> Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method
 GET -Uri http://169.254.169.254/latest/dynamic/instance-identity/
document
rsa2048
pkcs7
signature
```

IMDSv1

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/dynamic/instance-identity/
document
rsa2048
pkcs7
signature
```

For more information about dynamic data and examples of how to retrieve it, see Instance identity documents for Amazon EC2 instances.

User data

To retrieve user data from an instance, use one of the following URIs. To retrieve user data using the IPv6 address, you must enable it, and the instance must be a Nitro-based instance in a subnet that supports IPv6.

IPv4

```
http://169.254.169.254/latest/user-data
```

IPv6

```
http://[fd00:ec2::254]/latest/user-data
```

A request for user data returns the data as it is (content type `application/octet-stream`). If the instance does not have any user data, the request returns `404 - Not Found`.

Examples: Access with cURL to retrieve comma-separated text

The following examples use cURL to retrieve user data that was specified as comma-separated text.

IMDSv2

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/user-data
1234,john,reboot,true | 4512,richard, | 173,,,
```

IMDSv1

```
curl http://169.254.169.254/latest/user-data
1234,john,reboot,true | 4512,richard, | 173,,,
```

Examples: Access with PowerShell to retrieve comma-separated text

The following examples use PowerShell to retrieve user data that was specified as comma-separated text.

IMDSv2

```
[string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method GET -Uri http://169.254.169.254/latest/user-data
1234,john,reboot,true | 4512,richard, | 173,,,
```

IMDSv1

```
Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} `
-Method PUT -Uri http://169.254.169.254/latest/api/token} -Method GET -uri http://169.254.169.254/latest/user-data
1234,john,reboot,true | 4512,richard, | 173,,,
```

Examples: Access with cURL to retrieve a script

The following examples use cURL to retrieve user data that was specified as a script.

IMDSv2

```
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/user-data
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

IMDSv1

```
curl http://169.254.169.254/latest/user-data
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

Examples: Access with PowerShell to retrieve a script

The following examples use PowerShell to retrieve user data that was specified as a script.

IMDSv2

```
[string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method GET -Uri http://169.254.169.254/latest/user-data
<powershell>
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

IMDSv1

```
Invoke-RestMethod -uri http://169.254.169.254/latest/user-data
<powershell>
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
```

```
</powershell>
<persist>true</persist>
```

Query instance metadata options for existing instances

You can query the instance metadata options for your existing instances.

Console

To query the instance metadata options for an existing instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance and check the following fields:

   - **IMDSv2 –** The value is either **Required** or **Optional**.
   - **Allow tags in instance metadata –** The value is either **Enabled** or **Disabled**.
4. With your instance selected, choose **Actions**, **Instance settings**, **Modify instance metadata options**.

   The dialog box displays whether the instance metadata service is enabled or disabled for the selected instance.

AWS CLI

To query the instance metadata options for an existing instance

Use the describe-instances command.

```
aws ec2 describe-instances \
    --instance-id i-1234567898abcdef0 \
    --query 'Reservations[].Instances[].MetadataOptions'
```

PowerShell

To query the instance metadata options for an existing instance using the Tools for PowerShell

Use the Get-EC2Instance Cmdlet.

```
(Get-EC2Instance `
    -InstanceId i-1234567898abcdef0).Instances.MetadataOptions
```

Responses and error messages

All instance metadata is returned as text (HTTP content type `text/plain`).

A request for a specific metadata resource returns the appropriate value, or a `404 - Not Found` HTTP error code if the resource is not available.

A request for a general metadata resource (the URI ends with a /) returns a list of available resources, or a `404 - Not Found` HTTP error code if there is no such resource. The list items are on separate lines, terminated by line feeds (ASCII 10).

If an IMDSv1 request receives no response, it's likely that IMDSv2 is required.

For requests made using IMDSv2, the following HTTP error codes can be returned:

- `400 - Missing or Invalid Parameters` – The `PUT` request is not valid.
- `401 - Unauthorized` – The `GET` request uses an invalid token. The recommended action is to generate a new token.
- `403 - Forbidden` – The request is not allowed or the IMDS is turned off.
- `404 - Not Found` – The resource is not available or there is no such resource.
- `503` – The request could not be completed. Retry the request.

If the IMDS returns an error, **curl** prints the error message in the output and returns a success status code. The error message is stored in the `TOKEN` variable, which causes **curl** commands that use the token to fail. If you call **curl** with the **-f** option, it returns an error status code in the event of an HTTP server error. If you enable error handling, the shell can catch the error and stop the script.

Query throttling

We throttle queries to the IMDS on a per-instance basis, and we place limits on the number of simultaneous connections from an instance to the IMDS.

If you're using the IMDS to retrieve AWS security credentials, avoid querying for credentials during every transaction or concurrently from a high number of threads or processes, as this might lead to throttling. Instead, we recommend that you cache the credentials until they start approaching their expiry time. For more information about IAM role and security credentials associated with the role, see Retrieve security credentials from instance metadata.

If you are throttled while accessing the IMDS, retry your query with an exponential backoff strategy.

Use the Instance Metadata Service to access instance metadata

You can access instance metadata from a running instance using one of the following methods:

- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

  For examples, see Examples for IMDSv2.
- Instance Metadata Service Version 1 (IMDSv1) – a request/response method

  For examples, see Examples for IMDSv1.

By default, you can use either IMDSv1 or IMDSv2, or both.

You can configure the Instance Metadata Service (IMDS) on each instance so that local code or users must use IMDSv2. When you specify that IMDSv2 must be used, IMDSv1 no longer works. For information about how to configure your instance to use IMDSv2, see Configure the Instance Metadata Service options.

The PUT or GET headers are unique to IMDSv2. If these headers are present in the request, then the request is intended for IMDSv2. If no headers are present, it is assumed the request is intended for IMDSv1.

For an extensive review of IMDSv2, see Add defense in depth against open firewalls, reverse proxies, and SSRF vulnerabilities with enhancements to the EC2 Instance Metadata Service.

Topics

How Instance Metadata Service Version 2 works

IMDSv2 uses session-oriented requests. With session-oriented requests, you create a session token that defines the session duration, which can be a minimum of one second and a maximum of six hours. During the specified duration, you can use the same session token for subsequent requests. After the specified duration expires, you must create a new session token to use for future requests.

> **Note**
>
> The examples in this section use the IPv4 address of the Instance Metadata Service (IMDS): `169.254.169.254`. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: `[fd00:ec2::254]`. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on Nitro-based instances in an IPv6-supported subnet (dual stack or IPv6 only).

