What Is Amazon CloudWatch?

Amazon CloudWatch monitors your Amazon Web Services (AWS) resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications.

The CloudWatch home page automatically displays metrics about every AWS service you use. You can additionally create custom dashboards to display metrics about your custom applications, and display custom collections of metrics that you choose.

You can create alarms which watch metrics and send notifications or automatically make changes to the resources you are monitoring when a threshold is breached. For example, you can monitor the CPU usage and disk reads and writes of your Amazon EC2 instances and then use this data to determine whether you should launch additional instances to handle increased load. You can also use this data to stop under-used instances to save money.

With CloudWatch, you gain system-wide visibility into resource utilization, application performance, and operational health.

Accessing CloudWatch

You can access CloudWatch using any of the following methods:

- **Amazon CloudWatch console** – https://console.aws.amazon.com/cloudwatch/
- **AWS CLI** – For more information, see Getting Set Up with the AWS Command Line Interface in the AWS Command Line Interface User Guide.
- **CloudWatch API** – For more information, see the Amazon CloudWatch API Reference.
- **AWS SDKs** – For more information, see Tools for Amazon Web Services.

Related AWS Services

The following services are used along with Amazon CloudWatch:

- **Amazon Simple Notification Service (Amazon SNS)** coordinates and manages the delivery or sending of messages to subscribing endpoints or clients. You use Amazon SNS with CloudWatch to send messages when an alarm threshold has been reached. For more information, see Setting Up Amazon SNS Notifications (p. 67).
- **Amazon EC2 Auto Scaling** enables you to automatically launch or terminate Amazon EC2 instances based on user-defined policies, health status checks, and schedules. You can use a CloudWatch alarm with Amazon EC2 Auto Scaling to scale your EC2 instances based on demand. For more information, see Dynamic Scaling in the Amazon EC2 Auto Scaling User Guide.
- **AWS CloudTrail** enables you to monitor the calls made to the Amazon CloudWatch API for your account, including calls made by the AWS Management Console, AWS CLI, and other services. When CloudTrail logging is turned on, CloudWatch writes log files to the Amazon S3 bucket that you specified when you configured CloudTrail. For more information, see Logging Amazon CloudWatch API Calls with AWS CloudTrail (p. 306).
- **AWS Identity and Access Management (IAM)** is a web service that helps you securely control access to AWS resources for your users. Use IAM to control who can use your AWS resources (authentication) and what resources they can use in which ways (authorization). For more information, see Authentication and Access Control for Amazon CloudWatch (p. 282).
Amazon CloudWatch is basically a metrics repository. An AWS service—such as Amazon EC2—puts metrics into the repository, and you retrieve statistics based on those metrics. If you put your own custom metrics into the repository, you can retrieve statistics on these metrics as well.

You can use metrics to calculate statistics and then present the data graphically in the CloudWatch console. For more information about the other AWS resources that generate and send metrics to CloudWatch, see AWS Services That Publish CloudWatch Metrics (p. 261).

You can configure alarm actions to stop, start, or terminate an Amazon EC2 instance when certain criteria are met. In addition, you can create alarms that initiate Amazon EC2 Auto Scaling and Amazon Simple Notification Service (Amazon SNS) actions on your behalf. For more information about creating CloudWatch alarms, see Alarms (p. 7).

AWS Cloud computing resources are housed in highly available data center facilities. To provide additional scalability and reliability, each data center facility is located in a specific geographical area, known as a Region. Each Region is designed to be completely isolated from the other Regions, to achieve the greatest possible failure isolation and stability. Amazon CloudWatch does not aggregate data across Regions. Therefore, metrics are completely separate between Regions. For more information, see Regions and Endpoints in the Amazon Web Services General Reference.

Amazon CloudWatch Concepts

The following terminology and concepts are central to your understanding and use of Amazon CloudWatch:

- Namespaces (p. 3)
- Metrics (p. 3)
Namespaces

A namespace is a container for CloudWatch metrics. Metrics in different namespaces are isolated from each other, so that metrics from different applications are not mistakenly aggregated into the same statistics.

There is no default namespace. You must specify a namespace for each data point you publish to CloudWatch. You can specify a namespace name when you create a metric. These names must contain valid XML characters, and be fewer than 256 characters in length. Possible characters are: alphanumeric characters (0-9A-Za-z), period (.), hyphen (-), underscore (_), forward slash (/), hash (#), and colon (:).

The AWS namespaces typically use the following naming convention: AWS/service. For example, Amazon EC2 uses the AWS/EC2 namespace. For the list of AWS namespaces, see AWS Services That Publish CloudWatch Metrics (p. 261).

Metrics

Metrics are the fundamental concept in CloudWatch. A metric represents a time-ordered set of data points that are published to CloudWatch. Think of a metric as a variable to monitor, and the data points as representing the values of that variable over time. For example, the CPU usage of a particular EC2 instance is one metric provided by Amazon EC2. The data points themselves can come from any application or business activity from which you collect data.

AWS services send metrics to CloudWatch, and you can send your own custom metrics to CloudWatch. You can add the data points in any order, and at any rate you choose. You can retrieve statistics about those data points as an ordered set of time-series data.

Metrics exist only in the Region in which they are created. Metrics cannot be deleted, but they automatically expire after 15 months if no new data is published to them. Data points older than 15 months expire on a rolling basis; as new data points come in, data older than 15 months is dropped.

Metrics are uniquely defined by a name, a namespace, and zero or more dimensions. Each data point in a metric has a time stamp, and (optionally) a unit of measure. You can retrieve statistics from CloudWatch for any metric.

For more information, see Viewing Available Metrics (p. 27) and Publishing Custom Metrics (p. 45).

Time Stamps

Each metric data point must be associated with a time stamp. The time stamp can be up to two weeks in the past and up to two hours into the future. If you do not provide a time stamp, CloudWatch creates a time stamp for you based on the time the data point was received.

Time stamps are dateTime objects, with the complete date plus hours, minutes, and seconds (for example, 2016-10-31T23:59:59Z). For more information, see dateTime. Although it is not required, we recommend that you use Coordinated Universal Time (UTC). When you retrieve statistics from CloudWatch, all times are in UTC.

CloudWatch alarms check metrics based on the current time in UTC. Custom metrics sent to CloudWatch with time stamps other than the current UTC time can cause alarms to display the Insufficient Data state or result in delayed alarms.
Metrics Retention

CloudWatch retains metric data as follows:

- Data points with a period of less than 60 seconds are available for 3 hours. These data points are high-resolution custom metrics.
- Data points with a period of 60 seconds (1 minute) are available for 15 days
- Data points with a period of 300 seconds (5 minute) are available for 63 days
- Data points with a period of 3600 seconds (1 hour) are available for 455 days (15 months)

Data points that are initially published with a shorter period are aggregated together for long-term storage. For example, if you collect data using a period of 1 minute, the data remains available for 15 days with 1-minute resolution. After 15 days this data is still available, but is aggregated and is retrievable only with a resolution of 5 minutes. After 63 days, the data is further aggregated and is available with a resolution of 1 hour.

CloudWatch started retaining 5-minute and 1-hour metric data as of 9 July 2016.

Dimensions

A dimension is a name/value pair that is part of the identity of a metric. You can assign up to 10 dimensions to a metric.

Every metric has specific characteristics that describe it, and you can think of dimensions as categories for those characteristics. Dimensions help you design a structure for your statistics plan. Because dimensions are part of the unique identifier for a metric, whenever you add a unique name/value pair to one of your metrics, you are creating a new variation of that metric.

AWS services that send data to CloudWatch attach dimensions to each metric. You can use dimensions to filter the results that CloudWatch returns. For example, you can get statistics for a specific EC2 instance by specifying the InstanceId dimension when you search for metrics.

For metrics produced by certain AWS services, such as Amazon EC2, CloudWatch can aggregate data across dimensions. For example, if you search for metrics in the AWS/EC2 namespace but do not specify any dimensions, CloudWatch aggregates all data for the specified metric to create the statistic that you requested. CloudWatch does not aggregate across dimensions for your custom metrics.

Dimension Combinations

CloudWatch treats each unique combination of dimensions as a separate metric, even if the metrics have the same metric name. You can only retrieve statistics using combinations of dimensions that you specifically published. When you retrieve statistics, specify the same values for the namespace, metric name, and dimension parameters that were used when the metrics were created. You can also specify the start and end times for CloudWatch to use for aggregation.

For example, suppose that you publish four distinct metrics named ServerStats in the DataCenterMetric namespace with the following properties:

| Dimensions: | Server=Prod, Domain=Frankfurt, Unit: Count, Timestamp: 2016-10-31T12:30:00Z, Value: 105 |
| Dimensions: | Server=Beta, Domain=Frankfurt, Unit: Count, Timestamp: 2016-10-31T12:31:00Z, Value: 115 |
| Dimensions: | Server=Prod, Domain=Rio, Unit: Count, Timestamp: 2016-10-31T12:32:00Z, Value: 95 |
| Dimensions: | Server=Beta, Domain=Rio, Unit: Count, Timestamp: 2016-10-31T12:33:00Z, Value: 97 |
If you publish only those four metrics, you can retrieve statistics for these combinations of dimensions:

- Server=Prod, Domain=Frankfurt
- Server=Prod, Domain=Rio
- Server=Beta, Domain=Frankfurt
- Server=Beta, Domain=Rio

You can't retrieve statistics for the following dimensions or if you specify no dimensions:

- Server=Prod
- Server=Beta
- Domain=Frankfurt
- Domain=Rio

**Statistics**

Statistics are metric data aggregations over specified periods of time. CloudWatch provides statistics based on the metric data points provided by your custom data or provided by other AWS services to CloudWatch. Aggregations are made using the namespace, metric name, dimensions, and the data point unit of measure, within the time period you specify. The following table describes the available statistics.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum</td>
<td>The lowest value observed during the specified period. You can use this value to determine low volumes of activity for your application.</td>
</tr>
<tr>
<td>Maximum</td>
<td>The highest value observed during the specified period. You can use this value to determine high volumes of activity for your application.</td>
</tr>
<tr>
<td>Sum</td>
<td>All values submitted for the matching metric added together. This statistic can be useful for determining the total volume of a metric.</td>
</tr>
<tr>
<td>Average</td>
<td>The value of ( \text{Sum} / \text{SampleCount} ) during the specified period. By comparing this statistic with the Minimum and Maximum, you can determine the full scope of a metric and how close the average use is to the Minimum and Maximum. This comparison helps you to know when to increase or decrease your resources as needed.</td>
</tr>
<tr>
<td>SampleCount</td>
<td>The count (number) of data points used for the statistical calculation.</td>
</tr>
<tr>
<td>pNN.NN</td>
<td>The value of the specified percentile. You can specify any percentile, using up to two decimal places (for example, p95.45). Percentile statistics are not available for metrics that include any negative values. For more information, see Percentiles (p. 7).</td>
</tr>
</tbody>
</table>

You can add pre-calculated statistics. Instead of data point values, you specify values for SampleCount, Minimum, Maximum, and Sum (CloudWatch calculates the average for you). The values you add in this way are aggregated with any other values associated with the matching metric.

**Units**

Each statistic has a unit of measure. Example units include Bytes, Seconds, Count, and Percent. For the complete list of the units that CloudWatch supports, see the MetricDatum data type in the Amazon CloudWatch API Reference.
You can specify a unit when you create a custom metric. If you do not specify a unit, CloudWatch uses None as the unit. Units help provide conceptual meaning to your data. Though CloudWatch attaches no significance to a unit internally, other applications can derive semantic information based on the unit.

Metric data points that specify a unit of measure are aggregated separately. When you get statistics without specifying a unit, CloudWatch aggregates all data points of the same unit together. If you have two otherwise identical metrics with different units, two separate data streams are returned, one for each unit.

**Periods**

A period is the length of time associated with a specific Amazon CloudWatch statistic. Each statistic represents an aggregation of the metrics data collected for a specified period of time. Periods are defined in numbers of seconds, and valid values for period are 1, 5, 10, 30, or any multiple of 60. For example, to specify a period of six minutes, use 360 as the period value. You can adjust how the data is aggregated by varying the length of the period. A period can be as short as one second or as long as one day (86,400 seconds). The default value is 60 seconds.

Only custom metrics that you define with a storage resolution of 1 second support sub-minute periods. Even though the option to set a period below 60 is always available in the console, you should select a period that aligns to how the metric is stored. For more information about metrics that support sub-minute periods, see High-Resolution Metrics (p. 45).

When you retrieve statistics, you can specify a period, start time, and end time. These parameters determine the overall length of time associated with the statistics. The default values for the start time and end time get you the last hour’s worth of statistics. The values that you specify for the start time and end time determine how many periods CloudWatch returns. For example, retrieving statistics using the default values for the period, start time, and end time returns an aggregated set of statistics for each minute of the previous hour. If you prefer statistics aggregated in ten-minute blocks, specify a period of 600. For statistics aggregated over the entire hour, specify a period of 3600.

When statistics are aggregated over a period of time, they are stamped with the time corresponding to the beginning of the period. For example, data aggregated from 7:00pm to 8:00pm is stamped as 7:00pm. Additionally, data aggregated between 7:00pm and 8:00pm begins to be visible at 7:00pm, then the values of that aggregated data may change as CloudWatch collects more samples during the period.

Periods are also important for CloudWatch alarms. When you create an alarm to monitor a specific metric, you are asking CloudWatch to compare that metric to the threshold value that you specified. You have extensive control over how CloudWatch makes that comparison. Not only can you specify the period over which the comparison is made, but you can also specify how many evaluation periods are used to arrive at a conclusion. For example, if you specify three evaluation periods, CloudWatch compares a window of three data points. CloudWatch only notifies you if the oldest data point is breaching and the others are breaching or missing. For metrics that are continuously emitted, CloudWatch doesn't notify you until three failures are found.

**Aggregation**

Amazon CloudWatch aggregates statistics according to the period length that you specify when retrieving statistics. You can publish as many data points as you want with the same or similar time stamps. CloudWatch aggregates them according to the specified period length. CloudWatch does not aggregate data across Regions.

You can publish data points for a metric that share not only the same time stamp, but also the same namespace and dimensions. CloudWatch returns aggregated statistics for those data points. You can also publish multiple data points for the same or different metrics, with any time stamp.

For large datasets, you can insert a pre-aggregated dataset called a statistic set. With statistic sets, you give CloudWatch the Min, Max, Sum, and SampleCount for a number of data points. This is commonly
used when you need to collect data many times in a minute. For example, suppose you have a metric for the request latency of a webpage. It doesn’t make sense to publish data with every webpage hit. We suggest that you collect the latency of all hits to that webpage, aggregate them once a minute, and send that statistic set to CloudWatch.

Amazon CloudWatch doesn’t differentiate the source of a metric. If you publish a metric with the same namespace and dimensions from different sources, CloudWatch treats this as a single metric. This can be useful for service metrics in a distributed, scaled system. For example, all the hosts in a web server application could publish identical metrics representing the latency of requests they are processing. CloudWatch treats these as a single metric, allowing you to get the statistics for minimum, maximum, average, and sum of all requests across your application.

Percentiles

A percentile indicates the relative standing of a value in a dataset. For example, the 95th percentile means that 95 percent of the data is lower than this value and 5 percent of the data is higher than this value. Percentiles help you get a better understanding of the distribution of your metric data.

Percentiles are often used to isolate anomalies. In a typical distribution, 95 percent of the data is within two standard deviations from the mean and 99.7 percent of the data is within three standard deviations from the mean. Any data that falls outside three standard deviations is often considered to be an anomaly because it differs so greatly from the average value. For example, suppose that you are monitoring the CPU utilization of your EC2 instances to ensure that your customers have a good experience. If you monitor the average, this can hide anomalies. If you monitor the maximum, a single anomaly can skew the results. Using percentiles, you can monitor the 95th percentile of CPU utilization to check for instances with an unusually heavy load.

Some CloudWatch metrics support percentiles as a statistic. For these metrics, you can monitor your system and applications using percentiles as you would when using the other CloudWatch statistics (Average, Minimum, Maximum, and Sum). For example, when you create an alarm, you can use percentiles as the statistical function. You can specify the percentile with up to two decimal places (for example, p95.45).

Percentile statistics are available for custom metrics as long as you publish the raw, unsummarized data points for your custom metric. Percentile statistics are not available for metrics when any of the metric values are negative numbers.

CloudWatch needs raw data points to calculate percentiles. If you publish data using a statistic set instead, you can only retrieve percentile statistics for this data if one of the following conditions is true:

- The SampleCount value of the statistic set is 1 and Min, Max, and Sum are all equal.
- The Min and Max are equal, and Sum is equal to Min multiplied by SampleCount.

Alarms

You can use an alarm to automatically initiate actions on your behalf. An alarm watches a single metric over a specified time period, and performs one or more specified actions, based on the value of the metric relative to a threshold over time. The action is a notification sent to an Amazon SNS topic or an Auto Scaling policy. You can also add alarms to dashboards.

Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods.

When creating an alarm, select a period that is greater than or equal to the frequency of the metric to be monitored. For example, basic monitoring for Amazon EC2 provides metrics for your instances every 5
minutes. When setting an alarm on a basic monitoring metric, select a period of at least 300 seconds (5 minutes). Detailed monitoring for Amazon EC2 provides metrics for your instances every 1 minute. When setting an alarm on a detailed monitoring metric, select a period of at least 60 seconds (1 minute).

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms. For more information about high-resolution metrics, see Publishing Custom Metrics (p. 45).

For more information, see Using Amazon CloudWatch Alarms (p. 62) and Creating an Alarm from a Metric on a Graph (p. 44).

Amazon CloudWatch Resources

The following related resources can help you as you work with this service.

<table>
<thead>
<tr>

Getting Set Up

To use Amazon CloudWatch you need an AWS account. Your AWS account allows you to use services (for example, Amazon EC2) to generate metrics that you can view in the CloudWatch console, a point-and-click web-based interface. In addition, you can install and configure the AWS command line interface (CLI).

Sign Up for Amazon Web Services (AWS)

When you create an AWS account, we automatically sign up your account for all AWS services. You pay only for the services that you use.

If you have an AWS account already, skip to the next step. If you don't have an AWS account, use the following procedure to create one.

To sign up for an AWS account

2. Follow the online instructions.
   
   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

Sign in to the Amazon CloudWatch Console

To sign in to the Amazon CloudWatch console

2. If necessary, use the navigation bar to change the region to the region where you have your AWS resources.
3. Even if this is the first time you are using the CloudWatch console, Your Metrics could already report metrics, because you have used a AWS product that automatically pushes metrics to Amazon CloudWatch for free. Other AWS products require that you enable metrics.

   If you do not have any alarms, the Your Alarms section will have a Create Alarm button.

Set Up the AWS CLI

You can use the AWS CLI or the Amazon CloudWatch CLI to perform CloudWatch commands. Note that the AWS CLI replaces the CloudWatch CLI; we include new CloudWatch features only in the AWS CLI.

For information about how to install and configure the AWS CLI, see Getting Set Up with the AWS Command Line Interface in the AWS Command Line Interface User Guide.

For information about how to install and configure the Amazon CloudWatch CLI, see Set Up the Command Line Interface in the Amazon CloudWatch CLI Reference.
Getting Started with Amazon CloudWatch

Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

The CloudWatch overview home page appears.
The overview displays the following items, refreshed automatically.

- The upper left shows a list of AWS services you use in your account, along with the state of alarms in those services. The upper right shows two or four alarms in your account, depending on how many AWS services you use. The alarms shown are those in the ALARM state or those that most recently changed state.

These upper areas enable you to assess the health of your AWS services, by seeing the alarm states in every service and the alarms that most recently changed state. This helps you monitor and quickly diagnose issues.

- Below these areas is the default dashboard, if one exists. The default dashboard is a custom dashboard that you have created and named CloudWatch-Default. This is a convenient way for you to add metrics about your own custom services or applications to the overview page, or to bring forward additional key metrics from AWS services that you most want to monitor.

- If you use six or more AWS services, below the default dashboard is a link to the automatic cross-service dashboard. The cross-service dashboard automatically displays key metrics from every AWS service you use, without requiring you to choose what metrics to monitor or create custom dashboards. You can also use it to drill down to any AWS service and see even more key metrics for that service.

If you use fewer than six AWS services, the cross-service dashboard is shown automatically on this page.

From this overview, you can focus your view to a specific resource group or a specific AWS service. This enables you to narrow your view to a subset of resources in which you are interested. Using resource groups enables you to use tags to organize projects, focus on a subset of your architecture, or just distinguish between your production and development environments. For more information, see What Is AWS Resource Groups?.

**Topics**

- See Key Metrics From All AWS Services (p. 12)
- Focus on Metrics and Alarms in a Single AWS Service (p. 14)
- Focus on Metrics and Alarms in a Resource Group (p. 15)

### See Key Metrics From All AWS Services

If you use six or more AWS services, the cross-service dashboard is not displayed on the overview page. You can switch to this dashboard to see key metrics from all the AWS services that you are using.

#### To open the cross service dashboard

   The overview appears.

2. Near the bottom of the page, choose View cross service dashboard.

   The cross-service dashboard appears, showing each AWS service you are using, displayed in alphabetical order. For each service, one or two key metrics are displayed.

3. You can focus on a particular service in two ways:

   a. To see more key metrics for a service, choose its name from the list at the top of the screen, where Cross service dashboard is currently shown. Or, you can choose View Service dashboard next to the service name.
An automatic dashboard for that service is displayed, showing more metrics for that service. Additionally, for some services, the bottom of the service dashboard displays resources related to that service. You can choose one of those resources to that service console and focus further on that resource.

b. To see all the alarms related to a service, choose the button on the right of the screen next to that service name. The text on this button indicates how many alarms you have created in this service, and whether any are in the ALARM state.

When the alarms are displayed, multiple alarms that have similar settings (such as dimensions, threshold, or period) may be shown in a single graph.

You can then view details about an alarm and see the alarm history. To do so, hover on the alarm graph, and choose the actions icon, **View in alarms**.

The alarms view appears in a new browser tab, displaying a list of your alarms, along with details about the chosen alarm. To see the history for this alarm, choose the **History** tab.

4. You can focus on resources in a particular resource group. To do so, choose the resource group from the list at the top of the page where **All resources** is displayed.

For more information, see [Focus on Metrics and Alarms in a Resource Group](p. 15).

5. To change the time range shown in all graphs and alarms currently displayed, select the range you want next to **Time range** at the top of the screen. Choose **custom** to select from more time range options than those displayed by default.

6. Alarms are always refreshed once a minute. To refresh the view, choose the refresh icon (two curved arrows) at the top right of the screen. To change the automatic refresh rate for items on the screen other than alarms, choose the down arrow next to the refresh icon and choose the refresh rate you want. You can also choose to turn off automatic refresh.

### Remove a Service from Appearing in the Cross Service Dashboard

You can prevent a service's metrics from appearing in the cross service dashboard. This helps you focus your cross service dashboard on the services you most want to monitor.

If you remove a service from the cross service dashboard, the alarms for that service still appear in the views of your alarms.

**To remove a service's metrics from the cross service dashboard**

   The home page appears.

2. At the top of the page, under **Overview**, choose the service you want to remove.

   The view changes to show metrics from only that service.

3. Choose **Actions**, then clear the check box next to **Show on cross service dashboard**.
Focus on Metrics and Alarms in a Single AWS Service

On the CloudWatch home page, you can focus the view to a single AWS service. You can drill down further by focusing on both a single AWS service and a resource group at the same time. The following procedure shows only how to focus on an AWS service.

To focus on a single service

   The home page appears.
2. Choose the service name from the list at the top of the screen, where Overview is currently shown.
   The view changes to display graphs of key metrics from the selected service.
3. To switch to viewing the alarms for this service, choose Alarms dashboard at the top of the screen where Service dashboard is currently displayed.
4. When viewing metrics, you can focus on a particular metric in several ways:
   a. To see more details about the metrics in any graph, hover on the graph, and choose the actions icon, View in metrics.
      The graph appears in a new tab, with the relevant metrics listed below the graph. You can customize your view of this graph, changing the metrics and resources shown, the statistic, the period, and other factors to get a better understanding of the current situation.
   b. You can view log events from the time range shown in the graph. This may help you discover events that happened in your infrastructure that are causing an unexpected change in your metrics.
      To see the log events, hover on the graph, and choose the actions icon, View in logs.
      The CloudWatch Logs view appears in a new tab, displaying a list of your log groups. To see the log events in one of these log groups that occurred during the time range shown in the original graph, choose that log group.
5. When viewing alarms, you can focus on a particular alarm in several ways:
   • To see more details about an alarm, hover on the alarm, and choose the actions icon, View in alarms.
      The alarms view appears in a new tab, displaying a list of your alarms, along with details about the chosen alarm. To see the history for this alarm, choose the History tab.
6. Alarms are always refreshed one time per minute. To refresh the view, choose the refresh icon (two curved arrows) at the top right of the screen. To change the automatic refresh rate for items on the screen other than alarms, choose the down arrow next to the refresh icon and choose a refresh rate. You can also choose to turn off automatic refresh.
7. To change the time range shown in all graphs and alarms currently displayed, next to Time range at the top of the screen, choose the range. To select from more time range options than those displayed by default, choose custom.
8. To return to the cross-service dashboard, choose Overview in the list at the top of the screen that currently shows the service you are focusing on.

   Alternatively, from any view, you can choose CloudWatch at the top of the screen to clear all filters and return to the overview page.
Focus on Metrics and Alarms in a Resource Group

You can focus your view to display metrics and alarms from a single resource group. Using resource groups enables you to use tags to organize projects, focus on a subset of your architecture, or distinguish between your production and development environments. They also enable you to focus on each of these resource groups on the CloudWatch overview. For more information, see What Is AWS Resource Groups?

When you focus on a resource group, the display changes to show only the services where you have tagged resources as part of this resource group. The recent alarms area shows only alarms related to the resource group. Additionally, if you have created a dashboard with the name CloudWatch-Default-ResourceGroupName, it is displayed in the Default dashboard area.

You can drill down further by focusing on both a single AWS service and a resource group at the same time. The following procedure shows just how to focus on a resource group.

To focus on a single resource group

2. At the top of the page, where All resources is displayed, choose a resource group.
3. To see more metrics related to this resource group, near the bottom of the screen, choose View cross service dashboard.

   The cross-service dashboard appears, showing only the services related to this resource group. For each service, one or two key metrics are displayed.
4. To change the time range shown in all graphs and alarms currently displayed, for Time range at the top of the screen, select a range. To select from more time range options than those displayed by default, choose custom.
5. Alarms are always refreshed one time per minute. To refresh the view, choose the refresh icon (two curved arrows) at the top right of the screen. To change the automatic refresh rate for items on the screen other than alarms, choose the down arrow next to the refresh icon and choose a refresh rate. You can also choose to turn off automatic refresh.
6. To return to showing information about all the resources in your account, near the top of the screen where the name of the resource group is currently displayed, choose All resources.
Amazon CloudWatch dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view, even those resources that are spread across different Regions. You can use CloudWatch dashboards to create customized views of the metrics and alarms for your AWS resources.

With dashboards, you can create the following:

• A single view for selected metrics and alarms to help you assess the health of your resources and applications across one or more regions. You can select the color used for each metric on each graph, so that you can easily track the same metric across multiple graphs.
• An operational playbook that provides guidance for team members during operational events about how to respond to specific incidents.
• A common view of critical resource and application measurements that can be shared by team members for faster communication flow during operational events.

You can create dashboards by using the console, the AWS CLI, or the PutDashboard API.

• Add a Dashboard to Your Favorites List (p. 24)
• Change the Period Override Setting or Refresh Interval for the CloudWatch Dashboard (p. 25)
• Change the Time Range or Time Zone Format of a CloudWatch Dashboard (p. 25)

Creating a CloudWatch Dashboard

To get started with CloudWatch dashboards, you must first create a dashboard. You can create multiple dashboards. There is no limit on the number of CloudWatch dashboards in your AWS account. All dashboards are global, not Region-specific.

The steps in this section are for creating a dashboard using the console. You can also create a dashboard with the PutDashboard API, which uses a JSON string to define the dashboard contents. To create a dashboard using PutDashboard and base this dashboard on an existing dashboard, choose Actions and
then view/edit source to display and copy the JSON string of a current dashboard to use for your new dashboard.

For more information about creating a dashboard using the API, see PutDashboard in the Amazon CloudWatch API Reference.

To create a dashboard using the console

2. In the navigation pane, choose Dashboards and then Create dashboard.
3. In the Create new dashboard dialog box, enter a name for the dashboard and choose Create dashboard.

If you use the name CloudWatch-Default, the dashboard appears on the overview on the CloudWatch home page. For more information, see Getting Started with Amazon CloudWatch (p. 10).

If you use resource groups and name the dashboard CloudWatch-Default-ResourceGroupName, it appears on the CloudWatch home page when you focus on that resource group.

4. Do one of the following in the Add to this dashboard dialog box:
   - To add a graph to your dashboard, choose Line or Stacked area and choose Configure. In the Add metric graph dialog box, select the metrics to graph and choose Create widget. If a specific metric doesn't appear in the dialog box because it hasn't published data in more than 14 days, you can add it manually. For more information, see Graph Metrics Manually on a CloudWatch Dashboard (p. 21).
   - To add a number displaying a metric to the dashboard, choose Number and then Configure. In the Add metric graph dialog box, select the metrics to graph and choose Create widget.
   - To add a text block to your dashboard, choose Text and then Configure. In the New text widget dialog box, for Markdown, add and format your text using Markdown. Choose Create widget.
5. Optionally, choose Add widget and repeat step 4 to add another widget to the dashboard. You can repeat this step multiple times.
6. Choose Save dashboard.

Add or Remove a Graph from a CloudWatch Dashboard

You can add graphs containing one or more metrics to your dashboard for the resources you monitor. You can remove the graphs when they're no longer needed.

To add a graph to a dashboard

2. In the navigation pane, choose Dashboards and select a dashboard.
3. Choose Add widget.
4. Choose either Line or Stacked area and choose Configure.
5. In the All metrics tab, select the metrics to graph. If a specific metric doesn't appear in the dialog box because it hasn't published data in more than 14 days, you can add it manually. For more information, see Graph Metrics Manually on a CloudWatch Dashboard (p. 21).
6. (Optional) As you choose metrics to graph, you can specify a dynamic label to appear on the graph legend for each metric. Dynamic labels display a statistic about the metric and automatically update when the dashboard or graph is refreshed. To add a dynamic label, choose Graphed metrics and then Dynamic labels.
By default, the dynamic values you add to the label appear at the beginning of the label. You can then choose the Label value for the metric to edit the label. For more information, see Using Dynamic Labels (p. 41).

7. (Optional) As you choose metrics to graph, you can change their color on the graph. To do so, choose Graphed metrics and select the color square next to the metric to display a color picker box. Choose another color square in the color picker. Click outside the color picker to see your new color on the graph. Alternatively, in the color picker, you can enter the six-digit standard HTML hex color code for the color you want and press ENTER.

8. (Optional) To view more information about the metric being graphed, hover over the legend.

9. (Optional) To change the widget type, hover over the title area of the graph and choose Widget actions, Widget type.

10. (Optional) To change the statistic used for a metric, choose Graphed metrics, Statistic, and select the statistic you want to use. For more information, see Statistics (p. 5).

11. (Optional) To change the time range shown on the graph, choose either custom at the top of the graph or one of the time periods to the left of custom.

12. (Optional) Horizontal annotations help dashboard users quickly see when a metric has spiked to a certain level, or whether the metric is within a predefined range. To add a horizontal annotation, choose Graph options, Add horizontal annotation:
   a. For Label, enter a label for the annotation.
   b. For Value, enter the metric value where the horizontal annotation appears.
   c. For Fill, specify whether to use fill shading with this annotation. For example, choose Above or Below for the corresponding area to be filled. If you specify Between, another Value field appears, and the area of the graph between the two values is filled.
   d. For Axis, specify whether the numbers in Value refer to the metric associated with the left y-axis or the right y-axis, if the graph includes multiple metrics.

   You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

   Repeat these steps to add multiple horizontal annotations to the same graph.

   To hide an annotation, clear the check box in the left column for that annotation.

   To delete an annotation, choose x in the Actions column.

13. (Optional) Vertical annotations help you mark milestones in a graph, such as operational events or the beginning and end of a deployment. To add a vertical annotation, choose Graph options, Add vertical annotation:
   a. For Label, enter a label for the annotation. To show only the date and time on the annotation, keep the Label field blank.
   b. For Date, specify the date and time where the vertical annotation appears.
   c. For Fill, specify whether to use fill shading before or after a vertical annotation or between two vertical annotations. For example, choose Before or After for the corresponding area to be filled. If you specify Between, another Date field appears, and the area of the graph between the two values is filled.

   Repeat these steps to add multiple vertical annotations to the same graph.

   To hide an annotation, clear the check box in the left column for that annotation.

   To delete an annotation, choose x in the Actions column.

14. Choose Create widget.
15. Choose Save dashboard.

To remove a graph from a dashboard

2. In the navigation pane, choose Dashboards and select a dashboard.
3. Hover over the title of the graph and choose Widget actions and then Delete.
4. Choose Save dashboard. If you attempt to navigate away from the dashboard before you save your changes, you’re prompted to either save or discard your changes.

Move or Resize a Graph on a CloudWatch Dashboard

You can arrange and resize graphs on your CloudWatch dashboard.

To move a graph on a dashboard

2. In the navigation pane, choose Dashboards and select a dashboard.
3. Hover over the title of the graph until the selection icon appears. Select and drag the graph to a new location on the dashboard.
4. Choose Save dashboard.

To resize a graph

2. In the navigation pane, choose Dashboards and select a dashboard.
3. To increase or decrease the size, hover over the graph and drag the lower right corner of the graph.
4. Choose Save dashboard.

To enlarge a graph temporarily

2. In the navigation pane, choose Dashboards and select a dashboard.
3. Select the graph. Alternatively, hover over the title of the graph and choose Widget actions, Enlarge.

Edit a Graph on a CloudWatch Dashboard

You can edit a graph to change the title, statistic, or period, or to add or remove metrics. If you have multiple metrics displayed on a graph, you can reduce the clutter by temporarily hiding the metrics that don’t interest you.

To edit a graph on a dashboard

2. In the navigation pane, choose **Dashboards** and select a dashboard.
3. Hover over the title of the graph and choose **Widget actions**, **Edit**.
4. To change the graph's title, select the title, enter a new title, and press ENTER.
5. To change the time range shown on the graph, choose either **custom** at the top of the graph, or one of the time periods to the left of **custom**.
6. To change the type of widget between separate lines on a graph, stacked lines on a graph, and a number, choose the box next to the right of **custom** and select either **Line**, **Stacked area**, or **Number**.
7. In the lower half of the screen, in the **Graphed metrics** tab, you can change the dynamic label, colors, statistic, or period corresponding to a metric:
   a. (Optional) To specify a dynamic label for a metric, choose **Dynamic labels**. Dynamic labels display a statistic about the metric, and automatically update when the dashboard or graph is refreshed.
      By default, the dynamic values you add to the label appear at the beginning of the label. You can then choose the **Label** value for the metric to edit the label. For more information, see **Using Dynamic Labels** (p. 41).
   b. To change the color of one of the lines, select the color square next to the metric to display a color picker box. Choose another color in the color picker, and click outside the color picker to see your new color on the graph. Alternatively, in the color picker, you can enter the six-digit HTML hex color code for the color you want and press ENTER.
   c. To change the statistic, choose **Statistic** in the lower half of the window, and choose the new statistic you want. For more information, see **Statistics** (p. 5).
   d. To change the time period, which is next to **Statistic** in the lower half of the window, choose **Period** and select another value. This new setting is used on the dashboard only if the period setting of the dashboard itself is set to **Auto**. Otherwise, the period setting of the dashboard overrides the period setting for individual widgets.
8. To add or edit horizontal annotations, choose **Graph options**:
   a. To add a horizontal annotation, choose **Add horizontal annotation**.
   b. For **Label**, enter a label for the annotation.
   c. For **Value**, enter the metric value where the horizontal annotation appears.
   d. For **Fill**, specify how to use fill shading with this annotation. For example, choose **Above** or **Below** for the corresponding area to be filled. If you specify **Between**, another **Value** field appears, and the area of the graph between the two values is filled.
      You can change the fill color of an annotation by choosing the color square in the left column of the annotation.
   e. For **Axis**, specify whether the numbers in **Value** refer to the metric associated with the left y-axis or the right y-axis, if the graph includes multiple metrics.
   Repeat these steps to add multiple horizontal annotations to the same graph.
   To hide an annotation, clear the check box in the left column for that annotation.
   To delete an annotation, choose the x in the **Actions** column.
9. To add or edit vertical annotations, choose **Graph options**: **Add vertical annotation**:
   a. To add a vertical annotation, choose **Add vertical annotation**.
   b. For **Label**, enter a label for the annotation. To show only the date and time on the annotation, keep the **Label** field blank.
   c. For **Date**, specify the date and time where the vertical annotation appears.
d. For Fill, specify whether to use fill shading before or after a vertical annotation, or between two vertical annotations. For example, choose Before or After for the corresponding area to be filled. If you specify Between, another Date field appears, and the area of the graph between the two values is filled.

Repeat these steps to add multiple vertical annotations to the same graph.

To hide an annotation, clear the check box in the left column for that annotation.

To delete an annotation, choose \( x \) in the Actions column.

10. To hide or change the position of the graph legend, hover over the title of the graph and choose Widget actions, Edit. Hover over Legend and choose Hidden, Bottom, or Right.

11. To customize the y-axis, choose Graph options. You can enter a custom label in Label under Left Y Axis. If the graph also displays values on the right y-axis, you can customize that label, too. You can also set minimums and maximums on the y-axis values, and the graph displays only the value range that you specify.

12. When you're finished with your changes, choose Update widget.

To temporarily hide metrics for a graph on a dashboard

2. In the navigation pane, choose Dashboards and select a dashboard.
3. In the graph's footer, hover over the colored square in the legend. When it changes to an \( X \), choose it.
4. To restore the metric, choose the grayed-out square and metric name.

Graph Metrics Manually on a CloudWatch Dashboard

If a metric hasn't published data in the past 14 days, you can't find it when searching for metrics to add to a graph on a CloudWatch dashboard. Use the following steps to add any metric manually to an existing graph.

To add a metric that you can't find in search to a graph

2. In the navigation pane, choose Dashboards and select a dashboard.
3. The dashboard must already contain a graph where you want to add the metric. If it doesn't, create the graph and add any metric to it. For more information, see Add or Remove a Graph from a CloudWatch Dashboard (p. 17).

A JSON block appears. The block specifies the widgets on the dashboard and their contents. The following is an example of one part of this block, which defines one graph.

```json
{
    "type": "metric",
    "x": 0,
    "y": 0,
}
```
In this example, the following section defines the metric shown on this graph.

```json
[ "AWS/EBS", "VolumeReadOps", "VolumeId", "vol-1234567890abcdef0" ]
```

5. Add a comma after the end bracket if there isn’t already one and then add a similar bracketed section after the comma. In this new section, specify the namespace, metric name, and any necessary dimensions of the metric that you’re adding to the graph. The following is an example.

```json
[ "AWS/EBS", "VolumeReadOps", "VolumeId", "vol-1234567890abcdef0" ],
[ "MyNamespace", "MyMetricName", "DimensionName", "DimensionValue" ]
```

For more information about the formatting of metrics in JSON, see Properties of a Metric Widget Object.

6. Choose Update.

### Rename a Graph on a CloudWatch Dashboard

You can change the default name that CloudWatch assigns to a graph on your dashboard.

**To rename a graph on a dashboard**

2. In the navigation pane, choose Dashboards and select a dashboard.
3. Hover over the title of the graph and choose Widget actions and Edit.
4. On the Edit graph screen, near the top, choose the title of the graph.
5. For Title, enter a new name and choose Ok (check mark). In the lower-right corner of the Edit graph screen, choose Update widget.

### Add or Remove a Text Widget from a CloudWatch Dashboard

A text widget contains a block of text in Markdown format. You can add, edit, or remove text widgets from your CloudWatch dashboard.

**To add a text widget to a dashboard**

2. In the navigation pane, choose Dashboards and select a dashboard.
3. Choose Add widget.
4. Choose Text and then Configure.
5. For Markdown, add and format your text using Markdown and choose Create widget.
6. Choose Save dashboard.

To edit a text widget on a dashboard
2. In the navigation pane, choose Dashboards and select a dashboard.
3. Hover over the upper-right corner of the text block and choose Widget actions and then Edit.
4. Update the text as needed and choose Update widget.
5. Choose Save dashboard.

To remove a text widget from a dashboard
2. In the navigation pane, choose Dashboards and select a dashboard.
3. Hover over the upper-right corner of the text block and choose Widget actions and then Delete.
4. Choose Save dashboard.

Add or Remove an Alarm from a CloudWatch Dashboard

You can add alarms that you have created to your dashboard. When an alarm is on a dashboard, it turns red when it's in the ALARM state.

To add an alarm to a dashboard
2. In the navigation pane, choose Alarms, select the alarm to add, and then choose Add to Dashboard.
3. Select a dashboard, choose a widget type (Line, Stacked area, or Number) and then choose Add to dashboard.
4. To see your alarm on the dashboard, choose Dashboards in the navigation pane and select the dashboard.
5. (Optional) To temporarily make an alarm graph larger, select the graph.
6. (Optional) To change the widget type, hover over the title of the graph and choose Widget actions and then Widget type.

To remove an alarm from a dashboard
2. In the navigation pane, choose Dashboards and select a dashboard.
3. Hover over the title of the graph and choose Widget actions and then Delete.
4. Choose Save dashboard. If you attempt to navigate away from the dashboard before you save your changes, you're prompted to either save or discard your changes.
Monitor Resources in Multiple Regions Using a CloudWatch Dashboard

You can monitor AWS resources in multiple Regions using a single CloudWatch dashboard. For example, you can create a dashboard that shows CPU utilization for an EC2 instance located in the `us-west-2` Region with your billing metrics, which are located in the `us-east-1` Region.

**To monitor resources in multiple Regions in one dashboard**

2. In the navigation pane, choose **Metrics**.
3. In the navigation bar, select a Region.
4. Select the metrics to add to your dashboard.
5. For **Actions**, choose **Add to dashboard**.
6. For **Add to**, enter a name for the new dashboard and choose **Add to dashboard**.

   Alternatively, to add to an existing dashboard, choose **Existing dashboard**, select a dashboard, and then choose **Add to dashboard**.
7. To add metrics from another Region, select the next Region and repeat these steps.
8. Choose **Save dashboard**.

Link and Unlink Graphs on a CloudWatch Dashboard

You can link the graphs on your dashboard together, so that when you zoom in or zoom out on one graph, the other graphs zoom in or zoom out at the same time. You can unlink graphs to limit zoom to one graph.