The following examples use a shell script and IMDSv2 to retrieve the top-level instance metadata items. Each example:

- Creates a session token lasting six hours (21,600 seconds) using the PUT request
- Stores the session token header in a variable named `TOKEN` (Linux instances) or `token` (Windows instances)
- Requests the top-level metadata items using the token

Linux example

You can run two separate commands, or combine them.

Separate commands

First, generate a token using the following command.

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"`
```

Then, use the token to generate top-level metadata items using the following command.

```
[ec2-user ~]$ curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/
```

Combined commands

You can store the token and combine the commands. The following example combines the above two commands and stores the session token header in a variable named TOKEN.

> **Note**
>
> If there is an error in creating the token, instead of a valid token, an error message is stored in the variable, and the command will not work.

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
 && curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/
```

After you've created a token, you can reuse it until it expires. In the following example command, which gets the ID of the AMI used to launch the instance, the token that is stored in `$TOKEN` in the previous example is reused.

```
[ec2-user ~]$ curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/ami-id
```

Windows example

```
PS C:\> [string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
PS C:\> Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method GET -Uri http://169.254.169.254/latest/meta-data/
```

After you've created a token, you can reuse it until it expires. In the following example command, which gets the ID of the AMI used to launch the instance, the token that is stored in `$token` in the previous example is reused.

```
PS C:\> Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} `
 -Method GET -uri http://169.254.169.254/latest/meta-data/ami-id
```

When you use IMDSv2 to request instance metadata, the request must include the following:

1. Use a PUT request to initiate a session to the instance metadata service. The PUT request returns a token that must be included in subsequent GET requests to the instance metadata service. The token is required to access metadata using IMDSv2.
2. Include the token in all GET requests to the IMDS. When token usage is set to `required`, requests without a valid token or with an expired token receive a `401 - Unauthorized` HTTP error code.
   - The token is an instance-specific key. The token is not valid on other EC2 instances and will be rejected if you attempt to use it outside of the instance on which it was generated.
   - The PUT request must include a header that specifies the time to live (TTL) for the token, in seconds, up to a maximum of six hours (21,600 seconds). The token represents a logical session. The TTL specifies the length of time that the token is valid and, therefore, the duration of the session.
   - After a token expires, to continue accessing instance metadata, you must create a new session using another PUT.
   - You can choose to reuse a token or create a new token with every request. For a small number of requests, it might be easier to generate and immediately use a token each time you need to access the IMDS. But for efficiency, you can specify a longer duration for the token and reuse it rather than having to write a PUT request every time you need to request instance metadata. There is no practical limit on the number of concurrent tokens, each representing its own session. IMDSv2 is, however, still constrained by normal IMDS connection and throttling limits. For more information, see Query throttling.

HTTP GET and HEAD methods are allowed in IMDSv2 instance metadata requests. PUT requests are rejected if they contain an X-Forwarded-For header.

By default, the response to PUT requests has a response hop limit (time to live) of 1 at the IP protocol level. If you need a bigger hop limit, you can adjust it by using the modify-instance-metadata-options AWS CLI command. For example, you might need a bigger hop limit for backward compatibility with container services running on the instance. For more information, see Modify instance metadata options for existing instances.

Use a supported AWS SDK

To use IMDSv2, your EC2 instances must use an AWS SDK version that supports using IMDSv2. The latest versions of all the AWS SDKs support using IMDSv2.

> **Important**
>
> We recommend that you to stay up to date with SDK releases to keep up with the latest features, security updates, and underlying dependencies. Continued use of an unsupported SDK version is not recommended and is done at your discretion. For more information, see the AWS SDKs and Tools maintenance policy in the *AWS SDKs and Tools Reference Guide*.

The following are the minimum versions that support using IMDSv2:

- AWS CLI – 1.16.289
- AWS Tools for Windows PowerShell – 4.0.1.0
- AWS SDK for .NET – 3.3.634.1
- AWS SDK for C++ – 1.7.229
- AWS SDK for Go – 1.25.38
- AWS SDK for Go v2 – 0.19.0
- AWS SDK for Java – 1.11.678
- AWS SDK for Java 2.x – 2.10.21
- AWS SDK for JavaScript in Node.js – 2.722.0
- AWS SDK for Kotlin – 1.1.4
- AWS SDK for PHP – 3.147.7
- AWS SDK for Python (Botocore) – 1.13.25
- AWS SDK for Python (Boto3) – 1.12.6
- AWS SDK for Ruby – 3.79.0

Examples for IMDSv2

Run the following examples on your Amazon EC2 instance to retrieve the instance metadata for IMDSv2.

On Windows instances, you can use Windows PowerShell or you can install cURL or wget. If you install a third-party tool on a Windows instance, ensure that you read the accompanying documentation carefully, as the calls and the output might be different from what is described here.

Examples

- Get the available versions of the instance metadata
- Get the top-level metadata items
- Get the values for metadata items
- Get the list of available public keys
- Show the formats in which public key 0 is available
- Get public key 0 (in the OpenSSH key format)
- Get the subnet ID for an instance
- Get the instance tags for an instance

Get the available versions of the instance metadata

This example gets the available versions of the instance metadata. Each version refers to an instance metadata build when new instance metadata categories were released. The instance metadata build versions do not correlate with the Amazon EC2 API versions. The earlier versions are available to you in case you have scripts that rely on the structure and information present in a previous version.

subnet-be9b61d7
```

PowerShell

```
PS C:\> [string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
PS C:\> Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method GET -Uri http://169.254.169.254/latest/meta-data/network/interfaces/macs/02:29:96:8f:6a:2d/subnet-id
subnet-be9b61d7
```

Get the instance tags for an instance

If access to instance tags in the instance metadata is turned on, you can get the tags for a instance from instance metadata. For more information, see Retrieve tags from instance metadata.

Examples for IMDSv1

Run the following examples on your Amazon EC2 instance to retrieve the instance metadata for IMDSv1.

On Windows instances, you can use Windows PowerShell or you can install cURL or wget. If you install a third-party tool on a Windows instance, ensure that you read the accompanying documentation carefully, as the calls and the output might be different from what is described here.

Examples

- Get the available versions of the instance metadata
- Get the top-level metadata items
- Get the values for metadata items
- Get the list of available public keys
- Show the formats in which public key 0 is available
- Get public key 0 (in the OpenSSH key format)
- Get the subnet ID for an instance
- Get the instance tags for an instance

Get the available versions of the instance metadata

This example gets the available versions of the instance metadata. Each version refers to an instance metadata build when new instance metadata categories were released. The instance metadata build versions do not correlate with the Amazon EC2 API versions. The earlier versions are available to you in case you have scripts that rely on the structure and information present in a previous version.

Get the list of available public keys

This example gets the list of available public keys.

cURL

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/public-keys/
0=my-public-key
```

PowerShell

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/public-
keys/ 0=my-public-key
```

Show the formats in which public key 0 is available

This example shows the formats in which public key 0 is available.

cURL

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/public-keys/0/
openssh-key
```

PowerShell

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/public-
keys/0/openssh-key
openssh-key
```

Get public key 0 (in the OpenSSH key format)

This example gets public key 0 (in the OpenSSH key format).

cURL

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key

Get the instance tags for an instance

If access to instance tags in the instance metadata is turned on, you can get the tags for a instance from instance metadata. For more information, see Retrieve tags from instance metadata.

Transition to using Instance Metadata Service Version 2

If you want to migrate your instances so that local code or users must use Instance Metadata Service Version 2 (IMDSv2), we recommend that you use the following tools and transition path.

Topics

- Tools for helping with the transition to IMDSv2
- Recommended path to requiring IMDSv2

Tools for helping with the transition to IMDSv2

If your software uses IMDSv1, use the following tools to help reconfigure your software to use IMDSv2.

AWS software

The latest versions of the AWS CLI and AWS SDKs support IMDSv2. To use IMDSv2, make sure that your EC2 instances have the latest versions of the CLI and SDKs. For information about updating the CLI, see Installing or updating to the latest version of the AWS CLI in the *AWS Command Line Interface User Guide*.

All Amazon Linux 2 and Amazon Linux 2023 software packages support IMDSv2. In Amazon Linux 2023, IMDSv1 is disabled by default.

For the minimum AWS SDK versions that support IMDSv2, see Use a supported AWS SDK.

IMDS Packet Analyzer

The IMDS Packet Analyzer is an open-sourced tool that identifies and logs IMDSv1 calls from your instance's boot phase. This can assist in identifying the software making IMDSv1 calls on EC2 instances, allowing you to pinpoint exactly what you need to update to get your instances ready to use IMDSv2 only. You can run IMDS Packet Analyzer from a command line or install it as a service. For more information, see AWS ImdsPacketAnalyzer on *GitHub*.

CloudWatch

IMDSv2 uses token-backed sessions, while IMDSv1 does not. The `MetadataNoToken` CloudWatch metric tracks the number of calls to the Instance Metadata Service (IMDS) that are using IMDSv1. By tracking this metric to zero, you can determine if and when all of your software has been upgraded to use IMDSv2.

After you've disabled IMDSv1, you can use the `MetadataNoTokenRejected` CloudWatch metric to track the number of times an IMDSv1 call was attempted and rejected. By tracking this metric, you can ascertain whether your software needs to be updated to use IMDSv2.

For more information, see Instance metrics.

Updates to EC2 APIs and CLIs

For new instances, you can use the RunInstances API to launch new instances that require the use of IMDSv2. For more information, see Configure instance metadata options for new instances.

For existing instances, you can use the ModifyInstanceMetadataOptions API to require the use of IMDSv2. For more information, see Modify instance metadata options for existing instances.

To require the use of IMDSv2 on all new instances launched by Auto Scaling groups, your Auto Scaling groups can use either a launch template or a launch configuration. When you create a launch template or create a launch configuration, you must configure the `MetadataOptions` parameters to require the use of IMDSv2. The Auto Scaling group launches new instances using the new launch template or launch configuration, but existing instances are not affected. For existing instances in an Auto Scaling group, you can use the ModifyInstanceMetadataOptions API to require the use of IMDSv2 on the existing instances, or terminate the instances and the Auto Scaling group will launch new replacement instances with the instance metadata options settings that are defined in the new launch template or launch configuration.

Use an AMI that configures IMDSv2 by default

When you launch an instance, you can automatically configure it to use IMDSv2 by default (the `HttpTokens` parameter is set to `required`) by launching it with an AMI that is configured with the `ImdsSupport` parameter set to `v2.0`. You can set the `ImdsSupport` parameter to `v2.0` when you register the AMI using the register-image CLI command, or you can modify an existing AMI by using the modify-image-attribute CLI command. For more information, see Configure the AMI.

IAM policies and SCPs

You can use an IAM policy or AWS Organizations service control policy (SCP) to control users as follows:

- Can't launch an instance using the RunInstances API unless the instance is configured to use IMDSv2.
- Can't modify a running instance using the ModifyInstanceMetadataOptions API to re-enable IMDSv1.

The IAM policy or SCP must contain the following IAM condition keys:

- `ec2:MetadataHttpEndpoint`

- `ec2:MetadataHttpPutResponseHopLimit`
- `ec2:MetadataHttpTokens`

If a parameter in the API or CLI call does not match the state specified in the policy that contains the condition key, the API or CLI call fails with an `UnauthorizedOperation` response.

Furthermore, you can choose an additional layer of protection to enforce the change from IMDSv1 to IMDSv2. At the access management layer with respect to the APIs called via EC2 Role credentials, you can use a new condition key in either IAM policies or AWS Organizations service control policies (SCPs). Specifically, by using the condition key `ec2:RoleDelivery` with a value of `2.0` in your IAM policies, API calls made with EC2 Role credentials obtained from IMDSv1 will receive an `UnauthorizedOperation` response. The same thing can be achieved more broadly with that condition required by an SCP. This ensures that credentials delivered via IMDSv1 cannot actually be used to call APIs because any API calls not matching the specified condition will receive an `UnauthorizedOperation` error.

For example IAM policies, see [Work with instance metadata](). For more information on SCPs, see [Service control policies]() in the *AWS Organizations User Guide*.

Recommended path to requiring IMDSv2

Using the above tools, we recommend that you follow this path for transitioning to IMDSv2.

Step 1: At the start

Update the SDKs, CLIs, and your software that use Role credentials on their EC2 instances to versions compatible with IMDSv2. For more information about updating the CLI, see [Installing or updating to the latest version of the AWS CLI]() in the *AWS Command Line Interface User Guide*.

Then, change your software that directly accesses instance metadata (in other words, that does not use an SDK) using the IMDSv2 requests. You can use the [IMDS Packet Analyzer]() to identify the software that you need to change to use IMDSv2 requests.

Step 2: Track your transition progress

Track your transition progress by using the CloudWatch metric `MetadataNoToken`. This metric shows the number of IMDSv1 calls to the IMDS on your instances. For more information, see [Instance metrics]().

Step 3: When there is zero IMDSv1 usage

When the CloudWatch metric `MetadataNoToken` records zero IMDSv1 usage, your instances are ready to be fully transitioned to using IMDSv2. At this stage, you can do the following:

- **Account default**

  You can set IMDSv2 to be required as an account default. When an instance is launched, the instance configuration is automatically set to the account default.

  To set the account default, do the following:

  - Amazon EC2 console: On the EC2 Dashboard, under **Account attributes**, **Data protection and security**, for **IMDS defaults**, set **Instance metadata service** to **Enabled** and **Metadata version** to **V2 only (token required)**. For more information, see Set IMDSv2 as the default for the account.
  - AWS CLI: Use the modify-instance-metadata-defaults CLI command and specify `--http-tokens required` and `--http-put-response-hop-limit 2`.
- **New instances**

  When launching a new instance, you can do the following:

  - Amazon EC2 console: In the launch instance wizard, set **Metadata accessible** to **Enabled** and **Metadata version** to **V2 only (token required)**. For more information, see Configure the instance at launch.
  - AWS CLI: Use the run-instances command and specify that IMDSv2 is required.
- **Existing instances**

  For existing instances, you can do the following:

  - Amazon EC2 console: On the **Instances** page, select your instance, choose **Actions**, **Instance settings**, **Modify instance metadata options**, and for **IMDSv2**, choose **Required**. For more information, see Require the use of IMDSv2.
  - AWS CLI: Use the modify-instance-metadata-options CLI command to specify that only IMDSv2 is to be used.

  You can modify the instance metadata options on running instances, and you don't need to restart the instances after modifying the instance metadata options.

Step 4: Check if your instances are transitioned to IMDSv2

You can check if any instances are not yet configured to require the use of IMDSv2, in other words, IMDSv2 is still configured as `optional`. If any instances are still configured as `optional`, you can modify the instance metadata options to make IMDSv2 `required` by repeating the preceding Step 3.

To filter your instances:

- Amazon EC2 console: On the **Instances** page, filter your instances by using the **IMDSv2 = optional** filter. For more information about filtering, see Filter resources using the console. You can also view whether IMDSv2 is required or optional for each instance: In the **Preferences** window, toggle on **IMDSv2** to add the **IMDSv2** column to the **Instances** table.
- AWS CLI: Use the describe-instances command and filter by `metadata-options.http-tokens = optional`, as follows:

```
aws ec2 describe-instances --filters "Name=metadata-options.http-
tokens,Values=optional" --query "Reservations[*].Instances[*].[InstanceId]" --output
 text
```

Step 5: When all of your instances are transitioned to IMDSv2

The `ec2:MetadataHttpTokens`, `ec2:MetadataHttpPutResponseHopLimit`, and `ec2:MetadataHttpEndpoint` IAM condition keys can be used to control the use of the RunInstances and the ModifyInstanceMetadataOptions APIs and corresponding CLIs. If a policy is created, and a parameter in the API call does not match the state specified in the policy using the condition key, the API or CLI call fails with an `UnauthorizedOperation` response. For example IAM policies, see Work with instance metadata.

Furthermore, after you've disabled IMDSv1, you can use the `MetadataNoTokenRejected` CloudWatch metric to track the number of times an IMDSv1 call was attempted and rejected. If, after disabling IMDSv1, you have software that is not working properly and the `MetadataNoTokenRejected` metric records IMDSv1 calls, it's likely that this software needs to be updated to use IMDSv2.

Limit access to the Instance Metadata Service

You can consider using local firewall rules to disable access from some or all processes to the Instance Metadata Service (IMDS).

For Nitro-based instances, the IMDS can be reached from your own network when a network appliance within your VPC, such as a virtual router, forwards packets to the IMDS address, and the default source/destination check on the instance is disabled. To prevent a source from outside your VPC reaching the IMDS, we recommend that you modify the configuration of the network appliance to drop packets with the destination IPv4 address of the IMDS `169.254.169.254` and, if you enabled the IPv6 endpoint, the IPv6 address of the IMDS `[fd00:ec2::254]`.

Limit IMDS access for Linux instances

Using iptables to limit access

The following example uses Linux iptables and its `owner` module to prevent the Apache webserver (based on its default installation user ID of `apache`) from accessing 169.254.169.254. It uses a *deny rule* to reject all instance metadata requests (whether IMDSv1 or IMDSv2) from any process running as that user.

```
$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match owner
 --uid-owner apache --jump REJECT
```

Or, you can consider only allowing access to particular users or groups, by using *allow rules*. Allow rules might be easier to manage from a security perspective, because they require you to make a decision about what software needs access to instance metadata. If you use *allow rules*, it's less likely you will accidentally allow software to access the metadata service (that you did not intend to have access) if you later change the software or configuration on an instance. You can also combine group usage with allow rules, so that you can add and remove users from a permitted group without needing to change the firewall rule.

The following example prevents access to the IMDS by all processes, except for processes running in the user account `trustworthy-user`.

```
$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match
 owner ! --uid-owner trustworthy-user --jump REJECT
```

Note

- To use local firewall rules, you need to adapt the preceding example commands to suit your needs.
- By default, iptables rules are not persistent across system reboots. They can be made to be persistent by using OS features, not described here.

- The iptables `owner` module only matches group membership if the group is the primary group of a given local user. Other groups are not matched.

Using PF or IPFW to limit access

If you are using FreeBSD or OpenBSD, you can also consider using PF or IPFW. The following examples limit access to the IMDS to just the root user.

PF

```
$ block out inet proto tcp from any to 169.254.169.254
```

```
$ pass out inet proto tcp from any to 169.254.169.254 user root
```

IPFW

```
$ allow tcp from any to 169.254.169.254 uid root
```

```
$ deny tcp from any to 169.254.169.254
```

> **Note**
>
> The order of the PF and IPFW commands matter. PF defaults to last matching rule and IPFW defaults to first matching rule.

Limit IMDS access for Windows instances

Using Windows firewall to limit access

The following PowerShell example uses the built-in Windows firewall to prevent the Internet Information Server webserver (based on its default installation user ID of `NT AUTHORITY\IUSR`) from accessing 169.254.169.254. It uses a *deny rule* to reject all instance metadata requests (whether IMDSv1 or IMDSv2) from any process running as that user.

```
PS C:\> $blockPrincipal = New-Object -TypeName System.Security.Principal.NTAccount ("NT
 AUTHORITY\IUSR")
```

```
PS C:\> $BlockPrincipalSID =
 $blockPrincipal.Translate([System.Security.Principal.SecurityIdentifier]).Value
PS C:\> $BlockPrincipalSDDL = "D:(A;;CC;;;$BlockPrincipalSID)"
PS C:\> New-NetFirewallRule -DisplayName "Block metadata service from IIS" -Action
 block -Direction out `
-Protocol TCP -RemoteAddress 169.254.169.254 -LocalUser $BlockPrincipalSDDL
```

Or, you can consider only allowing access to particular users or groups, by using *allow rules*. Allow rules might be easier to manage from a security perspective, because they require you to make a decision about what software needs access to instance metadata. If you use *allow rules*, it's less likely you will accidentally allow software to access the metadata service (that you did not intend to have access) if you later change the software or configuration on an instance. You can also combine group usage with allow rules, so that you can add and remove users from a permitted group without needing to change the firewall rule.

The following example prevents access to instance metadata by all processes running as an OS group specified in the variable `blockPrincipal` (in this example, the Windows group `Everyone`), except for processes specified in `exceptionPrincipal` (in this example, a group called `trustworthy-users`). You must specify both deny and allow principals because Windows Firewall, unlike the `! --uid-owner trustworthy-user` rule in Linux iptables, does not provide a shortcut mechanism to allow only a particular principal (user or group) by denying all the others.