**To link the graphs on a dashboard**

2. In the navigation pane, choose **Dashboards** and select a dashboard.
3. Choose **Actions** and then **Link graphs**.

**To unlink the graphs on a dashboard**

2. In the navigation pane, choose **Dashboards** and select a dashboard.
3. Clear **Actions** and then **Link graphs**.

Add a Dashboard to Your Favorites List

You can add a CloudWatch dashboard to a list of favorite dashboards to help you find it quickly. The **Favorites** list appears at the bottom of the navigation pane.

**To add a dashboard to the Favorites list**

2. In the navigation pane, choose **Dashboards**.
3. Select the star symbol next to the dashboard to add it.

### Change the Period Override Setting or Refresh Interval for the CloudWatch Dashboard

You can specify how the period setting of graphs added to this dashboard are retained or modified.

#### To change the period override options

2. Choose **Actions**.
3. Under **Period override**, choose one of the following:
   
   - Choose **Auto** to have the period of the metrics on each graph automatically adapt to the dashboard's time range.
   - Choose **Do not override** to ensure that the period setting of each graph is always obeyed.
   - Choose one of the other options to cause graphs added to the dashboard to always adapt that chosen time as their period setting.

   The **Period override** always reverts to **Auto** when the dashboard is closed or the browser is refreshed. Different settings for **Period override** can't be saved.

You can change how often the data on your CloudWatch dashboard is refreshed or set it to automatically refresh.

#### To change the dashboard refresh interval

2. In the navigation pane, choose **Dashboards** and select a dashboard.
3. On the **Refresh options** menu (upper-right corner), choose **10 Seconds**, **1 Minute**, **2 Minutes**, **5 Minutes**, or **15 Minutes**.

**To automatically refresh the dashboard**

2. In the navigation pane, choose **Dashboards** and select a dashboard.
3. Choose **Refresh options** and then **Auto refresh**.

### Change the Time Range or Time Zone Format of a CloudWatch Dashboard

You can change the time range to display dashboard data over minutes, hours, days, or weeks. You can also change the time format to display dashboard data in UTC or local time.

**Note**

If you create a dashboard with graphs that contain close to 100 or more high-resolution metrics, we recommend that you set the time range to no longer than one hour to ensure
good dashboard performance. For more information about high-resolution metrics, see High-Resolution Metrics (p. 45).

To change the dashboard time range

2. In the navigation pane, choose Dashboards and select a dashboard.
3. Do one of the following:
   - Select one of the predefined ranges shown, which span from 1 hour to 1 week: 1h, 3h, 12h, 1d, 3d, or 1w.
   - Choose custom and then Relative. Select one of the predefined ranges, which span from 1 minute to 15 months.
   - Choose custom and then Absolute. Use the calendar picker or the text fields to specify the time range.

Note
When you change the time range of a graph while the aggregation period is set to Auto, CloudWatch might change the period. To manually set the period, choose Actions and select a new value for Period:

To change the dashboard time format

2. In the navigation pane, choose Dashboards and select a dashboard.
3. Choose custom.
4. From the upper corner, choose UTC or Local timezone.
Using Amazon CloudWatch Metrics

Metrics are data about the performance of your systems. By default, several services provide free metrics for resources (such as Amazon EC2 instances, Amazon EBS volumes, and Amazon RDS DB instances). You can also enable detailed monitoring some resources, such as your Amazon EC2 instances, or publish your own application metrics. Amazon CloudWatch can load all the metrics in your account (both AWS resource metrics and application metrics that you provide) for search, graphing, and alarms.

Metric data is kept for 15 months, enabling you to view both up-to-the-minute data and historical data.

Contents
• Viewing Available Metrics (p. 27)
• Searching for Available Metrics (p. 30)
• Getting Statistics for a Metric (p. 31)
• Graphing Metrics (p. 38)
• Publishing Custom Metrics (p. 45)
• Using Metric Math (p. 47)
• Using Search Expressions in Graphs (p. 53)

Viewing Available Metrics

Metrics are grouped first by namespace, and then by the various dimension combinations within each namespace. For example, you can view all EC2 metrics, EC2 metrics grouped by instance, or EC2 metrics grouped by Auto Scaling group.

Only the AWS services that you're using send metrics to Amazon CloudWatch.

To view available metrics by namespace and dimension using the console

2. In the navigation pane, choose Metrics.
3. Select a metric namespace (for example, EC2).
4. Select a metric dimension (for example, **Per-Instance Metrics**).

   ![Per-Instance Metrics](image)

5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:

   a. To sort the table, use the column heading.
   b. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.
   c. To filter by resource, choose the resource ID and then choose **Add to search**.
   d. To filter by metric, choose the metric name and then choose **Add to search**.

   ![Filtering Metrics](image)

**To view available metrics by namespace, dimension, or metric using the AWS CLI**

Use the **list-metrics** command to list CloudWatch metrics. For a list of the namespaces, metrics, and dimensions for all services that publish metrics, see [AWS Services That Publish CloudWatch Metrics](p. 261).

The following example specifies the **AWS/EC2** namespace to view all the metrics for Amazon EC2.

28
aws cloudwatch list-metrics --namespace AWS/EC2

The following is example output.

```
{
   "Metrics" : [ ...
   {
      "Namespace": "AWS/EC2",
      "Dimensions" : [ 
         {
            "Name": "InstanceId",
            "Value": "i-1234567890abcdef0"
         }
      ],
      "MetricName": "NetworkOut"
   },
   {
      "Namespace": "AWS/EC2",
      "Dimensions" : [ 
         {
            "Name": "InstanceId",
            "Value": "i-1234567890abcdef0"
         }
      ],
      "MetricName": "CPUUtilization"
   },
   {
      "Namespace": "AWS/EC2",
      "Dimensions" : [ 
         {
            "Name": "InstanceId",
            "Value": "i-1234567890abcdef0"
         }
      ],
      "MetricName": "NetworkIn"
   },
   ...
}
```

To list all the available metrics for a specified resource

The following example specifies the AWS/EC2 namespace and the InstanceId dimension to view the results for the specified instance only.

```
aws cloudwatch list-metrics --namespace AWS/EC2 --dimensions
Name=InstanceId,Value=i-1234567890abcdef0
```

To list a metric for all resources

The following example specifies the AWS/EC2 namespace and a metric name to view the results for the specified metric only.

```
aws cloudwatch list-metrics --namespace AWS/EC2 --metric-name CPUUtilization
```
Searching for Available Metrics

You can search within all of the metrics in your account using targeted search terms. Metrics are returned that have matching results within their namespace, metric name, or dimensions.

To search for available metrics in CloudWatch

2. In the navigation pane, choose Metrics.
3. In the search field on the All metrics tab, enter a search term, such as a metric name, namespace, dimension name or value, or resource name. This shows you all of the namespaces with metrics with this search term.

   For example, if you search for volume, this shows the namespaces that contain metrics with this term in their name.

   For more information on search, see Using Search Expressions in Graphs (p. 53)
4. To graph all the search results, choose Graph search

   or

   Select a namespace to view the metrics from that namespace. You can then do the following:

   a. To graph one or more metrics, select the check box next to each metric. To select all metrics, select the check box in the heading row of the table.
   b. To refine your search, hover over a metric name and choose Add to search or Search for this only.
   c. To view one of the resources on its console, choose the resource ID and then choose Jump to resource.
   d. To view help for a metric, select the metric name and choose What is this?

   The selected metrics appear on the graph.

5. (Optional) Select one of the buttons in the search bar to edit that part of the search term.
Getting Statistics for a Metric

The following examples show you how to get statistics for the CloudWatch metrics for your resources, such as your EC2 instances.

Examples

- Getting Statistics for a Specific Resource (p. 31)
- Aggregating Statistics Across Resources (p. 34)
- Aggregating Statistics by Auto Scaling Group (p. 35)
- Aggregating Statistics by Amazon Machine Image (AMI) (p. 37)

Getting Statistics for a Specific Resource

The following example shows you how to determine the maximum CPU utilization of a specific EC2 instance.

Requirements

- You must have the ID of the instance. You can get the instance ID using the Amazon EC2 console or the describe-instances command.
- By default, basic monitoring is enabled, but you can enable detailed monitoring. For more information, see Enable or Disable Detailed Monitoring for Your Instances in the Amazon EC2 User Guide for Linux Instances.

To display the average CPU utilization for a specific instance using the console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/
2. In the navigation pane, choose Metrics.
3. Select the EC2 metric namespace.
4. Select the Per-Instance Metrics dimension.
5. In the search field, enter **CPUUtilization** and press Enter. Select the row for the specific instance, which displays a graph for the CPUUtilization metric for the instance. To change the name of the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose **custom**.

6. To change the statistic, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, $p95.45$).
7. To change the period, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

**To get the CPU utilization per EC2 instance using the AWS CLI**

Use the `get-metric-statistics` command as follows to get the `CPUUtilization` metric for the specified instance.

```bash
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization --dimensions Name=InstanceId,Value=i-1234567890abcdef0 --statistics Maximum --start-time 2016-10-18T23:18:00 --end-time 2016-10-19T23:18:00 --period 360
```

The returned statistics are 6-minute values for the requested 24-hour time interval. Each value represents the maximum CPU utilization percentage for the specified instance for a particular 6-minute time period. The data points aren't returned in chronological order. The following shows the beginning of the example output (the full output includes data points for every 6 minutes of the 24-hour period).

```json
{
  "Datapoints": [
    {
      "Timestamp": "2016-10-19T00:18:00Z",
      "Maximum": 0.33000000000000002,
      "Unit": "Percent"
    },
    {
      "Timestamp": "2016-10-19T03:18:00Z",
      "Maximum": 99.670000000000002,
      "Unit": "Percent"
    },
    {
      "Timestamp": "2016-10-19T07:18:00Z",
      "Maximum": 0.34000000000000002,
      "Unit": "Percent"
    },
    ...
  ],
  "Label": "CPUUtilization"
}
```
Aggregating Statistics Across Resources

You can aggregate the metrics for AWS resources across multiple resources. Amazon CloudWatch can't aggregate data across Regions. Metrics are completely separate between Regions.

For example, you can aggregate statistics for your EC2 instances that have detailed monitoring enabled. Instances that use basic monitoring aren't included. Therefore, you must enable detailed monitoring (at an additional charge), which provides data in 1-minute periods. For more information, see Enable or Disable Detailed Monitoring for Your Instances in the Amazon EC2 User Guide for Linux Instances.

This example shows you how to get the average CPU usage for your EC2 instances. Because no dimension is specified, CloudWatch returns statistics for all dimensions in the AWS/EC2 namespace. To get statistics for other metrics, see AWS Services That Publish CloudWatch Metrics (p. 261).

Important
This technique for retrieving all dimensions across an AWS namespace doesn't work for custom namespaces that you publish to CloudWatch. With custom namespaces, you must specify the complete set of dimensions that are associated with any given data point to retrieve statistics that include the data point.

To display average CPU utilization for your EC2 instances

2. In the navigation pane, choose Metrics.
3. Choose the EC2 namespace and choose Across All Instances.
4. Select the row that contains CPUUtilization, which displays a graph for the metric for all your EC2 instances. To change the name of the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose custom.

5. To change the statistic, choose the Graphed metrics tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, p95.45).
To get average CPU utilization across your EC2 instances using the AWS CLI

Use the `get-metric-statistics` command as follows:

```bash
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization --statistics "Average" "SampleCount" --start-time 2016-10-11T23:18:00 --end-time 2016-10-12T23:18:00 --period 3600
```

The following is example output:

```json
{
    "Datapoints": [
        {
            "SampleCount": 238.0,
            "Timestamp": "2016-10-12T07:18:00Z",
            "Average": 0.038235294117647062,
            "Unit": "Percent"
        },
        {
            "SampleCount": 240.0,
            "Timestamp": "2016-10-12T09:18:00Z",
            "Average": 0.16670833333333332,
            "Unit": "Percent"
        },
        {
            "SampleCount": 238.0,
            "Timestamp": "2016-10-11T23:18:00Z",
            "Average": 0.041596638655462197,
            "Unit": "Percent"
        },
        ...
    ],
    "Label": "CPUUtilization"
}
```

Aggregating Statistics by Auto Scaling Group

You can aggregate statistics for the EC2 instances in an Auto Scaling group. Amazon CloudWatch can't aggregate data across Regions. Metrics are completely separate between Regions.

This example shows you how to get the total bytes written to disk for one Auto Scaling group. The total is computed for 1-minute periods for a 24-hour interval across all EC2 instances in the specified Auto Scaling group.

To display DiskWriteBytes for the instances in an Auto Scaling group using the console

2. In the navigation pane, choose Metrics.
3. Choose the EC2 namespace and then choose By Auto Scaling Group.
4. Select the row for the DiskWriteBytes metric and the specific Auto Scaling group, which displays a graph for the metric for the instances in the Auto Scaling group. To change the name of the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose custom.
5. To change the statistic, choose the Graphed metrics tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, \texttt{p95.45}).

6. To change the period, choose the Graphed metrics tab. Choose the column heading or an individual value and then choose a different value.

**To get DiskWriteBytes for the instances in an Auto Scaling group using the AWS CLI**

Use the \texttt{get-metric-statistics} command as follows.

```bash
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name DiskWriteBytes --dimensions Name=AutoScalingGroupName,Value=my-asg --statistics "Sum" "SampleCount" --start-time 2016-10-16T23:18:00 --end-time 2016-10-18T23:18:00 --period 360
```

The following is example output.

```json
{
    "Datapoints": [
        {
            "SampleCount": 18.0,
            "Timestamp": "2016-10-19T21:36:00Z",
            "Sum": 0.0,
            "Unit": "Bytes"
        },
        {
            "SampleCount": 5.0,
            "Timestamp": "2016-10-19T21:42:00Z",
            "Sum": 0.0,
            "Unit": "Bytes"
        }
    ],
    "Label": "DiskWriteBytes"
}
```
Aggregating Statistics by Amazon Machine Image (AMI)

You can aggregate statistics for the EC2 instances that have detailed monitoring enabled. Instances that use basic monitoring aren't included. For more information, see Enable or Disable Detailed Monitoring for Your Instances in the Amazon EC2 User Guide for Linux Instances.

This example shows you how to determine average CPU utilization for all instances that use the specified AMI. The average is over 60-second time intervals for a one-day period.

To display the average CPU utilization by AMI using the console

2. In the navigation pane, choose Metrics.
3. Choose the EC2 namespace and then choose By Image (AMI) Id.
4. Select the row for the CPUUtilization metric and the specific AMI, which displays a graph for the metric for the specified AMI. To change the name of the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose custom.
5. To change the statistic, choose the Graphed metrics tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, p95.45).
6. To change the period, choose the Graphed metrics tab. Choose the column heading or an individual value and then choose a different value.

To get the average CPU utilization by AMI using the AWS CLI

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization \   --dimensions Name=ImageId,Value=ami-3c47a355 --statistics Average \   --start-time 2016-10-10T00:00:00 --end-time 2016-10-11T00:00:00 --period 3600
```

The operation returns statistics that are one-hour values for the one-day interval. Each value represents an average CPU utilization percentage for EC2 instances running the specified AMI. The following is example output.
Graphing Metrics

You can use the CloudWatch console to graph metric data generated by other AWS services to make it easier to see the metric activity on your services. You can use the following procedures to graph metrics in CloudWatch.

Contents

- Graphing a Metric (p. 38)
- Using Dynamic Labels (p. 41)
- Modifying the Time Range or Time Zone Format for a Graph (p. 42)
- Modifying the Y-Axis for a Graph (p. 43)
- Creating an Alarm from a Metric on a Graph (p. 44)

Graphing a Metric

You can select metrics and create graphs of the data using the CloudWatch console.

CloudWatch supports the following statistics on metrics: Average, Minimum, Maximum, Sum, and SampleCount. For more information, see Statistics (p. 5).

You can view your data at different granularities. For example, you can choose a detailed view (for example, 1 minute), which can be useful when troubleshooting. You can choose a less detailed view (for example, 1 hour), which can be useful when viewing a broader time range (for example, 3 days) so that you can see trends over time. For more information, see Periods (p. 6).

Creating a Graph

To graph a metric

2. In the navigation pane, choose Metrics.
3. On the All metrics tab, enter a search term in the search field, such as a metric name or resource name, and press Enter.
For example, if you search for the CPUUtilization metric, you see the namespaces and dimensions with this metric.

4. Select one of the results for your search to view the metrics.

5. To graph one or more metrics, select the check box next to each metric. To select all metrics, select the check box in the heading row of the table.

6. (Optional) To add a band that shows expected values for the metric, choose the anomaly detection icon under **Actions** next to the metric.

CloudWatch uses up to two weeks of the metric's recent historical data to calculate a model for expected values, then displays this range of expected values as a band on the graph. CloudWatch adds a new row under the metric to display the anomaly detection band math expression, labeled **ANOMALY_DETECTION_BAND**. When you enable anomaly detection, you can immediately see a preview anomaly detection band which is an approximation of the anomaly detection band generated by the model. It takes up to 15 minutes for the actual anomaly detection band to appear.

By default, CloudWatch creates the upper and lower bounds of the band of expected values with a default value of two standard deviations. To change this number, change the value at the end of the formula under **Details** for the band.

- (Optional) You can also choose **Edit model** to change how the anomaly detection model is calculated. You can exclude past time periods from being used in the training for calculating the model, and specify the time zone to use for the model to accurately model fluctuations that depend on the time of day.

For more information, see CloudWatch Anomaly Detection (p. 92).
To hide the model from the graph, uncheck the line with the `ANOMALY_DETECTION_BAND` function or choose the x icon. To delete the model entirely, choose Edit model and then choose Delete model.

7. (Optional) As you choose metrics to graph, you can specify a dynamic label to appear on the graph legend for each metric. Dynamic labels display a statistic about the metric and automatically update when the dashboard or graph is refreshed. To add a dynamic label, choose Graphed metrics and then Dynamic labels.

   By default, the dynamic values you add to the label appear at the beginning of the label. You can then click the Label value for the metric to edit the label. For more information, see Using Dynamic Labels (p. 41).

8. To view more information about the metric being graphed, hover over the legend.

9. Horizontal annotations can help graph users quickly see when a metric has spiked to a certain level, or whether the metric is within a predefined range. To add a horizontal annotation, choose Graph options and then Add horizontal annotation:

   a. For Label, enter a label for the annotation.
   b. For Value, enter the metric value where the horizontal annotation appears.
   c. For Fill, specify whether to use fill shading with this annotation. For example, choose Above or Below for the corresponding area to be filled. If you specify Between, another Value field appears, and the area of the graph between the two values is filled.
   d. For Axis, specify whether the numbers in Value refer to the metric associated with the left Y-axis or the right Y-axis, if the graph includes multiple metrics.

   You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

   Repeat these steps to add multiple horizontal annotations to the same graph.

   To hide an annotation, clear the check box in the left column for that annotation.

   To delete an annotation, choose x in the Actions column.

10. To get a URL for your graph, choose Actions, Share. Copy the URL and save it or share it.

11. To add your graph to a dashboard, choose Actions, Add to dashboard.

## Updating a Graph

### To update your graph

1. To change the name of the graph, choose the pencil icon.
2. To change the time range, select one of the predefined values or choose **custom**. For more information, see Modifying the Time Range or Time Zone Format for a Graph (p. 42).
3. To change the statistic, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, `p95.45`).
4. To change the period, choose the **Graphed metrics** tab. Choose the column heading or an individual value and then choose a different value.
5. To add a horizontal annotation, choose **Graph options** and then Add horizontal annotation:

   a. For **Label**, enter a label for the annotation.
   b. For **Value**, enter the metric value where the horizontal annotation appears.
c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose **Above** or **Below** for the corresponding area to be filled. If you specify **Between**, another **Value** field appears, and the area of the graph between the two values is filled.

d. For **Axis**, specify whether the numbers in **Value** refer to the metric associated with the left y-axis or the right y-axis, if the graph includes multiple metrics.

You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

Repeat these steps to add multiple horizontal annotations to the same graph.

To hide an annotation, clear the check box in the left column for that annotation.

To delete an annotation, choose x in the **Actions** column.

6. To change the refresh interval, choose **Refresh options** and then select **Auto refresh** or choose **1 Minute**, **2 Minutes**, **5 Minutes**, or **15 Minutes**.

**Duplicating a Metric**

**To duplicate a metric**

1. Choose the **Graphed metrics** tab.
2. For **Actions**, choose the **Duplicate** icon.

3. Update the duplicate metric as needed.

**Using Dynamic Labels**

You can use dynamic labels with your graphs. Dynamic labels add a dynamically updated value to the label for the selected metric. The values displayed can include the average, maximum, minimum, sum, or the most recent data point. The dynamic value shown in the label is derived from the time range currently shown on the graph. This part of the label automatically updates when either the dashboard or the graph is refreshed.

If you use a dynamic label with a search expression, the dynamic label applies to every metric returned by the search.

The CloudWatch console makes it easy for you to add a dynamic value to a label. You can then further edit the label, to change the position of the dynamic value within the label or make other customizations.

**Dynamic Label Syntax**

Within a dynamic label, the dynamic values can include the following:
### Variable | Description
--- | ---
${AVG}$ | The average of the values in the time range currently shown in the graph.
${LAST}$ | The most recent of the values in the time range currently shown in the graph.
${LABEL}$ | Represents the default label for a metric
${MAX}$ | The maximum of the values in the time range currently shown in the graph.
${MIN}$ | The minimum of the values in the time range currently shown in the graph.
${SUM}$ | The sum of the values in the time range currently shown in the graph.

For example, suppose you have a search expression `SEARCH({AWS/Lambda, FunctionName} Errors ', 'Sum', 300)`, which finds the Errors for each of your Lambda functions. If you set the label to be `[max: ${MAX} Errors for Function Name ${LABEL}]`, the label for each metric is `[max: number Errors for Function Name Name]`.

You can add up to five dynamic statistical values to a label. You can use the ${LABEL}$ placeholder only once within each label.

### Modifying the Time Range or Time Zone Format for a Graph

You can change the time range or the time zone format of a graph.

#### Setting a Relative Time Range

You can set a relative time range for your graph.

**To specify a relative time range for a graph**

2. In the navigation pane, choose **Metrics**.
3. Select one of the predefined ranges shown at the top of the page, which span from 1 hour to 1 week ago.
4. For more predefined ranges, choose the **custom** menu and then choose **Relative**. Select one of the predefined ranges, which span from 5 minutes to 15 months ago.

#### Setting an Absolute Time Range

You can set an absolute time range for your graph.

**To specify an absolute time range for a graph**

2. In the navigation pane, choose **Metrics**.
3. Choose the **custom** menu and then choose **Absolute**. Use the calendar picker or the text fields to specify the time range.

### Setting the Time Zone Format

You can specify whether the graph uses UTC time or your local time.

**To specify the time zone for a graph**

2. In the navigation pane, choose **Metrics**.
3. Choose the **custom** menu and then choose **UTC** or **Local timezone**.

### Zooming In on a Graph

You can change the granularity of a graph and zoom in to see data over a shorter time period.

**To zoom in on a graph**

2. In the navigation pane, choose **Metrics**.
3. Choose and drag on the graph area and then release the drag.
4. To reset a zoomed-in graph, choose the **Reset zoom** icon.

### Modifying the Y-Axis for a Graph

You can set custom bounds for the -y-axis on a graph to help you see the data better. For example, you can change the bounds on a **CPUUtilization** graph to 100 percent so that it's easy to see whether the CPU is low (the plotted line is near the bottom of the graph) or high (the plotted line is near the top of the graph).

You can switch between two different y-axes for your graph. This is useful if the graph contains metrics that have different units or that differ greatly in their range of values.

**To modify the y-axis on a graph**

2. In the navigation pane, choose **Metrics**.
3. Select a metric namespace (for example, **EC2**) and then a metric dimension (for example, **Per-Instance Metrics**).
4. The **All metrics** tab displays all metrics for that dimension in that namespace. To graph a metric, select the check box next to the metric.
5. On the **Graph options** tab, specify the **Min** and **Max** values for **Left Y Axis**. The value of **Min** can't be greater than the value of **Max**.
Creating an Alarm from a Metric on a Graph

You can graph a metric and then create an alarm from the metric on the graph, which has the benefit of populating many of the alarm fields for you.

**To create an alarm from a metric on a graph**

2. In the navigation pane, choose **Metrics**.
3. Select a metric namespace (for example, **EC2**) and then a metric dimension (for example, **Per-Instance Metrics**).
4. The **All metrics** tab displays all metrics for that dimension in that namespace. To graph a metric, select the check box next to the metric.
5. To create an alarm for the metric, choose the **Graphed metrics** tab. For **Actions**, choose the alarm icon.
6. Under **Alarm Threshold**, enter a unique name for the alarm and a description of the alarm. For **Whenever**, specify a threshold and the number of periods.
7. Under **Actions**, select the type of action to have the alarm perform when the alarm is triggered.
8. (Optional) For **Period**, choose a different value. For **Statistic**, choose **Standard** to specify one of the statistics in the list or choose **Custom** to specify a percentile (for example, **p95.45**).
9. Choose Create Alarm.

Publishing Custom Metrics

You can publish your own metrics to CloudWatch using the AWS CLI or an API. You can view statistical graphs of your published metrics with the AWS Management Console.

CloudWatch stores data about a metric as a series of data points. Each data point has an associated time stamp. You can even publish an aggregated set of data points called a statistic set.

Topics
- High-Resolution Metrics (p. 45)
- Using Dimensions (p. 45)
- Publishing Single Data Points (p. 46)
- Publishing Statistic Sets (p. 47)
- Publishing the Value Zero (p. 47)

High-Resolution Metrics

Each metric is one of the following:
- Standard resolution, with data having a one-minute granularity
- High resolution, with data at a granularity of one second

Metrics produced by AWS services are standard resolution by default. When you publish a custom metric, you can define it as either standard resolution or high resolution. When you publish a high-resolution metric, CloudWatch stores it with a resolution of 1 second, and you can read and retrieve it with a period of 1 second, 5 seconds, 10 seconds, 30 seconds, or any multiple of 60 seconds.

High-resolution metrics can give you more immediate insight into your application's sub-minute activity. Keep in mind that every PutMetricData call for a custom metric is charged, so calling PutMetricData more often on a high-resolution metric can lead to higher charges. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms with a period of 10 or 30 seconds.

Using Dimensions

In custom metrics, the --dimensions parameter is common. A dimension further clarifies what the metric is and what data it stores. You can have up to 10 dimensions in one metric, and each dimension is defined by a name and value pair.

How you specify a dimension is different when you use different commands. With put-metric-data, you specify each dimension as MyName=MyValue, and with get-metric-statistics or put-metric-alarm you use
Publishing Single Data Points

To publish a single data point for a new or existing metric, use the `put-metric-data` command with one value and time stamp. For example, the following actions each publish one data point.

```plaintext
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService --value 2 --timestamp 2016-10-20T12:00:00.000Z
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService --value 4 --timestamp 2016-10-20T12:00:01.000Z
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService --value 5 --timestamp 2016-10-20T12:00:02.000Z
```

If you call this command with a new metric name, CloudWatch creates a metric for you. Otherwise, CloudWatch associates your data with the existing metric that you specified.

**Note**

When you create a metric, it can take up to 2 minutes before you can retrieve statistics for the new metric using the `get-metric-statistics` command. However, it can take up to 15 minutes before the new metric appears in the list of metrics retrieved using the `list-metrics` command.

Although you can publish data points with time stamps as granular as one-thousandth of a second, CloudWatch aggregates the data to a minimum granularity of 1 second. CloudWatch records the average (sum of all items divided by number of items) of the values received for each period, as well as the number of samples, maximum value, and minimum value for the same time period. For example, the `PageViewCount` metric from the previous examples contains three data points with time stamps just seconds apart. If you have your period set to 1 minute, CloudWatch aggregates the three data points because they all have time stamps within a 1-minute period.

You can use the `get-metric-statistics` command to retrieve statistics based on the data points that you published.
Publishing Statistic Sets

You can aggregate your data before you publish to CloudWatch. When you have multiple data points per minute, aggregating data minimizes the number of calls to `put-metric-data`. For example, instead of calling `put-metric-data` multiple times for three data points that are within 3 seconds of each other, you can aggregate the data into a statistic set that you publish with one call, using the `--statistic-values` parameter.

```
aws cloudwatch put-metric-data --metric-name PageViewCount --namespace MyService
  --statistic-values Sum=11,Minimum=2,Maximum=5,SampleCount=3 --timestamp 2016-10-14T12:00:00.000Z
```

CloudWatch needs raw data points to calculate percentiles. If you publish data using a statistic set instead, you can't retrieve percentile statistics for this data unless one of the following conditions is true:

- The `SampleCount` of the statistic set is 1
- The `Minimum` and the `Maximum` of the statistic set are equal

Publishing the Value Zero

When your data is more sporadic and you have periods that have no associated data, you can choose to publish the value zero (0) for that period or no value at all. If you use periodic calls to `PutMetricData` to monitor the health of your application, you might want to publish zero instead of no value. For example, you can set a CloudWatch alarm to notify you if your application fails to publish metrics every five minutes. You want such an application to publish zeros for periods with no associated data.

You might also publish zeros if you want to track the total number of data points or if you want statistics such as minimum and average to include data points with the value 0.

Using Metric Math

Metric math enables you to query multiple CloudWatch metrics and use math expressions to create new time series based on these metrics. You can visualize the resulting time series on the CloudWatch console.
Adding a Math Expression to a CloudWatch Graph

You can add a math expression to a graph on your CloudWatch dashboard. Each graph is limited to using a maximum of 100 metrics and expressions, so you can add a math expression only if the graph has 99 or fewer metrics. This applies even if not all the metrics are displayed on the graph.

To add a math expression to a graph

2. Create or edit a graph or line widget.
3. Choose Graphed metrics.
5. For the Details column, enter the math expression. The tables in the following section list the functions that you can use in the expression.
   
   To use a metric or the result of another expression as part of the formula for this expression, use the value shown in the Id column: for example, m1+m2 or e1-MIN(e1).
   
   You can change the value of Id. It can include numbers, letters, and underscore, and it must start with a lowercase letter. Changing the value of Id to a more meaningful name can also make a graph easier to understand: for example, changing from m1 and m2 to errors and requests.
6. For the Label column of the expression, enter a name that describes what the expression is calculating.

   If the result of an expression is an array of time series, each of those time series is displayed on the graph with a separate line, with different colors. Immediately under the graph is a legend for each line in the graph. For a single expression that produces multiple time series, the legend captions for those time series are in the format Expression-Label Metric-Label. For example, if the graph includes a metric with a label of Errors and an expression FILL(METRICS(), 0) that has a label of Filled With 0; one line in the legend would be Filled With 0: Errors. To have the legend show only the original metric labels, set Expression-Label to be empty.

   When one expression produces an array of time series on the graph, you can't change the colors used for each of those time series.
7. After you have added the desired expressions, you can optionally simplify the graph by hiding some of the original metrics. To hide a metric or expression, clear the check box to the left of the Id field.

Metric Math Syntax and Functions

The following sections explain the functions available for metric math. All functions must be written in uppercase letters (such as AVG), and the Id field for all metrics and math expressions must start with a lowercase letter.

The final result of any math expression must be a single time series or an array of time series. Some functions produce a scalar number. You can use these functions within a larger function that ultimately produces a time series. For example, taking the AVG of a single time series produces a scalar number, so it can't be the final expression result. But you could use it in the function m1-AVG(m1) to display a time series of the difference between each individual data point and the average value of that data point.
Data Type Abbreviations

Some functions are valid for only certain types of data. The abbreviations in the following list are used in the tables of functions to represent the types of data supported for each function:

- **S** represents a scalar number, such as 2, -5, or 50.25
- **TS** is a time series (a series of values for a single CloudWatch metric over time): for example, the CPUUtilization metric for instance i-1234567890abcdef0 over the last 3 days
- **TS[]** is an array of time series, such as the time series for multiple metrics

The METRICS() Function

The METRICS() function returns all the metrics in the request. Math expressions aren't included.

You can use METRICS() within a larger expression that produces a single time series or an array of time series. For example, the expression SUM(METRICS()) returns a time series (TS) that is the sum of the values of all the graphed metrics. METRICS()/100 returns an array of time series, each of which is a time series showing each data point of one of the metrics divided by 100.

You can use the METRICS() function with a string to return only the graphed metrics that contain that string in their Id field. For example, the expression SUM(METRICS("errors")) returns a time series that is the sum of the values of all the graphed metrics that have 'errors' in their Id field. You can also use SUM((METRICS("4xx"), METRICS("5xx"))) to match multiple strings.

Basic Arithmetic Functions

The following table lists the basic arithmetic functions that are supported. Missing values in time series are treated as 0. If the value of a data point causes a function to attempt to divide by zero, the data point is dropped.

<table>
<thead>
<tr>

</tbody>
</table>

Functions Supported for Metric Math

The following table describes the functions you can use in math expressions. Enter all functions in uppercase letters.
The final result of any math expression must be a single time series or an array of time series. Some functions in tables in the following sections produce a scalar number. You can use these functions within a larger function that ultimately produces a time series. For example, taking the \texttt{AVG} of a single time series produces a scalar number, so it can't be the final expression result. But you could use it in the function \texttt{m1-AVG(m1)} to display a time series of the difference between each individual data point and the average value of that data point.

In the following table, every example in the \textbf{Examples} column is an expression that results in a single time series or an array of time series. This shows how functions that return scalar numbers can be used as part of a valid expression that produces a single time series.

<td>TS</td>
<td>TS[]</td>
<td>Returns the rate of change of the metric per second. This is calculated as the difference between the latest data point value and the previous data point value, divided by the time difference in seconds between the two values.</td>
<td>RATE(m1)</td>
</tr>
<tr>
<td>SEARCH</td>
<td>Search expression</td>
<td>One or more TS</td>
<td>Returns one or more time series that match a search criteria that you specify. The SEARCH function enables you to add multiple related time series to a graph with one expression. The graph is dynamically updated to include new metrics that are added later and match the search criteria. For more information, see Using Search Expressions in Graphs (p. 53).</td>
<td></td>
</tr>
<tr>
<td>STDDEV</td>
<td>TS</td>
<td>S</td>
<td>The STDDEV of a single time series returns a scalar representing the standard deviation of all data points in the metric. The STDDEV of an array of time series returns a single time series.</td>
<td>m1/STDDEV(m1)</td>
</tr>
<tr>
<td>SUM</td>
<td>TS</td>
<td>S</td>
<td>The SUM of a single time series returns a scalar representing the sum of the values of all data points in the metric. The SUM of an array of time series returns a single time series.</td>
<td>SUM(METRICS())/SUM(m1)</td>
</tr>
</tbody>
</table>

*Using only a function that returns a scalar number is not valid, as all final results of expressions must be a single time series or an array of time series. Instead, use these functions as part of a larger expression that returns a time series.
Using Metric Math with the GetMetricData API Operation

You can use GetMetricData to perform calculations using math expressions, as well as to retrieve large batches of metric data in one API call. For more information, see GetMetricData.

Using Search Expressions in Graphs

Search expressions are a type of math expression that you can add to CloudWatch graphs. Search expressions enable you to quickly add multiple related metrics to a graph. They also enable you to create dynamic graphs that automatically add appropriate metrics to their display, even if those metrics don't exist when you first create the graph.

For example, you can create a search expression that displays the AWS/EC2 CPUUtilization metric for all instances in the Region. If you later launch a new instance, the CPUUtilization of the new instance is automatically added to the graph.

When you use a search expression in a graph, the search finds the search expression in metric names, namespaces, dimension names, and dimension values. You can use Boolean operators for more complex and powerful searches.

Topics

- CloudWatch Search Expression Syntax (p. 53)
- CloudWatch Search Expression Examples (p. 57)
- Creating a CloudWatch Graph with a Search Expression (p. 59)

CloudWatch Search Expression Syntax

A valid search expression has the following format.

```
SEARCH(' {Namespace, DimensionName1, DimensionName2, ...}, SearchTerm', 'Statistic', Period)
```

For example:

```
SEARCH(' {AWS/EC2,InstanceId} MetricName="CPUUtilization" ', 'Average', 300)
```

- The first part of the query after the word SEARCH, enclosed in curly braces, is the **metric schema** to be searched. The metric schema contains a metric namespace and one or more dimension names. Including a metric schema in a search query is optional. If specified, the metric schema must contain a namespace and can optionally contain one or more dimension names that are valid in that namespace.

  You don't need to use quote marks inside the metric schema unless a namespace or dimension name includes spaces or non-alphanumeric characters. In that case, you must enclose the name that contains those characters with double quotes.

- The **SearchTerm** is also optional, but a valid search must contain either the metric schema, the SearchTerm, or both. The SearchTerm usually contains one or more metric names or dimension values. The SearchTerm can include multiple terms to search for, by both partial match and exact match. It can also contain Boolean operators.

  The SearchTerm can include one or more designators, such as MetricName= as in this example, but using designators isn't required.
The metric schema and **Search Term** must be enclosed together in a pair of single quote marks.

- **The Statistic** is the name of any valid CloudWatch statistic. It must be enclosed by single quotes. For more information, see **Statistics** (p. 5).
- **The Period** is the aggregation time period in seconds.

The preceding example searches the **AWS/EC2** namespace for any metrics that have **InstanceId** as a dimension name. It returns all **CPUUtilization** metrics that it finds, with the graph showing the **Average** statistic with an aggregation period of 5 minutes.

**Search Expression Limits**

The maximum search expression query size is 1024 characters. You can have as many as five search expressions on one graph. A graph can display as many as 100 time series.

**CloudWatch Search Expressions: Tokenization**

When you specify a **Search Term**, the search function searches for **tokens**, which are substrings that CloudWatch automatically generates from full metric names, dimension names, dimension values, and namespaces. CloudWatch generates tokens distinguished by the camel-case capitalization in the original string. Numeric characters also serve as the start of new tokens, and non-alphanumeric characters serve as delimiters, creating tokens before and after the non-alphanumeric characters.

A continuous string of the same type of token delimiter character results in one token.

All generated tokens are in lowercase. The following table shows some examples of tokens generated.

<table>
<thead>
<tr>
<th>Original String</th>
<th>Tokens Generated</th>
</tr>
</thead>
<tbody>
<tr>
<td>CustomCount1</td>
<td>customcount1, custom, count, 1</td>
</tr>
<tr>
<td>SDBFailure</td>
<td>sdbfailure, sdb, failure</td>
</tr>
<tr>
<td>Project2-trial333</td>
<td>project2trial333, project, 2, trial, 333</td>
</tr>
</tbody>
</table>

**CloudWatch Search Expressions: Partial Matches**

When you specify a **Search Term**, the search term is also tokenized. CloudWatch finds metrics based on partial matches, which are matches of a single token generated from the search term to a single token generated from a metric name, namespace, dimension name, or dimension value.

Partial match searches to match a single token are case insensitive. For example, using any of the following search terms can return the **CustomCount1** metric:

- **count**
- **Count**
- **COUNT**

However, using **couNT** as a search term doesn’t find **CustomCount1** because the capitalization in the search term **couNT** is tokenized into **cou** and **NT**.

Searches can also match composite tokens, which are multiple tokens that appear consecutively in the original name. To match a composite token, the search is case sensitive. For example, if the original term is **CustomCount1**, searches for **CustomCount** or **Count1** are successful, but searches for **customcount** or **count1** aren’t.
CloudWatch Search Expressions: Exact Matches

You can define a search to find only exact matches of your search term by using double quotes around the part of the search term that requires an exact match. These double-quotes are enclosed in the single-quotes used around the entire search term. For example, `SEARCH(' {MyNamespace}, "CustomCount1" ', 'Maximum', 120)` finds the exact string `CustomCount1` if it exists as a metric name, dimension name, or dimension value in the namespace named `MyNamespace`. However, the searches `SEARCH(' {MyNamespace}, "customcount1" ', 'Maximum', 120)` or `SEARCH(' {MyNamespace}, "Custom" ', 'Maximum', 120)` do not find this string.

You can combine partial match terms and exact match terms in a single search expression. For example, `SEARCH(' {AWS/NetworkELB, LoadBalancer}, "ConsumedLCUs" OR flow ', 'Maximum', 120)` returns the Elastic Load Balancing metric named `ConsumedLCUs` as well as all Elastic Load Balancing metrics or dimensions that contain the token `flow`.

Using exact match is also a good way to find names with special characters, such as non-alphanumeric characters or spaces, as in the following example.

```
SEARCH(' {"My Namespace", "Dimension@Name"}, "Custom:Name[Special_Characters" ', 'Maximum', 120)
```

CloudWatch Search Expressions: Excluding a Metric Schema

All examples shown so far include a metric schema, in curly braces. Searches that omit a metric schema are also valid.

For example, `SEARCH(' "CPUUtilization" ', 'Average', 300)` returns all metric names, dimension names, dimension values, and namespaces that are an exact match for the string `CPUUtilization`. In the AWS metric namespaces, this can include metrics from several services including Amazon EC2, Amazon ECS, Amazon SageMaker, and others.

To narrow this search to only one AWS service, the best practice is to specify the namespace and any necessary dimensions in the metric schema, as in the following example. Although this narrows the search to the `AWS/EC2` namespace, it would still return results of other metrics if you have defined `CPUUtilization` as a dimension value for those metrics.

```
SEARCH(' {AWS/EC2, InstanceType} "CPUUtilization" ', 'Average', 300)
```

Alternatively you could add the namespace in the `SearchTerm` as in the following example. But in this example, the search would match any `AWS/EC2` string, even if it was a custom dimension name or value.

```
SEARCH(' "AWS/EC2" MetricName="CPUUtilization" ', 'Average', 300)
```

CloudWatch Search Expressions: Specifying Property Names in the Search

The following exact match search for "CustomCount1" returns all metrics with exactly that name.

```
SEARCH(' "CustomCount1" ', 'Maximum', 120)
```

But it also returns metrics with dimension names, dimension values, or namespaces of `CustomCount1`. To structure your search further, you can specify the property name of the type of object that you want to find in your searches. The following example searches all namespaces and returns metrics named `CustomCount1`.

```
SEARCH(' "CustomCount1" ', 'Maximum', 120)
```
You can also use namespaces and dimension name/value pairs as property names, as in the following examples. The first of these examples also illustrates that you can use property names with partial match searches as well.

```
SEARCH(' MetricName="CustomCount1" ', 'Maximum', 120)
```

```
SEARCH(' InstanceType=micro ', 'Average', 300)
```

```
SEARCH(' InstanceType="t2.micro" Namespace="AWS/EC2" ', 'Average', 300)
```

**CloudWatch Search Expressions: Non-Alphanumeric Characters**

Non-alphanumeric characters serve as delimiters, and mark where the names of metrics, dimensions, namespaces, and search terms are to be separated into tokens. When terms are tokenized, non-alphanumeric characters are stripped out and don’t appear in the tokens. For example, Network-Errors_2 generates the tokens network, errors, and 2.

Your search term can include any non-alphanumeric characters. If these characters appear in your search term, they can specify composite tokens in a partial match. For example, all of the following searches would find metrics named either Network-Errors-2 or NetworkErrors2.