```
PS C:\> $blockPrincipal = New-Object -TypeName System.Security.Principal.NTAccount
 ("Everyone")
PS C:\> $BlockPrincipalSID =
 $blockPrincipal.Translate([System.Security.Principal.SecurityIdentifier]).Value
PS C:\> $exceptionPrincipal = New-Object -TypeName System.Security.Principal.NTAccount
 ("trustworthy-users")
PS C:\> $ExceptionPrincipalSID =
 $exceptionPrincipal.Translate([System.Security.Principal.SecurityIdentifier]).Value
PS C:\> $PrincipalSDDL = "O:LSD:(D;;CC;;;$ExceptionPrincipalSID)(A;;CC;;;
$BlockPrincipalSID)"
PS C:\> New-NetFirewallRule -DisplayName "Block metadata service for
 $($blockPrincipal.Value), exception: $($exceptionPrincipal.Value)" -Action block -
Direction out `
-Protocol TCP -RemoteAddress 169.254.169.254 -LocalUser $PrincipalSDDL
```

Note

To use local firewall rules, you need to adapt the preceding example commands to suit your needs.

Using netsh rules to limit access

You can consider blocking all software using `netsh` rules, but those are much less flexible.

```
C:\> netsh advfirewall firewall add rule name="Block metadata service altogether"
 dir=out protocol=TCP remoteip=169.254.169.254 action=block
```

Note

- To use local firewall rules, you need to adapt the preceding example commands to suit your needs.
- `netsh` rules must be set from an elevated command prompt, and can't be set to deny or allow particular principals.

Configure the Instance Metadata Service options

The Instance Metadata Service (IMDS) runs locally on every EC2 instance. The *instance metadata options* refer to a set of configurations that control the accessibility and behavior of the IMDS on an EC2 instance.

You can configure the following instance metadata options on each instance:

Instance metadata service (IMDS): `enabled` | `disabled`

You can enable or disable the IMDS on an instance. When disabled, you or any code won't be able to access the instance metadata on the instance.

The IMDS has two endpoints on an instance: IPv4 (`169.254.169.254`) and IPv6 (`[fd00:ec2::254]`). When you enable the IMDS, the IPv4 endpoint is automatically enabled. If you want to enable the IPv6 endpoint, you need to do so explicitly.

IMDS IPv6 endpoint: `enabled` | `disabled`

You can explicitly enable the IPv6 IMDS endpoint on an instance. When the IPv6 endpoint is enabled, the IPv4 endpoint remains enabled. The IPv6 endpoint is only supported on Nitro-based instances in IPv6-supported subnets (dual stack or IPv6 only).

Metadata version: `IMDSv1 or IMDSv2 (token optional)` | `IMDSv2 only (token required)`

When requesting instance metadata, IMDSv2 calls require a token. IMDSv1 calls do not require a token. You can configure an instance to allow either IMDSv1 or IMDSv2 calls (where a token is optional), or to only allow IMDSv2 calls (where a token is required).

Metadata response hop limit: `1–64`

The hop limit is the number of network hops that the PUT response is allowed to make. You can set the hop limit to a minimum of 1 and a maximum of 64. In a container environment, a hop limit of 1 can cause issues. For information about how to mitigate these issues, see the information about container environments under Instance metadata access considerations.

Access to tags in instance metadata: `enabled` | `disabled`

You can enable or disable access to the instance's tags from an instance's metadata. For more information, see View tags for your EC2 instances using instance metadata.

To view an instance's current configuration, see Query instance metadata options for existing instances.

Where to configure instance metadata options

Instance metadata options can be configured at different levels, as follows:

- **Account** – You can set default values for the instance metadata options at the account level for each AWS Region. When an instance is launched, the instance metadata options are automatically set to the account-level values. You can change these values at launch. Account-level default values do not affect existing instances.
- **AMI** – You can set the `imds-support` parameter to `v2.0` when you register or modify an AMI. When an instance is launched with this AMI, the instance metadata version is automatically set to IMDSv2 and the hop limit is set to 2.

- **Instance –** You can change all the instance metadata options on an instance at launch, overriding the default settings. You can also change the instance metadata options after launch on a running or stopped instance. Note that changes may be restricted by an IAM or SCP policy.

For more information, see Configure instance metadata options for new instances and Modify instance metadata options for existing instances.

Order of precedence for instance metadata options

The value for each instance metadata option is determined at instance launch, following a hierarchical order of precedence. The hierarchy, with the highest precedence at the top, is as follows:

- **Precedence 1: Instance configuration at launch –** Values can be specified either in the launch template or in the instance configuration. Any values specified here override values specified at the account level or in the AMI.
- **Precedence 2: Account settings –** If a value is not specified at instance launch, then it is determined by the account-level settings (which are set for each AWS Region). Account-level settings either include a value for each metadata option, or indicate no preference at all.
- **Precedence 3: AMI configuration –** If a value is not specified at instance launch or at the account level, then it is determined by the AMI configuration. This applies only to `HttpTokens` and `HttpPutResponseHopLimit`.

Each metadata option is evaluated separately. The instance can be configured with a mix of direct instance configuration, account-level defaults, and the configuration from the AMI.

You can change the value of any metadata option after launch on a running or stopped instance, unless changes are restricted by an IAM or SCP policy.

Determine values for metadata options – Example 1

In this example, an EC2 instance is launched into a Region where the `HttpPutResponseHopLimit` is set to `1` at the account level. The specified AMI has `ImdsSupport` set to `v2.0`. No metadata options are specified directly on the instance at launch. The instance is launched with the following metadata options:

```
"MetadataOptions": {
    ...
```

```
    "HttpTokens": "required",
    "HttpPutResponseHopLimit": 1,
    ...
```

These values were determined as follows:

- **No metadata options specified at launch:** During the launch of the instance, specific values for the metadata options were not provided either in the instance launch parameters or in the launch template.
- **Account settings take next precedence:** In the absence of specific values specified at launch, the settings at the account level within the Region take precedence. This means that the default values configured at the account level are applied. In this case, the `HttpPutResponseHopLimit` was set to `1`.
- **AMI settings take last precedence:** In the absence of a specific value specified at launch or at the account level for `HttpTokens` (the instance metadata version), the AMI setting is applied. In this case, the AMI setting `ImdsSupport: v2.0` determined that `HttpTokens` was set to `required`. Note that while the AMI setting `ImdsSupport: v2.0` is designed to set `HttpPutResponseHopLimit: 2`, it was overridden by the account-level setting `HttpPutResponseHopLimit: 1`, which has higher precedence.

Determine values for metadata options – Example 2

In this example, the EC2 instance is launched with the same settings as in the previous Example 1, but with `HttpTokens` set to `optional` directly on the instance at launch. The instance is launched with the following metadata options:

```
"MetadataOptions": {
    ...
    "HttpTokens": "optional",
    "HttpPutResponseHopLimit": 1,
    ...
```

The value for `HttpPutResponseHopLimit` is determined in the same way as in Example 1. However, the value for `HttpTokens` is determined as follows: Metadata options configured on the instance at launch take first precedence. Even though the AMI was configured with `ImdsSupport: v2.0` (in other words, `HttpTokens` is set to `required`), the value specified on the instance at launch (`HttpTokens` set to `optional`) took precedence.

Set the instance metadata version

When an instance is launched, the value for the instance *metadata version* is either `IMDSv1 or IMDSv2 (token optional)` or `IMDSv2 only (token required)`.

At instance launch, you can either manually specify the value for the metadata version, or use the default value. If you manually specify the value, it overrides any defaults. If you opt not to manually specify the value, it will be determined by a combination of default settings, as outlined in the following table.

The table shows how the metadata version for an instance at launch (indicated by **Resulting instance configuration** in column 4) is determined by the settings at the different levels of configuration. The order of precedence is from left to right, where the first column takes the highest precedence, as follows:

- Column 1: **Launch parameter** – Represents the setting on the instance that you manually specify at launch.
- Column 2: **Account level default** – Represents the setting for the account.
- Column 3: **AMI default** – Represents the setting on the AMI.

Launch parameter	Account level default	AMI default	Resulting instance configuration
V2 only (token required)	No preference	V2 only	V2 only
V2 only (token required)	V2 only	V2 only	V2 only
V2 only (token required)	V1 or V2	V2 only	V2 only
V1 or V2 (token optional)	No preference	V2 only	V1 or V2
V1 or V2 (token optional)	V2 only	V2 only	V1 or V2

Launch parameter	Account level default	AMI default	Resulting instance configuration
V1 or V2 (token optional)	V1 or V2	V2 only	V1 or V2
Not set	No preference	V2 only	V2 only
Not set	V2 only	V2 only	V2 only
Not set	V1 or V2	V2 only	V1 or V2
V2 only (token required)	No preference	null	V2 only
V2 only (token required)	V2 only	null	V2 only
V2 only (token required)	V1 or V2	null	V2 only
V1 or V2 (token optional)	No preference	null	V1 or V2
V1 or V2 (token optional)	V2 only	null	V1 or V2
V1 or V2 (token optional)	V1 or V2	null	V1 or V2
Not set	No preference	null	V1 or V2
Not set	V2 only	null	V2 only
Not set	V1 or V2	null	V1 or V2

Use IAM condition keys to restrict instance metadata options

You can use IAM condition keys in an IAM policy or SCP as follows:

- Allow an instance to launch only if it's configured to require the use of IMDSv2
- Restrict the number of allowed hops
- Turn off access to instance metadata

Tasks

- Configure instance metadata options for new instances
- Modify instance metadata options for existing instances

> **Note**
>
> You should proceed cautiously and conduct careful testing before making any changes. Take note of the following:
>
> - If you enforce the use of IMDSv2, applications or agents that use IMDSv1 for instance metadata access will break.
> - If you turn off all access to instance metadata, applications or agents that rely on instance metadata access to function will break.
> - For IMDSv2, you must use `/latest/api/token` when retrieving the token.
> - (Windows only) If your PowerShell version is earlier than 4.0, you must update to Windows Management Framework 4.0 to require the use of IMDSv2.

Configure instance metadata options for new instances

You can configure the following instance metadata options for new instances.

Options

- Require the use of IMDSv2
- Enable the IMDS IPv4 and IPv6 endpoints
- Turn off access to instance metadata
- Allow access to tags in instance metadata

> **Note**
>
> The settings for these options are configured at the account level, either directly in the account or by using a declarative policy. They must be configured in each AWS Region where you want to configure instance metadata options. Using a declarative policy allows you to apply the settings across multiple Regions simultaneously, as well as across multiple accounts simultaneously. When a declarative policy is in use, you can't modify the settings directly within an account. This topic describes how to configure the settings directly within an account. For information about using declarative policies, see Declarative policies in the *AWS Organizations User Guide.*

Require the use of IMDSv2

You can use the following methods to require the use of IMDSv2 on your new instances.

To require IMDSv2

- Set IMDSv2 as the default for the account
- Configure the instance at launch
- Configure the AMI
- Use an IAM policy

Set IMDSv2 as the default for the account

You can set the default version for the instance metadata service (IMDS) at the account level for each AWS Region. This means that when you launch a *new* instance, the instance metadata version is automatically set to the account-level default. However, you can manually override the value at launch or after launch. For more information about how the account-level settings and manual overrides affect an instance, see Order of precedence for instance metadata options.

> **Note**
>
> Setting the account-level default does not reset *existing* instances. For example, if you set the account-level default to IMDSv2, any existing instances that are set to IMDSv1 are not affected. If you want to change the value on existing instances, you must manually change the value on the instances themselves.

You can set the account default for the instance metadata version to IMDSv2 so that all *new* instances in the account launch with IMDSv2 required, and IMDSv1 will be disabled. With this account default, when you launch an instance, the following are the default values for the instance:

- Console: **Metadata version** is set to **V2 only (token required)** and **Metadata response hop limit** is set to **2**.
- AWS CLI: `HttpTokens` is set to `required` and `HttpPutResponseHopLimit` is set to 2.

> **Note**
>
> Before setting the account default to IMDSv2, ensure that your instances do not depend on IMDSv1. For more information, see [Recommended path to requiring IMDSv2](#).

Console

To set IMDSv2 as the default for the account for the specified Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **EC2 Dashboard**.
4. Under **Account attributes**, choose **Data protection and security**.
5. Next to **IMDS defaults**, choose **Manage**.
6. On the **Manage IMDS defaults** page, do the following:

   a. For **Instance metadata service**, choose **Enabled**.

   b. For **Metadata version**, choose **V2 only (token required)**.

   c. For **Metadata response hop limit**, specify **2** if your instances will host containers. Otherwise, select **No preference**. When no preference is specified, at launch, the value defaults to **2** if the AMI has the setting `ImdsSupport: v2.0`; otherwise it defaults to **1**.

   d. Choose **Update**.

AWS CLI

To set IMDSv2 as the default for the account for the specified Region

Use the modify-instance-metadata-defaults command and specify the Region in which to modify the IMDS account level settings. Include `--http-tokens` set to `required` and `--http-put-response-hop-limit` set to 2 if your instances will host containers. Otherwise, specify `-1` to indicate no preference. When `-1` (no preference) is specified, at launch, the value defaults to 2 if the AMI has the setting `ImdsSupport: v2.0`; otherwise it defaults to 1.

```
aws ec2 modify-instance-metadata-defaults \
    --region us-east-1 \
    --http-tokens required \
    --http-put-response-hop-limit 2
```

The following is example output.

```
{
    "Return": true
}
```

To view the default account settings for the instance metadata options for the specified Region

Use the get-instance-metadata-defaults command and specify the Region.

```
aws ec2 get-instance-metadata-defaults --region us-east-1
```

The following is example output.

```
{
    "AccountLevel": {
        "HttpTokens": "required",
        "HttpPutResponseHopLimit": 2
    },
    "ManagedBy": "account"
}
```

The `ManagedBy` field indicates the entity that configured the settings. In this example, `account` indicates that the settings were configured directly in the account. A value of `declarative-policy` would mean the settings were configured by a declarative policy. For more information, see Declarative policies in the *AWS Organizations User Guide*.

To set IMDSv2 as the default for the account for all Regions

Use the modify-instance-metadata-defaults command to modify the IMDS account level settings for all Regions. Include `--http-tokens` set to `required` and `--http-put-response-hop-limit` set to 2 if your instances will host containers. Otherwise, specify `-1` to indicate no preference. When `-1` (no preference) is specified, at launch, the value defaults to 2 if the AMI has the setting `ImdsSupport: v2.0`; otherwise it defaults to 1.

```
echo -e "Region          \t Modified" ; \
echo -e "--------------  \t ---------" ; \
for region in $(
    aws ec2 describe-regions \
        --region us-east-1 \
        --query "Regions[*].[RegionName]" \
        --output text
    );
    do (output=$(
        aws ec2 modify-instance-metadata-defaults \
            --region $region \
            --http-tokens required \
            --http-put-response-hop-limit 2 \
            --output text)
        echo -e "$region        \t $output"
    );
done
```

The following is example output.

```
Region                   Modified
--------------           ---------
ap-south-1               True
eu-north-1               True
eu-west-3                True
...
```

To view the default account settings for the instance metadata options for all Regions

Use the get-instance-metadata-defaults command.

```
echo -e "Region   \t Level          Hops    HttpTokens" ; \
echo -e "-------------- \t ------------   ----    ----------" ; \
for region in $(
    aws ec2 describe-regions \
        --region us-east-1 \
```

```
        --query "Regions[*].[RegionName]" \
        --output text
    );
    do (output=$(
        aws ec2 get-instance-metadata-defaults \
            --region $region \
            --output text)
        echo -e "$region \t $output"
    );
done
```

The following is example output.

```
Region          Level          Hops    HttpTokens
--------------  ------------   ----    ----------
ap-south-1      ACCOUNTLEVEL   2       required
eu-north-1      ACCOUNTLEVEL   2       required
eu-west-3       ACCOUNTLEVEL   2       required
...
```

PowerShell

To set IMDSv2 as the default for the account for the specified Region

Use the Edit-EC2InstanceMetadataDefault command and specify the Region in which to modify the IMDS account level settings. Include `-HttpToken` set to `required` and `-HttpPutResponseHopLimit` set to 2 if your instances will host containers. Otherwise, specify `-1` to indicate no preference. When `-1` (no preference) is specified, at launch, the value defaults to 2 if the AMI has the setting `ImdsSupport: v2.0`; otherwise it defaults to 1.

```
Edit-EC2InstanceMetadataDefault `
    -Region us-east-1 `
    -HttpToken required `
    -HttpPutResponseHopLimit 2
```

The following is example output.

```
True
```

To view the default account settings for the instance metadata options for the specified Region

Use the Get-EC2InstanceMetadataDefault command and specify the Region.

```
Get-EC2InstanceMetadataDefault -Region us-east-1 | Format-List
```

The following is example output.

```
HttpEndpoint            :
HttpPutResponseHopLimit : 2
HttpTokens              : required
InstanceMetadataTags    :
```

To set IMDSv2 as the default for the account for all Regions

Use the Edit-EC2InstanceMetadataDefault Cmdlet to modify the IMDS account level settings for all Regions. Include `-HttpToken` set to `required` and `-HttpPutResponseHopLimit` set to 2 if your instances will host containers. Otherwise, specify `-1` to indicate no preference. When `-1` (no preference) is specified, at launch, the value defaults to 2 if the AMI has the setting `ImdsSupport: v2.0`; otherwise it defaults to 1.

```
(Get-EC2Region).RegionName | `
    ForEach-Object {
    [PSCustomObject]@{
        Region   = $_
        Modified = (Edit-EC2InstanceMetadataDefault `
                -Region $_ `
                -HttpToken required `
                -HttpPutResponseHopLimit 2)
    }
} | `
Format-Table Region, Modified -AutoSize
```

Expected output

```
Region         Modified
------         --------
ap-south-1         True
eu-north-1         True
eu-west-3          True
...
```

To view the default account settings for the instance metadata options for all Regions

Use the Get-EC2InstanceMetadataDefault Cmdlet.