```
network/errors
network+errors
network-errors
Network_Errors
```

When you're doing an exact value search, any non-alphanumeric characters used in the exact search must be the correct characters that appear in the string being searched for. For example, if you want to find Network-Errors-2, searching for "Network-Errors-2" is successful, but a search for "Network_Errors_2" isn't.

When you perform an exact match search, the following characters must be escaped with a backslash.

```
" \\
( )
```

For example, to find the metric name Europe\France Traffic(Network) by exact match, use the search term "Europe\\France Traffic\(Network\)"

**CloudWatch Search Expressions: Boolean Operators**

Search supports the use of the Boolean operators AND, OR, and NOT within the SearchTerm. Boolean operators are enclosed in the single quote marks that you use to enclose the entire search term. Boolean operators are case sensitive, so and, or, and not aren't valid as Boolean operators.

You can use AND explicitly in your search, such as

```
SEARCH('{AWS/EC2,InstanceId} network AND packets', 'Average', 300)
```

Not using any Boolean operator between search terms implicitly searches them as if there were an AND operator, so

```
SEARCH('{AWS/EC2,InstanceId} network packets', 'Average', 300)
```

yields the same search results.

Use NOT to exclude subsets of data from the results. For example,

```
SEARCH(' MetricName="CPUUtilization" NOT i-1234567890123456 ', 'Average', 300)
```

returns the CPUUtilization for all your instances, except for the instance i-1234567890123456. You can also use a NOT clause as the only search term. For example,

```
SEARCH( ' NOT Namespace=AWS ', 'Maximum', 120)
```

yields all your custom metrics (metrics with namespaces that don't include AWS).
You can use multiple NOT phrases in a query. For example, `SEARCH(' {AWS/EC2,InstanceId} MetricName="CPUUtilization" NOT "ProjectA" NOT "ProjectB" ', 'Average', 300)` returns the CPUUtilization of all instances in the Region, except for those with dimension values of ProjectA or ProjectB.

You can combine Boolean operators for more powerful and detailed searches, as in the following examples. Use parentheses to group the operators.

Both of the next two examples return all metric names containing ReadOps from both the EC2 and EBS namespaces.

```
SEARCH(' (EC2 OR EBS) AND MetricName=ReadOps ', 'Maximum', 120)
SEARCH(' (EC2 OR EBS) MetricName=ReadOps ', 'Maximum', 120)
```

The following example narrows the previous search to only results that include ProjectA, which could be the value of a dimension.

```
SEARCH(' (EC2 OR EBS) AND ReadOps AND ProjectA ', 'Maximum', 120)
```

The following example uses nested grouping. It returns Lambda metrics for Errors from all functions, and invocations of functions with names that include the strings ProjectA or ProjectB.

```
SEARCH(' {AWS/Lambda,FunctionName} MetricName="Errors" OR (MetricName="Invocations" AND (ProjectA OR ProjectB)) ', 'Average', 600)
```

### CloudWatch Search Expressions: Using Math Expressions

You can use a search expression within a math expressions in a graph.

For example, `SUM(SEARCH(' {AWS/Lambda, FunctionName}, MetricName="Errors" ', 'Sum', 300))` returns the sum of the Errors metric of all your Lambda functions.

Using separate lines for your search expression and math expression might yield more useful results. For example, suppose that you use the following two expressions in a graph. The first line displays separate Errors lines for each of your Lambda functions. The ID of this expression is e1. The second line adds another line showing the sum of the errors from all of the functions.

```
SEARCH(' {AWS/Lambda, FunctionName}, MetricName="Errors" ', 'Sum', 300)
SUM(e1)
```

### CloudWatch Search Expression Examples

The following examples illustrate more search expression uses and syntax. Let's start with a search for CPUUtilization across all instances in the Region and then look at variations.

This example displays one line for each instance in the Region, showing the CPUUtilization metric from the AWS/EC2 namespace.

```
SEARCH(' {AWS/EC2,InstanceId} MetricName="CPUUtilization" ', 'Average', 300)
```

Changing InstanceId to InstanceType changes the graph to show one line for each instance type used in the Region. Data from all instances of each type is aggregated into one line for that instance type.
Removing the dimension name but keeping the namespace in the schema, as in the following example, results in a single line showing the aggregation of CPUUtilization metrics for all instances in the Region.

```
SEARCH(' {AWS/EC2} MetricName="CPUUtilization" ', 'Average', 300)
```

The following example aggregates the CPUUtilization by instance type and displays one line for each instance type that includes the string **micro**.

```
SEARCH(' {AWS/EC2, InstanceType} InstanceType=micro MetricName="CPUUtilization" ', 'Average', 300)
```

This example narrows the previous example, changing the **InstanceType** to an exact search for **t2.micro** instances.

```
SEARCH(' {AWS/EC2, InstanceType} InstanceType="t2.micro" MetricName="CPUUtilization" ', 'Average', 300)
```

The following search removes the {metric schema} part of the query, so the CPUUtilization metric from all namespaces appears in the graph. This can return quite a few results because the graph includes multiple lines for the CPUUtilization metric from each AWS service, aggregated along different dimensions.

```
SEARCH(' MetricName="CPUUtilization" ', 'Average', 300)
```

To narrow these results a bit, you can specify two specific metric namespaces.

```
SEARCH(' MetricName="CPUUtilization" AND ("AWS/ECS" OR "AWS/ES") ', 'Average', 300)
```

The preceding example is the only way to do a search of specific multiple namespaces with one search query, as you can specify only one metric schema in each query. However, to add more structure, you could use two queries in the graph, as in the following example. This example also adds more structure by specifying a dimension to use to aggregate the data for Amazon ECS.

```
SEARCH(' {AWS/ECS, ClusterName}, MetricName="CPUUtilization" ', 'Average', 300)
SEARCH(' {AWS/EBS}, MetricName="CPUUtilization" ', 'Average', 300)
```

The following example returns the Elastic Load Balancing metric named ConsumedLCUs as well as all Elastic Load Balancing metrics or dimensions that contain the token **flow**.

```
SEARCH(' {AWS/NetworkELB, LoadBalancer}, "ConsumedLCUs" OR flow ', 'Maximum', 120)
```

The following example uses nested grouping. It returns Lambda metrics for **Errors** from all functions and **Invocations** of functions with names that include the strings **ProjectA** or **ProjectB**.

```
SEARCH(' {AWS/Lambda, FunctionName} MetricName="Errors" OR (MetricName="Invocations" AND (ProjectA OR ProjectB)) ', 'Average', 600)
```

The following example displays all of your custom metrics, excluding metrics generated by AWS services.
SEARCH(' NOT Namespace=AWS ', 'Average', 120)

The following example displays metrics with metric names, namespaces, dimension names, and dimension values that contain the string *Errors* as part of their name.

SEARCH(' Errors ', 'Average', 300)

The following example narrows that search to exact matches. For example, this search finds the metric name *Errors* but not metrics named *ConnectionErrors* or *errors*.

SEARCH(' "Errors" ', 'Average', 300)

The following example shows how to specify names that contain spaces or special characters in the metric schema part of the search term.

SEARCH(' {"Custom-Namespace", "Dimension Name With Spaces"}, ErrorCount ', 'Maximum', 120)

### Creating a CloudWatch Graph with a Search Expression

On the CloudWatch console, you can access search capability when you add a graph to a dashboard, or by using the **Metrics** view.

#### To add a graph with a search expression to an existing dashboard

2. In the navigation pane, choose **Dashboards** and select a dashboard.
3. Choose **Add widget**.
4. Choose either **Line** or **Stacked area** and choose **Configure**.
5. On the **Graphed metrics** tab, choose **Add a math expression**.
6. For **Details**, enter the search expression that you want. For example, `SEARCH('{AWS/EC2,InstanceId} MetricName="CPUUtilization" ', 'Average', 300)`
7. (Optional) To add another search expression or math expression to the graph, choose **Add a math expression**.
8. (Optional) After you add a search expression, you can specify a dynamic label to appear on the graph legend for each metric. Dynamic labels display a statistic about the metric and automatically update when the dashboard or graph is refreshed. To add a dynamic label, choose **Graphed metrics** and then **Dynamic labels**.

   By default, the dynamic values you add to the label appear at the beginning of the label. You can then click the **Label** value for the metric to edit the label. For more information, see Using Dynamic Labels (p. 41).

9. (Optional) To add a single metric to the graph, choose the **All metrics** tab and drill down to the metric you want.
10. (Optional) To change the time range shown on the graph, choose either **custom** at the top of the graph or one of the time periods to the left of **custom**.
11. (Optional) Horizontal annotations help dashboard users quickly see when a metric has spiked to a certain level or whether the metric is within a predefined range. To add a horizontal annotation, choose **Graph options** and then **Add horizontal annotation**:

   a. For **Label**, enter a label for the annotation.
b. For **Value**, enter the metric value where the horizontal annotation appears.

c. For **Fill**, specify whether to use fill shading with this annotation. For example, choose **Above** or **Below** for the corresponding area to be filled. If you specify **Between**, another **Value** field appears, and the area of the graph between the two values is filled.

d. For **Axis**, specify whether the numbers in **Value** refer to the metric associated with the left y-axis or the right y-axis if the graph includes multiple metrics.

You can change the fill color of an annotation by choosing the color square in the left column of the annotation.

Repeat these steps to add multiple horizontal annotations to the same graph.

To hide an annotation, clear the check box in the left column for that annotation.

To delete an annotation, choose the **x** in the **Actions** column.

12. (Optional) Vertical annotations help you mark milestones in a graph, such as operational events or the beginning and end of a deployment. To add a vertical annotation, choose **Graph options** and then **Add vertical annotation**:

a. For **Label**, enter a label for the annotation. To show only the date and time on the annotation, keep the **Label** field blank.

b. For **Date**, specify the date and time where the vertical annotation appears.

c. For **Fill**, specify whether to use fill shading before or after a vertical annotation or between two vertical annotations. For example, choose **Before** or **After** for the corresponding area to be filled. If you specify **Between**, another **Date** field appears, and the area of the graph between the two values is filled.

Repeat these steps to add multiple vertical annotations to the same graph.

To hide an annotation, clear the check box in the left column for that annotation.

To delete an annotation, choose the **x** in the **Actions** column.

13. Choose **Create widget**.

14. Choose **Save dashboard**.

**To use the Metrics view to graph searched metrics**

2. In the navigation pane, choose **Metrics**.

3. In the search field, enter the tokens to search for: for example, `cpuutilization t2.small`.

   Results that match your search appear.

4. To graph all of the metrics that match your search, choose **Graph search**.

   or

   To refine your search, choose one of the namespaces that appeared in your search results.

5. If you selected a namespace to narrow your results, you can do the following:

   a. To graph one or more metrics, select the check box next to each metric. To select all metrics, select the check box in the heading row of the table.

   b. To refine your search, hover over a metric name and choose **Add to search** or **Search for this only**.
c. To view help for a metric, select the metric name and choose **What is this?**.

The selected metrics appear on the graph.

6. (Optional) Select one of the buttons in the search bar to edit that part of the search term.
7. (Optional) To add the graph to a dashboard, choose **Actions** and then **Add to dashboard**.
Using Amazon CloudWatch Alarms

You can create a CloudWatch alarm that watches a single CloudWatch metric or the result of a math expression based on CloudWatch metrics. The alarm performs one or more actions based on the value of the metric or expression relative to a threshold over a number of time periods. The action can be an Amazon EC2 action, an Amazon EC2 Auto Scaling action, or a notification sent to an Amazon SNS topic.

You can also add alarms to CloudWatch dashboards and monitor them visually. When an alarm is on a dashboard, it turns red when it is in the ALARM state, making it easier for you to monitor its status proactively.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state, the state must have changed and been maintained for a specified number of periods.

After an alarm invokes an action due to a change in state, its subsequent behavior depends on the type of action that you have associated with the alarm. For Amazon EC2 Auto Scaling actions, the alarm continues to invoke the action for every period that the alarm remains in the new state. For Amazon SNS notifications, no additional actions are invoked.

**Note**

CloudWatch doesn't test or validate the actions that you specify, nor does it detect any Amazon EC2 Auto Scaling or Amazon SNS errors resulting from an attempt to invoke nonexistent actions. Make sure that your actions exist.

### Alarm States

An alarm has the following possible states:

- **OK** – The metric or expression is within the defined threshold.
- **ALARM** – The metric or expression is outside of the defined threshold.
- **INSUFFICIENT_DATA** – The alarm has just started, the metric is not available, or not enough data is available for the metric to determine the alarm state.

### Evaluating an Alarm

When you create an alarm, you specify three settings to enable CloudWatch to evaluate when to change the alarm state:

- **Period** is the length of time to evaluate the metric or expression to create each individual data point for an alarm. It is expressed in seconds. If you choose one minute as the period, there is one data point every minute.
- **Evaluation Period** is the number of the most recent periods, or data points, to evaluate when determining alarm state.
- **Datapoints to Alarm** is the number of data points within the evaluation period that must be breaching to cause the alarm to go to the ALARM state. The breaching data points don't have to be consecutive, they just must all be within the last number of data points equal to **Evaluation Period**.

In the following figure, the alarm threshold is set to three units. The alarm is configured to go to the ALARM state and both **Evaluation Period** and **Datapoints to Alarm** are 3. That is, when all existing data
points in the most recent three consecutive periods are above the threshold, the alarm goes to the ALARM state. In the figure, this happens in the third through fifth time periods. At period six, the value dips below the threshold, so one of the periods being evaluated is not breaching, and the alarm state changes to OK. During the ninth time period, the threshold is breached again, but for only one period. Consequently, the alarm state remains OK.

When you configure Evaluation Period and Datapoints to Alarm as different values, you're setting an "M out of N" alarm. Datapoints to Alarm is ("M") and Evaluation Period is ("N"). The evaluation interval is the number of data points multiplied by the period. For example, if you configure 4 out of 5 data points with a period of 1 minute, the evaluation interval is 5 minutes. If you configure 3 out of 3 data points with a period of 10 minutes, the evaluation interval is 30 minutes.

Configuring How CloudWatch Alarms Treat Missing Data

Sometimes some data points for a metric with an alarm don't get reported to CloudWatch. For example, this can happen when a connection is lost, a server goes down, or when a metric reports data only intermittently by design.

CloudWatch enables you to specify how to treat missing data points when evaluating an alarm. This can help you configure your alarm to go to the ALARM state when appropriate for the type of data being monitored. You can avoid false positives when missing data doesn't indicate a problem.

Similar to how each alarm is always in one of three states, each specific data point reported to CloudWatch falls under one of three categories:

- Not breaching (within the threshold)
- Breaching (violating the threshold)
- Missing

For each alarm, you can specify CloudWatch to treat missing data points as any of the following:

- notBreaching – Missing data points are treated as "good" and within the threshold,
- breaching – Missing data points are treated as "bad" and breaching the threshold
• `ignore` – The current alarm state is maintained
• `missing` – The alarm doesn’t consider missing data points when evaluating whether to change state

The best choice depends on the type of metric. For a metric that continually reports data, such as CPUUtilization of an instance, you might want to treat missing data points as breaching, because they might indicate that something is wrong. But for a metric that generates data points only when an error occurs, such as `ThrottledRequests` in Amazon DynamoDB, you would want to treat missing data as notBreaching. The default behavior is `missing`.

Choosing the best option for your alarm prevents unnecessary and misleading alarm condition changes, and also more accurately indicates the health of your system.

### How Alarm State Is Evaluated When Data Is Missing

No matter what value you set for how to treat missing data, when an alarm evaluates whether to change state, CloudWatch attempts to retrieve a higher number of data points than specified by `Evaluation Periods`. The exact number of data points it attempts to retrieve depends on the length of the alarm period and whether it is based on a metric with standard resolution or high resolution. The time frame of the data points that it attempts to retrieve is the *evaluation range*.

Once CloudWatch retrieves these data points, the following happens:

- If no data points in the evaluation range are missing, CloudWatch evaluates the alarm based on the most recent data points collected.
- If some data points in the evaluation range are missing, but the number of existing data points retrieved is equal to or more than the alarm’s `Evaluation Periods`, CloudWatch evaluates the alarm state based on the most recent existing data points that were successfully retrieved. In this case, the value you set for how to treat missing data is not needed and is ignored.
- If some data points in the evaluation range are missing, and the number of existing data points that were retrieved is lower than the alarm’s number of evaluation periods, CloudWatch fills in the missing data points with the result you specified for how to treat missing data, and then evaluates the alarm. However, any real data points in the evaluation range, no matter when they were reported, are included in the evaluation. CloudWatch uses missing data points only as few times as possible.

In all of these situations, the number of data points evaluated is equal to the value of `Evaluation Periods`. If fewer than the value of `Datapoints to Alarm` are breaching, the alarm state is set to OK. Otherwise, the state is set to ALARM.

**Note**

A particular case of this behavior is that CloudWatch alarms might repeatedly re-evaluate the last set of data points for a period of time after the metric has stopped flowing. This re-evaluation might cause the alarm to change state and re-execute actions, if it had changed state immediately prior to the metric stream stopping. To mitigate this behavior, use shorter periods.

The following tables illustrate examples of the alarm evaluation behavior. In the first table, `Datapoints to Alarm` and `Evaluation Periods` are both 3. CloudWatch retrieves the 5 most recent data points when evaluating the alarm.

Column 2 shows how many of the 3 necessary data points are missing. Even though the most recent 5 data points are evaluated, only 3 (the setting for `Evaluation Periods`) are necessary to evaluate the alarm state. The number of data points in Column 2 is the number of data points that must be "filled in", using the setting for how missing data is being treated.

Columns 3-6 show the alarm state that would be set for each setting of how missing data should be treated, shown at the top of each column. In the data points column, 0 is a non-breaching data point, X is a breaching data point, and - is a missing data point.
In the second row of the preceding table, the alarm stays OK even if missing data is treated as breaching, because the one existing data point is not breaching, and this is evaluated along with two missing data points which are treated as breaching. The next time this alarm is evaluated, if the data is still missing it will go to ALARM, as that non-breaching data point will no longer be among the 5 most recent data points retrieved. In the fourth row, the alarm goes to ALARM state in all cases because there are enough real data points so that the setting for how to treat missing data doesn't need to be considered.

In the next table, the Period is again set to 5 minutes, and Datapoints to Alarm is only 2 while Evaluation Periods is 3. This is a 2 out of 3, M out of N alarm.

If data points are missing soon after you create an alarm, and the metric was being reported to CloudWatch before you created the alarm, CloudWatch retrieves the most recent data points from before the alarm was created when evaluating the alarm.

## High-Resolution Alarms

If you set an alarm on a high-resolution metric, you can specify a high-resolution alarm with a period of 10 seconds or 30 seconds, or you can set a regular alarm with a period of any multiple of 60 seconds. There is a higher charge for high-resolution alarms. For more information about high-resolution metrics, see Publishing Custom Metrics (p. 45).
Alarms on Math Expressions

You can set an alarm on the result of a math expression that is based on one or more CloudWatch metrics. A math expression used for an alarm can include as many as 10 metrics. Each metric must be using the same period.

For an alarm based on a math expression, you can specify how you want CloudWatch to treat missing data points for the underlying metrics when evaluating the alarm.

Alarms based on math expressions can't perform Amazon EC2 actions.

For more information about metric math expressions and syntax, see Using Metric Math (p. 47).

Percentile-Based CloudWatch Alarms and Low Data Samples

When you set a percentile as the statistic for an alarm, you can specify what to do when there is not enough data for a good statistical assessment. You can choose to have the alarm evaluate the statistic anyway and possibly change the alarm state. Or, you can have the alarm ignore the metric while the sample size is low, and wait to evaluate it until there is enough data to be statistically significant.

For percentiles between 0.5 and 1.00, this setting is used when there are fewer than 10/(1-percentile) data points during the evaluation period. For example, this setting would be used if there were fewer than 1000 samples for an alarm on a p99 percentile. For percentiles between 0 and 0.5, the setting is used when there are fewer than 10/percentile data points.

Common Features of CloudWatch Alarms

The following features apply to all CloudWatch alarms:

- You can create up to 5000 alarms per Region per AWS account. To create or update an alarm, you use the PutMetricAlarm API action ([mon-put-metric-alarm](command)).
- Alarm names must contain only ASCII characters.
- You can list any or all of the currently configured alarms, and list any alarms in a particular state using DescribeAlarms ([mon-describe-alarms]). You can further filter the list by time range.
- You can disable and enable alarms by using DisableAlarmActions and EnableAlarmActions ([mon-disable-alarm-actions] and [mon-enable-alarm-actions]).
- You can test an alarm by setting it to any state using SetAlarmState ([mon-set-alarm-state]). This temporary state change lasts only until the next alarm comparison occurs.
- You can create an alarm using PutMetricAlarm ([mon-put-metric-alarm]) before you've created a custom metric. For the alarm to be valid, you must include all of the dimensions for the custom metric in addition to the metric namespace and metric name in the alarm definition.
- You can view an alarm's history using DescribeAlarmHistory ([mon-describe-alarm-history]). CloudWatch preserves alarm history for two weeks. Each state transition is marked with a unique timestamp. In rare cases, your history might show more than one notification for a state change. The timestamp enables you to confirm unique state changes.
- The number of evaluation periods for an alarm multiplied by the length of each evaluation period can't exceed one day.

Note
Some AWS resources don't send metric data to CloudWatch under certain conditions.
For example, Amazon EBS might not send metric data for an available volume that is not attached to an Amazon EC2 instance, because there is no metric activity to be monitored for that volume. If you have an alarm set for such a metric, you might notice its state change to `INSUFFICIENT_DATA`. This might indicate that your resource is inactive, and might not necessarily mean that there is a problem.

Setting Up Amazon SNS Notifications

Amazon CloudWatch uses Amazon SNS to send email. First, create and subscribe to an SNS topic. When you create a CloudWatch alarm, you can add this SNS topic to send an email notification when the alarm changes state. For more information, see the Amazon Simple Notification Service Getting Started Guide.

**Note**

Alternatively, if you plan to create your CloudWatch alarm using the AWS Management Console, you can skip this procedure because you can create the topic through the Create Alarm Wizard.

Setting Up an Amazon SNS Topic Using the AWS Management Console

First, create a topic, then subscribe to it. You can optionally publish a test message to the topic.

**To create an SNS topic**

2. On the Amazon SNS dashboard, under **Common actions**, choose **Create Topic**.
3. In the **Create new topic** dialog box, for **Topic name**, enter a name for the topic (for example, `my-topic`).
4. Choose **Create topic**.
5. Copy the **Topic ARN** for the next task (for example, `arn:aws:sns:us-east-1:111122223333:my-topic`).

**To subscribe to an SNS topic**

2. In the navigation pane, choose **Subscriptions**, **Create subscription**.
3. In the **Create subscription** dialog box, for **Topic ARN**, paste the topic ARN that you created in the previous task.
4. For **Protocol**, choose **Email**.
5. For **Endpoint**, enter an email address that you can use to receive the notification, and then choose **Create subscription**.
6. From your email application, open the message from AWS Notifications and confirm your subscription.

Your web browser displays a confirmation response from Amazon SNS.

**To publish a test message to an SNS topic**

2. In the navigation pane, choose **Topics**.
3. On the **Topics** page, select a topic and choose **Publish to topic**.
4. In the **Publish a message** page, for **Subject**, enter a subject line for your message, and for **Message**, enter a brief message.
5. Choose **Publish Message**.
6. Check your email to confirm that you received the message.

## Setting Up an SNS Topic Using the AWS CLI

First, you create an SNS topic, and then you publish a message directly to the topic to test that you have properly configured it.

### To set up an SNS topic

1. Create the topic using the `create-topic` command as follows.

   ```bash
   aws sns create-topic --name my-topic
   ```

   Amazon SNS returns a topic ARN with the following format:

   ```json
   {
     "TopicArn": "arn:aws:sns:us-east-1:111122223333:my-topic"
   }
   ```

2. Subscribe your email address to the topic using the `subscribe` command. If the subscription request succeeds, you receive a confirmation email message.

   ```bash
   aws sns subscribe --topic-arn arn:aws:sns:us-east-1:111122223333:my-topic --protocol email --notification-endpoint my-email-address
   ```

   Amazon SNS returns the following:

   ```json
   {
     "SubscriptionArn": "pending confirmation"
   }
   ```

3. From your email application, open the message from AWS Notifications and confirm your subscription.

   Your web browser displays a confirmation response from Amazon Simple Notification Service.

4. Check the subscription using the `list-subscriptions-by-topic` command.

   ```bash
   ```

   Amazon SNS returns the following:

   ```json
   {
     "Subscriptions": [
       {
         "Owner": "111122223333",
         "Endpoint": "me@mycompany.com",
         "Protocol": "email",
       }
     ]
   }
   ```
5. (Optional) Publish a test message to the topic using the `publish` command.

```bash
aws sns publish --message "Verification" --topic arn:aws:sns:us-east-1:111122233333:my-topic
```

Amazon SNS returns the following.

```
{
  "MessageId": "42f189a0-3094-5cf6-8fd7-c2dde61a4d7d"
}
```

6. Check your email to confirm that you received the message.

---

Create a CloudWatch Alarm Based on a Static Threshold

You choose a CloudWatch metric for the alarm to watch, and the threshold for that metric. The alarm goes to ALARM state when the metric breaches the threshold for a specified number of evaluation periods.

CloudWatch has changed the alarm user interface. By default, you're shown the new user interface, but you can choose to return to the old user interface. This topic contains steps for each.

**To create an alarm based on a single metric using the new alarms user interface**

2. In the navigation pane, choose Alarms, Create Alarm.
3. Choose Select Metric and do one of the following:
   - Choose the service namespace that contains the metric that you want. Continue choosing options as they appear to narrow the choices. When a list of metrics appears, select the check box next to the metric that you want.
   - In the search box, enter the name of a metric, dimension, or resource ID and press Enter. Then choose one of the results and continue until a list of metrics appears. Select the check box next to the metric that you want.
4. Choose the Graphed metrics tab.
   a. Under Statistic, choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, `p95.45`).
   b. Under Period, choose the evaluation period for the alarm. When evaluating the alarm, each period is aggregated into one data point.

You can also choose whether the y-axis legend appears on the left or right while you're creating the alarm. This preference is used only while you're creating the alarm.

5. Choose Select metric.

   The Specify metric and conditions page appears, showing a graph and other information about the metric and statistic you have selected.

6. Under Conditions, specify the following:
   a. Enter a name and description for the alarm. The name must contain only ASCII characters.
   b. For Whenever metric is, specify whether the metric must be greater than, less than, or equal to the threshold. Under than..., specify the threshold value.
c. Choose **Additional configuration**. For **Datapoints to alarm**, specify how many evaluation periods (data points) must be in the **ALARM** state to trigger the alarm. If the two values here match, you create an alarm that goes to **ALARM** state if that many consecutive periods are breaching.

To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Evaluating an Alarm (p. 62).

d. For **Missing data treatment**, choose how to have the alarm behave when some data points are missing. For more information, see Configuring How CloudWatch Alarms Treat Missing Data (p. 63).

e. If the alarm uses a percentile as the monitored statistic, a **Percentiles with low samples** box appears. Use it to choose whether to evaluate or ignore cases with low sample rates. If you choose **ignore (maintain alarm state)**, the current alarm state is always maintained when the sample size is too low. For more information, see Percentile-Based CloudWatch Alarms and Low Data Samples (p. 66).

6. Choose **Next**.

7. Under **Notification**, select an SNS topic to notify when the alarm is in **ALARM** state, **OK** state, or **INSUFFICIENT_DATA** state.

To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

To have the alarm not send notifications, choose **Remove**.

8. To have the alarm perform Auto Scaling or EC2 actions, choose the appropriate button and choose the alarm state and action to perform.

9. When finished, choose **Next**.

10. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.

11. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

**To use the older user interface to create an alarm based on a single metric**

2. In the navigation pane, choose **Alarms, Create Alarm**.

3. Choose **Select Metric** and do one of the following:
   a. Choose the service namespace that contains the metric that you want. Continue choosing options as they appear to narrow the choices. When a list of metrics appears, select the check box next to the metric that you want.
   b. In the search box, enter the name of a metric, dimension, or resource ID and press Enter. Then choose one of the results and continue until a list of metrics appears. Select the check box next to the metric that you want.

4. Choose the **Graphed metrics** tab.
   a. Under **Statistic**, choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, \(p_{95.45}\)).
   b. Under **Period**, choose the evaluation period for the alarm. When evaluating the alarm, each period is aggregated into one data point.

You can also choose whether the y-axis legend appears on the left or right while you're creating the alarm. This preference is used only while you're creating the alarm.

5. Choose **Select metric**.

6. Enter a name and description for the alarm. The name must contain only ASCII characters.
Creating a CloudWatch Alarm Based on Anomaly Detection

CloudWatch anomaly detection is in open preview. The preview is open to AWS accounts in all commercial AWS Regions except Asia Pacific (Hong Kong), AWS GovCloud (US), China (Beijing) Region, and China (Ningxia) Region. You do not need to request access. Features may be added or changed before announcing General Availability. Please contact anomalydetectionfeedback@amazon.com for any feedback, questions, or if you would like to be informed when updates are available.

You can create a standard resolution alarm based on CloudWatch anomaly detection, which mines past metric data and creates a model of expected values. The expected values take into account the typical hourly, daily, and weekly patterns in the metric.

You specify a number of standard deviations which CloudWatch uses with the model to determine the "normal" range of values for the metric, with a higher number of standard deviations producing a thicker band of "normal" values.

You can choose whether the alarm is triggered when the metric value is above the band of expected values, below the band, or either above or below the band.

For more information, see CloudWatch Anomaly Detection (p. 92).

**Note**

If you create an anomaly detection alarm on a metric that you're already using anomaly detection for in the Metrics console for visualization purposes, the threshold that you set for...
the alarm doesn’t change the threshold that you’re already using for visualization. For more information, see Creating a Graph (p. 38).

To create an alarm based on anomaly detection

2. In the navigation pane, choose Alarms, Create Alarm.
3. Choose Select Metric and do one of the following:
   - Choose the service namespace that contains the metric that you want. To narrow the choices, continue choosing options as they appear. When a list of metrics appears, select the check box next to the metric that you want.
   - In the search box, enter the name of a metric, dimension, or resource ID and press Enter. Then choose one of the results and continue until a list of metrics appears. Select the check box next to the metric that you want.
4. Choose the Graphed metrics tab.
   a. Under Statistic, choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, p95.45).
   b. Under Period, choose the evaluation period for the alarm. When evaluating the alarm, each period is aggregated into one data point. For anomaly detection alarms, the value must be one minute or longer.

   You can also choose whether the y-axis legend appears on the left or right while you’re creating the alarm. This preference is used only while you’re creating the alarm.
   c. Choose Select metric.

   The Specify metric and conditions page appears, showing a graph and other information about the metric and statistic you have selected.
5. Under Conditions, specify the following:
   a. Choose Anomaly detection.

   If the model for this metric and statistic already exists, CloudWatch displays the anomaly detection band in the sample graph at the top of the screen. If the model does not already exist, the model will be generated when you finish creating the alarm. It takes up to 15 minutes for the actual anomaly detection band generated by the model to appear in the graph. Before that, the band you see is an approximation of the anomaly detection band.
   b. For Whenever metric is, specify whether the metric must be greater than, less than, or outside (in either direction) the band to trigger the alarm.
   c. For Anomaly detection threshold, choose the number of standard deviations to use to create the band that will be used as the normal range of values. Choosing a higher number creates a thicker band that will be more tolerant of metric changes, and a lower number creates a thinner band that will go to ALARM state with smaller metric deviations.
   d. Choose Additional configuration. For Datapoints to alarm, specify how many evaluation periods (data points) must be in the ALARM state to trigger the alarm. If the two values here match, you create an alarm that goes to ALARM state if that many consecutive periods are breaching.

   To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Evaluating an Alarm (p. 62).
   e. For Missing data treatment, choose how to have the alarm behave when some data points are missing. For more information, see Configuring How CloudWatch Alarms Treat Missing Data (p. 63).
   f. If the alarm uses a percentile as the monitored statistic, a Percentiles with low samples box appears. Use it to choose whether to evaluate or ignore cases with low sample rates. If you
choose **ignore (maintain alarm state)**, the current alarm state is always maintained when the sample size is too low. For more information, see Percentile-Based CloudWatch Alarms and Low Data Samples (p. 66).

6. Choose **Next**.
7. Under **Notification**, select an SNS topic to notify when the alarm is in **ALARM** state, **OK** state, or **INSUFFICIENT_DATA** state.

   To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

   To have the alarm not send notifications, choose **Remove**.
8. To have the alarm perform Auto Scaling or EC2 actions, choose the appropriate button and choose the alarm state and action to perform.
9. When finished, choose **Next**.
10. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose **Next**.
11. Under **Preview and create**, confirm that the information and conditions are what you want, then choose **Create alarm**.

### Modifying an Anomaly Detection Model

Once you have created an alarm, you can adjust the anomaly detection model. You can exclude certain time periods from being used in the model creation, and you can specify whether to adjust the model for daylight savings time changes.

You can choose to exclude time periods in both the past and the future.

**To adjust the anomaly detection model for an alarm**

2. In the navigation pane, choose **Alarms**.
3. Choose the name of the alarm. Use the search box to find the alarm if necessary.
4. Choose **View in metrics**.
5. In the lower part of the screen, choose **Edit model**.
6. To exclude a time period from being used to produce the model, choose **Add another time range to exclude from training**. Then select or enter the days and times to exclude from training, and choose **Apply**.
7. If the metric is sensitive to daylight savings time changes, select the appropriate time zone in the **Metric timezone** box.
8. Choose **Update**.

### Deleting an Anomaly Detection Model

Using anomaly detection for an alarm accrues AWS charges. If you no longer need an anomaly detection model for an alarm, you should delete the alarm and then the model. If you delete the model without deleting the alarm, the alarm automatically recreates the model.

**To delete an alarm**

Creating an Alarm Based on a Metric Math Expression

To create an alarm based on a math expression using the new alarm user interface

2. In the navigation pane, choose Alarms, Create Alarm.
3. Choose Select Metric and do one of the following:
   a. Choose the service namespace that contains a specific metric. Continue choosing options as they appear to narrow the choices. When a list of metrics appears, select the check box next to the right metric.
   b. In the search box, enter the name of a metric, dimension, or resource ID and press Enter. Choose one of the results and continue until a list of metrics appears. Select the check box next to the right metric.
   (Optional) To add another metric to use in the math expression, under All metrics, choose All, find the specific metric, and then select the check box next to it. You can add up to 10 metrics.
4. Choose Graphed metrics. For each metric added, do the following:
   a. Under Statistic, choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, p95 . 45).
   b. Under Period, choose the evaluation period for the alarm. When evaluating the alarm, each period is aggregated into one data point.
      You can also choose whether the y-axis legend appears on the left or right while you're creating the alarm. This preference is used only while you're creating the alarm.
5. Choose Add a math expression. A new row appears for the expression.
6. On the new row, under the Details column, enter the math expression and press Enter. For information about the functions and syntax that you can use, see Metric Math Syntax and Functions (p. 48).

To use a metric or the result of another expression as part of the formula for this expression, use the value shown in the Id column: for example, \( m1+m2 \) or \( e1-MIN(e1) \).

You can change the value of Id. It can include numbers, letters, and underscores, and it must start with a lowercase letter. Changing the value of Id to a more meaningful name can also make the alarm graph easier to understand.

7. (Optional) Add more math expressions, using both metrics and the results of other math expressions in the formulas of the new math expressions.

8. When you have the expression to use for the alarm, clear the check boxes to the left of every other expression and every metric on the page. Only the check box next to the expression to use for the alarm should be selected. The expression that you choose for the alarm must produce a single time series and show only one line on the graph. Then choose Select metric.

The Specify metric and conditions page appears, showing a graph and other information about the math expression that you have selected.

9. For Whenever expression is, specify whether the expression must be greater than, less than, or equal to the threshold. Under than..., specify the threshold value.

10. Choose Additional configuration. For Datapoints to alarm, specify how many evaluation periods (data points) must be in the ALARM state to trigger the alarm. If the two values here match, you create an alarm that goes to ALARM state if that many consecutive periods are breaching.

To create an M out of N alarm, specify a lower number for the first value than you specify for the second value. For more information, see Evaluating an Alarm (p. 62).

11. For Missing data treatment, choose how to have the alarm behave when some data points are missing. For more information, see Configuring How CloudWatch Alarms Treat Missing Data (p. 63).

12. Choose Next.

13. Under Notification, select an SNS topic to notify when the alarm is in ALARM state, OK state, or INSUFFICIENT_DATA state.

To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose Add notification.

To have the alarm not send notifications, choose Remove.

14. To have the alarm perform Auto Scaling or EC2 actions, choose the appropriate button and choose the alarm state and action to perform.

15. When finished, choose Next.

16. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose Next.

17. Under Preview and create, confirm that the information and conditions are what you want, then choose Create alarm.

You can also add alarms to a dashboard. For more information, see Add or Remove an Alarm from a CloudWatch Dashboard (p. 23).

To create an alarm based on a math expression using the older user interface

2. In the navigation pane, choose Alarms, Create Alarm.
3. Choose Select Metric and do one of the following:
• Choose the service namespace that contains a specific metric. Continue choosing options as they appear to narrow the choices. When a list of metrics appear, select the check box next to the right metric.

• In the search box, enter the name of a metric, dimension, or resource ID and press Enter. Choose one of the results and continue until a list of metrics appear. Select the check box next to the right metric.

(Optional) To add another metric to use in the math expression, under All metrics, choose All, find the specific metric and then select the check box next to it. You can add up to 10 metrics.

4. Choose Graphed metrics. For each metric added, do the following:
   a. Under Statistic, choose one of the statistics or predefined percentiles, or specify a custom percentile (for example, p95 . 45).
   b. Under Period, choose the evaluation period for the alarm. When evaluating the alarm, each period is aggregated into one data point.

   You can also choose whether the y-axis legend appears on the left or right while you’re creating the alarm. This preference is used only while you’re creating the alarm.

5. Choose Add a math expression. A new row appears for the expression.

6. On the new row, under the Details column, enter the math expression and press Enter. For information about the functions and syntax that you can use, see Metric Math Syntax and Functions (p. 48).

   To use a metric or the result of another expression as part of the formula for this expression, use the value shown in the Id column. For example, m1+m2 or e1-MIN(e1).

   You can change the value of Id. It can include numbers, letters, and underscores, and it must start with a lowercase letter. Changing the value of Id to a more meaningful name can also make the alarm graph easier to understand.

7. (Optional) Add more math expressions, using both metrics and the results of other math expressions in the formulas of the new math expressions.

8. When you have the expression to use for the alarm, clear the check boxes to the left of every other expression and every metric on the page. Only the check box next to the expression to use for the alarm should be selected. The expression that you choose for the alarm must produce a single time series and show only one line on the graph. Then choose Select metric.

9. Enter a name and description for the alarm. The name must contain only ASCII characters.

10. For Whenever, specify the alarm condition.
    a. For is, specify whether the expression result must be greater than, less than, or equal to the threshold and specify the threshold value.
    b. For for, specify how many evaluation periods (data points) must be in the ALARM state to trigger the alarm. Initially, you can change only the second value, and the first value changes to match your entry. This creates an alarm that goes to the ALARM state if that many consecutive periods are breaching.

   To create an M out of N alarm, choose the pencil icon. You can then change the M number to be different than the N number. For more information, see Evaluating an Alarm (p. 62).

11. Under Additional settings, for Treat missing data as, choose how to have the alarm behave when some data points are missing. For more information, see Configuring How CloudWatch Alarms Treat Missing Data (p. 63).

12. Under Actions, select the type of action to have the alarm to perform when the alarm is triggered. Choose +Notification or +AutoScaling Action to have the alarm perform multiple actions. Specify at least one action.

13. Choose Create Alarm.
Editing a CloudWatch Alarm

You can edit an existing alarm and update the Amazon SNS email notification list that it uses.

CloudWatch has changed the alarm user interface. By default, you’re shown the new user interface, but you can choose to return to the old user interface. This topic contains steps for each.

To edit an alarm using the new alarm user interface

2. In the navigation pane, choose Alarms.
3. Choose the name of the alarm.
4. Choose Edit.

The Specify metric and conditions page appears, showing a graph and other information about the metric and statistic that you selected.

5. To change the metric, choose Edit, choose the All metrics tab, and do one of the following:
   • Choose the service namespace that contains the metric that you want. Continue choosing options as they appear to narrow the choices. When a list of metrics appears, select the check box next to the metric that you want.
   • In the search box, enter the name of a metric, dimension, or resource ID and press Enter. Then choose one of the results and continue until a list of metrics appears. Select the check box next to the metric that you want.

Choose Select metric.

6. To change other aspects of the alarm, choose the appropriate options. To change how many data points must be breaching for the alarm to go into ALARM state or to change how missing data is treated, choose Additional configuration.

7. Choose Next.

8. Under Notification, Auto Scaling action, and EC2 action, optionally edit the actions taken when the alarm is triggered. Then choose Next.

9. Optionally change the alarm description.

   You can't change the name of an existing alarm. You can copy an alarm and give the new alarm a different name. To copy an alarm, select the check box next to the alarm name in the alarm list and choose Action, Copy.

10. Choose Next.

11. Under Preview and create, confirm that the information and conditions are what you want, then choose Update alarm.

To edit an alarm using the older alarms user interface

2. In the navigation pane, choose Alarms.
3. Select the alarm and choose Actions, Modify.
4. On the Modify Alarm page, update the alarm as necessary and choose Save Changes. To modify the expression, metrics, period, or statistic, first choose Edit near the top of the screen.

   You can't change the name of an existing alarm. You can change the description. Or you can copy the alarm and give the new alarm a different name. To copy an alarm, select the alarm and then choose Actions, Copy.
To update an email notification list that was created using the Amazon SNS console

2. In the navigation pane, choose Topics and then select the ARN for your notification list (topic).
3. Do one of the following:
   - To add an email address, choose Create subscription. For Protocol, choose Email. For Endpoint, enter the email address of the new recipient. Choose Create subscription.
   - To remove an email address, choose the Subscription ID. Choose Other subscription actions, Delete subscriptions.
4. Choose Publish to topic.

Creating a CPU Usage Alarm That Sends Email

You can create a CloudWatch alarm that sends an email message using Amazon SNS when the alarm changes state from OK to ALARM.

The alarm changes to the ALARM state when the average CPU use of an EC2 instance exceeds a specified threshold for consecutive specified periods.

Setting Up a CPU Usage Alarm Using the AWS Management Console

Use these steps to use the AWS Management Console to create a CPU usage alarm.

To create an alarm that sends email based on CPU usage

2. In the navigation pane, choose Alarms, Create Alarm.
3. Under EC2 Metrics, choose a metric category (for example, Per-Instance Metrics).
4. Select a metric as follows:
   a. Select a row with the instance and the CPUUtillization metric.
   b. For the statistic, choose Average, choose one of the predefined percentiles, or specify a custom percentile (for example, p95.45).
   c. Choose a period (for example, 5 minutes).
   d. Choose Next.
5. Define the alarm as follows:

   a. Under **Alarm Threshold**, enter a unique name for the alarm (for example, `myHighCpuAlarm`) and a description of the alarm (for example, **CPU usage exceeds 70 percent**). Alarm names must contain only ASCII characters.

   b. Under **Whenever**, for **is**, choose **>** and enter **70**. For **for**, enter **2**. This specifies that the alarm is triggered if the CPU usage is above 70 percent for two consecutive sampling periods.

   ![Alarm Configuration Diagram]

   - **Alarm Threshold**
     - **Name**: `myHighCpuAlarm`
     - **Description**: CPU usage exceeds 70 percent
     - **Whenever**: CPUUtilization
       - **is**: > 70
       - **for**: 2 consecutive period(s)

   c. Under **Additional settings**, for **Treat missing data as**, choose **bad (breaching threshold)**, as missing data points might indicate that the instance is down.

   d. Under **Actions**, for **Whenever this alarm**, choose **State is ALARM**. For **Send notification to**, select an existing SNS topic or create a new one.
Setting Up a CPU Usage Alarm Using the AWS CLI

Use these steps to use the AWS CLI to create a CPU usage alarm.

To create an alarm that sends email based on CPU usage

1. Set up an SNS topic. For more information, see Setting Up Amazon SNS Notifications (p. 67).
2. Create an alarm using the `put-metric-alarm` command as follows.

```bash
aws cloudwatch put-metric-alarm --alarm-name cpu-mon --alarm-description "Alarm when CPU exceeds 70%" --metric-name CPUUtilization --namespace AWS/EC2 --statistic Average --period 300 --threshold 70 --comparison-operator GreaterThanThreshold --dimensions Name=InstanceId,Value=i-12345678 --evaluation-periods 2 --alarm-actions arn:aws:sns:us-east-1:11112223333:my-topic --unit Percent
```

3. Test the alarm by forcing an alarm state change using the `set-alarm-state` command.
   a. Change the alarm state from INSUFFICIENT_DATA to OK.

```bash
aws cloudwatch set-alarm-state --alarm-name cpu-mon --state-reason "initializing" --state-value OK
```

   b. Change the alarm state from OK to ALARM.

```bash
aws cloudwatch set-alarm-state --alarm-name cpu-mon --state-reason "initializing" --state-value ALARM
```

   c. Check that you have received an email notification about the alarm.

Creating a Load Balancer Latency Alarm That Sends Email

You can set up an Amazon SNS notification and configure an alarm that monitors latency exceeding 100 ms for your Classic Load Balancer.
Setting Up a Latency Alarm Using the AWS Management Console

Use these steps to use the AWS Management Console to create a load balancer latency alarm.

To create a load balancer latency alarm that sends email

2. In the navigation pane, choose Alarms, Create Alarm.
3. Under CloudWatch Metrics by Category, choose the ELB Metrics category.
4. Select the row with the Classic Load Balancer and the Latency metric.
5. For the statistic, choose Average, choose one of the predefined percentiles, or specify a custom percentile (for example, \texttt{p95.45}).
6. For the period, choose 1 Minute.
7. Choose Next.
8. Under Alarm Threshold, enter a unique name for the alarm (for example, \texttt{myHighCpuAlarm}) and a description of the alarm (for example, \texttt{Alarm when Latency exceeds 100s}). Alarm names must contain only ASCII characters.
9. Under Whenever, for is, choose \texttt{> and enter 0.1}. For for, enter \texttt{3}.
10. Under Additional settings, for Treat missing data as, choose ignore (maintain alarm state) so that missing data points don't trigger alarm state changes.
    
    For Percentiles with low samples, choose ignore (maintain the alarm state) so that the alarm evaluates only situations with adequate numbers of data samples.
11. Under Actions, for Whenever this alarm, choose State is ALARM. For Send notification to, choose an existing SNS topic or create a new one.

    To create an SNS topic, choose New list. For Send notification to, enter a name for the SNS topic (for example, \texttt{myHighCpuAlarm}), and for Email list, enter a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent.
12. Choose Create Alarm.

Setting Up a Latency Alarm Using the AWS CLI

Use these steps to use the AWS CLI to create a load balancer latency alarm.

To create a load balancer latency alarm that sends email

1. Set up an SNS topic. For more information, see Setting Up Amazon SNS Notifications (p. 67).
2. Create the alarm using the \texttt{put-metric-alarm} command as follows:

\begin{verbatim}
aws cloudwatch put-metric-alarm --alarm-name lb-mon --alarm-description "Alarm when Latency exceeds 100s" --metric-name Latency --namespace AWS/ELB --statistic Average --period 60 --threshold 100 --comparison-operator GreaterThanThreshold --dimensions Name=LoadBalancerName,Value=my-server --evaluation-periods 3 --alarm-actions arn:aws:sns:us-east-1:111122233333:my-topic --unit Seconds
\end{verbatim}

3. Test the alarm by forcing an alarm state change using the \texttt{set-alarm-state} command.
Creating a Storage Throughput Alarm

You can set up an SNS notification and configure an alarm that sends email when Amazon EBS exceeds 100 MB throughput.

Setting Up a Storage Throughput Alarm Using the AWS Management Console

Use these steps to use the AWS Management Console to create an alarm based on Amazon EBS throughput.

To create a storage throughput alarm that sends email

2. In the navigation pane, choose Alarms, Create Alarm.
3. Under EBS Metrics, choose a metric category.
4. Select the row with the volume and the VolumeWriteBytes metric.
5. For the statistic, choose Average. For the period, choose 5 Minutes. Choose Next.
6. Under Alarm Threshold, enter a unique name for the alarm (for example, myHighWriteAlarm) and a description of the alarm (for example, VolumeWriteBytes exceeds 100,000 KiB/s). Alarm names must contain only ASCII characters.
7. Under Whenever, for is, choose > and enter 100000. For for, enter 15 consecutive periods. A graphical representation of the threshold is shown under Alarm Preview.
8. Under Additional settings, for Treat missing data as, choose ignore (maintain alarm state) so that missing data points don’t trigger alarm state changes.
9. Under Actions, for Whenever this alarm, choose State is ALARM. For Send notification to, choose an existing SNS topic or create one.

To create an SNS topic, choose New list. For Send notification to, enter a name for the SNS topic (for example, myHighCpuAlarm), and for Email list, enter a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.

10. Choose Create Alarm.
Setting Up a Storage Throughput Alarm Using the AWS CLI

Use these steps to use the AWS CLI to create an alarm based on Amazon EBS throughput.

To create a storage throughput alarm that sends email

1. Create an SNS topic. For more information, see Setting Up Amazon SNS Notifications (p. 67).
2. Create the alarm.

```
```

3. Test the alarm by forcing an alarm state change using the set-alarm-state command.
   a. Change the alarm state from INSUFFICIENT_DATA to OK.

```
aws cloudwatch set-alarm-state --alarm-name ebs-mon --state-reason "initializing" --state-value OK
```

b. Change the alarm state from OK to ALARM.

```
aws cloudwatch set-alarm-state --alarm-name ebs-mon --state-reason "initializing" --state-value ALARM
```

c. Change the alarm state from ALARM to INSUFFICIENT_DATA.

```
aws cloudwatch set-alarm-state --alarm-name ebs-mon --state-reason "initializing" --state-value INSUFFICIENT_DATA
```

d. Check that you have received an email notification about the alarm.

Create Alarms to Stop, Terminate, Reboot, or Recover an Instance

Using Amazon CloudWatch alarm actions, you can create alarms that automatically stop, terminate, reboot, or recover your EC2 instances. You can use the stop or terminate actions to help you save money when you no longer need an instance to be running. You can use the reboot and recover actions to automatically reboot those instances or recover them onto new hardware if a system impairment occurs.

There are a number of scenarios in which you might want to automatically stop or terminate your instance. For example, you might have instances dedicated to batch payroll processing jobs or scientific computing tasks that run for a period of time and then complete their work. Rather than letting those instances sit idle (and accrue charges), you can stop or terminate them, which helps you to save money. The main difference between using the stop and the terminate alarm actions is that you can easily restart a stopped instance if you need to run it again later. You can also keep the same instance ID and root volume. However, you cannot restart a terminated instance. Instead, you must launch a new instance.
Adding Stop Actions to Amazon CloudWatch Alarms

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them off. You can

To set up a CloudWatch alarm action that can reboot, stop, or terminate an instance, you must use a service-linked IAM role, AWSServiceRoleForCloudWatchEvents. The AWSServiceRoleForCloudWatchEvents IAM role enables AWS to perform alarm actions on your behalf.

To create the service-linked role for CloudWatch Events, use the following command:

```
aws iam create-service-linked-role --aws-service-name events.amazonaws.com
```

Contents

- Adding Terminate Actions to Amazon CloudWatch Alarms (p. 85)
- Adding Reboot Actions to Amazon CloudWatch Alarms (p. 86)
- Adding Recover Actions to Amazon CloudWatch Alarms (p. 87)
- Viewing the History of Triggered Alarms and Actions (p. 88)

Adding Stop Actions to Amazon CloudWatch Alarms

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them off. You can
create an alarm that is triggered when the average CPU utilization percentage has been lower than 10 percent for 24 hours, signaling that it is idle and no longer in use. You can adjust the threshold, duration, and period to suit your needs, plus you can add an SNS notification, so that you will receive an email when the alarm is triggered.

Amazon EC2 instances that use an Amazon Elastic Block Store volume as the root device can be stopped or terminated, whereas instances that use the instance store as the root device can only be terminated.

To create an alarm to stop an idle instance using the Amazon CloudWatch console

2. In the navigation pane, choose Alarms, Create Alarm.
3. For the Select Metric step, do the following:
   a. Under EC2 Metrics, choose Per-Instance Metrics.
   b. Select the row with the instance and the CPUUtilization metric.
   c. For the statistic, choose Average.
   d. Choose a period (for example, 1 Hour).
   e. Choose Next.
4. For the Define Alarm step, do the following:
   a. Under Alarm Threshold, type a unique name for the alarm (for example, Stop EC2 instance) and a description of the alarm (for example, Stop EC2 instance when CPU is idle too long). Alarm names must contain only ASCII characters.
   b. Under Whenever, for is, choose < and type 10. For for, type 24 consecutive periods.
      A graphical representation of the threshold is shown under Alarm Preview.
   c. Under Notification, for Send notification to, choose an existing SNS topic or create a new one.
      To create an SNS topic, choose New list. For Send notification to, type a name for the SNS topic (for example, Stop_EC2_Instance). For Email list, type a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.
   d. Choose EC2 Action.
   e. For Whenever this alarm, choose State is ALARM. For Take this action, choose Stop this instance.
   f. Choose Create Alarm.

Adding Terminate Actions to Amazon CloudWatch Alarms

You can create an alarm that terminates an EC2 instance automatically when a certain threshold has been met (as long as termination protection is not enabled for the instance). For example, you might want to terminate an instance when it has completed its work, and you don't need the instance again. If you might want to use the instance later, you should stop the instance instead of terminating it. For information about enabling and disabling termination protection for an instance, see Enabling Termination Protection for an Instance in the Amazon EC2 User Guide for Linux Instances.

To create an alarm to terminate an idle instance using the Amazon CloudWatch console

2. In the navigation pane, choose Alarms, Create Alarm.
Adding Reboot Actions to Amazon CloudWatch Alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically reboots the instance. The reboot alarm action is recommended for Instance Health Check failures (as opposed to the recover alarm action, which is suited for System Health Check failures). An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it remains on the same physical host, so your instance keeps its public DNS name, private IP address, and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing hour, unlike stopping and restarting your instance. For more information about rebooting an instance, see Reboot Your Instance in the Amazon EC2 User Guide for Linux Instances.

Important
To avoid a race condition between the reboot and recover actions, avoid setting the same evaluation period for both a reboot alarm and a recover alarm. We recommend that you set reboot alarms to three evaluation periods of one minute each.

To create an alarm to reboot an instance using the Amazon CloudWatch console
2. In the navigation pane, choose Alarms, Create Alarm.
3. For the Select Metric step, do the following:
   a. Under EC2 Metrics, choose Per-Instance Metrics.
Adding Recover Actions to Amazon CloudWatch Alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. Terminated instances cannot be recovered. A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata.

When the StatusCheckFailed_System alarm is triggered, and the recover action is initiated, you will be notified by the Amazon SNS topic that you chose when you created the alarm and associated the recover action. During instance recovery, the instance is migrated during an instance reboot, and any data that is in-memory is lost. When the process is complete, information is published to the SNS topic you've configured for the alarm. Anyone who is subscribed to this SNS topic will receive an email notification that includes the status of the recovery attempt and any further instructions. You will notice an instance reboot on the recovered instance.

The recover action can be used only with StatusCheckFailed_System, not with StatusCheckFailed_Instance.

Examples of problems that cause system status checks to fail include:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

The recover action is supported only on:

- The A1, C3, C4, C5, C5n, M3, M4, M5, M5a, P3, R3, R4, R5, R5a, T2, T3, X1, and X1e instance types
• Instances in a VPC
• Instances with default or dedicated instance tenancy
• Instances that use Amazon EBS volumes only (do not configure instance store volumes)

If your instance has a public IPv4 address, it retains the public IP address after recovery.

Important
To avoid a race condition between the reboot and recover actions, avoid setting the same evaluation period for both a reboot alarm and a recover alarm. We recommend that you set recover alarms to two evaluation periods of one minute each and reboot alarms to three evaluation periods of one minute each.

To create an alarm to recover an instance using the Amazon CloudWatch console

2. In the navigation pane, choose Alarms, Create Alarm.
3. For the Select Metric step, do the following:
   a. Under EC2 Metrics, choose Per-Instance Metrics.
   b. Select the row with the instance and the StatusCheckFailed_System metric.
   c. For the statistic, choose Minimum.
   d. Choose a period (for example, 1 Minute).

Important
To avoid a race condition between the reboot and recover actions, avoid setting the same evaluation period for both a reboot alarm and a recover alarm. We recommend that you set recover alarms to two evaluation periods of one minute each.

   e. Choose Next.
4. For the Define Alarm step, do the following:
   a. Under Alarm Threshold, type a unique name for the alarm (for example, Recover EC2 instance) and a description of the alarm (for example, Recover EC2 instance when health checks fail). Alarm names must contain only ASCII characters.
   b. Under Whenever, for is, choose > and type 0. For for, type 2 consecutive periods.
   c. Under Notification, for Send notification to, choose an existing SNS topic or create a new one.

To create an SNS topic, choose New list. For Send notification to, type a name for the SNS topic (for example, Recover_EC2_Instance). For Email list, type a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a topic subscription confirmation email. You must confirm the subscription before notifications can be sent to an email address.
   d. Choose EC2 Action.
   e. For Whenever this alarm, choose State is ALARM. For Take this action, choose Recover this instance.
   f. Choose Create Alarm.

Viewing the History of Triggered Alarms and Actions

You can view alarm and action history in the Amazon CloudWatch console. Amazon CloudWatch keeps the last two weeks’ worth of alarm and action history.

To view the history of triggered alarms and actions

2. In the navigation pane, choose **Alarms** and select an alarm.
3. To view the most recent state transition along with the time and metric values, choose **Details**.
4. To view the most recent history entries, choose **History**.

Creating a Billing Alarm to Monitor Your Estimated AWS Charges

You can monitor your estimated AWS charges by using Amazon CloudWatch. When you enable the monitoring of estimated charges for your AWS account, the estimated charges are calculated and sent several times daily to CloudWatch as metric data.

Billing metric data is stored in the US East (N. Virginia) Region and represents worldwide charges. This data includes the estimated charges for every service in AWS that you use, in addition to the estimated overall total of your AWS charges.

The alarm triggers when your account billing exceeds the threshold you specify. It triggers only when actual billing exceeds the threshold. It doesn't use projections based on your usage so far in the month.

If you create a billing alarm at a time when your charges have already exceeded the threshold, the alarm goes to the **ALARM** state immediately.

**Tasks**
- Enabling Billing Alerts (p. 89)
- Creating a Billing Alarm (p. 90)
- Deleting a Billing Alarm (p. 90)

Enabling Billing Alerts

Before you can create an alarm for your estimated charges, you must enable billing alerts, so that you can monitor your estimated AWS charges and create an alarm using billing metric data. After you enable billing alerts, you can't disable data collection, but you can delete any billing alarms that you created.

After you enable billing alerts for the first time, it takes about 15 minutes before you can view billing data and set billing alarms.

**Requirements**
- You must be signed in using account root user credentials or as an IAM user that has been given permission to view billing information.
- For consolidated billing accounts, billing data for each linked account can be found by logging in as the paying account. You can view billing data for total estimated charges and estimated charges by service for each linked account, in addition to the consolidated account.

**To enable the monitoring of estimated charges**
2. In the navigation pane, choose **Billing Preferences**.
3. Choose **Receive Billing Alerts**.
4. Choose **Save preferences**.
Creating a Billing Alarm

After you’ve enabled billing alerts, you can create a billing alarm. In this procedure, you create an alarm that sends an email message when your estimated charges for AWS exceed a specified threshold.

Note
This procedure uses the advanced options. For more information about using the simple options, see Create a Billing Alarm (p. 275) in Monitor Your Estimated Charges Using CloudWatch.

To create a billing alarm using the CloudWatch console

2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and represents worldwide charges.
3. In the navigation pane, choose Alarms, Create Alarm.
4. Choose Select metric. In the All metrics tab, choose Billing, Total Estimated Charge.
5. Select the check box next to EstimatedCharges, and choose Select metric.
6. Under Conditions, choose Static.
7. For Whenever EstimatedCharges is, choose Greater.
8. For than, enter the monetary amount (for example, 200) that must be exceeded to trigger the alarm.

Note
The preview graph displays your current charges for the month.
9. Choose Next.
10. Under Notification, select an SNS topic to notify when the alarm is in ALARM state.

   To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose Add notification.
11. When finished, choose Next.
12. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose Next.
13. Under Preview and create, confirm that the information and conditions are what you want, then choose Create alarm.

Deleting a Billing Alarm

You can delete your billing alarm when you no longer need it.

To delete a billing alarm

2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose Alarms.
4. Select the check box next to the alarm and choose Actions, Delete.
5. When prompted for confirmation, choose Yes, Delete.
Hiding Amazon EC2 Auto Scaling Alarms

When you view your alarms in the AWS Management Console, you can hide the alarms related to Amazon EC2 Auto Scaling. This feature is available only in the AWS Management Console.

To temporarily hide Amazon EC2 Auto Scaling alarms

2. In the navigation pane, choose Alarms and select Hide all AutoScaling alarms.
CloudWatch Anomaly Detection

CloudWatch anomaly detection is in open preview. The preview is open to AWS accounts in all commercial AWS Regions. You do not need to request access. Features may be added or changed before announcing General Availability. Please contact anomalydetectionfeedback@amazon.com for any feedback, questions, or if you would like to be informed when updates are available.

On August 29, 2019, we added support for using AWS CloudFormation to deploy alarms based on anomaly detection models. For more information, see AWS::CloudWatch::Alarm.

On August 27, 2019, we deployed the preview anomaly detection band feature. Now when you enable anomaly detection, you can immediately see a preview band which is an approximation of the anomaly detection band that will be generated by the model.

When you enable anomaly detection for a metric, CloudWatch applies machine-learning algorithms to the metric’s past data to create a model of the metric’s expected values. The model generates two metrics, one that represents the upper band of normal metric behavior, and another that represents the lower band.

You can use the model of expected values in two ways:

- You can create anomaly detection alarms based on a metric’s expected value. These types of alarms don’t have a static threshold for determining alarm state, but instead compare the metric’s value to the expected value based on the anomaly detection model. You specify a number of standard deviations that CloudWatch uses along with the model to determine the “normal” range of values for the metric, where a higher number of standard deviations produces a thicker band of “normal” values.

  You can choose whether the alarm is triggered when the metric value is above the band of expected values, below the band, or either above or below the band.

  For more information, see Creating a CloudWatch Alarm Based on Anomaly Detection (p. 71).

- When viewing a graph of metric data, you can overlay the expected values onto the graph as a band, instantly making it visually clear which values in the graph are out of the normal range. For more information, see Creating a Graph (p. 38).

  You can enable anomaly detection using the AWS Management Console, the AWS CLI, AWS CloudFormation, or the AWS SDK. You can also retrieve the upper and lower values of the model’s band by using the GetMetricData API request with the ANOMALY_DETECTION_BAND metric math function. For more information, see GetMetricData.

The links in the previous list are for creating an anomaly detection model using the AWS Management Console. You can also create anomaly detection models using the AWS API, the AWS CLI, and AWS CloudFormation.
How CloudWatch Anomaly Detection Works

When you enable anomaly detection for a metric, CloudWatch applies machine-learning algorithms to the metric's past data to create a model of the metric's expected values, taking into account trends and hourly, daily, and weekly patterns of the metric. The machine-learning algorithm trains on up to two weeks of metric data, but you can enable anomaly detection on a metric even if the metric does not have a full two weeks of data.

When you enable anomaly detection, you can immediately see a preview anomaly detection band which is an approximation of the anomaly detection band that will be generated by the model. It takes up to 15 minutes for the actual anomaly detection band to appear.

The machine-learning model is specific to a metric and a statistic. For example, if you enable anomaly detection for a metric using the $\text{AVG}$ statistic, the model is specific to the $\text{AVG}$ statistic.

After you have created a model, it constantly updates itself, using the latest data from the metric.

After you enable anomaly detection on a metric, you can optionally choose to exclude specified time periods of the metric from being used to train the model. This way, you can exclude deployments or other unusual events from being used for model training, ensuring the most accurate model is created.

Using anomaly detection models for alarms incurs charges on your AWS account. For more information, see Amazon CloudWatch Pricing.
Using Container Insights

Use CloudWatch Container Insights to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. Container Insights is available for Amazon Elastic Container Service, Amazon Elastic Kubernetes Service, and Kubernetes platforms on Amazon EC2. The metrics include utilization for resources such as CPU, memory, disk, and network. Container Insights also provides diagnostic information, such as container restart failures, to help you isolate issues and resolve them quickly. You can also set CloudWatch alarms on metrics that Container Insights collects.

The metrics that Container Insights collects are available in CloudWatch automatic dashboards. You can analyze and troubleshoot container performance and logs data with CloudWatch Logs Insights.

Operational data is collected as performance log events. These are entries that use a structured JSON schema that enables high-cardinality data to be ingested and stored at scale. From this data, CloudWatch creates aggregated metrics at the cluster, node, pod, task, and service level as CloudWatch metrics.

Metrics collected by Container Insights are charged as custom metrics. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

In Amazon EKS and Kubernetes, Container Insights uses a containerized version of the CloudWatch agent to discover all of the running containers in a cluster. It then collects performance data at every layer of the performance stack.

Currently, Container Insights isn't supported in AWS Batch.

Container Insights supports encryption with the customer master key (CMK) for the logs and metrics that it collects. To enable this encryption, you must manually enable KMS encryption for the log group that receives Container Insights data. This results in Container Insights encrypting this data using the provided CMK. For more information, see Encrypt Log Data in CloudWatch Logs Using AWS KMS.

Note
For Amazon ECS, network metrics are available only for containers in bridge network mode. They are not available for containers in awsvpc network mode or host network mode.

Supported Regions for Amazon ECS

Container Insights for Amazon ECS is supported in the following Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)
- Canada (Central)
- EU (Frankfurt)
- EU (Ireland)
- EU (London)
- EU (Paris)
- Asia Pacific (Tokyo)
• Asia Pacific (Seoul)
• Asia Pacific (Singapore)
• Asia Pacific (Sydney)
• Asia Pacific (Mumbai)
• South America (São Paulo)

AWS Fargate is not supported in EU (Paris) or South America (São Paulo).

Supported Regions for Amazon EKS and Kubernetes

Container Insights for Amazon EKS and Kubernetes is supported in the following Regions:

• US East (N. Virginia)
• US East (Ohio)
• US West (N. California)
• US West (Oregon)
• Canada (Central)
• EU (Frankfurt)
• EU (Ireland)
• EU (London)
• EU (Paris)
• Asia Pacific (Mumbai)
• Asia Pacific (Singapore)
• Asia Pacific (Sydney)
• Asia Pacific (Tokyo)
• Asia Pacific (Seoul)
• South America (São Paulo)

Topics
• Setting Up Container Insights (p. 95)
• Viewing Container Insights Metrics (p. 111)
• Metrics Collected by Container Insights (p. 113)
• Container Insights Performance Log Reference (p. 119)
• Troubleshooting Container Insights (p. 139)
• Building Your Own CloudWatch Agent Docker Image (p. 140)

Setting Up Container Insights

The Container Insights setup process is different for Amazon ECS and Amazon EKS and Kubernetes.

Topics
• Setting Up Container Insights on Amazon ECS (p. 96)
• Setting Up Container Insights on Amazon EKS and Kubernetes (p. 97)
Setting Up Container Insights on Amazon ECS

You can enable Container Insights on existing Amazon ECS clusters and on new clusters that you create. For existing clusters, you use the AWS CLI. For new clusters, use either the Amazon ECS console or the AWS CLI.

If you’re using Amazon ECS on an Amazon EC2 instance, to collect network and storage metrics from Container Insights you must launch that instance using an AMI that includes Amazon ECS agent version 1.29. For information about updating your agent version, see Updating the Amazon ECS Container Agent.

Currently, you can’t enable Container Insights when you use AWS CloudFormation to create a new cluster. As a workaround, you can use the AWS CLI to set account-level permission to enable Container Insights for any new Amazon ECS clusters created in your account. To do so, enter the following command.

```
aws ecs put-account-setting --name "containerInsights" --value "enabled"
```

Setting Up Container Insights on Existing Amazon ECS Clusters

To enable Container Insights on an existing Amazon ECS cluster, enter the following command.

```
aws ecs update-cluster-settings --cluster myCICluster --settings name=containerInsights,value=enabled
```

Setting Up Container Insights on New Amazon ECS Clusters

There are two ways to enable Container Insights on new Amazon ECS clusters. You can configure Amazon ECS so that all new clusters are enabled for Container Insights by default, or you can enable a new cluster when you create it.

Using the AWS Management Console

You can enable Container Insights on all new clusters by default, or on an individual cluster as you create it.

To enable Container Insights on all new clusters by default

1. Open the Amazon ECS console at https://console.aws.amazon.com/ecs/.
2. In the navigation pane, choose Account Settings.
3. Select the check box at the bottom of the page to enable the Container Insights default.

If you haven’t used the preceding procedure to enable Container Insights on all new clusters by default, use the following steps to create a cluster with Container Insights enabled.

To create a cluster with Container Insights enabled

1. Open the Amazon ECS console at https://console.aws.amazon.com/ecs/.
2. In the navigation pane, choose Clusters.
3. Choose Create cluster.
4. On the next page, do the following:
   a. Name your cluster.
   b. If you don’t have a VPC already, select the check box to create one. You can use the default values for the VPC.
c. Fill out all other needed information, including instance type.

d. Select **Enabled Container Insights**.

e. Choose **Create**.

You can now create task definitions, run tasks, and launch services in the cluster. For more information, see the following:

- Creating a Task Definition
- Running Tasks
- Creating a Service

**Setting Up Container Insights on New Amazon ECS Clusters Using the AWS CLI**

To enable Container Insights on all new clusters by default, enter the following.

```
aws ecs put-account-setting --name "containerInsights" --value "enabled"
```

If you didn’t use the preceding command to enable Container Insights on all new clusters by default, enter the following command to create a new cluster with Container Insights enabled. You must be running version 1.16.200 or later of the AWS CLI for the following command to work.

```
aws ecs create-cluster --cluster-name myCICluster --settings "name=containerInsights,value=enabled"
```

**Disabling Container Insights on Amazon ECS Clusters**

To disable Container Insights on an existing Amazon ECS cluster, enter the following command.

```
aws ecs update-cluster-settings --cluster myCICluster --settings name=containerInsights,value=disabled
```

**Setting Up Container Insights on Amazon EKS and Kubernetes**

The overall process for setting up Container Insights on Amazon EKS or Kubernetes is as follows:

1. Verify that you have the necessary prerequisites.
2. Set up the CloudWatch agent as a DaemonSet on your Amazon EKS cluster or Kubernetes cluster to send metrics to CloudWatch, and set up FluentD as a DaemonSet to send logs to CloudWatch Logs.

   You can perform these steps at once as part of the quick start setup, or do them separately.

3. (Optional) Set up Amazon EKS control plane logging.
4. (Optional) Set up the CloudWatch agent as a StatsD endpoint on the cluster to send StatsD metrics to CloudWatch.

**Topics**

- Verify Prerequisites (p. 98)
- Quick Start Setup for Container Insights on Amazon EKS (p. 99)
- Set Up the CloudWatch Agent to Collect Cluster Metrics (p. 99)
Set Up FluentD as a DaemonSet to Send Logs to CloudWatch Logs (p. 102)
(Optional) Set Up Amazon EKS Control Plane Logging (p. 107)
(Optional) Set Up the CloudWatch Agent as a StatsD Endpoint to Send StatsD Metrics to CloudWatch (p. 107)
Updating or Deleting Container Insights on Amazon EKS and Kubernetes (p. 110)

Verify Prerequisites

Before you install Container Insights on Amazon EKS or Kubernetes, verify the following:

- You have a functional Amazon EKS or Kubernetes cluster with nodes attached in one of the Regions that supports the Container Insights for Amazon EKS and Kubernetes. For the list of supported Regions, see Using Container Insights (p. 94).
- You have kubectl installed and running. For more information, see Installing kubectl in the Amazon EKS User Guide.
- If you're using Kubernetes running on AWS instead of using Amazon EKS, the following prerequisites are also necessary:
  - Be sure that your Kubernetes cluster has enabled role-based access control (RBAC). For more information, see Using RBAC Authorization in the Kubernetes Reference.
  - Your kubelet has enabled Webhook authorization mode. For more information, see Kubelet authentication/authorization in the Kubernetes Reference.
  - Your container runtime is Docker.

You must also attach a policy to the IAM role of your Amazon EKS worker nodes to enable them to send metrics and logs to CloudWatch.

To add the necessary policy to the IAM role for your worker nodes

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Select one of the worker node instances and choose the IAM role in the description.
3. On the IAM role page, choose Attach policies.
4. In the list of policies, select the check box next to CloudWatchAgentServerPolicy. If necessary, use the search box to find this policy.
5. Choose Attach policies.

If you're running a Kubernetes cluster outside Amazon EKS, you might not already have an IAM role attached to your worker nodes. If not, you must first attach an IAM role to the instance and then add the policy as explained in the previous steps. For more information on attaching a role to an instance, see Attaching an IAM Role to an Instance in the Amazon EC2 User Guide for Windows Instances.

If you're running a Kubernetes cluster outside Amazon EKS and you want to collect EBS volume IDs in the metrics, you must add another policy to the IAM role attached to the instance. Add the following as an inline policy. For more information, see Adding and Removing IAM Identity Permissions in the IAM User Guide.

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Action": [ "ec2:DescribeVolumes"
    ],
```
Quick Start Setup for Container Insights on Amazon EKS

To complete the setup of Container Insights, you can follow the quick start instructions in this section. Alternatively, you can instead follow the instructions in the following two sections, Set Up the CloudWatch Agent to Collect Cluster Metrics (p. 99) and Set Up FluentD as a DaemonSet to Send Logs to CloudWatch Logs (p. 102). Those sections provide more details on how CloudWatch agent works with Amazon EKS and the configuration, but require you to perform more installation steps.

To deploy Container Insights using the quick start, enter the following command.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/master/k8s-yaml-templates/quickstart/cwagent-fluentd-quickstart.yaml | sed "s/{{cluster_name}}/Cluster_Name/;s/{{region_name}}/Region/" | kubectl apply -f -
```

In this command, `Cluster_Name` is the name of your Amazon EKS or Kubernetes cluster, and `Region` is the name of the Region where the logs are published. We recommend that you use the same Region where your cluster is deployed to reduce the AWS outbound data transfer costs.

For example, to deploy Container Insights on the cluster named `MyCluster` and publish the logs and metrics to US West (Oregon), enter the following command.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/master/k8s-yaml-templates/quickstart/cwagent-fluentd-quickstart.yaml | sed "s/{{cluster_name}}/MyCluster/;s/{{region_name}}/us-west-2/" | kubectl apply -f -
```

Deleting Container Insights

If you want to remove Container Insights after using the quick start setup, enter the following command.

```
curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/master/k8s-yaml-templates/quickstart/cwagent-fluentd-quickstart.yaml | sed "s/{{cluster_name}}/Cluster_Name/;s/{{region_name}}/Region/" | kubectl delete -f -
```

Set Up the CloudWatch Agent to Collect Cluster Metrics

To set up Container Insights to collect metrics, you can follow the steps in Quick Start Setup for Container Insights on Amazon EKS (p. 99) or you can follow the steps in this section. In the following steps, you set up the CloudWatch agent to be able to collect metrics from your clusters.

Step 1: Create a Namespace for CloudWatch

Use the following step to create a Kubernetes namespace called `amazon-cloudwatch` for CloudWatch. You can skip this step if you have already created this namespace.

**To create a namespace for CloudWatch**

- Enter the following command.

```
```
Step 2: Create a Service Account in the Cluster

Use the following step to create a service account for the CloudWatch agent, if you do not already have one.

To create a service account for the CloudWatch agent

- Enter the following command.

```
```

If you didn't follow the previous steps, but you already have a service account for the CloudWatch agent that you want to use, you must ensure that it has the following rules. Additionally, in the rest of the steps in the Container Insights installation, you must use the name of that service account instead of `cloudwatch-agent`.

<table>
<thead>
<tr>
<th>rules:</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiGroups: [&quot;&quot;]</td>
</tr>
<tr>
<td>resources: [&quot;pods&quot;, &quot;nodes&quot;, &quot;endpoints&quot;]</td>
</tr>
<tr>
<td>verbs: [&quot;watch&quot;, &quot;list&quot;]</td>
</tr>
<tr>
<td>apiGroups: [&quot;&quot;]</td>
</tr>
<tr>
<td>resources: [&quot;nodes/proxy&quot;]</td>
</tr>
<tr>
<td>verbs: [&quot;get&quot;]</td>
</tr>
<tr>
<td>apiGroups: [&quot;&quot;]</td>
</tr>
<tr>
<td>resources: [&quot;nodes/stats&quot;, &quot;configmaps&quot;, &quot;events&quot;]</td>
</tr>
<tr>
<td>verbs: [&quot;create&quot;]</td>
</tr>
<tr>
<td>apiGroups: [&quot;&quot;]</td>
</tr>
<tr>
<td>resources: [&quot;configmaps&quot;]</td>
</tr>
<tr>
<td>resourceNames: [&quot;cwagent-clusterleader&quot;]</td>
</tr>
<tr>
<td>verbs: [&quot;get&quot;, &quot;update&quot;]</td>
</tr>
<tr>
<td>nonResourceURLs: [&quot;/metrics&quot;]</td>
</tr>
<tr>
<td>verbs: [&quot;get&quot;]</td>
</tr>
</tbody>
</table>

Step 3: Create a ConfigMap for the CloudWatch Agent

Use the following steps to create a ConfigMap for the CloudWatch agent.

To create a ConfigMap for the CloudWatch agent

1. Download the ConfigMap YAML to your `kubectl` client host by running the following command:

```
```

2. Edit the downloaded YAML file, as follows:

   - **cluster_name** – In the `kubernetes` section, replace `{{cluster-name}}` with the name of your cluster. Remove the `{{}}` characters. Alternatively, if you're using an Amazon EKS cluster, you can delete the "cluster_name" field and value. If you do, the CloudWatch agent detects the cluster name from the Amazon EC2 tags.

3. (Optional) Make further changes to the ConfigMap based on your monitoring requirements, as follows:

   - **metrics_collection_interval** – In the `kubernetes` section, you can specify how often the agent collects metrics. The default is 60 seconds. The default cadvisor collection interval in kubelet is 15 seconds, so don't set this value to less than 15 seconds.
• **endpoint_override** – In the `logs` section, you can specify the CloudWatch Logs endpoint if you want to override the default endpoint. You might want to do this if you’re publishing from a cluster in a VPC and you want the data to go to a VPC endpoint.

• **force_flush_interval** – In the `logs` section, you can specify the interval for batching log events before they are published to CloudWatch Logs. The default is 5 seconds.

• **region** – By default, the agent published metrics to the Region where the worker node is located. To override this, you can add a `region` field in the `agent` section: for example, "region": "us-west-2".

• **statsd** section – If you want the CloudWatch Logs agent to also run as a StatsD listener in each worker node of your cluster, you can add a `statsd` section to the `metrics` section, as in the following example. For information about other StatsD options for this section, see Retrieve Custom Metrics with StatsD (p. 205).

```json
"metrics": {
  "metrics_collected": {
    "statsd": {
      "service_address": "8125"
    }
  }
}
```

A full example of the JSON section is as follows.

```json
{
  "agent": {
    "region": "us-east-1"
  },
  "logs": {
    "metrics_collected": {
      "kubernetes": {
        "cluster_name": "MyCluster",
        "metrics_collection_interval": 60
      }
    },
    "force_flush_interval": 5,
    "endpoint_override": "logs.us-east-1.amazonaws.com"
  },
  "metrics": {
    "metrics_collected": {
      "statsd": {
        "service_address": "8125"
      }
    }
  }
}
```

4. Create the ConfigMap in the cluster by running the following command.

```
kubectl apply -f cwagent-configmap.yaml
```

**Step 4: Deploy the CloudWatch Agent as a DaemonSet**

To finish the installation of the CloudWatch agent and begin collecting container metrics, use the following steps.

**To deploy the CloudWatch agent as a DaemonSet**

1. • If you do not want to use StatsD on the cluster, enter the following command.
If you do want to use StatsD, follow these steps:

a. Download the DaemonSet YAML to your `kubectl` client host by running the following command.

```bash
```

b. Uncomment the `port` section in the `cwagent-daemonset.yaml` file as in the following:

```yaml
ports:
  - containerPort: 8125
    hostPort: 8125
    protocol: UDP
```

c. Deploy the CloudWatch agent in your cluster by running the following command.

```bash
kubectl apply -f cwagent-daemonset.yaml
```

2. Validate that the agent is deployed by running the following command.

```bash
kubectl get pods -n amazon-cloudwatch
```

When complete, the CloudWatch agent creates a log group named `/aws/containerinsights/Cluster_Name/performance` and sends the performance log events to this log group. If you also set up the agent as a StatsD listener, the agent also listens for StatsD metrics on port 8125 with the IP address of the node where the application pod is scheduled.

**Troubleshooting**

If the agent doesn't deploy correctly, try the following:

- Run the following command to get the list of pods.

```bash
kubectl get pods -n amazon-cloudwatch
```

- Run the following command and check the events at the bottom of the output.

```bash
kubectl describe pod pod-name -n amazon-cloudwatch
```

- Run the following command to check the logs.

```bash
kubectl logs pod-name -n amazon-cloudwatch
```

**Set Up FluentD as a DaemonSet to Send Logs to CloudWatch Logs**

To set up FluentD to collect logs from your containers, you can follow the steps in *Quick Start Setup for Container Insights on Amazon EKS* (p. 99) or you can follow the steps in this section. In the following
steps, you set up FluentD as a DaemonSet to send logs to CloudWatch Logs. When you complete this step, FluentD creates the following log groups if they don’t already exist.

<table>
<thead>
<tr>
<th>Log Group Name</th>
<th>Log Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>/aws/containerinsights/Cluster_Name/application</td>
<td>All log files in /var/log/containers</td>
</tr>
<tr>
<td>/aws/containerinsights/Cluster_Name/host</td>
<td>Logs from /var/log/dmesg, /var/log/secure, and /var/log/messages</td>
</tr>
<tr>
<td>/aws/containerinsights/Cluster_Name/dataplane</td>
<td>The logs in /var/log/journal for kubelet.service, kubeproxy.service, and docker.service.</td>
</tr>
</tbody>
</table>

**Step 1: Create a Namespace for CloudWatch**

Use the following step to create a Kubernetes namespace called `amazon-cloudwatch` for CloudWatch. You can skip this step if you have already created this namespace.

**To create a namespace for CloudWatch**

- Enter the following command.

  ```bash
  ```

**Step 2: Install FluentD**

Start this process by downloading FluentD. When you finish these steps, the deployment creates the following resources on the cluster:

- A service account named `fluentd` in the `amazon-cloudwatch` namespace. This service account is used to run the FluentD DaemonSet. For more information, see Managing Service Accounts in the Kubernetes Reference.
- A cluster role named `fluentd` in the `amazon-cloudwatch` namespace. This cluster role grants get, list, and watch permissions on pod logs to the `fluentd` service account. For more information, see API Overview in the Kubernetes Reference.
- A ConfigMap named `fluentd-config` in the `amazon-cloudwatch` namespace. This ConfigMap contains the configuration to be used by FluentD. For more information, see Configure a Pod to Use a ConfigMap in the Kubernetes Tasks documentation.

**To install FluentD**

1. Create a ConfigMap named `cluster-info` with the cluster name and the AWS Region that the logs will be sent to. Run the following command, updating the placeholders with your cluster and Region names.

   ```bash
   kubectl create configmap cluster-info \
   --from-literal=cluster.name=cluster_name \
   --from-literal=logs.region=region_name -n amazon-cloudwatch
   ```

2. Download and deploy the FluentD DaemonSet to the cluster by running the following command.
3. Validate the deployment by running the following command. Each node should have one pod named `fluentd-cloudwatch-*`.

```
kubectl get pods -n amazon-cloudwatch
```

### Step 3: Verify the FluentD Setup

To verify your FluentD setup, use the following steps.

**To verify the FluentD setup for Container Insights**

2. In the navigation pane, choose **Logs**. Make sure you're in the Region where you deployed FluentD to your containers.

   In the list of log groups in the Region, you should see the following:

   - `/aws/containerinsights/Cluster_Name/application`
   - `/aws/containerinsights/Cluster_Name/host`
   - `/aws/containerinsights/Cluster_Name/dataplane`

   If you see these log groups, the FluentD setup is verified.

### Multiline Log Support

On August 19 2019, we added multiline log support for the logs collected by FluentD.

By default, the multiline log entry starter is any character with no white space. This means that all log lines that start with a character that does not have white space are considered as a new multiline log entry.

If your own application logs use a different multiline starter, you can support them by making two changes in the `fluentd.yaml` file.

First, exclude them from the default multiline support by adding the pathnames of your log files to an `exclude_path` field in the `containers` section of `fluentd.yaml`. The following is an example.

```
<source>
  @type tail
  @id in_tail_container_logs
  @label @containers
  path /var/log/containers/*.log
  exclude_path ["full_pathname_of_log_file", "full_pathname_of_log_file2"]
</source>
```

Next, add a block for your log files to the `fluentd.yaml` file. The example below is used for the CloudWatch agent's log file, which uses a timestamp regular expression as the multiline starter. You can copy this block and add it to `fluentd.yaml`. Change the indicated lines to reflect your application log file name and the multiline starter that you want to use.
Amazon CloudWatch User Guide
Setting Up Container Insights
on Amazon EKS and Kubernetes

Reducing the Log Volume From FluentD (Optional)

By default, we send FluentD application logs and Kubernetes metadata to CloudWatch. If you want to reduce the volume of data being sent to CloudWatch, you can stop one or both of these data sources from being sent to CloudWatch.

To stop FluentD application logs, remove the following section from the `fluentd.yaml` file.

```
<source>
  @type tail
  @id in_tail_fluentd_logs
  @label fluentd_logs
  path /var/log/containers/fluentd*
  pos_file /var/log/fluentd.log.pos
  tag *
  read_from_head true
  <parse>
    @type json
    time_format %Y-%m-%dT%H:%M:%S.%NZ
  </parse>
</source>
```
To remove Kubernetes metadata from being appended to log events that are sent to CloudWatch, add one line to the record_transformer section in the fluentd.yaml file. In the log source where you want to remove this metadata, add the following line.

```
remove_keys $.kubernetes.pod_id, $.kubernetes.master_url, $.kubernetes.container_image_id, $.kubernetes.namespace_id
```

For example:

```
<filter **>
  @type record_transformer
  @id filter_containers_stream_transformer
  <record>
    stream_name #{tag_parts[3]}
  </record>
</filter>
```

**Troubleshooting**

If you don't see these log groups and are looking in the correct Region, check the logs for the FluentD DaemonSet pods to look for the error.

Run the following command and make sure that the status is Running.

```
kubectl get pods -n amazon-cloudwatch
```

In the results of the previous command, note the pod name that starts with fluentd-cloudwatch. Use this pod name in the following command.

```
kubectl logs pod_name -n amazon-cloudwatch
```
If the logs have errors related to IAM permissions, check the IAM role attached to the cluster nodes. For more information about the permissions required to run an Amazon EKS cluster, see Amazon EKS IAM Policies, Roles, and Permissions in the Amazon EKS User Guide.

If the pod status is CreateContainerConfigError, get the exact error by running the following command.

```bash
kubectl describe pod pod_name -n amazon-cloudwatch
```

(Optional) Set Up Amazon EKS Control Plane Logging

If you’re using Amazon EKS, you can optionally enable Amazon EKS control plane logging, to provide audit and diagnostic logs directly from the Amazon EKS control plane to CloudWatch Logs. For more information, see Amazon EKS Control Plane Logging.

(Optional) Set Up the CloudWatch Agent as a StatsD Endpoint to Send StatsD Metrics to CloudWatch

This section explains how to set up and configure the CloudWatch agent as a StatsD endpoint on an Amazon EKS cluster or Kubernetes cluster to collect StatsD metrics from the containers and publish them to CloudWatch. You might want to do this if you’re already using StatsD.

You have three options for how to deploy the CloudWatch agent as a StatsD endpoint in a cluster:

**Deploy a single CloudWatch agent inside the cluster as a service**

We recommend this option if you want to aggregate all StatsD metrics across the cluster before publishing them to CloudWatch. This option also scales well, and consumes fewer resources than deploying the agent as a sidecar.

**Deploy the CloudWatch agent as a DaemonSet to each worker node**

We recommend this option if you want aggregate StatsD metrics across Kubernetes worker nodes, or if you have concern about the scalability of a single CloudWatch agent serving all StatsD metrics across the whole cluster. It also consumes fewer resources than deploying the agent as a sidecar.

The downside is that you are not able to scale on a single node because only one container will be running on each node.

**Deploy the CloudWatch agent as a sidecar**

We recommend this option if you don’t want to aggregate StatsD metrics across pods. Resources such as CPU, memory, and network are isolated at the pod level so that it’s flexible for customers to plug the agent into their pods.

The disadvantages of this method include resource consumption— for example, 1000 pods has 1000 CloudWatch agent containers. Additionally, metrics coming from different tasks can’t be aggregated.

**Step 1: Create a Namespace for CloudWatch**

Use the following steps to create a Kubernetes namespace called `amazon-cloudwatch` for CloudWatch. You can skip these steps if you have already created this namespace.

**To create a namespace for CloudWatch**

- Download and apply the namespace YAML to your `kubectl` client host by running the following command.
Step 2: Create a ConfigMap for StatsD

No matter which option you choose, you must create a ConfigMap for StatsD.

To create a ConfigMap for StatsD to send metrics from a cluster

1. Download the ConfigMap YAML to your `kubectl` client host by running the following command:

   ```bash
   ```

   This YAML file has a JSON configuration blob embedded.

2. Edit the JSON configuration blob. Be sure that the JSON blob remains in valid JSON format when you're done.

   a. You can edit the StatsD items in the `statsd` section. For more information, see Retrieve Custom Metrics with StatsD (p. 205).

   b. You can edit general items in the `agent` section. For more information, see CloudWatch Agent Configuration File: Agent Section (p. 180).

   In the `agent` section, we recommend that you set `omit_hostname` to `true`. Otherwise, the agent adds the hostname of the worker node where the agent pod is running as a dimension of the StatsD metrics. Using this hostname as a dimension can make the viewing of metrics more difficult if the agent pod is rescheduled to a different worker node.

   By default, CloudWatch publishes the metrics to the AWS Region where the worker node is located. To override this, you can add a `region` field to the `agent` section. For example, "region": "us-west-2".

3. Run the following command to create the ConfigMap in the cluster.

   ```bash
   kubectl apply -f cwagent-statsd-configmap.yaml
   ```

Step 3: Deploy CloudWatch Agent

To deploy the CloudWatch agent to send StatsD metrics, use the steps in one of the following sections.

Option 1: Deploy a Single CloudWatch Agent in the Cluster

This section explains how to deploy a single CloudWatch agent in a cluster to send StatsD metrics to CloudWatch. When the deployment is complete and the agent is running, it starts listening on the URL `cloudwatch-agent-statsd.amazon-cloudwatch.svc:8125`. Your application inside the cluster can emit StatsD metrics to this URL.

To deploy a single CloudWatch agent in a cluster

1. Download and deploy the deployment YAML by entering the following command.

   ```bash
   ```
2. Validate the deployment by entering the following command.

```
kubectl get pods -n amazon-cloudwatch
```

**Option 2: Deploy the CloudWatch Agent as a DaemonSet to Each Worker Node**

This option is for deploying the CloudWatch agent as a DaemonSet to each worker node. When the deployment is complete and the agent is running, it starts listening on `NodeIP:8125`. Your application inside the cluster can emit StatsD metrics to port 8125 with the IP of the node where your application pod is scheduled.

**To deploy the CloudWatch agent on each worker node**

1. Download and deploy the DaemonSet YAML by running the following command.

```
```

2. Validate the deployment by running the following command.

```
kubectl get pods -n amazon-cloudwatch
```

**Option 3: Deploy the CloudWatch Agent as a Sidecar**

This section explains how to deploy the CloudWatch agent as a sidecar. The agent collects the StatsD metrics from the applications running in the same pod. The following is an example YAML file that starts the CloudWatch agent as a sidecar to an Amazon Linux container.

```yaml
apiVersion: v1
kind: Pod
metadata:
  namespace: default
  name: amazonlinux
spec:
  containers:
    - name: amazonlinux
      image: amazonlinux
      command: ["/bin/sh"]
      args: ["-c", "sleep 300"]
    - name: cloudwatch-agent
      image: amazon/cloudwatch-agent
      imagePullPolicy: Always
      resources:
        limits:
          cpu: 200m
          memory: 100Mi
        requests:
          cpu: 200m
          memory: 100Mi
      volumeMounts:
        - name: cwagentconfig
          mountPath: /etc/cwagentconfig
  volumes:
    - name: cwagentconfig
      configMap:
        name: cwagentstatsdconfig
      terminationGracePeriodSeconds: 60
```
Updating or Deleting Container Insights on Amazon EKS and Kubernetes

Use the steps in these sections to update your CloudWatch agent container image, or to remove Container Insights from an Amazon EKS or Kubernetes cluster.

Topics

- Updating the CloudWatch Agent Container Image (p. 110)
- Deleting the CloudWatch Agent and FluentD for Container Insights (p. 111)

Updating the CloudWatch Agent Container Image

If you need to update your container image to the latest version, use the steps in this section.

To update your container image

1. Apply the latest `cwagent-serviceaccount.yaml` file by entering the following command.

   ```bash
   ```

2. This step is necessary only for customers who upgraded their containerized CloudWatch agent from a version earlier than 1.226589.0, which was released on August 20, 2019.

   In the Configmap file `cwagentconfig`, change the keyword `structuredlogs` to `logs`
   
   a. First, open the existing `cwagentconfig` in edit mode by entering the following command.

   ```bash
   kubectl edit cm cwagentconfig -n amazon-cloudwatch
   ```
   
   In the file, if you see the keyword `structuredlogs`, change it to `logs`

   b. Enter `wq` to save the file and exit edit mode.

3. Apply the latest `cwagent-daemonset.yaml` file by entering the following command.

   ```bash
   ```

You can achieve rolling updates of the CloudWatch agent DaemonSet anytime that you change your configuration in `cwagent-configmap.yaml`. To do so, you must make sure the `.spec.template` section in the `cwagent-daemonset.yaml` file has changes. Otherwise, Kubernetes treats the DaemonSet as unchanged. A common practice is to add the hash value of the ConfigMap into `.spec.template.metadata.annotations.configHash`, as in the following example.

   ```bash
   yq w -i cwagent-daemonset.yaml spec.template.metadata.annotations.configHash $(kubectl get cm/cwagentconfig -n amazon-cloudwatch -o yaml | sha256sum)
   ```

   This adds a hash value into the `cwagent-daemonset.yaml` file, as in the following example.
Finding Container Insights Metrics

After you have Container Insights set up and it’s collecting metrics, you can view those metrics on the CloudWatch automatic dashboards.

For more information about yq, see yq.

Deleting the CloudWatch Agent and FluentD for Container Insights

To delete all resources related to the CloudWatch agent and Fluentd, enter the following command. In this command, Cluster is the name of your Amazon EKS or Kubernetes cluster, and Region is the name of the Region where the logs are published.

curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/master/kubernetes-templates/quickstart/cwagent-fluentd-quickstart.yaml | sed "s/{{cluster_name}}/Cluster_Name/;s/{{region_name}}/Region/" | kubectl delete -f -

Viewing Container Insights Metrics

After you have Container Insights set up and it’s collecting metrics, you can view those metrics on the CloudWatch automatic dashboards.

For more information about yq, see yq.

Deleting the CloudWatch Agent and FluentD for Container Insights

To delete all resources related to the CloudWatch agent and Fluentd, enter the following command. In this command, Cluster is the name of your Amazon EKS or Kubernetes cluster, and Region is the name of the Region where the logs are published.

curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/master/kubernetes-templates/quickstart/cwagent-fluentd-quickstart.yaml | sed "s/{{cluster_name}}/Cluster_Name/;s/{{region_name}}/Region/" | kubectl delete -f -

Viewing Container Insights Metrics

After you have Container Insights set up and it’s collecting metrics, you can view those metrics on the CloudWatch automatic dashboards.

For more information about yq, see yq.

Deleting the CloudWatch Agent and FluentD for Container Insights

To delete all resources related to the CloudWatch agent and Fluentd, enter the following command. In this command, Cluster is the name of your Amazon EKS or Kubernetes cluster, and Region is the name of the Region where the logs are published.

curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/master/kubernetes-templates/quickstart/cwagent-fluentd-quickstart.yaml | sed "s/{{cluster_name}}/Cluster_Name/;s/{{region_name}}/Region/" | kubectl delete -f -

Viewing Container Insights Metrics

Deleting the CloudWatch Agent and FluentD for Container Insights

To delete all resources related to the CloudWatch agent and Fluentd, enter the following command. In this command, Cluster is the name of your Amazon EKS or Kubernetes cluster, and Region is the name of the Region where the logs are published.

curl https://raw.githubusercontent.com/aws-samples/amazon-cloudwatch-container-insights/master/kubernetes-templates/quickstart/cwagent-fluentd-quickstart.yaml | sed "s/{{cluster_name}}/Cluster_Name/;s/{{region_name}}/Region/" | kubectl delete -f -
Choose Run query. The query results are displayed.

For more information about CloudWatch Logs Insights, see Analyze Log Data With CloudWatch Logs Insights.

6. At the node, pod, or task level, to view logs about one or more resources currently displayed in the list at the bottom of the page, select the check boxes next to the names of those resources. Then choose Actions and select one of the options in the list. You can view logs or AWS X-Ray traces of the resource.

A new browser appears, showing the information you requested.

You can set a CloudWatch alarm on any metric that Container Insights collects. For more information, see Using Amazon CloudWatch Alarms (p. 62)

Using CloudWatch Logs Insights to View Container Insights Data

Container Insights collects metrics by using performance log events, which are stored in CloudWatch Logs. You can use CloudWatch Logs Insights queries for additional views of your container data.

For more information about CloudWatch Logs Insights, see Analyze Log Data with CloudWatch Logs Insights. For more information about the log fields you can use in queries, see ??? (p. 122).

To use CloudWatch Logs Insights to query your container metric data

2. In the navigation pane, choose Insights.

   Near the top of the screen is the query editor. When you first open CloudWatch Logs Insights, this box contains a default query that returns the 20 most recent log events.

3. In the box above the query editor, select one of the Container Insights log groups to query. For the following example queries to work, the log group name must end with performance.

   When you select a log group, CloudWatch Logs Insights automatically detects fields in the data in the log group and displays them in Discovered fields in the right pane. It also displays a bar graph of log events in this log group over time. This bar graph shows the distribution of events in the log group that matches your query and time range, not only the events displayed in the table.

4. In the query editor, replace the default query with the following query and choose Run query.

```plaintext
STATS avg(node_cpu_utilization) as avg_node_cpu_utilization by NodeName
| SORT avg_node_cpu_utilization DESC
```

This query shows a list of nodes, sorted by average node CPU utilization.

5. To try another example, replace that query with another query and choose Run query. More sample queries are listed later on this page.

```plaintext
STATS avg(number_of_container_restarts) as avg_number_of_container_restarts by PodName
| SORT avg_number_of_container_restarts DESC
```

This query displays a list of your pods, sorted by average number of container restarts.

6. If you want to try another query, you can use include fields in the list at the right of the screen. For more information about query syntax, see CloudWatch Logs Insights Query Syntax.
Other Sample Queries for Container Insights

List of your pods, sorted by average number of container restarts

```
STATS avg(number_of_container_restarts) as avg_number_of_container_restarts by PodName
| SORT avg_number_of_container_restarts DESC
```

Pods requested vs. pods running

```
fields @timestamp, @message
| sort @timestamp desc
| filter Type="Pod"
| stats min(pod_number_of_containers) as requested, min(pod_number_of_running_containers)
  as running, ceil(avg(pod_number_of_containers-pod_number_of_running_containers)) as pods_missing by kubernetes.pod_name
| sort pods_missing desc
```

Count of cluster node failures

```
stats avg(cluster_failed_node_count) as CountOfNodeFailures
| filter Type="Cluster"
| sort @timestamp desc
```

Application log errors

```
Count by container name: stats count() as countoferrors by kubernetes.container_name
| filter stream="stderr"
| sort countoferrors desc
```

Disk usage by container name

```
stats floor(avg(container_filesystem_usage/1024)) as container_filesystem_usage_avg_kb by
InstanceId, kubernetes.container_name, device
| filter Type="ContainerFS"
| sort container_filesystem_usage_avg_kb desc
```

CPU usage by container name

```
stats pct(container_cpu_usage_total, 50) as CPUPercMedian by kubernetes.container_name
| filter Type="Container"
```

Metrics Collected by Container Insights

Container Insights collects one set of metrics for Amazon ECS and AWS Fargate, and a different set for Amazon EKS and Kubernetes.

Topics
- Amazon ECS Container Insights Metrics (p. 114)
- Amazon EKS and Kubernetes Container Insights Metrics (p. 116)
Amazon ECS Container Insights Metrics

The following table lists the metrics and dimensions that Container Insights collects for Amazon ECS. These metrics are in the ECS/ContainerInsights namespace. For more information, see Metrics (p. 3).

If you do not see any Container Insights metrics in your console, be sure that you have completed the setup of Container Insights. Metrics do not appear before Container Insights has been set up completely. For more information, see Setting Up Container Insights (p. 95).

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Dimensions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ContainerInstanceCount</td>
<td>ClusterName</td>
<td>The number of EC2 instances running the Amazon ECS agent that are registered with a cluster.</td>
</tr>
<tr>
<td>CpuUtilized</td>

### Amazon EKS and Kubernetes Container Insights Metrics

The following table lists the metrics and dimensions that Container Insights collects for Amazon EKS and Kubernetes. These metrics are in the ContainerInsights namespace. For more information, see Metrics (p. 3).

If you do not see any Container Insights metrics in your console, be sure that you have completed the setup of Container Insights. Metrics do not appear before Container Insights has been set up completely. For more information, see Setting Up Container Insights (p. 95).

<table>
<thead>

Container Insights Performance Log Reference

This section includes reference information about how Container Insights uses performance log events to collect metrics.

Topics
- Container Insights Performance Log Events for Amazon ECS (p. 119)
- Container Insights Performance Log Events for Amazon EKS and Kubernetes (p. 122)
- Relevant Fields in Performance Log Events for Amazon EKS and Kubernetes (p. 133)

Container Insights Performance Log Events for Amazon ECS

The following are examples of the performance log events that Container Insights collects from Amazon ECS.

Type: Container

```
{
  "Version": "0",
  "Type": "Container",
  "ContainerName": "mysql",
  "TaskId": "7c7bce41-8f2f-4673-b1a3-0e57ef51168f",
  "TaskDefinitionFamily": "hello_world",
  "TaskDefinitionRevision": "2",
  "ContainerInstanceId": "12345678-db61-4b1b-b0ec-93ad21467cc9",
  "EC2InstanceId": "i-1234567890123456",
  "ServiceName": "myCIService",
  "ClusterName": "myCICluster",
  "Timestamp": 1561586749104,
  "CpuUtilized": 1.8381139895790504,
  "CpuReserved": 30.0,
  "MemoryUtilized": 295,
  "MemoryReserved": 400,
  "StorageReadBytes": 10817536,
  "StorageWriteBytes": 2085376000,
  "NetworkRxBytes": 6522,
  "NetworkRxDropped": 0,
  "NetworkRxErrors": 0,
  "NetworkRxPackets": 83,
  "NetworkTxBytes": 3904,
  "NetworkTxDropped": 0,
  "NetworkTxErrors": 0,
  "NetworkTxPackets": 44
}
```

Type: Task

```
{
  "Version": "0",
```

Relevant Fields in Performance Log Events for Amazon EKS and Kubernetes

For Amazon EKS and Kubernetes, the containerized CloudWatch agent emits data as performance log events. This enables CloudWatch to ingest and store high-cardinality data. CloudWatch uses the data in the performance log events to create aggregated CloudWatch metrics at the cluster, node, and pod levels without the need to lose granular details.

The following table lists the fields in these performance log events that are relevant to the collection of Container Insights metric data. You can use CloudWatch Logs Insights to query for any of these fields to collect data or investigate issues. For more information, see Analyze Log Data With CloudWatch Logs Insights.

Metrics Calculation Examples

This section includes examples that show how some of the values in the preceding table are calculated.

Suppose that you have a cluster in the following state.

Node1
- node_cpu_limit = 4
- node_cpu_usage_total = 3

Pod1
- pod_cpu_usage_total = 2

  Container1
  - container_cpu_limit = 1
  - container_cpu_request = 1
  - container_cpu_usage_total = 0.8

  Container2
  - container_cpu_limit = null
  - container_cpu_request = null
  - container_cpu_usage_total = 1.2

Pod2
- pod_cpu_usage_total = 0.4

  Container3
  - container_cpu_limit = 1
  - container_cpu_request = 0.5
  - container_cpu_usage_total = 0.4

Node2
- node_cpu_limit = 8
- node_cpu_usage_total = 1.5

Pod3
- pod_cpu_usage_total = 1

  Container4
  - container_cpu_limit = 2
  - container_cpu_request = 2
  - container_cpu_usage_total = 1

The following table shows how pod CPU metrics are calculated using this data.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Formula</th>
<th>Pod1</th>
<th>Pod2</th>
<th>Pod3</th>
</tr>
</thead>
<tbody>
<tr>
<td>pod_cpu_utilization</td>
<td>pod_cpu_usage_total / node_cpu_limit</td>
<td>2 / 4 = 50%</td>
<td>0.4 / 4 = 10%</td>
<td>1 / 8 = 12.5%</td>
</tr>
<tr>
<td>pod_cpu_utilization_over_pod_limit</td>

Troubleshooting Container Insights

The following sections can help if you're having trouble issues with Container Insights.

**Failed Deployment on Amazon EKS or Kubernetes**

If the agent doesn't deploy correctly on a Kubernetes cluster, try the following:

- Run the following command to get the list of pods.

  ```bash
  kubectl get pods -n amazon-cloudwatch
  ```

- Run the following command and check the events at the bottom of the output.

  ```bash
  kubectl describe pod pod-name -n amazon-cloudwatch
  ```

- Run the following command to check the logs.

  ```bash
  kubectl logs pod-name -n amazon-cloudwatch
  ```

**Unauthorized panic: Cannot retrieve cadvisor data from kubelet**

If your deployment fails with the error `Unauthorized panic: Cannot retrieve cadvisor data from kubelet`, your kubelet might not have Webhook authorization mode enabled. This mode is required for Container Insights. For more information, see Verify Prerequisites (p. 98).

**Deploying Container Insights on a Deleted and Re-Created Cluster**

If you delete an existing cluster that does not have Container Insights enabled, and you re-create it with the same name, you can't enable Container Insights on this new cluster at the time you re-create it. You can enable it by re-creating it, and then entering the following command:

```bash
aws ecs update-cluster-settings --cluster myCICluster --settings name=containerInsights,value(enabled
```
Metrics Don't Appear in the Console

If you don't see any Container Insights metrics in the AWS Management Console, be sure that you have completed the setup of Container Insights. Metrics don't appear before Container Insights has been set up completely. For more information, see Setting Up Container Insights (p. 95).

CrashLoopBackoff Error on the CloudWatch Agent

If you see a CrashLoopBackoff error for the CloudWatch agent, make sure that your IAM permissions are set correctly. For more information, see Verify Prerequisites (p. 98).

CloudWatch Agent or FluentD Pod Stuck in Pending

If you have a CloudWatch agent or FluentD pod stuck in Pending or with a FailedScheduling error, determine if your nodes have enough compute resources based on the number of cores and amount of RAM required by the agents. Enter the following command to describe the pod:

```bash
kubectl describe pod cloudwatch-agent-85ppg -n amazon-cloudwatch
```

Building Your Own CloudWatch Agent Docker Image

Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent

The unified CloudWatch agent enables you to do the following:

- Collect more system-level metrics from Amazon EC2 instances across operating systems. The metrics can include in-guest metrics, in addition to the metrics for EC2 instances. The additional metrics that can be collected are listed in Metrics Collected by the CloudWatch Agent (p. 207).
- Collect system-level metrics from on-premises servers. These can include servers in a hybrid environment as well as servers not managed by AWS.
- Retrieve custom metrics from your applications or services using the StatsD and collectd protocols. StatsD is supported on both Linux servers and servers running Windows Server. collectd is supported only on Linux servers.
- Collect logs from Amazon EC2 instances and on-premises servers, running either Linux or Windows Server.

You can store and view the metrics that you collect with the CloudWatch agent in CloudWatch just as you can with any other CloudWatch metrics. The default namespace for metrics collected by the CloudWatch agent is CWAgent, although you can specify a different namespace when you configure the agent.

The logs collected by the unified CloudWatch agent are processed and stored in Amazon CloudWatch Logs, just like logs collected by the older CloudWatch Logs agent. For information about CloudWatch Logs pricing, see Amazon CloudWatch Pricing.

Metrics collected by the CloudWatch agent are billed as custom metrics. For more information about CloudWatch metrics pricing, see Amazon CloudWatch Pricing.

The steps in this section explain how to install the unified CloudWatch agent on Amazon EC2 instances and on-premises servers. For more information about the metrics that the CloudWatch agent can collect, see Metrics Collected by the CloudWatch Agent (p. 207).

Supported Operating Systems

The CloudWatch agent is supported on AMD64 architecture on the following operating systems:

- Amazon Linux version 2014.03.02 or later
- Amazon Linux 2
- Ubuntu Server versions 18.04, 16.04, and 14.04
- CentOS versions 7.6, 7.2, 7.0, 6.8, and 6.5
- Red Hat Enterprise Linux (RHEL) versions 8, 7.6, 7.5, 7.4, 7.2, 7.0, and 6.5
- Debian 8.0
- SUSE Linux Enterprise Server (SLES) 12 or later
The agent is supported on ARM64 architecture on the following operating systems:

- Amazon Linux 2
- Ubuntu Server version 18.04
- Red Hat Enterprise Linux (RHEL) version 7.6

**Installation Process Overview**

You can download and install the CloudWatch agent manually using the command line, or you can integrate it with SSM. The general flow of installing the CloudWatch agent using either method is as follows:

1. Create IAM roles or users that enable the agent to collect metrics from the server and optionally to integrate with AWS Systems Manager.
2. Download the agent package.
3. Modify the CloudWatch agent configuration file and specify the metrics that you want to collect.
4. Install and start the agent on your servers. As you install the agent on an EC2 instance, you attach the IAM role that you created in step 1. As you install the agent on an on-premises server, you specify a named profile that contains the credentials of the IAM user that you created in step 1.

**Contents**

- Installing the CloudWatch Agent (p. 142)
- Create the CloudWatch Agent Configuration File (p. 174)
- Metrics Collected by the CloudWatch Agent (p. 207)
- Common Scenarios with the CloudWatch Agent (p. 216)
- Troubleshooting the CloudWatch Agent (p. 223)

### Installing the CloudWatch Agent

You can download and install the CloudWatch agent using either the command line with an Amazon S3 download link, using SSM, or using an AWS CloudFormation template.

**Contents**

- Installing the CloudWatch Agent Using the Command Line (p. 142)
- Installing the CloudWatch Agent Using AWS Systems Manager (p. 153)
- Installing the CloudWatch Agent Using AWS CloudFormation (p. 165)
- Verifying the Signature of the CloudWatch Agent Package (p. 170)

### Installing the CloudWatch Agent Using the Command Line

Use the following topics to download, configure, and install the CloudWatch agent package.

**Topics**

- Download and Configure the CloudWatch Agent Using the Command Line (p. 143)
- Create IAM Roles and Users for Use With CloudWatch Agent (p. 146)
- Installing and Running the CloudWatch Agent on Your Servers (p. 147)
Download and Configure the CloudWatch Agent Using the Command Line

Use the following steps to download the CloudWatch agent package, create IAM roles or users, and optionally modify the common configuration file.

Download the CloudWatch Agent Package Using an S3 Download Link

You can use an Amazon S3 download link to download the CloudWatch agent package. Choose the download link from this table, depending on your architecture and platform.

For each download link, there is a general link as well as links for each Region. For example, for Amazon Linux and Amazon Linux 2 and the AMD64 architecture, three of the valid download links are:

You can also download a README file about the latest changes to the agent, and a file that indicates the version number that is available for download. These files are in the following locations:

<table>
<thead>
<tr>
<th>Architecture</th>
<th>Platform</th>
<th>Download Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMD64</td>
<td>Amazon Linux and Amazon Linux 2</td>
<td><a href="https://s3.amazonaws.com/amazoncloudwatch-agent/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm">https://s3.amazonaws.com/amazoncloudwatch-agent/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm</a></td>
</tr>
<tr>
<td>AMD64</td>
<td>Centos</td>
<td><a href="https://s3.amazonaws.com/amazoncloudwatch-agent/centos/amd64/latest/amazon-cloudwatch-agent.rpm">https://s3.amazonaws.com/amazoncloudwatch-agent/centos/amd64/latest/amazon-cloudwatch-agent.rpm</a></td>
</tr>
</tbody>
</table>

143
<table>

<td>Signature File Link</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| ARM64        | Amazon Linux 2 | https://s3.amazonaws.com/amazoncloudwatch-agent/amazon_linux/arm64/latest/amazon-cloudwatch-agent.rpm  
| ARM64        | Redhat       | https://s3.amazonaws.com/amazoncloudwatch-agent/redhat/arm64/latest/amazon-cloudwatch-agent.rpm  
| ARM64        | Ubuntu       | https://s3.amazonaws.com/amazoncloudwatch-agent/ubuntu/arm64/latest/amazon-cloudwatch-agent.deb  

To use the command line to download and install the CloudWatch agent package

1. Download the CloudWatch agent.
On a Linux server, enter the following. For download-link, use the appropriate download link from the previous table.

```
wget download-link
```

On a server running Windows Server, download the following file:

```
```

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the Signature of the CloudWatch Agent Package (p. 170).

3. Install the package. If you downloaded an RPM package on a Linux server, change to the directory containing the package and enter the following:

```
sudo rpm -U ./amazon-cloudwatch-agent.rpm
```

If you downloaded a DEB package on a Linux server, change to the directory containing the package and enter the following:

```
sudo dpkg -i -R ./amazon-cloudwatch-agent.deb
```

If you downloaded an MSI package on a server running Windows Server, change to the directory containing the package and enter the following:

```
msiexec /i amazon-cloudwatch-agent.msi
```

This command also works from within PowerShell. For more information about MSI command options, see Command-Line Options in the Microsoft Windows documentation.

Create and Modify the Agent Configuration File

After you have downloaded the CloudWatch agent, you must create the configuration file before you start the agent on any servers. For more information, see Create the CloudWatch Agent Configuration File (p. 174).

Create IAM Roles and Users for Use With CloudWatch Agent

Access to AWS resources requires permissions. You create an IAM role, an IAM user, or both to grant permissions that the CloudWatch agent needs to write metrics to CloudWatch. If you're going to use the agent on Amazon EC2 instances, you must create an IAM role. If you're going to use the agent on on-premises servers, you must create an IAM user.

**Note**

We recently modified the following procedures by using new CloudWatchAgentServerPolicy and CloudWatchAgentAdminPolicy policies created by Amazon, instead of requiring customers to create these policies themselves. For writing files to and downloading files from the Parameter Store, the policies created by Amazon support only files with names that start with AmazonCloudWatch-. If you have a CloudWatch agent configuration file with a file name that doesn’t start with AmazonCloudWatch-, these policies can't be used to write the file to Parameter Store or download it from Parameter Store.
If you're going to run the CloudWatch agent on Amazon EC2 instances, use the following steps to create the necessary IAM role. This role provides permissions for reading information from the instance and writing it to CloudWatch.

**To create the IAM role necessary to run the CloudWatch agent on EC2 instances**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose Roles and then Create role.
3. For Choose the service that will use this role, choose EC2 Allows EC2 instances to call AWS services on your behalf. Choose Next: Permissions.
4. In the list of policies, select the check box next to CloudWatchAgentServerPolicy. If necessary, use the search box to find the policy.
5. Choose Next: Review.
6. Confirm that CloudWatchAgentServerPolicy appears next to Policies. In Role name, enter a name for the role, such as CloudWatchAgentServerRole. Optionally give it a description. Then choose Create role.

   The role is now created.

   The role is now created.

If you're going to run the CloudWatch agent on on-premises servers, use the following steps to create the necessary IAM user.

**To create the IAM user necessary for the CloudWatch agent to run on on-premises servers**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose Users and then Add user.
3. Enter the user name for the new user.
4. Select Programmatic access and choose Next: Permissions.
5. Choose Attach existing policies directly.
6. In the list of policies, select the check box next to CloudWatchAgentServerPolicy. If necessary, use the search box to find the policy.
7. Choose Next: Review.
8. Confirm that the correct policies are listed, and choose Create user.
9. Next to the name of the new user, choose Show. Copy the access key and secret key to a file so that you can use them when installing the agent. Choose Close.

**Installing and Running the CloudWatch Agent on Your Servers**

After you have created the agent configuration file that you want and created an IAM role or IAM user, use the following steps to install and run the agent on your servers, using that configuration. First, attach an IAM role or IAM user to the server that will run the agent. Then, on that server, download the agent package and start it using the agent configuration you created.

**Download the CloudWatch Agent Package Using an S3 Download Link**

On each server where you will run the agent, download the agent package. Choose the download link from this table, depending on your architecture and platform.
For each download link, there is a general link as well as links for each Region. For example, for Amazon Linux and Amazon Linux 2 and the AMD64 architecture, three of the valid download links are:

<table>
<thead>
<tr>
<th>Architecture</th>
<th>Platform</th>
<th>Download Link</th>
<th>Signature File Link</th>
</tr>
</thead>
</table>
| AMD64        | Amazon Linux and Amazon Linux 2 | https://s3.amazonaws.com/amazoncloudwatch-agent/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm  
| AMD64        | Centos                 | https://s3.amazonaws.com/amazoncloudwatch-agent/centos/amd64/latest/amazon-cloudwatch-agent.rpm  
| AMD64        | Redhat                | https://s3.amazonaws.com/amazoncloudwatch-agent/redhat/amd64/latest/amazon-cloudwatch-agent.rpm  
| AMD64        | SUSE                   | https://s3.amazonaws.com/amazoncloudwatch-agent/suse/amd64/latest/amazon-cloudwatch-agent.rpm  
<table>
<thead>
<tr>
<th>Architecture</th>
<th>Platform</th>
<th>Download Link</th>
<th>Signature File Link</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>AMD64</td>
<td>agent-region/suse/amd64/latest/amazon-cloudwatch-agent.rpm</td>
<td>agent-region/suse/amd64/latest/amazon-cloudwatch-agent.rpm.sig</td>
</tr>
</tbody>
</table>
To use the command line to install the CloudWatch agent on an Amazon EC2 instance

1. Download the CloudWatch agent. For a Linux server, enter the following. For `download-link`, use the appropriate download link from the previous table.

   ```bash
   wget download-link
   ```

   For a server running Windows Server, download the following file:

   ```bash
   ```

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the Signature of the CloudWatch Agent Package (p. 170).

3. Install the package. If you downloaded an RPM package on a Linux server, change to the directory containing the package and enter the following:

   ```bash
   sudo rpm -U ./amazon-cloudwatch-agent.rpm
   ```

   If you downloaded a DEB package on a Linux server, change to the directory containing the package and enter the following:

   ```bash
   sudo dpkg -i -E ./amazon-cloudwatch-agent.deb
   ```

   If you downloaded an MSI package on a server running Windows Server, change to the directory containing the package and enter the following:

   ```bash
   msiexec /i amazon-cloudwatch-agent.msi
   ```
This command also works from within PowerShell. For more information about MSI command options, see Command-Line Options in the Microsoft Windows documentation.

(Installing on an EC2 Instance) Attaching an IAM Role

To enable the CloudWatch agent to send data from the instance, you must attach an IAM role to the instance. The role to attach is CloudWatchAgentServerRole.

For more information on attaching an IAM role to an instance, see Attaching an IAM Role to an Instance in the Amazon EC2 User Guide for Windows Instances.

(Installing on an On-Premises Server) Specify IAM Credentials and AWS Region

To enable the CloudWatch agent to send data from an on-premises server, you must specify the access key and secret key of the IAM user that you created earlier. For more information about creating this user, see Create IAM Roles and Users for Use With CloudWatch Agent (p. 146).

You also must specify the AWS Region to send the metrics to, using the region field in the [AmazonCloudWatchAgent] section of the AWS config file, as in the following example.

```
[profile AmazonCloudWatchAgent]
region = us-west-1
```

The following is an example of using the aws configure command to create a named profile for the CloudWatch agent. This example assumes that you are using the default profile name of AmazonCloudWatchAgent.

To create the AmazonCloudWatchAgent profile for the CloudWatch agent

- On Linux servers, enter the following command and follow the prompts:
  ```
sudo aws configure --profile AmazonCloudWatchAgent
  ```
- On Windows Server, open PowerShell as an administrator, enter the following command, and follow the prompts.
  ```
aws configure --profile AmazonCloudWatchAgent
  ```

(Optional) Modify the Common Configuration for Proxy or Region Information

The CloudWatch agent includes a configuration file called common-config.toml. You can optionally use this file to specify proxy and Region information.

On a server running Linux, this file is in the /opt/aws/amazon-cloudwatch-agent/etc directory. On a server running Windows Server, this file is in the C:\ProgramData\Amazon\AmazonCloudWatchAgent directory.

The default common-config.toml is as follows.

```toml
# This common-config is used to configure items used for both ssm and cloudwatch access

### Configuration for shared credential.
### Default credential strategy will be used if it is absent here:
```
## Instance role is used for EC2 case by default.
## AmazonCloudWatchAgent profile is used for onPremise case by default.
# [credentials]
#  shared_credential_profile = "{profile_name}"
#  shared_credential_file= "{file_name}"

## Configuration for proxy.
## System-wide environment-variable will be read if it is absent here.
## i.e. HTTP_PROXY/http_proxy; HTTPS_PROXY/https_proxy; NO_PROXY/no_proxy
## Note: system-wide environment-variable is not accessible when using ssm run-command.
## Absent in both here and environment-variable means no proxy will be used.
# [proxy]
#  http_proxy = "{http_url}"
#  https_proxy = "{https_url}"
#  no_proxy = "{domain}"

All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually or by using the RunShellScript Run Command in Systems Manager:

- **shared_credential_profile** – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, AmazonCloudWatchAgent is used. For more information about creating this profile, see [Installing on an On-Premises Server] Specify IAM Credentials and AWS Region (p. 151).

On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different AWS Region. To do so, specify a named profile that includes a region field specifying the name of the Region to send to.

If you specify a **shared_credential_profile**, you must also remove the # from the beginning of the [credentials] line.

- **shared_credential_file** – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is `/root/.aws` on Linux and is `C:\Users\Administrator\.aws` on Windows Server.

The first example below shows the syntax of a valid **shared_credential_file** line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the \ characters.

```
shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
```

```
shared_credential_file= "/usr/username/credentials"
```

If you specify a **shared_credential_file**, you must also remove the # from the beginning of the [credentials] line.

- **Proxy settings** – If your servers use HTTP or HTTPS proxies to contact AWS services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

### Start the CloudWatch Agent Using the Command Line

Follow these steps to use the command line to start the CloudWatch agent on a server.

**To use the command line to start the CloudWatch agent on a server**

1. Copy the agent configuration file that you want to use to the server where you're going to run the agent. Note the pathname where you copy it to.
2. In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

On an EC2 instance running Linux, enter the following:

```bash
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -c file:configuration-file-path -s
```

On an on-premises server running Linux, enter the following:

```bash
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m onPremise -c file:configuration-file-path -s
```

On an EC2 instance running Windows Server, enter the following from the PowerShell console:

```bash
./amazon-cloudwatch-agent-ctl.ps1 -a fetch-config -m ec2 -c file:configuration-file-path -s
```

On an on-premises server running Windows Server, enter the following from the PowerShell console:

```bash
./amazon-cloudwatch-agent-ctl.ps1 -a fetch-config -m onPremise -c file:configuration-file-path -s
```

## Installing the CloudWatch Agent Using AWS Systems Manager

Use the following topics to install and run the CloudWatch agent using AWS Systems Manager.

**Topics**
- Create IAM Roles and Users for Use with the CloudWatch Agent (p. 153)
- Download and Configure the CloudWatch Agent (p. 156)
- Installing the CloudWatch Agent on EC2 Instances Using Your Agent Configuration (p. 158)
- Installing the CloudWatch Agent on On-Premises Servers (p. 161)

## Create IAM Roles and Users for Use with the CloudWatch Agent

Access to AWS resources requires permissions. You can create IAM roles and users that include the permissions that you need for the CloudWatch agent to write metrics to CloudWatch and for the CloudWatch agent to communicate with Amazon EC2 and AWS Systems Manager. You use IAM roles on Amazon EC2 instances, and you use IAM users with on-premises servers.

One role or user enables CloudWatch agent to be installed on a server and send metrics to CloudWatch. The other role or user is needed to store your CloudWatch agent configuration in Systems Manager Parameter Store. Parameter Store enables multiple servers to use one CloudWatch agent configuration.

The ability to write to Parameter Store is a broad and powerful permission. You should use it only when you need it, and it shouldn't be attached to multiple instances in your deployment. If you store your CloudWatch agent configuration in Parameter Store, we recommend the following:

- Set up one instance where you perform this configuration.
• Use the IAM role with permissions to write to Parameter Store only on this instance.
• Use the IAM role with permissions to write to Parameter Store only while you are working with and saving the CloudWatch agent configuration file.

**Note**
We recently modified the following procedures by using new `CloudWatchAgentServerPolicy` and `CloudWatchAgentAdminPolicy` policies created by Amazon, instead of requiring customers to create these policies themselves. For writing files to and downloading files from Parameter Store, the policies created by Amazon support only files with names that start with `AmazonCloudWatch-`. If you have a CloudWatch agent configuration file with a file name that doesn’t start with `AmazonCloudWatch-`, these policies can’t be used to write the file to Parameter Store or to download the file from Parameter Store.

### Create IAM Roles to Use with the CloudWatch Agent on Amazon EC2 Instances

The first procedure creates the IAM role that you must attach to each Amazon EC2 instance that runs the CloudWatch agent. This role provides permissions for reading information from the instance and writing it to CloudWatch.

The second procedure creates the IAM role that you must attach to the Amazon EC2 instance being used to create the CloudWatch agent configuration file. This step is necessary if you're going to store this file in Systems Manager Parameter Store so that other servers can use it. This role provides permissions for writing to Parameter Store, in addition to the permissions for reading information from the instance and writing it to CloudWatch. This role includes permissions sufficient to run the CloudWatch agent as well as to write to Parameter Store.

**To create the IAM role necessary for each server to run the CloudWatch agent**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles and then choose Create role.
3. Under Select type of trusted entity, choose AWS service.
4. Immediately under Choose the service that will use this role, choose EC2, and then choose Next: Permissions.
5. In the list of policies, select the check box next to `CloudWatchAgentServerPolicy`. If necessary, use the search box to find the policy.
6. To use Systems Manager to install or configure the CloudWatch agent, select the box next to `AmazonSSMManagedInstanceCore`. This AWS managed policy enables an instance to use Systems Manager service core functionality. If necessary, use the search box to find the policy. This policy isn't necessary if you start and configure the agent only through the command line.
7. Choose Next: Tags.
8. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role, and then choose Next: Review.
9. For Role name, enter a name for your new role, such as `CloudWatchAgentServerRole` or another name that you prefer.
10. (Optional) For Role description, enter a description.
11. Confirm that `CloudWatchAgentServerPolicy` and optionally `AmazonSSMManagedInstanceCore` appear next to Policies.
12. Choose Create role.

The role is now created.

The following procedure creates the IAM role that can also write to Parameter Store. You can use this role to store the agent configuration file in Parameter Store so that other servers can retrieve it.
The permissions for writing to Parameter Store provide broad access. This role shouldn’t be attached to all your servers, and only administrators should use it. After you create the agent configuration file and copy it to Parameter Store, you should detach this role from the instance and use CloudWatchAgentServerRole instead.

**To create the IAM role for an administrator to write to Parameter Store**

1. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
2. In the navigation pane, choose **Roles** and then choose **Create role**.
3. Under **Select type of trusted entity**, choose **AWS service**.
4. Immediately under **Choose the service that will use this role**, choose **EC2**, and then choose **Next: Permissions**.
5. In the list of policies, select the check box next to **CloudWatchAgentAdminPolicy**. If necessary, use the search box to find the policy.
6. To use Systems Manager to install or configure the CloudWatch agent, select the box next to **AmazonSSMManagedInstanceCore**. This AWS managed policy enables an instance to use Systems Manager service core functionality. If necessary, use the search box to find the policy. This policy isn’t necessary if you start and configure the agent only through the command line.
7. Choose **Next: Tags**.
8. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role, and then choose **Next: Review**.
9. For **Role name**, enter a name for your new role, such as **CloudWatchAgentAdminRole** or another name that you prefer.
10. (Optional) For **Role description**, enter a description.
11. Confirm that **CloudWatchAgentAdminPolicy** and optionally **AmazonSSMManagedInstanceCore** appear next to **Policies**.
12. Choose **Create role**.

   The role is now created.

**Create IAM Users to Use with the CloudWatch Agent on On-Premises Servers**

The first procedure creates the IAM user that you need to run the CloudWatch agent. This user provides permissions to send data to CloudWatch.

The second procedure creates the IAM user that you can use when creating the CloudWatch agent configuration file. Use this procedure to store this file in Systems Manager Parameter Store so that other servers can use it. This user provides permissions to write to Parameter Store, in addition to the permissions to write data to CloudWatch.

**To create the IAM user necessary for the CloudWatch agent to write data to CloudWatch**

1. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
2. In the navigation pane, choose **Users**, and then choose **Add user**.
3. Enter the user name for the new user.
4. For **Access type**, select **Programmatic access**, and then choose **Next: Permissions**.
5. For **Set permissions**, choose **Attach existing policies directly**.
6. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy.
7. To use Systems Manager to install or configure the CloudWatch agent, select the box next to **AmazonSSMManagedInstanceCore**. This AWS managed policy enables an instance to use Systems
Install the CloudWatch Agent Using Systems Manager

Manager service core functionality. (If necessary, use the search box to find the policy. This policy isn't necessary if you start and configure the agent only through the command line.)

8. Choose Next: Tags.
9. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role, and then choose Next: Review.
10. Confirm that the correct policies are listed, and then choose Create user.
11. In the row for the new user, choose Show. Copy the access key and secret key to a file so that you can use them when installing the agent. Choose Close.

The following procedure creates the IAM user that can also write to Parameter Store. If you're going to store the agent configuration file in Parameter Store so that other servers can use it, you need to use this IAM user. This IAM user provides permissions for writing to Parameter Store. This user also provides the permissions for reading information from the instance and writing it to CloudWatch. The permissions for writing to Systems Manager Parameter Store provide broad access. This IAM user shouldn't be attached to all your servers, and only administrators should use it. You should use this IAM user only when you are storing the agent configuration file in Parameter Store.

**To create the IAM user necessary to store the configuration file in Parameter Store and send information to CloudWatch**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Users, and then choose Add user.
3. Enter the user name for the new user.
4. For Access type, select Programmatic access, and then choose Next: Permissions.
5. For Set permissions, choose Attach existing policies directly.
6. In the list of policies, select the check box next to CloudWatchAgentAdminPolicy. If necessary, use the search box to find the policy.
7. To use Systems Manager to install or configure the CloudWatch agent, select the check box next to AmazonSSMMInstanceCore. This AWS managed policy enables an instance to use Systems Manager service core functionality. (If necessary, use the search box to find the policy. This policy isn't necessary if you start and configure the agent only through the command line.)
8. Choose Next: Tags.
9. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role, and then choose Next: Review.
10. Confirm that the correct policies are listed, and then choose Create user.
11. In the row for the new user, choose Show. Copy the access key and secret key to a file so that you can use them when installing the agent. Choose Close.

**Download and Configure the CloudWatch Agent**

This section explains how to use Systems Manager to download the agent and then how to create your agent configuration file. Before you can use Systems Manager to download the agent, you must make sure that the instance is configured correctly for Systems Manager.

**Installing or Updating SSM Agent**

On an Amazon EC2 instance, the CloudWatch agent requires that the instance is running version 2.2.93.0 or later. Before you install the CloudWatch agent, update or install SSM Agent on the instance if you haven't already done so.

For information about installing or updating SSM Agent on an instance running Linux, see Installing and Configuring SSM Agent on Linux Instances in the AWS Systems Manager User Guide.
Install the CloudWatch Agent Using Systems Manager

For information about installing or updating the SSM Agent, see Working with SSM Agent in the AWS Systems Manager User Guide.

(Optional) Verify Systems Manager Prerequisites

Before you use Systems Manager Run Command to install and configure the CloudWatch agent, verify that your instances meet the minimum Systems Manager requirements. For more information, see Systems Manager Prerequisites in the AWS Systems Manager User Guide.

Verify Internet Access

Your Amazon EC2 instances must have outbound internet access to send data to CloudWatch or CloudWatch Logs. For more information about how to configure internet access, see Internet Gateways in the Amazon VPC User Guide.

The endpoints and ports to configure on your proxy are as follows:

- If you're using the agent to collect metrics, you must whitelist the CloudWatch endpoints for the appropriate Regions. These endpoints are listed in Amazon CloudWatch in the Amazon Web Services General Reference.
- If you're using the agent to collect logs, you must whitelist the CloudWatch Logs endpoints for the appropriate Regions. These endpoints are listed in Amazon CloudWatch Logs in the Amazon Web Services General Reference.
- If you're using Systems Manager to install the agent or Parameter Store to store your configuration file, you must whitelist the Systems Manager endpoints for the appropriate Regions. These endpoints are listed in AWS Systems Manager in the Amazon Web Services General Reference.

Use the following steps to download the CloudWatch agent package using Systems Manager.

**To download the CloudWatch agent using Systems Manager**

2. In the navigation pane, choose Run Command.
   -or-
   If the AWS Systems Manager home page opens, scroll down and choose Explore Run Command.
3. Choose Run command.
4. In the Command document list, choose AWS-ConfigureAWSPackage.
5. In the Targets area, choose the instance to install the CloudWatch agent on. If you don't see a specific instance, it might not be configured as a managed instance for use with Systems Manager. For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the AWS Systems Manager User Guide.
6. In the Action list, choose Install.
7. In the Name field, enter AmazonCloudWatchAgent.
8. Keep Version set to latest to install the latest version of the agent.
10. Optionally, in the Targets and outputs areas, select the button next to an instance name and choose View output. Systems Manager should show that the agent was successfully installed.

Create and Modify the Agent Configuration File

After you have downloaded the CloudWatch agent, you must create the configuration file before you start the agent on any servers.
If you're going to save your agent configuration file in the Systems Manager Parameter Store, you must use an EC2 instance to save to the Parameter Store. Additionally, you must first attach to that instance the CloudWatchAgentAdminRole IAM role. For more information about attaching roles, see Attaching an IAM Role to an Instance in the Amazon EC2 User Guide for Windows Instances.

For more information about creating the CloudWatch agent configuration file, see Create the CloudWatch Agent Configuration File (p. 174).

**Installing the CloudWatch Agent on EC2 Instances Using Your Agent Configuration**

After you have a CloudWatch agent configuration saved in Parameter Store, you can use it when you install the agent on other servers.

**Topics**

- Attach an IAM Role to the Instance (p. 158)
- Download the CloudWatch Agent Package on an Amazon EC2 Instance (p. 158)
- (Optional) Modify the Common Configuration and Named Profile for CloudWatch Agent (p. 159)
- Start the CloudWatch Agent (p. 160)

**Attach an IAM Role to the Instance**

You must attach the CloudWatchAgentServerRole IAM role to the EC2 instance to be able to run the CloudWatch agent on the instance. This role enables the CloudWatch agent to perform actions on the instance.

For more information, see Attaching an IAM Role to an Instance in the Amazon EC2 User Guide for Windows Instances.

**Download the CloudWatch Agent Package on an Amazon EC2 Instance**

You can download the CloudWatch agent package using either Systems Manager Run Command or an Amazon S3 download link. For information about using an Amazon S3 download link, see Download the CloudWatch Agent Package Using an S3 Download Link (p. 143).

**Download the CloudWatch Agent on an Amazon EC2 Instance Using Systems Manager**

Before you can use Systems Manager to install the CloudWatch agent, you must make sure that the instance is configured correctly for Systems Manager.

**Installing or Updating SSM Agent**

On an Amazon EC2 instance, the CloudWatch agent requires that the instance is running version 2.2.93.0 or later. Before you install the CloudWatch agent, update or install SSM Agent on the instance if you haven't already done so.

For information about installing or updating SSM Agent on an instance running Linux, see Installing and Configuring the SSM Agent on Linux Instances in the AWS Systems Manager User Guide.

For information about installing or updating SSM Agent on an instance running Windows Server, see Installing and Configuring SSM Agent on Windows Instances in the AWS Systems Manager User Guide.

**(Optional) Verify Systems Manager Prerequisites**

Before you use Systems Manager Run Command to install and configure the CloudWatch agent, verify that your instances meet the minimum Systems Manager requirements. For more information, see Setting Up AWS Systems Manager in the AWS Systems Manager User Guide.
Verify Internet Access

Your Amazon EC2 instances must have outbound internet access in order to send data to CloudWatch or CloudWatch Logs. For more information about how to configure internet access, see Internet Gateways in the Amazon VPC User Guide.

Download the CloudWatch Agent Package

Systems Manager Run Command enables you to manage the configuration of your instances. You specify a Systems Manager document, specify parameters, and execute the command on one or more instances. SSM Agent on the instance processes the command and configures the instance as specified.

To download the CloudWatch agent using Run Command

2. In the navigation pane, choose Run Command.
   -or-
   If the AWS Systems Manager home page opens, scroll down and choose Explore Run Command.
3. Choose Run command.
4. In the Command document list, choose AWS-ConfigureAWSPackage.
5. In the Targets area, choose the instance on which to install the CloudWatch agent. If you do not see a specific instance, it might not be configured for Run Command. For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the AWS Systems Manager User Guide.
6. In the Action list, choose Install.
7. In the Name box, enter AmazonCloudWatchAgent.
8. Keep Version set to latest to install the latest version of the agent.
10. Optionally, in the Targets and outputs areas, select the button next to an instance name and choose View output. Systems Manager should show that the agent was successfully installed.

(Optional) Modify the Common Configuration and Named Profile for CloudWatch Agent

The CloudWatch agent includes a configuration file called common-config.toml. You can use this file optionally specify proxy and Region information.

On a server running Linux, this file is in the /opt/aws/amazon-cloudwatch-agent/etc directory. On a server running Windows Server, this file is in the C:\ProgramData\Amazon \AmazonCloudWatchAgent directory.

The default common-config.toml is as follows:

```toml
# This common-config is used to configure items used for both ssm and cloudwatch access

## Configuration for shared credential.
## Default credential strategy will be used if it is absent here:
## Instance role is used for EC2 case by default.
## AmazonCloudWatchAgent profile is used for onPremise case by default.
[credentials]
shared_credential_profile = "{profile_name}"
shared_credential_file = "{file_name}"```
All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually, or by using the RunShellScript Run Command in Systems Manager:

- **shared_credential_profile** – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, AmazonCloudWatchAgent is used.

On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different AWS Region. To do so, specify a named profile that includes a region field specifying the name of the Region to send to.

If you specify a shared_credential_profile, you must also remove the # from the beginning of the [credentials] line.

- **shared_credential_file** – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is /root/.aws on Linux and is C:\Users\Administrator\.aws on Windows Server.

The first example below shows the syntax of a valid shared_credential_file line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the \\ characters.

```
shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
```

```
shared_credential_file= "/usr/username/credentials"
```

If you specify a shared_credential_file, you must also remove the # from the beginning of the [credentials] line.

- **Proxy settings** – If your servers use HTTP or HTTPS proxies to contact AWS services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

### Start the CloudWatch Agent

You can start the agent using Systems Manager Run Command or the command line.

**Start the CloudWatch Agent Using Systems Manager Run Command**

Follow these steps to start the agent using Systems Manager Run Command.

**To start the CloudWatch agent using Run Command**

2. In the navigation pane, choose Run Command.

-or-

---

160
Install the CloudWatch Agent Using Systems Manager

If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.

3. Choose **Run command**.
4. In the **Command document** list, choose **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, choose the instance where you installed the CloudWatch agent.
6. In the **Action** list, choose **configure**.
7. In the **Optional Configuration Source** list, choose **ssm**.
8. In the **Optional Configuration Location** box, enter the name of the agent configuration file that you created and saved to Systems Manager Parameter Store, as explained in Create the CloudWatch Agent Configuration File (p. 174).
9. In the **Optional Restart** list, choose **yes** to start the agent after you have finished these steps.
10. Choose **Run**.
11. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully started.

Start the CloudWatch Agent on an Amazon EC2 Instance Using the Command Line

Follow these steps to use the command line to install the CloudWatch agent on an Amazon EC2 instance.

To use the command line to start the CloudWatch agent on an Amazon EC2 instance

- In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

**Linux:** If you saved the configuration file in the Systems Manager Parameter Store, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -c ssm:configuration-parameter-store-name -s
```

**Linux:** If you saved the configuration file on the local computer, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -c file:configuration-file-path -s
```

**Windows Server:** If you saved the agent configuration file in Systems Manager Parameter Store, enter the following from the PowerShell console:

```
./amazon-cloudwatch-agent-ctl.ps1 -a fetch-config -m ec2 -c ssm:configuration-parameter-store-name -s
```

**Windows Server:** If you saved the agent configuration file on the local computer, enter the following from the PowerShell console:

```
./amazon-cloudwatch-agent-ctl.ps1 -a fetch-config -m ec2 -c file:configuration-file-path -s
```

Installing the CloudWatch Agent on On-Premises Servers

If you have downloaded the CloudWatch agent on one computer and created the agent configuration file you want, you can use that configuration file to install the agent on other on-premises servers.
Install the CloudWatch Agent Using Systems Manager

Download the CloudWatch Agent on an On-Premises Server

You can download the CloudWatch agent package using either Systems Manager Run Command or an Amazon S3 download link. For information about using an Amazon S3 download link, see Download the CloudWatch Agent Package Using an S3 Download Link (p. 143).

Download Using Systems Manager

To use Systems Manager Run Command, you must register your on-premises server with Amazon EC2 Systems Manager. For more information, see Setting Up Systems Manager in Hybrid Environments in the AWS Systems Manager User Guide.

If you have already registered your server, update SSM Agent to the latest version.

For information about updating SSM Agent on a server running Linux, see Install SSM Agent for a Hybrid Environment (Linux) in the AWS Systems Manager User Guide.

For information about updating the SSM Agent on a server running Windows Server, see Install SSM Agent for a Hybrid Environment (Windows) in the AWS Systems Manager User Guide.

To use the SSM Agent to download the CloudWatch agent package on an on-premises server

2. In the navigation pane, choose Run Command.
   -or-
   If the AWS Systems Manager home page opens, scroll down and choose Explore Run Command.
3. Choose Run command.
4. In the Command document list, select the button next to AWS-ConfigureAWSPackage.
5. In the Targets area, select the server to install the CloudWatch agent on. If you don't see a specific server, it might not be configured for Run Command. For more information, see Setting Up AWS Systems Manager for Hybrid Environments in the AWS Systems Manager User Guide.
6. In the Action list, choose Install.
7. In the Name box, enter AmazonCloudWatchAgent.
8. Keep Version blank to install the latest version of the agent.

The agent package is downloaded, and the next steps are to configure and start it.

(Installing on an On-Premises Server) Specify IAM Credentials and AWS Region

To enable the CloudWatch agent to send data from an on-premises server, you must specify the access key and secret key of the IAM user that you created earlier. For more information about creating this user, see Create IAM Roles and Users for Use with the CloudWatch Agent (p. 153).

You also must specify the AWS Region to send the metrics to, using the region field.

Following is an example of this file.

```
[AmazonCloudWatchAgent]
aws_access_key_id=my_access_key
aws_secret_access_key=my_secret_key
region = us-west-1
```

For my_access_key and my_secret_key, use the keys from the IAM user that doesn't have the permissions to write to Systems Manager Parameter Store. For more information about the IAM users...
needed for CloudWatch agent, see Create IAM Users to Use with the CloudWatch Agent on On-Premises Servers (p. 155).

If you name this profile AmazonCloudWatchAgent, you don't need to do anything more. Optionally, you can give it a different name and specify that name as the value for shared_credential_profile in the common-config.toml file, which is explained in the following section.

Following is an example of using the aws configure command to create a named profile for the CloudWatch agent. This example assumes that you're using the default profile name of AmazonCloudWatchAgent.

**To create the AmazonCloudWatchAgent profile for the CloudWatch agent**

- On Linux servers, enter the following command and follow the prompts:

  ```bash
  sudo aws configure --profile AmazonCloudWatchAgent
  ```

  On Windows Server, open PowerShell as an administrator, enter the following command, and follow the prompts.

  ```bash
  aws configure --profile AmazonCloudWatchAgent
  ```

**(Optional) Modifying the Common Configuration and Named Profile for CloudWatch Agent**

The CloudWatch agent includes a configuration file called common-config.toml. You can optionally use this file to specify proxy and Region information.

On a server running Linux, this file is in the /opt/aws/amazon-cloudwatch-agent/etc directory. On a server running Windows Server, this file is in the C:\ProgramData\Amazon\AmazonCloudWatchAgent directory.

The default common-config.toml is as follows:

```toml
# This common-config is used to configure items used for both ssm and cloudwatch access

## Configuration for shared credential.
## Default credential strategy will be used if it is absent here:
## Instance role is used for EC2 case by default.
## AmazonCloudWatchAgent profile is used for onPremise case by default.
# [credentials]
#    shared_credential_profile = "{profile_name}"  
#    shared_credential_file= "{file_name}"

## Configuration for proxy.
## System-wide environment-variable will be read if it is absent here.
## i.e. HTTP_PROXY/http_proxy; HTTPS_PROXY/https_proxy; NO_PROXY/no_proxy
## Note: system-wide environment-variable is not accessible when using ssm run-command.
## Absent in both here and environment-variable means no proxy will be used.
# [proxy]
#    http_proxy = "{http_url}"  
#    https_proxy = "{https_url}"  
#    no_proxy = "{domain}"  
```

All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually, or by using the RunShellScript Run Command in Systems Manager:
• **shared_credential_profile** – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, *AmazonCloudWatchAgent* is used. For more information about creating this profile, see *(Installing on an On-Premises Server)* Specify IAM Credentials and AWS Region (p. 162).

  On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different AWS Region. To do so, specify a named profile that includes a `region` field specifying the name of the Region to send to.

  If you specify a `shared_credential_profile`, you must also remove the `#` from the beginning of the `[credentials]` line.

• **shared_credential_file** – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is `/root/.aws` on Linux and is `C:\Users\Administrator\.aws` on Windows Server.

  The first example below shows the syntax of a valid `shared_credential_file` line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the `\` characters.

  ```
  shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
  ```

  ```
  shared_credential_file= "/usr/username/.aws/credentials"
  ```

  If you specify a `shared_credential_file`, you must also remove the `#` from the beginning of the `[credentials]` line.

• **Proxy settings** – If your servers use HTTP or HTTPS proxies to contact AWS services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

### Starting the CloudWatch Agent

You can start the CloudWatch agent using either Systems Manager Run Command or the command line.

**To use SSM Agent to start the CloudWatch agent on an on-premises server**

2. In the navigation pane, choose **Run Command**.
   - or -
   If the AWS Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, select the button next to **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, select the instance where you installed the agent.
6. In the **Action** list, choose **configure**.
7. In the **Mode** list, choose **onPremise**.
8. In the **Optional Configuration Location** box, enter the name of the agent configuration file that you created with the wizard and stored in the Parameter Store.
9. Choose **Run**.

   The agent starts with the configuration you specified in the configuration file.
To use the command line to start the CloudWatch agent on an on-premises server

- In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

  **Linux:** If you saved the configuration file in the Systems Manager Parameter Store, enter the following:

  ```bash
  sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m onPremise -c ssm:configuration-parameter-store-name -s
  ```

  **Linux:** If you saved the configuration file on the local computer, enter the following:

  ```bash
  sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m onPremise -c file:configuration-file-path -s
  ```

  **Windows Server:** If you saved the agent configuration file in Systems Manager Parameter Store, enter the following from the PowerShell console:

  ```powershell
  .\amazon-cloudwatch-agent-ctl.ps1 -a fetch-config -m onPremise -c ssm:configuration-parameter-store-name -s
  ```

  **Windows Server:** If you saved the agent configuration file on the local computer, enter the following from the PowerShell console:

  ```powershell
  .\amazon-cloudwatch-agent-ctl.ps1 -a fetch-config -m onPremise -c file:configuration-file-path -s
  ```

## Installing the CloudWatch Agent Using AWS CloudFormation

Amazon has uploaded several AWS CloudFormation templates to GitHub to help you install and update the CloudWatch agent. For more information about using AWS CloudFormation, see What is AWS CloudFormation?

The template location is Deploy the Amazon CloudWatch agent to EC2 instances using AWS CloudFormation. This location includes both inline and ssm directories. Each of these directories contains templates for both Linux and Windows instances.

- The templates in the inline directory have the CloudWatch agent configuration embedded into the AWS CloudFormation template. By default, the Linux templates collect the metrics `mem_used_percent` and `swap_used_percent`, and the Windows templates collect `Memory % Committed Bytes In Use` and `Page File % Usage`.

To modify these templates to collect different metrics, modify the following section of the template. The following example is from the template for Linux servers. Follow the format and syntax of the agent configuration file to make these changes. For more information, see Manually Create or Edit the CloudWatch Agent Configuration File (p. 179).

```json
{
  "metrics":{
    "append_dimensions":{
      "AutoScalingGroupName":"${aws:AutoScalingGroupName}",
      "ImageId":"${aws:ImageId}"
    }
  }
}
"InstanceId": "${aws:InstanceId}"
, "InstanceType": "${aws:InstanceType}"
},
"metrics_collected":{
  "mem":{
    "measurement": [
      "mem_used_percent"
    ]
  },
  "swap":{
    "measurement": [
      "swap_used_percent"
    ]
  }
}
}

Note
In the inline templates, all placeholder variables must have an exclamation mark (!) before them as an escape character. You can see this in the example template. If you add other placeholder variables, be sure to add an exclamation mark before the name.

- The templates in the ssm directory load an agent configuration file from Parameter Store. To use these templates, you must first create a configuration file and upload it to Parameter Store. You then provide the Parameter Store name of the file in the template. You can create the configuration file manually or by using the wizard. For more information, see Create the CloudWatch Agent Configuration File (p. 174).

You can use both types of templates for installing the CloudWatch agent and for updating the agent configuration.

Tutorial: Install and Configure the CloudWatch Agent Using an AWS CloudFormation Inline Template

This tutorial walks you through using AWS CloudFormation to install the CloudWatch agent on a new Amazon EC2 instance. This tutorial installs on a new instance running Amazon Linux 2 using the inline templates, which don't require the use of the JSON configuration file or Parameter Store. The inline template includes the agent configuration in the template. In this tutorial, you use the default agent configuration contained in the template.

After the procedure for installing the agent, the tutorial continues with how to update the agent.

To use AWS CloudFormation to install the CloudWatch agent on a new instance

1. Download the template from GitHub. In this tutorial, download the inline template for Amazon Linux 2 as follows:
   

3. Choose Create stack.
4. For Choose a template, select Upload a template to Amazon S3, choose the downloaded template, and choose Next.
5. On the Specify Details page, fill out the following parameters and choose Next:
   
   - Stack name: Choose a stack name for your AWS CloudFormation stack.
Using AWS CloudFormation

- **IAMRole**: Choose an IAM role that has permissions to write CloudWatch metrics and logs. For more information, see Create IAM Roles to Use with the CloudWatch Agent on Amazon EC2 Instances (p. 146).

- **InstanceAMI**: Choose an AMI that is valid in the Region where you're going to launch your stack.

- **InstanceType**: Choose a valid instance type.

- **KeyName**: To enable SSH access to the new instance, choose an existing Amazon EC2 key pair. If you don’t already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 Key Pairs in the Amazon EC2 User Guide for Linux Instances.

- **SSHLLocation**: Specifies the IP address range that can be used to connect to the instance using SSH. The default allows access from any IP address.

6. On the **Options** page, you can choose to tag your stack resources. Choose **Next**.

7. On the **Review** page, review your information, acknowledge that the stack might create IAM resources, and then choose **Create**.

If you refresh the console, you see that the new stack has the CREATE_IN_PROGRESS status.

8. When the instance is created, you can see it in the Amazon EC2 console. Optionally, you can connect to the host and check the progress.

Use the following command to confirm that the agent is installed:

```
rpm -qa amazon-cloudwatch-agent
```

Use the following command to confirm that the agent is running:

```
ps aux | grep amazon-cloudwatch-agent
```

The next procedure demonstrates using AWS CloudFormation to update the CloudWatch agent using an inline template. The default inline template collects the `mem_used_percent` metric. In this tutorial, you change the agent configuration to stop collecting that metric.

**To use AWS CloudFormation to update the CloudWatch agent**

1. In the template that you downloaded in the previous procedure, remove the following lines and then save the template:

   ```json
   "mem": {
       "measurement": [
           "mem_used_percent"
       ]
   },
   ```

3. On the AWS CloudFormation dashboard, select the stack that you created and choose **Update Stack**.

4. For **Select Template**, select **Upload a template to Amazon S3**, choose the template that you modified, and choose **Next**.

5. On the **Options** page, choose **Next** and then **Next**.

6. On the **Review** page, review your information and choose **Update**.

   After some time, you see **UPDATE_COMPLETE**.
Tutorial: Install the CloudWatch Agent Using AWS CloudFormation and Parameter Store

This tutorial walks you through using AWS CloudFormation to install the CloudWatch agent on a new Amazon EC2 instance. This tutorial installs on a new instance running Amazon Linux 2 using an agent configuration file that you create and save in Parameter Store.

After the procedure for installing the agent, the tutorial continues with how to update the agent.

To use AWS CloudFormation to install the CloudWatch agent on a new instance using a configuration from Parameter Store

1. If you haven't done so already, download the CloudWatch agent package to one of your computers so that you can create the agent configuration file. For more information and downloading the agent using Parameter Store, see Download and Configure the CloudWatch Agent (p. 156). For more information on downloading the package using the command line, see Download and Configure the CloudWatch Agent Using the Command Line (p. 143).

2. Create the agent configuration file and save it in Parameter Store. For more information, see Create the CloudWatch Agent Configuration File (p. 174).

3. Download the template from GitHub as follows:
   ```bash
   ```

5. Choose Create stack.

6. For Choose a template, select Upload a template to Amazon S3, choose the template that you downloaded, and choose Next.

7. On the Specify Details page, fill out the following parameters accordingly and choose Next:
   - **Stack name**: Choose a stack name for your AWS CloudFormation stack.
   - **IAMRole**: Choose an IAM role that has permissions to write CloudWatch metrics and logs. For more information, see Create IAM Roles to Use with the CloudWatch Agent on Amazon EC2 Instances (p. 154).
   - **InstanceAMI**: Choose an AMI that is valid in the Region where you're going to launch your stack.
   - **InstanceType**: Choose a valid instance type.
   - **KeyName**: To enable SSH access to the new instance, choose an existing Amazon EC2 key pair. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 Key Pairs in the Amazon EC2 User Guide for Linux Instances.
   - **SSHLocation**: Specifies the IP address range that can be used to connect to the instance using SSH. The default allows access from any IP address.
   - **SSMKey**: Specifies the agent configuration file that you created and saved in Parameter Store.

8. On the Options page, you can choose to tag your stack resources. Choose Next.

9. On the Review page, review your information, acknowledge that the stack might create IAM resources, and then choose Create.

   If you refresh the console, you see that the new stack has the CREATE_IN_PROGRESS status.

10. When the instance is created, you can see it in the Amazon EC2 console. Optionally, you can connect to the host and check the progress.

   Use the following command to confirm that the agent is installed:

   ```bash
   168
   ```
rpm -qa amazon-cloudwatch-agent

Use the following command to confirm that the agent is running:

ps aux | grep amazon-cloudwatch-agent

The next procedure demonstrates using AWS CloudFormation to update the CloudWatch agent, using an agent configuration that you saved in Parameter Store.

To use AWS CloudFormation to update the CloudWatch agent using a configuration in Parameter Store

1. Change the agent configuration file stored in Parameter Store to the new configuration that you want.
2. In the AWS CloudFormation template that you downloaded in the section called “Tutorial: Install the CloudWatch Agent Using AWS CloudFormation and Parameter Store” (p. 168) topic, change the version number. For example, you might change VERSION=1.0 to VERSION=2.0.
4. On the AWS CloudFormation dashboard, select the stack that you created and choose Update Stack.
5. For Select Template, select Upload a template to Amazon S3, select the template that you just modified, and choose Next.
6. On the Options page, choose Next and then Next.
7. On the Review page, review your information and choose Update.

After some time, you see UPDATE_COMPLETE.

Troubleshooting Installation of the CloudWatch Agent with AWS CloudFormation

This section helps you troubleshoot issues with installing and updating the CloudWatch agent using AWS CloudFormation.

Detecting When an Update Fails

If you use AWS CloudFormation to update your CloudWatch agent configuration, and use an invalid configuration, the agent stops sending any metrics to CloudWatch. A quick way to check whether an agent configuration update succeeded is to look at the cfn-init-cmd.log file. On a Linux server, the file is located at /var/log/cfn-init-cmd.log. On a Windows instance, the file is located at C:\cfn\log\cfn-init-cmd.log.

Metrics Are Missing

If you don’t see metrics that you expect to see after installing or updating the agent, confirm that the agent is configured to collect that metric. To do this, check the amazon-cloudwatch-agent.json file to make sure that the metric is listed, and check that you are looking in the correct metric namespace. For more information, see CloudWatch Agent Files and Locations (p. 225).
Verifying the Signature of the CloudWatch Agent Package

GPG signature files are included for CloudWatch agent packages on Linux servers. You can use a public key to verify that the agent download file is original and unmodified.

For Windows Server, you can use the MSI to verify the signature.

To find the correct signature file, see the following table. For each architecture and operating system there is a general link as well as links for each Region. For example, for Amazon Linux and Amazon Linux 2 and the AMD64 architecture, three of the valid links are:

<table>
<thead>
<tr>
<th>Architecture</th>
<th>Platform</th>
<th>Download Link</th>
<th>Signature File Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Architecture</td>
<td>Platform</td>
<td>Download Link</td>
<td>Signature File Link</td>
</tr>
<tr>
<td>--------------</td>
<td>----------</td>
<td>---------------</td>
<td>---------------------</td>
</tr>
</tbody>
</table>
To verify the CloudWatch agent package on a Linux server

1. Download the public key.

   ```shell
   shell$ wget https://s3.amazonaws.com/amazoncloudwatch-agent/assets/amazon-cloudwatch-agent.gpg
   ```

2. Import the public key into your keyring.

   ```shell
   shell$ gpg --import amazon-cloudwatch-agent.gpg
   gpg: key 3B789C72: public key "Amazon CloudWatch Agent" imported
   gpg: Total number processed: 1
   gpg: imported: 1 (RSA: 1)
   ```

Make a note of the key value, as you need it in the next step. In the preceding example, the key value is 3B789C72.
3. Verify the fingerprint by running the following command, replacing `key-value` with the value from the preceding step:

```
shell$ gpg --fingerprint key-value
```

```
pub  2048R/3B789C72  2017-11-14
    Key fingerprint = 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
uid                  Amazon CloudWatch Agent
```

The fingerprint string should be equal to the following:

9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72

If the fingerprint string doesn't match, don't install the agent. Contact Amazon Web Services.

After you have verified the fingerprint, you can use it to verify the signature of the CloudWatch agent package.

4. Download the package signature file using `wget`. To determine the correct signature file, see the preceding table.

```
wget Signature File Link
```

5. To verify the signature, run `gpg --verify`.

```
shell$ gpg --verify signature-filename agent-download-filename
```

```
gpg: Signature made Wed 29 Nov 2017 03:00:59 PM PST using RSA key ID 3B789C72
gpg: Good signature from "Amazon CloudWatch Agent"
gpg: WARNING: This key is not certified with a trusted signature! Primary key fingerprint: 9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72
```

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

**To verify the CloudWatch agent package on a server running Windows Server**

1. Download and install GnuPG for Windows from [https://gnupg.org/download/](https://gnupg.org/download/). When installing, include the `Shell Extension (GpgEx)` option.

   You can perform the remaining steps in Windows PowerShell.

2. Download the public key.

   ```
   ```

3. Import the public key into your keyring.

   ```
   PS> gpg --import amazon-cloudwatch-agent.gpg
   gpg: Key 3B789C72: public key "Amazon CloudWatch Agent" imported
   gpg: Total number processed: 1
   gpg: imported: 1 (RSA: 1)
   ```
Make a note of the key value because you need it in the next step. In the preceding example, the key value is 3B789C72.

4. Verify the fingerprint by running the following command, replacing `key-value` with the value from the preceding step:

```
PS> gpg --fingerprint key-value
```

```
pub   rsa2048 2017-11-14 [SC]
  9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72
uid           [ unknown] Amazon CloudWatch Agent
```

The fingerprint string should be equal to the following:

```
9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72
```

If the fingerprint string doesn't match, don't install the agent. Contact Amazon Web Services.

After you have verified the fingerprint, you can use it to verify the signature of the CloudWatch agent package.

5. Download the package signature file using `wget`. To determine the correct signature file, see CloudWatch Agent Download Links (p. 143).

6. To verify the signature, run `gpg --verify`.

```
PS> gpg --verify sig-filename agent-download-filename
```

```
gpg: Signature made 11/29/17 23:00:45 Coordinated Universal Time
gpg: using RSA key D58167303B789C72
gpg: Good signature from "Amazon CloudWatch Agent" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg: There is no indication that the signature belongs to the owner.
Primary key fingerprint: 9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72
```

If the output includes the phrase BAD signature, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

---

**Create the CloudWatch Agent Configuration File**

Before running the CloudWatch agent on any servers, you must create a CloudWatch agent configuration file.

The agent configuration file is a JSON file that specifies the metrics and logs that the agent is to collect, including custom metrics. You can create it by using the wizard or by creating it yourself from scratch. You could also use the wizard to initially create the configuration file and then modify it manually. If you create or modify the file manually, the process is more complex, but you have more control over the metrics collected and can specify metrics not available through the wizard.

Any time you change the agent configuration file, you must then restart the agent to have the changes take effect.

After you have created a configuration file, you can save it manually as a JSON file and then use this file when installing the agent on your servers. Alternatively, you can store it in Systems Manager Parameter Store if you're going to use Systems Manager when you install the agent on servers.
Create the CloudWatch Agent Configuration File with the Wizard

The agent configuration file wizard, `amazon-cloudwatch-agent-config-wizard`, asks a series of questions, including the following:

- Are you installing the agent on an Amazon EC2 instance or an on-premises server?
- Is the server running Linux or Windows Server?
- Do you want the agent to also send log files to CloudWatch Logs? If so, do you have an existing CloudWatch Logs agent configuration file? If yes, the CloudWatch agent can use this file to determine the logs to collect from the server.
- If you're going to collect metrics from the server, do you want to monitor one of the default sets of metrics or customize the list of metrics that you collect?
- Do you want to collect custom metrics from your applications or services, using StatsD or `collectd`?
- Are you migrating from an existing SSM Agent?

The wizard can autodetect the credentials and AWS Region to use if you have the AWS credentials and configuration files in place before you start the wizard. For more information about these files, see Configuration and Credential Files in the AWS Systems Manager User Guide.

In the AWS credentials file, the wizard checks for default credentials and also looks for an `AmazonCloudWatchAgent` section such as the following:

```
[AmazonCloudWatchAgent]
aws_access_key_id = my_secret_key
aws_secret_access_key = my_access_key
```

The wizard displays the default credentials, the credentials from the `AmazonCloudWatchAgent`, and an Others option. You can select which credentials to use. If you choose Others, you can input credentials.

For `my_access_key` and `my_secret_key`, use the keys from the IAM user that has the permissions to write to Systems Manager Parameter Store. For more information about the IAM users needed for the CloudWatch agent, see Create IAM Users to Use with the CloudWatch Agent on On-Premises Servers (p. 155).

In the AWS configuration file, you can specify the Region that the agent sends metrics to if it's different than the `[default]` section. The default is to publish the metrics to the Region where the Amazon EC2 instance is located. If the metrics should be published to a different Region, specify the Region here. In the following example, the metrics are published to the us-west-1 Region.

```
[AmazonCloudWatchAgent]
region = us-west-1
```

CloudWatch Agent Predefined Metric Sets

The wizard is configured with predefined sets of metrics, with different detail levels. These sets of metrics are shown in the following tables. For more information about these metrics, see Metrics Collected by the CloudWatch Agent (p. 207).

Amazon EC2 instances running Linux
### Create the CloudWatch Agent Configuration File with the Wizard

#### Detail Level and Metrics Included

<table>
<thead>
<tr>
<th>Detail Level</th>
<th>Metrics Included</th>
</tr>
</thead>
</table>
| **Basic**    | **Mem**: mem_used_percent  
               | **Disk**: disk_used_percent  
               | The disk metrics such as disk_used_percent have a dimension for Partition, which means that the number of custom metrics generated is dependent on the number of partitions associated with your instance. The number of disk partitions you have depends on which AMI you are using and the number of Amazon EBS volumes you attach to the server. |
| **Standard** | **CPU**: cpu_usage_idle, cpu_usage_iowait, cpu_usage_user, cpu_usage_system  
               | **Disk**: disk_used_percent, disk_inodes_free  
               | **Diskio**: diskio_io_time  
               | **Mem**: mem_used_percent  
               | **Swap**: swap_used_percent  
               | |
| **Advanced** | **CPU**: cpu_usage_idle, cpu_usage_iowait, cpu_usage_user, cpu_usage_system  
               | **Disk**: disk_used_percent, disk_inodes_free  
               | **Diskio**: diskio_io_time, diskio_write_bytes, diskio_read_bytes, diskio_writes, diskio_reads  
               | **Mem**: mem_used_percent  
               | **Netstat**: netstat_tcp_established, netstat_tcp_time_wait  
               | **Swap**: swap_used_percent  
               | |

Manually Create or Edit the CloudWatch Agent Configuration File

### Run the CloudWatch Agent Configuration Wizard

#### To create the CloudWatch agent configuration file

1. Start the CloudWatch agent configuration wizard by entering the following:

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-config-wizard
   ```

   On a server running Windows Server, enter the following:

   ```
   cd "C:\Program Files\Amazon\AmazonCloudWatchAgent"
   amazon-cloudwatch-agent-config-wizard.exe
   ```

2. Answer the questions to customize the configuration file for your server.

3. If you're storing the configuration file locally, the configuration file `config.json` is stored in the current working directory. You can then copy this file to other servers where you want to install the agent.

   If you're going to use Systems Manager to install and configure the agent, be sure to answer **Yes** when prompted whether to store the file in Systems Manager Parameter Store. You can also choose to store the file in Parameter Store even if you aren't using the SSM Agent to install the CloudWatch agent. To be able to store the file in Parameter Store, you must use an IAM role with sufficient permissions. For more information, see Create IAM Roles and Users for Use with the CloudWatch Agent (p. 153).

### Manually Create or Edit the CloudWatch Agent Configuration File

The CloudWatch agent configuration file is a JSON file with three sections: `agent`, `metrics`, and `logs`.

- The `agent` section includes fields for the overall configuration of the agent. If you use the wizard, it doesn't create an `agent` section.
- The `metrics` section specifies the custom metrics for collection and publishing to CloudWatch. If you're using the agent only to collect logs, you can omit the `metrics` section from the file.
- The `logs` section specifies what log files are published to CloudWatch Logs. This can include events from the Windows Event Log if the server runs Windows Server.

The following sections explain the structure and fields of this JSON file. You can also view the schema definition for this configuration file. The schema definition is located at `installation-directory/doc/amazon-cloudwatch-agent-schema.json` on Linux servers, and at `installation-directory/amazon-cloudwatch-agent-schema.json` on servers running Windows Server.

If you create or edit the agent configuration file manually, you can give it any name. For simplicity in troubleshooting, we recommend that you name it `/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json` on a Linux server and `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json` on servers running Windows Server. After you have created the file, you can copy it to other servers where you want to install the agent.
CloudWatch Agent Configuration File: Agent Section

The `agent` section can include the following fields. The wizard doesn't create an `agent` section. Instead, the wizard omits it and uses the default values for all fields in this section.

- `metrics_collection_interval` – Optional. Specifies how often all metrics specified in this configuration file are to be collected. You can override this value for specific types of metrics.

  This value is specified in seconds. For example, specifying 10 sets metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-Resolution Metrics (p. 45).

  The default value is 60.

- `region` – Specifies the Region to use for the CloudWatch endpoint when an Amazon EC2 instance is being monitored. The metrics collected are sent to this Region, such as `us-west-1`. If you omit this field, the agent sends metrics to the Region where the Amazon EC2 instance is located.

  If you are monitoring an on-premises server, this field isn't used, and the agent reads the Region from the `AmazonCloudWatchAgent` profile of the AWS configuration file.

- `credentials` – Specifies an IAM role to use when sending metrics and logs to a different AWS account. If specified, this field contains one parameter, `role_arn`.

  - `role_arn` – Specifies the Amazon Resource Name (ARN) of an IAM role to use for authentication when sending metrics and logs to a different AWS account. For more information, see Sending Metrics and Logs to a Different Account (p. 221).

- `debug` – Optional. Specifies running the CloudWatch agent with debug log messages. The default value is `false`.

- `logfile` – Specifies the location where the CloudWatch agent writes log messages. If you specify an empty string, the log goes to stderr. If you don't specify this option, the default locations are the following:

  - Windows Server: `C:\ProgramData\Amazon\CloudWatchAgent\Logs\amazon-cloudwatch-agent.log`

  The CloudWatch agent automatically rotates the log file that it creates. A log file is rotated out when it reaches 100 MB in size. The agent keeps the rotated log files for up to seven days, and it keeps as many as five backup log files that have been rotated out. Backup log files have a timestamp appended to their filename. The timestamp shows the date and time that the file was rotated out: for example, `amazon-cloudwatch-agent-2018-06-08T21-01-50.247.log.gz`.

- `omit_hostname` – Optional. By default, the hostname is published as a dimension of metrics that are collected by the agent. Set this value to `true` to prevent the hostname from being published as a dimension. The default value is `false`.

- `run_as_user` – Optional. Specifies a user to use to run the CloudWatch agent. If you don't specify this parameter, the root user is used. This option is valid only on Linux servers.

  If you specify this option, the user must exist before you start the CloudWatch agent. For more information, see Running the CloudWatch Agent as a Different User (p. 216).

The following is an example of an `agent` section.

```json
"agent": {
  "metrics_collection_interval": 60,
  "region": "us-west-1",
```
CloudWatch Agent Configuration File: Metrics Section

On servers running either Linux or Windows Server, the `metrics` section includes the following fields:

- **namespace** – Optional. The namespace to use for the metrics collected by the agent. The default value is `CWAgent`. The maximum length is 255 characters.
- **append_dimensions** – Optional. Adds Amazon EC2 metric dimensions to all metrics collected by the agent. For each dimension, you must specify a key-value pair, where the key matches an Amazon EC2 dimension: `ImageID: image-id`, `InstanceId: instance-id`, `InstanceType: instance-type`, or `AutoScalingGroupName: AutoScaling-group-name`.

If you specify a value that depends on Amazon EC2 metadata and you use proxies, you must make sure that the server can access the endpoint for Amazon EC2. For more information about these endpoints, see Amazon Elastic Compute Cloud (Amazon EC2) in the Amazon Web Services General Reference.

- **aggregation_dimensions** – Optional. Specifies the dimensions that collected metrics are to be aggregated on. For example, if you roll up metrics on the `AutoScalingGroupName` dimension, the metrics from all instances in each Auto Scaling group are aggregated and can be viewed as a whole.

You can roll up metrics along single or multiple dimensions. For example, specifying `[["InstanceId"], ["InstanceType"], ["InstanceId", "InstanceType"] ]` aggregates metrics for instance ID singly, instance type singly, and for the combination of the two dimensions.

You can also specify `[]` to roll up all metrics into one collection, disregarding all dimensions.

- **endpoint_override** – Specifies a FIPS endpoint or private link to use as the endpoint where the agent sends metrics. Specifying this and setting a private link enables you to send the metrics to an Amazon VPC endpoint. For more information, see What Is Amazon VPC?.

The value of `endpoint_override` must be a string that is a URL.

- **metrics_collected** – Required. Specifies which metrics are to be collected, including custom metrics collected through StatsD or collectd. This section includes several subsections.

The contents of the `metrics_collected` section depend on whether this configuration file is for a server running Linux or Windows Server.

- **force_flush_interval** – Specifies in seconds the maximum amount of time that metrics remain in the memory buffer before being sent to the server. No matter the setting for this, if the size of the metrics in the buffer reaches 40 KB or 20 different metrics, the metrics are immediately sent to the server.

The default value is 60.

- **credentials** – Specifies an IAM role to use when sending metrics to a different account. If specified, this field contains one parameter, `role_arn`.
  
  - **role_arn** – Specifies the ARN of an IAM role to use for authentication when sending metrics to a different account. For more information, see Sending Metrics and Logs to a Different Account (p. 221). If specified here, this value overrides the `role_arn` specified in the agent section of the configuration file, if any.

**Linux**

On servers running Linux, the `metrics_collected` section of the configuration file can also contain the following fields.
Manually Create or Edit the CloudWatch Agent Configuration File

Many of these fields can include a measurement sections that lists the metrics you want to collect for that resource. These measurement sections can either specify the complete metric name such as swap_used, or just the part of the metric name that will be appended to the type of resource. For example, specifying reads in the measurement section of the diskio section causes the diskio_reads metric to be collected.

- **collectd** – Optional. Specifies that you want to retrieve custom metrics using the collectd protocol. You use collectd software to send the metrics to the CloudWatch agent. For more information, see Retrieve Custom Metrics with collectd (p. 206).
- **cpu** – Optional. Specifies that CPU metrics are to be collected. This section is valid only for Linux instances. This section can include as many as three fields:
  - **resources** – Optional. Specifies that per-cpu metrics are to be collected. The only allowed value is *. If you include this field and value, per-cpu metrics are collected.
  - **totalcpu** – Optional. Specifies whether to report cpu metrics aggregated across all cpu cores. The default is true.
  - **measurement** – Specifies the array of cpu metrics to be collected. Possible values are time_active, time_guest, time_guest_nice, time_idle, time_iowait, time_irq, time_nice, time_softirq, time_steal, time_system, time_user, usage_active, usage_guest, usage_guest_nice, usage_idle, usage_iowait, usage_irq, usage_nice, usage_softirq, usage_steal, usage_system, and usage_user. This field is required if you include cpu.

  By default, the unit for cpu_usage_* metrics is Percent, and cpu_time_* metrics don't have a unit.

Within the entry for each individual metric, you might optionally specify one or both of the following:

- **rename** – Specifies a different name for this metric.
- **unit** – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the MetricDatum.

- **metrics_collection_interval** – Optional. Specifies how often to collect the cpu metrics, overriding the global metrics_collection_interval specified in the agent section of the configuration file.

  This value is specified in seconds. For example, specifying 10 sets metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-Resolution Metrics (p. 45).

- **append_dimensions** – Optional. Additional dimensions to use for only the cpu metrics. If you specify this field, it's used in addition to dimensions specified in the global append_dimensions field that is used for all types of metrics that the agent collects.

- **disk** – Optional. Specifies that disk metrics are to be collected. This section is valid only for Linux instances. This section can include as many as two fields:
  - **resources** – Optional. Specifies an array of disk mount points. This field limits CloudWatch to collect metrics from only the listed mount points. You can specify * as the value to collect metrics from all mount points. The default value is to collect metrics from all mount points.
  - **measurement** – Specifies the array of disk metrics to be collected. Possible values are free, total, used, used_percent, inodes_free, inodes_used, and inodes_total. This field is required if you include disk.

  **Note**
  The disk metrics have a dimension for Partition, which means that the number of custom metrics generated is dependent on the number of partitions associated with your...
instance. The number of disk partitions you have depends on which AMI you are using and the number of Amazon EBS volumes you attach to the server.

To see the default units for each disk metric, see Metrics Collected by the CloudWatch Agent on Linux Instances (p. 208).

Within the entry for each individual metric, you might optionally specify one or both of the following:

- **rename** – Specifies a different name for this metric.

- **unit** – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the Unit description in MetricDatum.

- **ignore_file_system_types** – Specifies file system types to exclude when collecting disk metrics. Valid values include sysfs, devtmpfs, and so on.

- **drop_device** – Setting this to true causes Device to not be included as a dimension for disk metrics.

Preventing Device from being used as a dimension can be useful on instances that use the Nitro system because on those instances the device names change for each disk mount when the instance is rebooted. This can cause inconsistent data in your metrics and cause alarms based on these metrics to go to INSUFFICIENT DATA state.

The default is false.

- **metrics_collection_interval** – Optional. Specifies how often to collect the disk metrics, overriding the global metrics_collection_interval specified in the agent section of the configuration file.

This value is specified in seconds.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-Resolution Metrics (p. 45).

- **append_dimensions** – Optional. Additional dimensions to use for only the disk metrics. If you specify this field, it is used in addition to dimensions specified in the append_dimensions field that is used for all types of metrics collected by the agent.

- **diskio** – Optional. Specifies that disk i/o metrics are to be collected. This section is valid only for Linux instances. This section can include as many as two fields:

  - **resources** – Optional. If you specify an array of devices, CloudWatch collects metrics from only those devices. Otherwise, metrics for all devices are collected. You can also specify * as the value to collect metrics from all devices.

  - **measurement** – Specifies the array of diskio metrics to be collected. Possible values are reads, writes, read_bytes, write_bytes, read_time, write_time, io_time, and iops_in_progress. This field is required if you include diskio.

Within the entry for each individual metric, you might optionally specify one or both of the following:

- **rename** – Specifies a different name for this metric.

- **unit** – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the Unit description in MetricDatum.

- **metrics_collection_interval** – Optional. Specifies how often to collect the diskio metrics, overriding the global metrics_collection_interval specified in the agent section of the configuration file.

This value is specified in seconds.
If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-Resolution Metrics (p. 45).

- `append_dimensions` – Optional. Additional dimensions to use for only the diskio metrics. If you specify this field, it is used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `swap` – Optional. Specifies that swap memory metrics are to be collected. This section is valid only for Linux instances. This section can include as many as three fields:
  - `measurement` – Specifies the array of swap metrics to be collected. Possible values are `free`, `used`, and `used_percent`. This field is required if you include `swap`.

To see the default units for each `swap` metric, see Metrics Collected by the CloudWatch Agent on Linux Instances (p. 208).

Within the entry for each individual metric, you might optionally specify one or both of the following:
  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in `MetricDatum`.

- `metrics_collection_interval` – Optional. Specifies how often to collect the swap metrics, overriding the global `metrics_collection_interval` specified in the agent section of the configuration file.

This value is specified in seconds.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-Resolution Metrics (p. 45).

- `append_dimensions` – Optional. Additional dimensions to use for only the swap metrics. If you specify this field, it is used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics collected by the agent. It's collected as a high-resolution metric.

- `mem` – Optional. Specifies that memory metrics are to be collected. This section is valid only for Linux instances. This section can include as many as three fields:
  - `measurement` – Specifies the array of memory metrics to be collected. Possible values are `active`, `available`, `available_percent`, `buffered`, `cached`, `free`, `inactive`, `total`, `used`, and `used_percent`. This field is required if you include `mem`.

To see the default units for each `mem` metric, see Metrics Collected by the CloudWatch Agent on Linux Instances (p. 208).

Within the entry for each individual metric, you might optionally specify one or both of the following:
  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in `MetricDatum`.

- `metrics_collection_interval` – Optional. Specifies how often to collect the mem metrics, overriding the global `metrics_collection_interval` specified in the agent section of the configuration file.

This value is specified in seconds.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-Resolution Metrics (p. 45).
• **append_dimensions** – Optional. Additional dimensions to use for only the mem metrics. If you specify this field, it’s used in addition to dimensions specified in the **append_dimensions** field that is used for all types of metrics that the agent collects.

• **net** – Optional. Specifies that networking metrics are to be collected. This section is valid only for Linux instances. This section can include as many as four fields:
  - **resources** – Optional. If you specify an array of network interfaces, CloudWatch collects metrics from only those interfaces. Otherwise, metrics for all devices are collected. You can also specify * as the value to collect metrics from all interfaces.
  - **measurement** – Specifies the array of networking metrics to be collected. Possible values are `bytes_sent`, `bytes_recv`, `drop_in`, `drop_out`, `err_in`, `err_out`, `packets_sent`, and `packets_recv`. This field is required if you include net.

To see the default units for each net metric, see **Metrics Collected by the CloudWatch Agent on Linux Instances** (p. 208).

Within the entry for each individual metric, you might optionally specify one or both of the following:
  - **rename** – Specifies a different name for this metric.
  - **unit** – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the **Unit** description in **MetricDatum**.

• **metrics_collection_interval** – Optional. Specifies how often to collect the net metrics, overriding the global **metrics_collection_interval** specified in the agent section of the configuration file.

This value is specified in seconds. For example, specifying 10 sets metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see **High-Resolution Metrics** (p. 45).

• **append_dimensions** – Optional. Additional dimensions to use for only the net metrics. If you specify this field, it’s used in addition to dimensions specified in the **append_dimensions** field that is used for all types of metrics collected by the agent.

• **netstat** – Optional. Specifies that TCP connection state and UDP connection metrics are to be collected. This section is valid only for Linux instances. This section can include as many as three fields:
  - **measurement** – Specifies the array of netstat metrics to be collected. Possible values are `tcp_close`, `tcp_close_wait`, `tcp_closing`, `tcp_established`, `tcp_fin_wait1`, `tcp_fin_wait2`, `tcp_last_ack`, `tcp_listen`, `tcp_none`, `tcp_syn_sent`, `tcp_syn_recv`, `tcp_time_wait`, and `udp_socket`. This field is required if you include netstat.

To see the default units for each netstat metric, see **Metrics Collected by the CloudWatch Agent on Linux Instances** (p. 208).

Within the entry for each individual metric, you might optionally specify one or both of the following:
  - **rename** – Specifies a different name for this metric.
  - **unit** – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the **Unit** description in **MetricDatum**.

• **metrics_collection_interval** – Optional. Specifies how often to collect the netstat metrics, overriding the global **metrics_collection_interval** specified in the agent section of the configuration file.

This value is specified in seconds.
If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-Resolution Metrics (p. 45).

- append_dimensions – Optional. Additional dimensions to use for only the netstat metrics. If you specify this field, it’s used in addition to dimensions specified in the append_dimensions field that is used for all types of metrics collected by the agent.

- processes – Optional. Specifies that process metrics are to be collected. This section is valid only for Linux instances. This section can include as many as three fields:
  - measurement – Specifies the array of processes metrics to be collected. Possible values are blocked, dead, idle, paging, running, sleeping, stopped, total, total_threads, wait, and zombies. This field is required if you include processes.

For all processes metrics, the default unit is Count.

Within the entry for each individual metric, you might optionally specify one or both of the following:
- rename – Specifies a different name for this metric.
- unit – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the Unit description in MetricDatum.

- metrics_collection_interval – Optional. Specifies how often to collect the process metrics, overriding the global metrics_collection_interval specified in the agent section of the configuration file.

  This value is specified in seconds. For example, specifying 10 sets metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-Resolution Metrics (p. 45).

- append_dimensions – Optional. Additional dimensions to use for only the process metrics. If you specify this field, it’s used in addition to dimensions specified in the append_dimensions field that is used for all types of metrics collected by the agent.

- procstat – Optional. Specifies that you want to retrieve metrics from individual processes. For more information, see Collect Process Metrics with the procstat Plugin (p. 198).

- statsd – Optional. Specifies that you want to retrieve custom metrics using the StatsD protocol. The CloudWatch agent acts as a daemon for the protocol. You use any standard StatsD client to send the metrics to the CloudWatch agent. For more information, see Retrieve Custom Metrics with StatsD (p. 205).

The following is an example of a metrics section for a Linux server. In this example, three CPU metrics, three netstat metrics, three process metrics, and one disk metric are collected, and the agent is set up to receive additional metrics from a collectd client.

```json
"metrics": {
  "metrics_collected": {
    "collectd": {},
    "cpu": {
      "resources": ["*"]
    },
    "measurement": [
      {"name": "cpu_usage_idle", "rename": "CPU_USAGE_IDLE", "unit": "Percent"},
      {"name": "cpu_usage_nice", "rename": "CPU_USAGE_NICE", "unit": "Percent"},
      {"name": "cpu_usage_guest"}
    ],
    "totalcpu": false,
  }
```
"metrics_collection_interval": 10,
"append_dimensions": {
  "test": "test1",
  "date": "2017-10-01"
}
},
"netstat": {
  "measurement": [
    "tcp_established",
    "tcp_syn_sent",
    "tcp_close"
  ],
  "metrics_collection_interval": 60
},
"disk": {
  "measurement": [
    "used_percent"
  ],
  "resources": [
    "*"
  ],
  "drop_device": true
},
"processes": {
  "measurement": [
    "running",
    "sleeping",
    "dead"
  ]
}
},
"append_dimensions": {
  "ImageId": "${aws:ImageId}",
  "InstanceId": "${aws:InstanceId}",
  "InstanceType": "${aws:InstanceType}",
  "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
},
"aggregation_dimensions": ["AutoScalingGroupName", ["InstanceId", "InstanceType"], []]

Windows Server

In the metrics_collected section for Windows Server, you can have subsections for each Windows performance object, such as Memory, Processor, and LogicalDisk. For information about what objects and counters are available, see the Microsoft Windows documentation.

Within the subsection for each object, you specify a measurement array of the counters to collect. The measurement array is required for each object that you specify in the configuration file. You can also specify a resources field to name the instances to collect metrics from. You can also specify * for resources to collect separate metrics for every instance. If you omit resources, the data for all instances is aggregated into one set. For objects that don't have instances, omit resources.

Within each object section, you can also specify the following optional fields:

- **metrics_collection_interval** – Optional. Specifies how often to collect the metrics for this object, overriding the global metrics_collection_interval specified in the agent section of the configuration file.

  This value is specified in seconds. For example, specifying 10 sets metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.
If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-Resolution Metrics (p. 45).

- append_dimensions – Optional. Specifies additional dimensions to use for only the metrics for this object. If you specify this field, it's used in addition to dimensions specified in the global append_dimensions field that is used for all types of metrics collected by the agent.

Within each counter section, you can also specify the following optional fields:

- rename – Specifies a different name to be used in CloudWatch for this metric.
- unit – Specifies the unit to use for this metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the Unit description in MetricDatum.

There are two other optional sections that you can include in metrics_collected:

- statsd – Enables you to retrieve custom metrics using the StatsD protocol. The CloudWatch agent acts as a daemon for the protocol. You use any standard StatsD client to send the metrics to the CloudWatch agent. For more information, see Retrieve Custom Metrics with StatsD (p. 205).
- procstat – Enables you to retrieve metrics from individual processes. For more information, see Collect Process Metrics with the procstat Plugin (p. 198).

The following is an example metrics section for use on Windows Server. In this example, many Windows metrics are collected, and the computer is also set to receive additional metrics from a StatsD client.

```json
"metrics": {
  "metrics_collected": {
    "statsd": {},
    "Processor": {
      "measurement": [
        {"name": "% Idle Time", "rename": "CPU_IDLE", "unit": "Percent"},
        "% Interrupt Time",
        "% User Time",
        "% Processor Time"
      ],
      "resources": ["*"],
      "append_dimensions": {
        "d1": "win_foo",
        "d2": "win_bar"
      }
    },
    "LogicalDisk": {
      "measurement": [
        {"name": "% Idle Time", "unit": "Percent"},
        {"name": "% Disk Read Time", "rename": "DISK_READ"},
        "% Disk Write Time"
      ],
      "resources": ["*"],
    },
    "Memory": {
      "metrics_collection_interval": 5,
      "measurement": [
        "Available Bytes",
        "Cache Faults/sec",
        "Page Faults/sec",
      ]
    }
  }
}
```
CloudWatch Agent Configuration File: Logs Section

The `logs` section includes the following fields:

- **logs_collected** – Required if the `logs` section is included. Specifies which log files and Windows event logs are to be collected from the server. It can include two fields, `files` and `windows_events`.
- **files** – Specifies which regular log files the CloudWatch agent is to collect. It contains one field, `collect_list`, which further defines these files.
- **collect_list** – Required if `files` is included. Contains an array of entries, each of which specifies one log file to collect. Each of these entries can include the following fields:
  - **file_path** – Specifies the path of the log file to upload to CloudWatch Logs. Standard Unix glob matching rules are accepted, with the addition of ** as a super asterisk. For example, specifying `/var/log/**.log` causes all .log files in the `/var/log` directory tree to be collected. For more examples, see Glob Library.

You can also use the standard asterisk as a standard wildcard. For example, `/var/log/system.log*` matches files such as `system.log_1111`, `system.log_2222`, and so on in `/var/log`. 

```json

"Pages/sec"
],
"append_dimensions": {
  "d3": "win_bo"
}
},
"Network Interface": {
  "metrics_collection_interval": 5,
  "measurement": [
    "Bytes Received/sec",
    "Bytes Sent/sec",
    "Packets Received/sec",
    "Packets Sent/sec"
  ],
  "resources": [
    "*"
  ],
  "append_dimensions": {
    "d3": "win_bo"
  }
},
"System": {
  "measurement": [
    "Context Switches/sec",
    "System Calls/sec",
    "Processor Queue Length"
  ],
  "append_dimensions": {
    "d1": "win_foo",
    "d2": "win_bar"
  }
},
"append_dimensions": {
  "ImageId": "${aws:ImageId}"
},
"InstanceId": "${aws:InstanceId}"
},
"AutoScalingGroupName": "${aws:AutoScalingGroupName}"
",
"aggregation_dimensions" : [["ImageId"],["InstanceId", "InstanceType"],["d1"],[[]]]
"
```
Only the latest file is pushed to CloudWatch Logs based on file modification time. We recommend that you use wildcards to specify a series of files of the same type, such as `access_log.2018-06-01-01` and `access_log.2018-06-01-02`, but not multiple kinds of files, such as `access_log.80` and `access_log.443`. To specify multiple kinds of files, add another log stream entry to the agent configuration file so that each kind of log file goes to a different log stream.

- **log_group_name** – Optional. Specifies what to use as the log group name in CloudWatch Logs. As part of the name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}` retrieves the hostname from the EC2 metadata, and `{local_hostname}` uses the hostname from the network configuration file.

If you use these variables to create many different log groups, keep in mind the limit of 5000 log groups per account per Region.

Allowed characters include a–z, A–Z, 0–9, ‘_’ (underscore), ‘-’ (hyphen), ‘/’ (forward slash), and ‘.’ (period).

We recommend that you specify this field to prevent confusion. If you omit this field, the file path up to the final dot is used as the log group name. For example, if the file path is `/tmp/TestLogFile.log.2017-07-11-14`, the log group name is `/tmp/TestLogFile.log`.

- **log_stream_name** – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}` retrieves the hostname from the EC2 metadata, and `{local_hostname}` uses the hostname from the network configuration file.

If you omit this field, the default value of `{instance_id}` is used. If a log stream doesn't already exist, it's created automatically.

- **timezone** – Optional. Specifies the time zone to use when putting timestamps on log events. The valid values are UTC and Local. The default value is Local.

- **timestamp_format** – Optional. Specifies the timestamp format, using plaintext and special symbols that start with `%`. If you omit this field, the current time is used. If you use this field, you can use the symbols in the following list as part of the format. This list of symbols is different than the list used by the older CloudWatch Logs agent. For a summary of these differences, see Timestamp Differences Between the Unified CloudWatch Agent and the Older CloudWatch Logs Agent (p. 223)

%y

Year without century as a zero-padded decimal number

%Y

Year with century as a decimal number

%b

Month as the locale's abbreviated name

%B

Month as the locale's full name

%m

Month as a zero-padded decimal number

%-m

Month as a decimal number (not zero-padded)
%d

Day of the month as a zero-padded decimal number

%-d

Day of the month as a decimal number (not zero-padded)

%A

Full name of weekday, such as Monday

%a

Abbreviation of weekday, such as Mon

%H

Hour (in a 24-hour clock) as a zero-padded decimal number

%I

Hour (in a 12-hour clock) as a zero-padded decimal number

%-I

Hour (in a 12-hour clock) as a decimal number (not zero-padded)

%p

AM or PM

%M

Minutes as a zero-padded decimal number

%-M

Minutes as a decimal number (not zero-padded)

%S

Seconds as a zero-padded decimal number

%-S

Seconds as a decimal number (not zero padded)

%Z

Time zone, for example PST

%z

Time zone, expressed as the offset between the local time zone and UTC. For example, -0700. Only this format is supported. For example, -07:00 isn't a valid format.

- multi_line_start_pattern – Specifies the pattern for identifying the start of a log message. A log message is made of a line that matches the pattern and any subsequent lines that don't match the pattern.

If you omit this field, multi-line mode is disabled, and any line that begins with a non-whitespace character closes the previous log message and starts a new log message.

If you include this field, you can specify {timestamp_format} to use the same regular expression as your timestamp format. Otherwise, you can specify a different regular expression for CloudWatch Logs to use to determine the start lines of multi-line entries.

- encoding – Specified the encoding of the log file so that it can be read correctly. If you specify an incorrect coding, there might be data loss because characters that can't be decoded are replaced with other characters.
The default value is utf-8. The following are all possible values:

- The windows_events section specifies the type of Windows events to collect from servers running Windows Server. It includes the following fields:
  - collect_list – Required if windows_events is included. Specifies the types and levels of Windows events to be collected. Each log to be collected has an entry in this section, which can include the following fields:
    - event_name – Specifies the type of Windows events to log. This is equivalent to the Windows event log channel name: for example, System, Security, Application, and so on. This field is required for each type of Windows event to log.
    - event_levels – Specifies the levels of event to log. You must specify each level to log. Possible values include INFORMATION, WARNING, ERROR, CRITICAL, and VERBOSE. This field is required for each type of Windows event to log.
  - log_group_name – Required. Specifies what to use as the log group name in CloudWatch Logs.
  - log_stream_name – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use {instance_id}, {hostname}, {local_hostname}, and {ip_address} as variables within the name. {hostname} retrieves the hostname from the EC2 metadata, and {local_hostname} uses the hostname from the network configuration file.
    If you omit this field, the default value of {instance_id} is used. If a log stream doesn’t already exist, it’s created automatically.
    - event_format – Optional. Specifies the format to use when storing Windows events in CloudWatch Logs. xml uses the XML format as in Windows Event Viewer. text uses the legacy CloudWatch Logs agent format.
  - log_stream_name – Required. Specifies the default log stream name to be used for any logs or Windows events that don’t have individual log stream names defined in their entry in collect_list.
  - endpoint_override – Specifies a FIPS endpoint or private link to use as the endpoint where the agent sends logs. Specifying this field and setting a private link enables you to send the logs to an Amazon VPC endpoint. For more information, see What Is Amazon VPC?
    The value of endpoint_override must be a string that is a URL.
  - force_flush_interval – Specifies in seconds the maximum amount of time that logs remain in the memory buffer before being sent to the server. No matter the setting for this field, if the size of the logs in the buffer reaches 1 MB, the logs are immediately sent to the server. The default value is 5.
  - credentials – Specifies an IAM role to use when sending logs to a different AWS account. If specified, this field contains one parameter, role_arn.
  - role_arn – Specifies the ARN of an IAM role to use for authentication when sending logs to a different AWS account. For more information, see Sending Metrics and Logs to a Different Account (p. 221). If specified here, this overrides the role_arn specified in the agent section of the configuration file, if any.

The following is an example of a logs section.

```
"logs": {
}
```
CloudWatch Agent Configuration File: Complete Examples

The following is an example of a complete CloudWatch agent configuration file for a Linux server.

The items listed in the measurement sections for the metrics you want to collect can either specify the complete metric name such or just the part of the metric name that will be appended to the type of resource. For example, specifying either reads or diskio_reads in the measurement section of the diskio section will cause the diskio_reads metric to be collected.

This example includes both ways of specifying metrics in the measurement section.

```json
{  
  "agent": {  
    "metrics_collection_interval": 10,  
    "logfile": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log"  
  },  
  "metrics": {  
    "metrics_collected": {  
      "cpu": {
```
Manually Create or Edit the CloudWatch Agent Configuration File

```json
"resources": [
  "*"
],
"measurement": [
  {
    "name": "cpu_usage_idle", "rename": "CPU_USAGE_IDLE", "unit": "Percent"},
  {
    "name": "cpu_usage_nice", "unit": "Percent"},
  "cpu_usage_guest"
],
"totalcpu": false,
"metrics_collection_interval": 10,
"append_dimensions": {
  "customized_dimension_key_1": "customized_dimension_value_1",
  "customized_dimension_key_2": "customized_dimension_value_2"
}
},
"disk": {
  "resources": [
    "/",
    "/tmp"
  ],
  "measurement": [
    {
      "name": "free", "rename": "DISK_FREE", "unit": "Gigabytes"},
      "total",
      "used"
    ],
  "ignore_file_system_types": ["sysfs", "devtmpfs"],
  "metrics_collection_interval": 60,
  "append_dimensions": {
    "customized_dimension_key_3": "customized_dimension_value_3",
    "customized_dimension_key_4": "customized_dimension_value_4"
  }
},
"diskio": {
  "resources": [
    "*"
  ],
  "measurement": [
    "reads",
    "writes",
    "read_time",
    "write_time",
    "io_time"
  ],
  "metrics_collection_interval": 60
},
"swap": {
  "measurement": [
    "swap_used",
    "swap_free",
    "swap_used_percent"
  ]
},
"mem": {
  "measurement": [
    "mem_used",
    "mem_cached",
    "mem_total"
  ],
  "metrics_collection_interval": 1
},
"net": {
  "resources": [
    "eth0"
  ]
}
```
The following is an example of a complete CloudWatch agent configuration file for a server running Windows Server.

```json
{
    "agent": {
        "metrics_collection_interval": 60,
```
"logfile": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\Logs\\amazon-cloudwatch-agent.log"
},
"metrics": {
  "metrics_collected": {
    "Processor": {
      "measurement": [
        {"name": "% Idle Time", "rename": "CPU_IDLE", "unit": "Percent"},
        "% Interrupt Time",
        "% User Time",
        "% Processor Time"
      ],
      "resources": [
        "*"
      ],
      "append_dimensions": {
        "customized_dimension_key_1": "customized_dimension_value_1",
        "customized_dimension_key_2": "customized_dimension_value_2"
      }
    },
    "LogicalDisk": {
      "measurement": [
        {"name": "% Idle Time", "unit": "Percent"},
        {"name": "% Disk Read Time", "rename": "DISK_READ"},
        "% Disk Write Time"
      ],
      "resources": [
        "*"
      ]
    },
    "customizedObjectName": {

}
Save the CloudWatch Agent Configuration File Manually

If you create or edit the CloudWatch agent configuration file manually, you can give it any name. For simplicity in troubleshooting, we recommend that you name it `/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json` on a Linux server and `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json` on servers running Windows Server. After you have created the file, you can copy it to other servers where you want to run the agent.

Uploading the CloudWatch Agent Configuration File to Systems Manager Parameter Store

If you plan to use the SSM Agent to install the CloudWatch agent on servers, after you manually edit the CloudWatch agent configuration file, you can upload it to Systems Manager Parameter Store. To do so, use the Systems Manager `put-parameter` command.

To be able to store the file in Parameter Store, you must use an IAM role with sufficient permissions. For more information, see Create IAM Roles and Users for Use with the CloudWatch Agent (p. 153).

Use the following command, where `parameter name` is the name to be used for this file in Parameter Store and `configuration_file_pathname` is the path and file name of the configuration file that you edited.

```
aws ssm put-parameter --name "parameter name" --type "String" --value file://configuration_file_pathname
```

Collect Process Metrics with the procstat Plugin

The `procstat` plugin enables you to collect metrics from individual processes. It is supported on Linux servers and on servers running Windows Server 2008 or later.

Topics
- Configuring the CloudWatch Agent for procstat (p. 198)
- Metrics Collected by Procstat (p. 200)

Configuring the CloudWatch Agent for procstat

To use the procstat plugin, add a `procstat` section in the `metrics_collected` section of the CloudWatch agent configuration file. There are three ways to specify the processes to monitor. You can use only one of these methods, but you can use that method to specify one or more processes to monitor.

- **pid_file**: Selects processes by the names of the process identification number (PID) files they create.
- **exe**: Selects the processes that have process names that match the string that you specify, using regular expression matching rules. For more information, see Syntax.
- **pattern**: Selects processes by the command lines used to start the processes. All processes are selected that have command lines matching the specified string using regular expression matching rules. The entire command line is checked, including parameters and options used with the command.

The CloudWatch agent uses only one of these methods, even if you include more than one of the above sections. If you specify more than one section, the CloudWatch agent uses the `pid_file` section if it is present. If not, it uses the `exe` section.

On Linux servers, the strings that you specify in an `exe` or `pattern` section are evaluated as regular expressions. On servers running Windows Server, these strings are evaluated as WMI queries. For more information, see LIKE Operator.
Whichever method you use, you can include an optional `metrics_collection_interval` parameter, which specifies how often in seconds to collect those metrics. If you omit this parameter, the default value of 60 seconds is used.

In the examples in the following sections, the `procstat` section is the only section included in the `metrics_collected` section of the agent configuration file. Actual configuration files can also include other sections in `metrics_collected`. For more information, see Manually Create or Edit the CloudWatch Agent Configuration File (p. 179).

**Configuring with Pid_file**

The following example `procstat` section monitors the processes that create the PID files `example1.pid` and `example2.pid`. Different metrics are collected from each process. Metrics collected from the process that creates `example2.pid` are collected every 10 seconds, and the metrics collected from the `example1.pid` process are collected every 60 seconds, the default value.

```json
{  "metrics": {  "metrics_collected": {  "procstat": [  {  "pid_file": "/var/run/example1.pid",  "measurement": [  "cpu_usage",  "memory_rss"  ]  },  {  "pid_file": "/var/run/example2.pid",  "measurement": [  "read_bytes",  "read_count",  "write_bytes"  ],  "metrics_collection_interval": 10  ]  }  }  }
```

**Configuring with Exe**

The following example `procstat` section monitors all processes with names that match the strings `agent` or `plugin`. The same metrics are collected from each process.

```json
{  "metrics": {  "metrics_collected": {  "procstat": [  {  "exe": "agent",  "measurement": [  "cpu_time",  "cpu_time_system",  "cpu_time_user"  ]  },  {  "exe": "plugin",  "measurement": [  "cpu_time",  "cpu_time_system",  "cpu_time_user"  ]  }  ]  }  }
```
Configuring with Pattern

The following example `procstat` section monitors all processes with command lines that match the strings `config` or `-c`. The same metrics are collected from each process.

```
{
  "metrics": {
    "metrics_collected": {
      "procstat": [
        {
          "pattern": "config",
          "measurement": [
            "rlimit_memory_data_hard",
            "rlimit_memory_data_soft",
            "rlimit_memory_stack_hard",
            "rlimit_memory_stack_soft"
          ]
        },
        {
          "pattern": "-c",
          "measurement": [
            "rlimit_memory_data_hard",
            "rlimit_memory_data_soft",
            "rlimit_memory_stack_hard",
            "rlimit_memory_stack_soft"
          ]
        }
      ]
    }
  }
}
```

Metrics Collected by Procstat

The following table lists the metrics that you can collect with the `procstat` plugin.

The CloudWatch agent adds `procstat` to the beginning of the following metric names. There is a different syntax depending on whether it was collected from a Linux server or a server running Windows Server. For example, the `cpu_time` metric appears as `procstat_cpu_time` when collected from Linux and as `procstat_cpu_time` when collected from Windows Server.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Available On</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpu_time</td>
<td>Linux</td>
<td>The amount of time that the process uses the CPU. This metric is measured in hundredths of a second. Unit: Count</td>

</tbody>
</table>
## Retrieve Custom Metrics with StatsD

You can retrieve custom metrics from your applications or services using the CloudWatch agent with the StatsD protocol. StatsD is supported on both Linux servers and servers running Windows Server. CloudWatch supports the following StatsD format:

```
MetricName: value|type|@sample_rate|#tag1: value, tag1...
```

- **MetricName**: A string with no colons, bars, # characters, or @ characters.
- **value**: This can be either integer or float.
- **type**: Specify c for counter, g for gauge, ms for timer, h for histogram, or s for set.
- **sample_rate**: (Optional) A float between 0 and 1, inclusive. Use only for counter, histogram, and timer metrics. The default value is 1 (sampling 100% of the time).
- **tags**: (Optional) A comma-separated list of tags. StatsD tags are similar to dimensions in CloudWatch. Use colons for key/value tags, such as env:prod.

You can use any StatsD client that follows this format to send the metrics to the CloudWatch agent. For more information about some of the available StatsD clients, see the StatsD client page on GitHub.

To collect these custom metrics, add a "statsd": {} line to the metrics_collected section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it’s done for you. For more information, see Create the CloudWatch Agent Configuration File (p. 174).
The **StatsD** default configuration works for most users. There are three optional fields that you can add to the **statsd** section of the agent configuration file as needed:

- **service_address** – The service address to which the CloudWatch agent should listen. The format is `ip:port`. If you omit the IP address, the agent listens on all available interfaces. Only the UDP format is supported, so you don’t need to specify a UDP prefix.
  
  The default value is `:8125`.

- **metrics_collection_interval** – How often in seconds that the **StatsD** plugin runs and collects metrics. The default value is 10 seconds. The range is 1–172,000.

- **metrics_aggregation_interval** – How often in seconds CloudWatch aggregates metrics into single data points. The default value is 60 seconds.

  For example, if `metrics_collection_interval` is 10 and `metrics_aggregation_interval` is 60, CloudWatch collects data every 10 seconds. After each minute, the six data readings from that minute are aggregated into a single data point, which is sent to CloudWatch.

  The range is 0–172,000. Setting `metrics_aggregation_interval` to 0 disables the aggregation of **StatsD** metrics.

The following is an example of the **statsd** section of the agent configuration file, using the default port and custom collection and aggregation intervals.

```json
{
    "metrics":{
        "metrics_collected":{
            "statsd":{
                "service_address":":8125",
                "metrics_collection_interval":60,
                "metrics_aggregation_interval":300
            }
        }
    }
}
```

### Retrieve Custom Metrics with collectd

You can retrieve custom metrics from your applications or services using the CloudWatch agent with the collectd protocol, which is supported only on Linux servers. You use the collectd software to send the metrics to the CloudWatch agent. For the collectd metrics, the CloudWatch agent acts as the server while the collectd plug-in acts as the client.

The collectd software is not installed automatically on every server. For more information, see the Download page for collectd.

To collect these custom metrics, add a `"collectd": {}` line to the **metrics_collected** section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it is done for you. For more information, see Create the CloudWatch Agent Configuration File (p. 174).

Optional parameters are also available. If you are using collectd and you do not use `/etc/collectd/auth_file` as your `collectd_auth_file`, you must set some of these options.

- **service_address**: The service address to which the CloudWatch agent should listen. The format is `"udp://ip:port`. The default is `udp://127.0.0.1:25826`.

- **name_prefix**: A prefix to attach to the beginning of the name of each collectd metric. The default is `collectd_`. The maximum length is 255 characters.

- **collectd_security_level**: Sets the security level for network communication. The default is `encrypt`.

---

206
**encrypt** specifies that only encrypted data is accepted. **sign** specifies that only signed and encrypted data is accepted. **none** specifies that all data is accepted. If you specify a value for **collectd_auth_file**, encrypted data is decrypted if possible.

For more information, see Client setup and Possible interactions in the collectd Wiki.

- **collectd_auth_file** Sets a file in which user names are mapped to passwords. These passwords are used to verify signatures and to decrypt encrypted network packets. If given, signed data is verified and encrypted packets are decrypted. Otherwise, signed data is accepted without checking the signature and encrypted data cannot be decrypted.

  The default is `/etc/collectd/auth_file`.

  If **collectd_security_level** is set to **none**, this is optional. If you set **collectd_security_level** to encrypt or **sign**, you must specify **collectd_auth_file**.

  For the format of the auth file, each line is a user name followed by a colon and any number of spaces followed by the password. For example:

  ```
  user1: user1_password
  user2: user2_password
  ```

- **collectd_typesdb**: A list of one or more files that contain the dataset descriptions. The list must be surrounded by brackets, even if there is just one entry in the list. Each entry in the list must be surrounded by double quotes. If there are multiple entries, separate them with commas. The default is `"/usr/share/collectd/types.db"`. For more information, see https://collectd.org/documentation/manpages/types.db.5.shtml.

- **metrics_aggregation_interval**: How often in seconds CloudWatch aggregates metrics into single data points. The default is 60 seconds. The range is 0 to 172,000. Setting it to 0 disables the aggregation of collectd metrics.

The following is an example of the collectd section of the agent configuration file.

```json
{
  "metrics":{
    "metrics_collected":{
      "collectd":{
        "name_prefix":"My_collectd_metrics_",
        "metrics_aggregation_interval":120
      }
    }
  }
}
```

---

### Metrics Collected by the CloudWatch Agent

You can collect metrics from servers by installing the CloudWatch agent on the server. You can install the agent on both Amazon EC2 instances and on-premises servers, and on servers running either Linux or Windows Server. If you install the agent on an Amazon EC2 instance, the metrics it collects are in addition to the metrics enabled by default on Amazon EC2 instances.

For information about installing the CloudWatch agent on an instance, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent (p. 141).
Metrics Collected by the CloudWatch Agent on Windows Server Instances

On a server running Windows Server, installing the CloudWatch agent enables you to collect the metrics associated with the counters in Windows Performance Monitor. The CloudWatch metric names for these counters are created by putting a space between the object name and the counter name. For example, the % Interrupt Time counter of the Processor object is given the metric name Processor % Interrupt Time in CloudWatch. For more information about Windows Performance Monitor counters, see the Microsoft Windows Server documentation.

The default namespace for metrics collected by the CloudWatch agent is CWAgent, although you can specify a different namespace when you configure the agent.

Metrics Collected by the CloudWatch Agent on Linux Instances

The following table lists metrics that you can collect with the CloudWatch agent on Linux instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpu_time_active</td>
<td>The amount of time that the CPU is active in any capacity. This metric is measured in hundredths of a second. Unit: None</td>
</tr>
<tr>
<td>cpu_time_guest</td>
<td>The amount of time that the CPU is running a virtual CPU for a guest operating system. This metric is measured in hundredths of a second. Unit: None</td>
</tr>
<tr>
<td>cpu_time_guest_nice</td>
<td>The amount of time that the CPU is running a virtual CPU for a guest operating system, which is low-priority and can be interrupted by other processes. This metric is measured in hundredths of a second. Unit: None</td>
</tr>
<tr>
<td>cpu_time_idle</td>
<td>The amount of time that the CPU is idle. This metric is measured in hundredths of a second. Unit: None</td>
</tr>
<tr>
<td>cpu_time_iowait</td>

Common Scenarios with the CloudWatch Agent

The following sections outline how to complete some common configuration and customization tasks when using the CloudWatch agent.

Topics

- Running the CloudWatch Agent as a Different User (p. 216)
- Adding Custom Dimensions to Metrics Collected by the CloudWatch Agent (p. 217)
- Multiple CloudWatch Agent Configuration Files (p. 218)
- Aggregating or Rolling Up Metrics Collected by the CloudWatch Agent (p. 220)
- Collecting High-Resolution Metrics With the CloudWatch agent (p. 220)
- Sending Metrics and Logs to a Different Account (p. 221)
- Timestamp Differences Between the Unified CloudWatch Agent and the Older CloudWatch Logs Agent (p. 223)

Running the CloudWatch Agent as a Different User

On Linux servers, the CloudWatch runs as the root user by default. To have the agent run as a different user, use the `run_as_user` parameter in the `agent` section in the CloudWatch agent configuration file. This option is available only on Linux servers.

If you're already running the agent with the root user and want to change to using a different user, use one of the following procedures.

**To run the CloudWatch agent as a different user on an EC2 instance running Linux**

1. Download and install a new CloudWatch agent package. For more information, see Download the CloudWatch Agent Package Using an S3 Download Link (p. 143).
2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.
3. Provide credentials for this user in one of these ways:
   - If the file `/home/root/.aws/credentials` exists, you must create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be `/home/username/.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see (Optional) Modify the Common Configuration for Proxy or Region Information (p. 151).
   - If the file `/home/root/.aws/credentials` does not exist, you can do one of the following:
     - Create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be `/home/username/.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see (Optional) Modify the Common Configuration for Proxy or Region Information (p. 151).
• Instead of creating a credentials file, attach an IAM role to the instance. The agent uses this role as the credential provider.

4. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch Agent Configuration File (p. 174)

5. Give the user necessary permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.

6. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -c file:configuration-file-path -s
```

To run the CloudWatch agent as a different user on an on-premises server running Linux

1. Download and install a new CloudWatch agent package. For more information, see Download the CloudWatch Agent Package Using an S3 Download Link (p. 143).

2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.

3. Store the credentials of this user to a path that the user can access, such as `/home/username/.aws/credentials`.

4. Set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see (Optional) Modify the Common Configuration for Proxy or Region Information (p. 151).

5. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch Agent Configuration File (p. 174)

6. Give the user necessary permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.

7. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -c file:configuration-file-path -s
```

Adding Custom Dimensions to Metrics Collected by the CloudWatch Agent

To add custom dimensions such as tags to metrics collected by the agent, add the `append_dimensions` field to the section of the agent configuration file that lists those metrics.

For example, the following example section of the configuration file adds a custom dimension named `stackName` with a value of `Prod` to the `cpu` and `disk` metrics collected by the agent.

```
"cpu":{
    "resources":[
```
Multiple CloudWatch Agent Configuration Files

You can set up the CloudWatch agent to use multiple configuration files. For example, you can use a common configuration file that collects a set of metrics and logs that you always want to collect from all servers in your infrastructure. You can then use additional configuration files that collect metrics from certain applications or in certain situations.

To set this up, first create the configuration files that you want to use. Any configuration files that will be used together on the same server must have different file names. You can store the configuration files on servers or in Parameter Store.

Start the CloudWatch agent using the `fetch-config` option and specify the first configuration file. To append the second configuration file to the running agent, use the same command but with the `append-config` option. All metrics and logs listed in either configuration file are collected. The following example Linux commands illustrate this scenario using configurations stores as files. The first line starts the agent using the `infrastructure.json` configuration file, and the second line appends the `app.json` configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -c file:/tmp/infrastructure.json -s
```

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -m ec2 -c file:/tmp/app.json -s
```

The following example configuration files illustrate a use for this feature. The first configuration file is used for all servers in the infrastructure, and the second collects only logs from a certain application and is appended to servers running that application.

**infrastructure.json**

```json
{
  "*":
  "measurement": [
    "cpu_usage_guest",
    "cpu_usage_nice",
    "cpu_usage_idle"
  ],
  "totalcpu": false,
  "append_dimensions": {
    "stackName": "Prod"
  }
},
"disk": {
  "resources": [
    "/",
    "/tmp"
  ],
  "measurement": [
    "total",
    "used"
  ],
  "append_dimensions": {
    "stackName": "Prod"
  }
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

**Multiple CloudWatch Agent Configuration Files**

You can set up the CloudWatch agent to use multiple configuration files. For example, you can use a common configuration file that collects a set of metrics and logs that you always want to collect from all servers in your infrastructure. You can then use additional configuration files that collect metrics from certain applications or in certain situations.

To set this up, first create the configuration files that you want to use. Any configuration files that will be used together on the same server must have different file names. You can store the configuration files on servers or in Parameter Store.

Start the CloudWatch agent using the `fetch-config` option and specify the first configuration file. To append the second configuration file to the running agent, use the same command but with the `append-config` option. All metrics and logs listed in either configuration file are collected. The following example Linux commands illustrate this scenario using configurations stores as files. The first line starts the agent using the `infrastructure.json` configuration file, and the second line appends the `app.json` configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -c file:/tmp/infrastructure.json -s
```

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -m ec2 -c file:/tmp/app.json -s
```

The following example configuration files illustrate a use for this feature. The first configuration file is used for all servers in the infrastructure, and the second collects only logs from a certain application and is appended to servers running that application.

**infrastructure.json**

```json
{
```
"metrics": {
  "metrics_collected": {
    "cpu": {
      "resources": ["*"]
    },
    "measurement": ["usage_active"],
    "totalcpu": true
  },
  "mem": {
    "measurement": ["used_percent"]
  }
},

"logs": {
  "logs_collected": {
    "files": {
      "collect_list": [
        {
          "log_group_name": "amazon-cloudwatch-agent.log"
        },
        {
          "file_path": "/var/log/messages",
          "log_group_name": "/var/log/messages"
        }
      ]
    }
  }
}

app.json

{
  "logs": {
    "logs_collected": {
      "files": {
        "collect_list": [
          {
            "file_path": "/app/app.log*",
            "log_group_name": "/app/app.log"
          }
        ]
      }
    }
  }
}

Any configuration files appended to the configuration must have different file names from each other and from the initial configuration file. If you use append-config with a configuration file with the same file name as a configuration file that the agent is already using, the append command overwrites the information from the first configuration file instead of appending to it. This is true even if the two configuration files with the same file name are on different file paths.

The preceding example shows the use of two configuration files, but there is no limit to the number of configuration files that you can append to the agent configuration. You can also mix the use of configuration files located on servers and configurations located in Parameter Store.
Aggregating or Rolling Up Metrics Collected by the CloudWatch Agent

To aggregate or roll up metrics collected by the agent, add an aggregation_dimensions field to the section for that metric in the agent configuration file.

For example, the following configuration file snippet rolls up metrics on the AutoScalingGroupName dimension. The metrics from all instances in each Auto Scaling group are aggregated and can be viewed as a whole.

```
"metrics": {
    "cpu":{},
    "disk":{},
    "aggregation_dimensions": ["AutoScalingGroupName"]
}
```

To roll up along the combination of each InstanceId and InstanceType dimensions in addition to rolling up on the Auto Scaling group name, add the following.

```
"metrics": {
    "cpu":{},
    "disk":{},
    "aggregation_dimensions": ["AutoScalingGroupName", ["InstanceId", "InstanceType"]]
}
```

To roll up metrics into one collection instead, use [].

```
"metrics": {
    "cpu":{},
    "disk":{},
    "aggregation_dimensions": [[]]
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Collecting High-Resolution Metrics With the CloudWatch agent

The metrics_collection_interval field specifies the time interval for the metrics collected, in seconds. By specifying a value of less than 60 for this field, the metrics are collected as high-resolution metrics.

For example, if your metrics should all be high-resolution and collected every 10 seconds, specify 10 as the value for metrics_collection_interval under the agent section as a global metrics collection interval.

```
"agent": {
    "metrics_collection_interval": 10
}
```

Alternatively, the following example sets the cpu metrics to be collected every second, and all other metrics are collected every minute.
Sending Metrics and Logs to a Different Account

To have the CloudWatch agent send the metrics, logs, or both to a different account, specify a `role_arn` parameter in the agent configuration file on the sending server. The `role_arn` value specifies an IAM role in the target account that the agent uses when sending data to the target account. This role enables the sending account to assume a corresponding role in the target account when delivering the metrics or logs to the target account.

You can also specify two separate `role_arn` strings in the agent configuration file: one to use when sending metrics and another for sending logs.

The following example of part of the `agent` section of the configuration file sets the agent to use `CrossAccountAgentRole` when sending metrics and logs to a different account.

```
{
    "agent": {
        "credentials": {
            "role_arn": "CrossAccountAgentRole"
        }
    }
}
```

Alternatively, the following example sets different roles for the sending account to use for sending metrics and logs:

```
"metrics": {
```
"credentials": {
   "role_arn": "RoleToSendMetrics"
 },
"metrics_collected": {...

"logs": {
   "credentials": {
      "role_arn": "RoleToSendLogs"
   }
   ...

Policies Needed

When you specify a role_arn in the agent configuration file, you must also make sure the IAM roles of the sending and target accounts have certain policies. The roles in both the sending and target accounts should have CloudWatchAgentServerPolicy. For more information about assigning this policy to a role, see Create IAM Roles to Use with the CloudWatch Agent on Amazon EC2 Instances (p. 154).

The role in the sending account also must include the following policy. You add this policy on the Permissions tab in the IAM console when you edit the role.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["sts:AssumeRole"],
      }
   ]
}
```

The role in the target account must include the following policy so that it recognizes the IAM role used by the sending account. You add this policy on the Trust relationships tab in the IAM console when you edit the role. The role in the target account where you add this policy is the role you created in Create IAM Roles and Users for Use With CloudWatch Agent (p. 146). This role is the role specified in agent-role-in-target-account in the policy used by the sending account.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "AWS": ["arn:aws:iam::sending-account-ID:role/role-specified-in-role_arn"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```
Timestamp Differences Between the Unified CloudWatch Agent and the Older CloudWatch Logs Agent

The CloudWatch agent supports a different set of symbols for timestamp formats, compared to the older CloudWatch Logs agent. These differences are shown in the following table.

<table>
<thead>
<tr>
<th>Symbols Supported by Both Agents</th>
<th>Symbols Supported Only by Unified CloudWatch Agent</th>
<th>Symbols Supported Only by Older CloudWatch Logs Agent</th>
</tr>
</thead>
<tbody>
<tr>
<td>%A, %a, %b, %B, %d, %H, %l, %m, %M, %p, %S, %y, %Y, %Z, %z</td>
<td>%d, %l, %M, %S</td>
<td>%c, %f, %j, %U, %W, %w</td>
</tr>
</tbody>
</table>

For more information about the meanings of the symbols supported by the new CloudWatch agent, see CloudWatch Agent Configuration File: Logs Section in the Amazon CloudWatch User Guide. For information about symbols supported by the CloudWatch Logs agent, see Agent Configuration File in the Amazon CloudWatch Logs User Guide.

Troubleshooting the CloudWatch Agent

Use the following information to help troubleshoot problems with the CloudWatch agent.

Topics
- CloudWatch Agent Command Line Parameters (p. 223)
- Installing the CloudWatch Agent Using Run Command Fails (p. 224)
- The CloudWatch Agent Won't Start (p. 224)
- Verify That the CloudWatch Agent Is Running (p. 224)
- Where Are the Metrics? (p. 225)
- The CloudWatch Agent Won't Start, and the Error Mentions an Amazon EC2 Region (p. 225)
- Unable to Find Credentials on Windows Server (p. 225)
- CloudWatch Agent Files and Locations (p. 225)
- Logs Generated by the CloudWatch Agent (p. 226)
- Stopping and Restarting the CloudWatch Agent (p. 227)

CloudWatch Agent Command Line Parameters

To see the full list of parameters supported by the CloudWatch agent, enter the following at the command line at a computer where you have it installed:

```
amazon-cloudwatch-agent-ctl -help
```
Installing the CloudWatch Agent Using Run Command Fails

To install the CloudWatch agent using Systems Manager Run Command, the SSM Agent on the target server must be version 2.2.93.0 or later. If your SSM Agent isn't the correct version, you might see errors that include the following messages:

no latest version found for package AmazonCloudWatchAgent on platform linux

failed to download installation package reliably

For information about updating your SSM Agent version, see Installing and Configuring SSM Agent in the AWS Systems Manager User Guide.

The CloudWatch Agent Won't Start

If the CloudWatch agent fails to start, there might be an issue in your configuration. Configuration information is logged in the configuration-validation.log file. This file is located in /opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log on Linux servers and in %Env:ProgramData%\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log on servers running Windows Server.

Verify That the CloudWatch Agent Is Running

You can query the CloudWatch agent to find whether it's running or stopped. You can use AWS Systems Manager to do this remotely. You can also use the command line, but only to check the local server.

To query the status of the CloudWatch agent using Run Command

2. In the navigation pane, choose Run Command.
   -or-
   If the AWS Systems Manager home page opens, scroll down and choose Explore Run Command.
3. Choose Run command.
4. In the Command document list, choose AmazonCloudWatch-ManageAgent.
5. In the Target area, choose the instance to check.
6. In the Action list, choose status.
7. Keep Optional Configuration Source and Optional Configuration Location blank.

If the agent is running, the output resembles the following.

```json
{   "status": "running",   "starttime": "2017-12-12T18:41:18",   "version": "1.73.4"
}
```
If the agent is stopped, the "status" field displays "stopped".

To query the status of the CloudWatch agent locally using the command line

- On a Linux server, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a status
```

- On a server running Windows Server, enter the following in PowerShell as an administrator:

```
& $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m ec2 -a status
```

Where Are the Metrics?

If the CloudWatch agent has been running but you can't find metrics collected by it in the AWS Management Console or the AWS CLI, confirm that you're using the correct namespace. By default, the namespace for metrics collected by the agent is CWAgent. You can customize this namespace using the namespace field in the metrics section of the agent configuration file. If you don't see the metrics that you expect, check the configuration file to confirm the namespace being used.

When you first download the CloudWatch agent package, the agent configuration file is `amazon-cloudwatch-agent.json`. This file is in the directory where you ran the configuration wizard, or you might have moved it to a different directory. If you use the configuration wizard, the agent configuration file output from the wizard is named config.json. For more information about the configuration file, including the namespace field, see CloudWatch Agent Configuration File: Metrics Section (p. 181).

The CloudWatch Agent Won't Start, and the Error Mentions an Amazon EC2 Region

If the agent doesn't start and the error message mentions an Amazon EC2 Region endpoint, you might have configured the agent to need access to the Amazon EC2 endpoint without granting that access.

For example, if you specify a value for the append_dimensions parameter in the agent configuration file that depends on Amazon EC2 metadata and you use proxies, you must make sure that the server can access the endpoint for Amazon EC2. For more information about these endpoints, see Amazon Elastic Compute Cloud (Amazon EC2) in the Amazon Web Services General Reference.

Unable to Find Credentials on Windows Server

On Windows Server, if you have credentials in a location other than `$SystemDrive\Users\Administrator\.aws` on Windows Server 2008 or Windows Server 2012, or `$SystemDrive\Documents and Settings\Administrator\.aws` on Windows Server 2003, you can specify your own credential path by using the shared_credential_file option in common.toml.

If you don't have a credential file, you must create one. For more information, see (Optional) Modify the Common Configuration for Proxy or Region Information (p. 151).

CloudWatch Agent Files and Locations

The following table lists the files installed by and used with the CloudWatch agent, along with their locations on servers running Linux or Windows Server.
### Logs Generated by the CloudWatch Agent

The agent generates a log while it runs. This log includes troubleshooting information. This log is the `amazon-cloudwatch-agent.log` file. This file is located in `/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log` on Linux servers and in `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\amazon-cloudwatch-agent.log` on servers running Windows Server.

<table>
<thead>
<tr>
<th>File</th>
<th>Linux Location</th>
<th>Windows Server Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>The control script that controls starting, stopping, and</td>
<td>/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl or /usr/bin/amazon-cloudwatch-agent-ctl</td>
<td><code>$Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1</code></td>
</tr>
<tr>
<td>restarting the agent.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>The log file the agent writes to. You might need to attach this</td>
<td>/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log or /var/log/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.log</td>
<td><code>$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\amazon-cloudwatch-agent.log</code></td>
</tr>
<tr>
<td>when contacting AWS Support.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Agent configuration validation file.</td>
<td>/opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log or /var/log/amazon/amazon-cloudwatch-agent/configuration-validation.log</td>
<td><code>$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log</code></td>
</tr>
<tr>
<td>The JSON file used to configure the agent immediately after the</td>
<td>/opt/aws/amazon-cloudwatch-agent/bin/config.json</td>
<td><code>$Env:ProgramData\Amazon\AmazonCloudWatchAgent\config.json</code></td>
</tr>
<tr>
<td>wizard creates it.</td>
<td></td>

</tr>
<tr>
<td>For more information, see Create the CloudWatch Agent Configuration File (p. 174).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>The JSON file used to configure the agent if this configuration</td>
<td>/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json or /etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.json</td>
<td><code>$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json</code></td>
</tr>
<tr>
<td>file has been downloaded from Parameter Store.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TOML file used to specify Region and credential information to be</td>
<td>/opt/aws/amazon-cloudwatch-agent/etc/common-config.toml or /etc/amazon/amazon-cloudwatch-agent/common-config.toml</td>
<td><code>$Env:ProgramData\Amazon\AmazonCloudWatchAgent\common-config.toml</code></td>
</tr>
<tr>
<td>used by the agent, overriding system defaults.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
You can configure the agent to log additional details in the `amazon-cloudwatch-agent.log` file. In the agent configuration file, in the `agent` section, set the `debug` field to `true`, then reconfigure and restart the CloudWatch agent. To disable the logging of this extra information, set the `debug` field to `false` reconfigure and restart the agent. For more information, see Manually Create or Edit the CloudWatch Agent Configuration File (p. 179).

**Stopping and Restarting the CloudWatch Agent**

You can manually stop the CloudWatch agent using either AWS Systems Manager or the command line. When you stop it manually, you also prevent it from automatically starting at the system reboot.

**To stop the CloudWatch agent using Run Command**

2. In the navigation pane, choose Run Command.
   - or -
   If the AWS Systems Manager home page opens, scroll down and choose Explore Run Command.
3. Choose Run command.
4. In the Command document list, choose AmazonCloudWatch-ManageAgent.
5. In the Targets area, choose the instance where you installed the CloudWatch agent.
6. In the Action list, choose stop.
7. Keep Optional Configuration Source and Optional Configuration Location blank.

**To stop the CloudWatch agent locally using the command line**

- On a Linux server, enter the following:

  ```
  sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a stop
  ```

  On a server running Windows Server, enter the following in PowerShell as an administrator:

  ```
  & %Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m ec2 -a stop
  ```

To restart the agent, follow the instructions in Start the CloudWatch Agent (p. 160).
Amazon CloudWatch Application Insights for .NET and SQL Server

Amazon CloudWatch Application Insights facilitates observability for .NET and SQL Server applications. It can help you set up the best monitors for your application resources to continuously analyze data for signs of problems with your applications. Application Insights, which is powered by SageMaker and other AWS technologies, provides automated dashboards that show potential problems with monitored applications, helping you to quickly isolate ongoing issues with your applications and infrastructure. The enhanced visibility into the health of your applications that Application Insights provides can help you reduce your mean time to repair (MTTR) so that you don't have to pull in multiple teams and experts to troubleshoot your application issues.

When you add your applications to Amazon CloudWatch Application Insights for .NET and SQL Server, it scans the resources in the applications and recommends and configures metrics and logs on CloudWatch for application components. Application components may include SQL Server backend databases and Microsoft IIS/Web tiers. Application Insights analyzes metric patterns using historical data to detect anomalies, and continuously detects errors and exceptions from your application logs, including .NET, SQL Server error log, and IIS. It correlates these observations using a combination of classification algorithms and built-in rules. Then it automatically creates dashboards that show the relevant observations and problem severity information to help you prioritize your actions. For common problems in .NET and SQL application stacks, such as application latency, SQL Server failed backups, memory leaks, large HTTP requests, and aborted I/O operations, it provides additional insights that point to a possible root cause and steps for resolution. Built-in integration with AWS Systems Manager OpsCenter allows you to resolve issues by running the relevant Systems Manager Automation document.

Topics
- What Is Amazon CloudWatch Application Insights for .NET and SQL Server? (p. 228)
- Getting Started with Amazon CloudWatch Application Insights for .NET and SQL Server (p. 231)
- View and Troubleshoot Problems Detected by Amazon CloudWatch Application Insights for .NET and SQL Server (p. 242)
- How Amazon CloudWatch Application Insights for .NET and SQL Server Works (p. 245)
- Logs and Metrics Supported by Amazon CloudWatch Application Insights for .NET and SQL Server (p. 251)

What Is Amazon CloudWatch Application Insights for .NET and SQL Server?

CloudWatch Application Insights for .NET and SQL Server helps you monitor your .NET and SQL Server applications. It identifies and sets up key metrics and logs across your application resources and technology stack (for example, your database, web (IIS) and application servers, OS, load balancers, and queues). It continuously monitors the metrics and logs to detect and correlate anomalies and errors. When errors and anomalies are detected, Application Insights generates CloudWatch Events. To aid with troubleshooting, it creates automated dashboards for the detected problems, which include correlated metric anomalies and log errors, along with additional insights to point you to the potential root cause. The automated dashboards help you to take swift remedial actions to keep your applications healthy and to prevent impact to the end users of your application. It also creates OpsItems so you can resolve problems using Systems Manager OpsCenter.
Automatic Set Up of Monitors for Application Resources

CloudWatch Application Insights for .NET and SQL Server reduces the time it takes to set up monitoring for your applications. It does this by scanning your application resources, providing a customizable list of recommended metrics and logs, and setting them up on CloudWatch to provide necessary visibility into your application resources, such as Amazon EC2 and Elastic Load Balancers (ELB). It also sets up dynamic alarms on monitored metrics. The alarms are automatically updated based on anomalies detected in the previous two weeks.

Problem Detection and Notification

CloudWatch Application Insights for .NET and SQL Server detects signs of potential problems with your application, such as metric anomalies and log errors. It correlates these observations to surface potential problems with your application. It then generates CloudWatch Events, which can be configured to receive notifications or take actions (p. 244). This eliminates the need for you to create individual alarms on metrics or log errors.

Faster Troubleshooting

CloudWatch Application Insights for .NET and SQL Server creates CloudWatch automatic dashboards for problems that are detected. The dashboards show details about the problem, including the associated metric anomalies and log errors to help you with troubleshooting. They also provide additional insights that point to potential root causes of the anomalies and errors.

Contents

- Concepts (p. 229)
- Pricing (p. 229)
- Related AWS Services (p. 230)
- Supported Application Components (p. 230)
- Supported Technology Stack (p. 231)

Concepts

The following concepts are important for understanding how Application Insights monitors your application.

Component

An auto-grouped, standalone, or custom grouping of similar resources that make up an application. We recommend grouping similar resources into custom components for better monitoring.

Observation

An individual event (metric anomaly, log error, or exception) that is detected with an application or application resource.

Problem

Problems are detected by correlating, classifying, and grouping related observations.

For definitions of other key concepts for CloudWatch Application Insights for .NET and SQL Server, see Amazon CloudWatch Concepts.

Pricing

CloudWatch Application Insights for .NET and SQL Server sets up recommended metrics and logs for selected application resources using CloudWatch Metrics, Logs, and CloudWatch Events for notifications.
on detected problems. These features are charged to your AWS account according to CloudWatch pricing. For the detected problems, it creates CloudWatch Events and automatic dashboards. You are not charged for setup assistance, monitoring data analysis, or problem detection.

Related AWS Services

The following services are used along with CloudWatch Application Insights for .NET and SQL Server:

- **Amazon CloudWatch** provides system-wide visibility into resource utilization, application performance, and operational health. It collects and tracks metrics, sends alarm notifications, automatically updates resources that you are monitoring based on the rules that you define, and allows you to monitor your own custom metrics. CloudWatch Application Insights for .NET and SQL Server is initiated through CloudWatch—specifically, within the CloudWatch default operational dashboards. For more information, see the Amazon CloudWatch User Guide.

- **AWS Resource Groups** help you to organize the resources that make up your application. With Resource Groups, you can manage and automate tasks on a large number of resources at one time. Only one Resource Group can be registered for a single application. For more information, see the AWS Resource Groups User Guide.

- **IAM** is a web service that helps you to securely control access to AWS resources for your users. Use IAM to control who can use your AWS resources (authentication), and to control the resources they can use and how they can use them (authorization). For more information, see Authentication and Access Control for Amazon CloudWatch.

- **Amazon EC2** provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, to configure security and networking, and to manage storage. You can scale up or down to handle changes in requirements or spikes in popularity, which reduces your need to forecast traffic. For more information, see the Amazon EC2 User Guide for Linux Instances or Amazon EC2 Guide for Windows Instances.

- **Elastic Load Balancing** distributes incoming applications or network traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in multiple Availability Zones. For more information, see the Elastic Load Balancing User Guide.

- **Amazon EC2 Auto Scaling** helps ensure that you have the correct number of EC2 instances available to handle the load for your application. For more information, see the Amazon EC2 Auto Scaling User Guide.

- **Amazon SQS** offers a secure, durable, and available hosted queue that allows you to integrate and decouple distributed software systems and components. For more information, see the Amazon SQS User Guide.

- **AWS Systems Manager OpsCenter** aggregates and standardizes OpsItems across services while providing contextual investigation data about each OpsItem, related OpsItems, and related resources. OpsCenter also provides Systems Manager Automation documents (runbooks) that you can use to quickly resolve issues. You can specify searchable, custom data for each OpsItem. You can also view automatically-generated summary reports about OpsItems by status and source. For more information, see the AWS Systems Manager User Guide.

Supported Application Components

CloudWatch Application Insights for .NET and SQL Server scans your Resource Group—in this case, a group of resources used by a .NET application—to identify application components. Components can be standalone, auto-grouped (such as instances in an Auto Scaling group or behind a load balancer), or custom (by grouping together individual EC2 instances). The following components are supported by CloudWatch Application Insights for .NET and SQL Server:

- Amazon EC2
- Amazon RDS
• Elastic Load Balancing: Application Load Balancer and Classic Load Balancer (all target instances of these load balancers are identified and configured).
• Amazon EC2 Auto Scaling groups: AWS Auto Scaling (Auto Scaling groups are dynamically configured for all target instances; if your application scales up, CloudWatch Application Insights for .NET and SQL Server automatically configure the new instances). Auto Scaling groups are not supported for CloudFormation-based Resource Groups.
• Amazon Simple Queue Service (Amazon SQS)

Any other component type resources are ignored by CloudWatch Application Insights for .NET and SQL Server. If a component type that is supported does not appear in your Application Insights application, the component may already be registered and managed by another application you own that is monitored by Application Insights.

## Supported Technology Stack

CloudWatch Application Insights for .NET and SQL Server supports:

• Front-end: Microsoft Internet Information Services (IIS) Web Server
• Worker-tier: .NET Framework
• Database: Microsoft SQL Server running on RDS or EC2

## Getting Started with Amazon CloudWatch Application Insights for .NET and SQL Server

To get started on CloudWatch Application Insights for .NET and SQL Server, verify that you have met the prerequisites outlined below and have created an IAM policy. Then, you can get started using the console link to enable CloudWatch Application Insights for .NET and SQL Server. To configure your application resources, follow the steps under Setting Up Your Application (p. 233).

### Contents

- Accessing CloudWatch Application Insights for .NET and SQL Server (p. 231)
- Prerequisites (p. 232)
- IAM Policy (p. 232)
- Setting Up Your Application (p. 233)

## Accessing CloudWatch Application Insights for .NET and SQL Server

If you have access to CloudWatch Application Insights for .NET and SQL Server, you can manage it through one of the following interfaces:

• **CloudWatch console**: To add monitors for your application, choose **Settings** in the left navigation pane of the CloudWatch console. From the **Settings** page, choose **Application Insights for .NET and SQL Server**. After your application is configured, you can use the CloudWatch console to view and analyze problems that are detected.

• **AWS Command Line Interface (AWS CLI)**: You can use the AWS CLI to access AWS API operations. For more information, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide. For the API reference, see the Amazon CloudWatch Application Insights for .NET and SQL Server API Reference.
Prerequisites

You must complete the following prerequisites to configure an application with CloudWatch Application Insights:

- **AWS Systems Manager enablement:** You must install Systems Manager Agent (SSM Agent), and your instances must be SSM enabled. For steps on how to install the SSM Agent, see Setting Up AWS Systems Manager.

- **EC2 Instance Role:** You must attach the AmazonEC2RoleForSSM to enable Systems Manager (see Using Identity-based Policies (IAM Policies) for AWS Systems Manager) and the CloudWatchAgentServerPolicy to enable instance metrics and logs to be emitted through CloudWatch. See Create IAM Roles and Users for Use With CloudWatch Agent for more information.

- **AWS Resource Group:** To onboard your .NET and SQL Server applications to CloudWatch Application Insights for .NET and SQL Server, you must create a Resource Group that includes all associated AWS resources used by your application stack. This includes application load balancers, EC2 instances running IIS and web front-end, .NET worker tiers, and your SQL Server database. CloudWatch Application Insights for .NET and SQL Server automatically includes Auto Scaling groups using the same tags or CloudFormation stacks as your Resource Group, because Auto Scaling groups are not currently supported by Resource Groups. For more information, see Getting Started with AWS Resource Groups.

- **IAM permissions:** For non-Admin users, you must create an AWS Identity and Access Management (IAM) Policy and attach it to your user identity. See IAM Policy (p. 232).

- **Service-linked role:** CloudWatch Application Insights for .NET and SQL Server uses AWS Identity and Access Management (IAM) service-linked roles. You don’t need to manually create a service-linked role. Instead, it is created for you when you create your first CloudWatch Application Insights for .NET and SQL Server application in the AWS Management Console. For more information, see Using Service-Linked Roles for CloudWatch Application Insights for .NET and SQL Server (p. 296).

IAM Policy

To use CloudWatch Application Insights for .NET and SQL Server, you must create an Identity and Access Management (IAM) policy and attach it to your IAM user identity. The IAM policy defines the user permissions.

**To create an IAM policy using the console**

To create an IAM policy using the IAM console, follow these steps.

1. Go to the IAM console. In the left navigation pane, select Policies.
2. At the top of the page, select Create policy.
3. Select the JSON tab.
4. Copy and paste the following JSON document under the JSON tab.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "applicationinsights:*",
                "iam:CreateServiceLinkedRole",
                "iam:ListRoles"
            ],
            "Effect": "Allow",
            "Resource": "***"
        }
    ]
}
```
5. Select **Review Policy**.
6. Enter a **Name** for the policy, for example, “AppInsightsPolicy.” Optionally, enter a **Description**.
7. Select **Create Policy**.
8. Select **Users** from the left navigation pane.
9. Select the **User name** of the user to which you would like to attach the policy.
10. Select **Add permissions**.
11. Select **Attach existing policies directly**.
12. Search for the policy that you just created, and select the check box to the left of the policy name.
13. Select **Next: Review**.
14. Make sure that the correct policy is listed, and select **Add permissions**.
15. Make sure that you log in with the user associated with the policy that you just created when you use CloudWatch Application Insights for .NET and SQL Server.

**To create an IAM policy using the AWS CLI**

To create an IAM policy using the AWS CLI, run the `create-policy` operation from the command line using the JSON document above as a file in your current folder.

**To create an IAM policy using AWS Tools for Windows PowerShell**

To create an IAM policy using the AWS Tools for Windows PowerShell, run the `New-IAMPolicy` cmdlet using the JSON document above as a file in your current folder.

### Setting Up Your Application

This section provides steps for setting up, configuring, and managing your Application Insights for .NET and SQL Server application using the console, the AWS CLI, and AWS Tools for Windows PowerShell.

**Topics**

- Add and Configure an Application with the CloudWatch Console (p. 233)
- Disable an Application with the Console (p. 235)
- Disable Monitoring for an Application Component with the Console (p. 235)
- Delete an Application with the Console (p. 235)
- Add and Manage an Application with Application Insights Using the Command Line (p. 235)
- Manage and Update Monitoring Using the Command Line (p. 239)

### Add and Configure an Application with the CloudWatch Console

**Add and configure an application from the CloudWatch console**

To get started with CloudWatch Application Insights for .NET and SQL Server from the CloudWatch console, follow these steps.

1. **Start.** Open the CloudWatch console landing page. From the left navigation pane, choose **Settings**. From the **Settings** page, choose **Application Insights for .NET and SQL Server > View applications to get started**.

2. **Add an Application.** To set up monitoring for your .NET and SQL Server application, on the Application Insights for .NET and SQL Server page, select **Add an application**. This page shows the
list of applications that are monitored with Application Insights for .NET and SQL Server, along with their monitoring status. After you select **Add an application**, you will be taken to the **Add an application** page.

3. **Select Resource Group.** On the **Add an application** page, to add an application to CloudWatch Application Insights for .NET and SQL Server, choose an AWS Resource Group from the dropdown list that contains your application resources. These resources include front-end servers, load balancers, auto scaling groups, and database servers.

CloudWatch Application Insights for .NET and SQL Server supports both tag-based and CloudFormation-based Resource Groups (with the exception of Auto Scaling groups). For more information, see [Working with Tag Editor](#).

If you have not created a Resource Group for your .NET application, you can create one. For more information, see the [AWS Resource Groups User Guide](#).

4. **Add Monitoring Details.** After you add an application, you are taken to the **Monitoring Details** page, which lists the application components, resources in those components, and their monitoring status. Components are auto-grouped, standalone, or custom groupings of similar resources that make up an application. By default, CloudWatch Application Insights for .NET and SQL Server groups instances that are in Auto Scaling groups, and instances that are behind your Elastic Load Balancers. On this page, you can configure custom components and can manage monitoring for each application component. For supported components, see [Supported Application Components (p. 230)](#).

5. **Configure components.** After selecting a Resource Group, you are prompted to configure components. We recommend grouping similar resources, such as .NET web server instances, into custom components for easier onboarding and better monitoring and insights. By default, CloudWatch Application Insights for .NET and SQL Server groups instances that are in Auto Scaling groups, and instances that are behind your Elastic Load Balancers. For supported components, see [Supported Application Components (p. 230)](#).

Under **Application components**, for each component for which you want to set up monitors, select the component and select **Manage Monitoring**.

6. **Enable Monitors.** To set up monitoring for an application component, select the components that you want to monitor and then choose **Manage Monitoring**. Select the **Enable Monitoring** check box. When you select the check box, the dropdown populates with the relevant application tiers. Choose the application tier for the selected component. The tiers indicate the part of the application stack running on the selected resources.

Based on your tier selection, CloudWatch Application Insights for .NET and SQL Server makes recommendations for logs to monitor for the selected component. This recommendation can be customized according to your needs.

For each log, specify the file path for the log on your EC2 instance. The corresponding log group name has a default value but can be customized. For SQL Server error log and IIS log, a default file path location is assigned. If you do not want to store your logs in the default location, you should update this default file path. For log path and log name guidance, see [Paths](#).

CloudWatch Application Insights for .NET and SQL Server also sets up relevant metrics for your application resources. They are monitored for approximately two weeks to identify the appropriate metrics thresholds. If you have created the metrics in the past, CloudWatch Application Insights for .NET and SQL Server pulls historical data for the last two weeks to identify the thresholds and to set the alarms accordingly. For newly created metrics, it may take up to three days before alarms are created.

7. **Save monitors.** When you are finished selecting and customizing logs and metrics, select **Save** to set up monitors for the selected component. When you select **Save**, Application Insights sets up the CloudWatch Agent configuration files for all of the instances in your application based on the recommended metrics and your selection of logs. It can take up to an hour for this process to complete.
CloudWatch Application Insights for .NET and SQL Server also sets up CloudWatch alarms for selected metrics in the component. The alarms are dynamically updated by monitoring historical metric patterns from the past two weeks.

When you select **Cancel**, Application Insights only deletes your current selections.

When you create a new application with CloudWatch Application Insights for .NET and SQL Server, the service-linked role is created for you. To delete the service-linked role, you must first delete all of your applications on CloudWatch Applications Insights for .NET and SQL Server and then manually delete the role. For more information, see Using Service-Linked Roles for CloudWatch Application Insights for .NET and SQL Server (p. 296).

CloudWatch Application Insights for .NET and SQL Server is now set to monitor metrics and logs for your application. It may take up to two weeks for the system to generate meaningful insights.

*If your Resource Group is already configured and you want to save your configuration but don’t want CloudWatch Application Insights for .NET and SQL Server to monitor your application, you can disable CloudWatch Application Insights for .NET and SQL Server. You can also delete your configuration.

8. **Add AWS Systems Manager OpsCenter Integration.** To view and get notified when problems are detected for selected applications, select the **Integrate with AWS OpsCenter** check box on the **Monitoring Details** page. To track the operations that are taken to resolve operational work items (OpsItems) that are related to your AWS resources, provide the SNS topic ARN.

9. **View monitoring (optional).** After your application has been set up for monitoring, you can view and troubleshoot detected problems and insights in the default overview page of the CloudWatch console. You can view detected problems, alarms, and dashboards by selecting **View Insights** from the Application Insights landing page, or on the CloudWatch landing page.

### Disable an Application with the Console

To disable an application, from the CloudWatch dashboard, under **Settings**, select the application that you want to disable. Under **Actions**, choose **Disable**. When you disable an application, monitoring is disabled, but Application Insights stores the saved monitors for application components.

### Disable Monitoring for an Application Component with the Console

To disable monitoring for an application component, from the Application Details page select the component for which you want to disable monitoring. Choose **Manage Monitors**, and then uncheck the **Enable Monitoring** check box.

### Delete an Application with the Console

To delete an application, from the CloudWatch dashboard, under **Settings**, select the application that you want to delete. Under **Actions**, choose **Delete**. This deletes monitoring and deletes all of the saved monitors for application components. The application resources are not deleted.

### Add and Manage an Application with Application Insights Using the Command Line

You can add, get information about, manage, and configure your Application Insights application using the command line.

**Topics**
• Add an Application (p. 236)
• Describe an Application (p. 236)
• List Components in an Application (p. 236)
• Describe a Component (p. 237)
• Group Similar Resources into a Custom Component (p. 237)
• Ungroup a Custom Component (p. 237)
• Update an Application (p. 238)
• Update a Custom Component (p. 238)

Add an Application

Add an application using the AWS CLI

To use the AWS CLI to add an application for your resource group called my-resource-group, with OpsCenter enabled to deliver the created opsItem to the SNS topic ARN arn:aws:sns:us-east-1:123456789012:MyTopic, use the following command.

```bash
aws application-insights create-application --resource-group-name my-resource-group --ops-center-enabled --ops-item-sns-topic-arn arn:aws:sns:us-east-1:123456789012:MyTopic
```

Add an application using AWS Tools for Windows PowerShell

To use AWS Tools for Windows PowerShell to add an application for your resource group called my-resource-group with OpsCenter enabled to deliver the created opsItem to the SNS topic ARN arn:aws:sns:us-east-1:123456789012:MyTopic, use the following command.

```powershell
New-CWAIApplication -ResourceGroupName my-resource-group -OpsCenterEnabled true -OpsItemSNSTopicArn arn:aws:sns:us-east-1:123456789012:MyTopic
```

Describe an Application

Describe an application using the AWS CLI

To use the AWS CLI to describe an application created on a resource group called my-resource-group, use the following command.

```bash
aws application-insights describe-application --resource-group-name my-resource-group
```

Describe an application using AWS Tools for Windows PowerShell

To use the AWS Tools for Windows PowerShell to describe an application created on a resource group called my-resource-group, use the following command.

```powershell
Get-CWAIApplication -ResourceGroupName my-resource-group
```

List Components in an Application

List components in an application using the AWS CLI

To use the AWS CLI to list the components created on a resource group called my-resource-group, use the following command.

```bash
aws application-insights list-components --resource-group-name my-resource-group
```

List components in an application using AWS Tools for Windows PowerShell
To use the AWS Tools for Windows PowerShell to list the components created on a resource group called my-resource-group, use the following command.

```
Get-CWAIComponentList -ResourceGroupName my-resource-group
```

Describe a Component

Describe a component using the AWS CLI

You can use the following AWS CLI command to describe a component called my-component that belongs to an application created on a resource group called my-resource-group.

```
aws application-insights describe-component --resource-group-name my-resource-group --component-name my-component
```

Describe a component using AWS Tools for Windows PowerShell

You can use the following AWS Tools for Windows PowerShell command to describe a component called my-component that belongs to an application created on a resource group called my-resource-group.

```
Get-CWAIComponent -ComponentName my-component -ResourceGroupName my-resource-group
```

Group Similar Resources into a Custom Component

We recommend grouping similar resources, such as .NET web server instances, into custom components for easier onboarding and better monitoring and insights. Currently, Application Insights for .NET and SQL Server supports custom groups for EC2 instances.

To group resources into a custom component using the AWS CLI

To use the AWS CLI to group three instances (arn:aws:ec2:us-east-1:123456789012:instance/i-11111, arn:aws:ec2:us-east-1:123456789012:instance/i-22222, and arn:aws:ec2:us-east-1:123456789012:instance/i-33333) together into a custom component called my-component for an application created for the resource group called my-resource-group, use the following command.

```
```

To group resources into a custom component using AWS Tools for Windows PowerShell

To use AWS Tools for Windows PowerShell to group three instances (arn:aws:ec2:us-east-1:123456789012:instance/i-11111, arn:aws:ec2:us-east-1:123456789012:instance/i-22222, and arn:aws:ec2:us-east-1:123456789012:instance/i-33333) together into a custom component called my-component, for an application created for the resource group called my-resource-group, use the following command.

```
```

Ungroup a Custom Component

To ungroup a custom component using the AWS CLI
To use the AWS CLI to ungroup a custom component named `my-component` in an application created on the resource group, `my-resource-group`, use the following command.

```
aws application-insights delete-component --resource-group-name my-resource-group --component-name my-new-component
```

To ungroup a custom component using AWS Tools for Windows PowerShell

To use the AWS Tools for Windows PowerShell to ungroup a custom component named `my-component` in an application created on the resource group, `my-resource-group`, use the following command.

```
Remove-CWAIComponent -ComponentName my-component -ResourceGroupName my-resource-group
```

Update an Application

Update an application using the AWS CLI

You can use the AWS CLI to update an application to generate AWS Systems Manager OpsCenter OpsItems for problems detected with the application, and to associate the created OpsItems to the SNS topic `arn:aws:sns:us-east-1:123456789012:MyTopic`, using the following command.

```
aws application-insights update-application --resource-group-name my-resource-group --ops-center-enabled --ops-item-sns-topic-arn arn:aws:sns:us-east-1:123456789012:MyTopic
```

Update an application using AWS Tools for Windows PowerShell

You can use the AWS Tools for Windows PowerShell to update an application to generate AWS Systems Manager OpsCenter OpsItems for problems detected with the application, and to associate the created OpsItems to the SNS topic `arn:aws:sns:us-east-1:123456789012:MyTopic`, using the following command.

```
Update-CWAIAplication -ResourceGroupName my-resource-group -OpsCenterEnabled true -OpsItemSNSTopicArn arn:aws:sns:us-east-1:123456789012:MyTopic
```

Update a Custom Component

Update a custom component using the AWS CLI

You can use the AWS CLI to update a custom component called `my-component` with a new component name, `my-new-component`, and an updated group of instances, by using the following command.

```
```

Update a custom component using AWS Tools for Windows PowerShell

You can use the AWS Tools for Windows PowerShell to update a custom component called `my-component` with a new component name, `my-new-component`, and an updated group of instances, by using the following command.

```
```
Manage and Update Monitoring Using the Command Line

You can manage and update monitoring for your Application Insights application using the command line.

Topics

• List Problems with Your Application (p. 239)
• Describe an Application Problem (p. 239)
• Describe the Anomalies or Errors Associated with a Problem (p. 240)
• Describe an Anomaly or Error with the Application (p. 240)
• Describe the Monitoring Configurations of a