```
(Get-EC2Region).RegionName | `
    ForEach-Object {
    [PSCustomObject]@{
        Region = $_
        HttpPutResponseHopLimit = (Get-EC2InstanceMetadataDefault -Region
 $_).HttpPutResponseHopLimit
        HttpTokens              = (Get-EC2InstanceMetadataDefault -Region
 $_).HttpTokens
    }
} | `
Format-Table -AutoSize
```

Example output

```
Region         HttpPutResponseHopLimit HttpTokens
------         ----------------------- ----------
ap-south-1                           2 required
eu-north-1                           2 required
eu-west-3                            2 required
...
```

Configure the instance at launch

When you launch an instance, you can configure the instance to require the use of IMDSv2 by configuring the following fields:

- Amazon EC2 console: Set **Metadata version** to **V2 only (token required)**.
- AWS CLI: Set `HttpTokens` to `required`.

When you specify that IMDSv2 is required, you must also enable the Instance Metadata Service (IMDS) endpoint by setting **Metadata accessible** to **Enabled** (console) or `HttpEndpoint` to `enabled` (AWS CLI).

In a container environment, when IMDSv2 is required, we recommend setting the hop limit to 2. For more information, see Instance metadata access considerations.

Console

To require the use of IMDSv2 on a new instance

- When launching a new instance in the Amazon EC2 console, expand **Advanced details**, and do the following:
  - For **Metadata accessible**, choose **Enabled**.
  - For **Metadata version**, choose **V2 only (token required)**.
  - (Container environment) For **Metadata response hop limit**, choose **2**.

  For more information, see Advanced details.

AWS CLI

To require the use of IMDSv2 on a new instance

The following run-instances example launches a `c6i.large` instance with `--metadata-options` set to `HttpTokens=required`. When you specify a value for `HttpTokens`, you must also set `HttpEndpoint` to `enabled`. Because the secure token header is set to `required` for metadata retrieval requests, this requires the instance to use IMDSv2 when requesting instance metadata.

In a container environment, when IMDSv2 is required, we recommend setting the hop limit to 2 with `HttpPutResponseHopLimit=2`.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type c6i.large \
 ...
    --metadata-options 
 "HttpEndpoint=enabled,HttpTokens=required,HttpPutResponseHopLimit=2"
```

PowerShell

To require the use of IMDSv2 on a new instance

The following New-EC2Instance Cmdlet example launches a `c6i.large` instance with `MetadataOptions_HttpEndpoint` set to `enabled` and the `MetadataOptions_HttpTokens` parameter to `required`. When you specify a value for

HttpTokens, you must also set HttpEndpoint to enabled. Because the secure token header is set to required for metadata retrieval requests, this requires the instance to use IMDSv2 when requesting instance metadata.

```
New-EC2Instance `
    -ImageId ami-0abcdef1234567890 `
    -InstanceType c6i.large `
    -MetadataOptions_HttpEndpoint enabled `
    -MetadataOptions_HttpTokens required
```

AWS CloudFormation

To specify the metadata options for an instance using AWS CloudFormation, see the AWS::EC2::LaunchTemplate MetadataOptions property in the *AWS CloudFormation User Guide*.

Configure the AMI

When you register a new AMI or modify an existing AMI, you can set the imds-support parameter to v2.0. Instances launched from this AMI will have **Metadata version** set to **V2 only (token required)** (console) or HttpTokens set to required (AWS CLI). With these settings, the instance requires that IMDSv2 is used when requesting instance metadata.

Note that when you set imds-support to v2.0, instances launched from this AMI will also have **Metadata response hop limit** (console) or http-put-response-hop-limit (AWS CLI) set to **2**.

> **Important**
>
> Do not use this parameter unless your AMI software supports IMDSv2. After you set the value to v2.0, you can't undo it. The only way to "reset" your AMI is to create a new AMI from the underlying snapshot.

To configure a new AMI for IMDSv2

Use one of the following methods to configure a new AMI for IMDSv2.

AWS CLI

The following register-image example registers an AMI using the specified snapshot of an EBS root volume as device /dev/xvda. Specify v2.0 for the imds-support parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
aws ec2 register-image \
    --name my-image \
    --root-device-name /dev/xvda \
    --block-device-mappings DeviceName=/dev/
xvda,Ebs={SnapshotId=snap-0123456789example} \
    --architecture x86_64 \
    --imds-support v2.0
```

PowerShell

The following Register-EC2Image Cmdlet example registers an AMI using the specified snapshot of an EBS root volume as device `/dev/xvda`. Specify `v2.0` for the `ImdsSupport` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
Register-EC2Image `
    -Name 'my-image' `
    -RootDeviceName /dev/xvda `
    -BlockDeviceMapping  (
    New-Object `
        -TypeName Amazon.EC2.Model.BlockDeviceMapping `
        -Property @{
        DeviceName = '/dev/xvda';
        EBS        = (New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice -Property
 @{
                SnapshotId = 'snap-0123456789example'
                VolumeType = 'gp3'
                } )
        }  ) `
    -Architecture X86_64 `
    -ImdsSupport v2.0
```

To configure an existing AMI for IMDSv2

Use one of the following methods to configure an existing AMI for IMDSv2.

AWS CLI

The following modify-image-attribute example modifies an existing AMI for IMDSv2 only. Specify `v2.0` for the `imds-support` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
aws ec2 modify-image-attribute \
    --image-id ami-0abcdef1234567890 \
    --imds-support v2.0
```

PowerShell

The following Edit-EC2ImageAttribute Cmdlet example modifies an existing AMI for IMDSv2 only. Specify `v2.0` for the `imds-support` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
Edit-EC2ImageAttribute `
    -ImageId ami-0abcdef1234567890 `
    -ImdsSupport 'v2.0'
```

Use an IAM policy

You can create an IAM policy that prevents users from launching new instances unless they require IMDSv2 on the new instance.

To enforce the use of IMDSv2 on all new instances by using an IAM policy

To ensure that users can only launch instances that require the use of IMDSv2 when requesting instance metadata, you can specify that the condition to require IMDSv2 must be met before an instance can be launched. For the example IAM policy, see Work with instance metadata.

Enable the IMDS IPv4 and IPv6 endpoints

The IMDS has two endpoints on an instance: IPv4 (`169.254.169.254`) and IPv6 (`[fd00:ec2::254]`). When you enable the IMDS, the IPv4 endpoint is automatically enabled. The IPv6 endpoint remains disabled even if you launch an instance into an IPv6-only subnet. To enable the IPv6 endpoint, you need to do so explicitly. When you enable the IPv6 endpoint, the IPv4 endpoint remains enabled.

You can enable the IPv6 endpoint at instance launch or after.

Requirements for enabling the IPv6 endpoint

- The selected instance type is a Nitro-based instance.
- The selected subnet supports IPv6, where the subnet is either dual stack or IPv6 only.

Use any of the following methods to launch an instance with the IMDS IPv6 endpoint enabled.

Console

To enable the IMDS IPv6 endpoint at instance launch

- Launch the instance in the Amazon EC2 console with the following specified under **Advanced details**:
  - For **Metadata IPv6 endpoint**, choose **Enabled**.

For more information, see Advanced details.

AWS CLI

To enable the IMDS IPv6 endpoint at instance launch

The following run-instances example launches a `c6i.large` instance with the IPv6 endpoint enabled for the IMDS. To enable the IPv6 endpoint, for the `--metadata-options` parameter, specify `HttpProtocolIpv6=enabled`. When you specify a value for `HttpProtocolIpv6`, you must also set `HttpEndpoint` to `enabled`.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type c6i.large \
    ...
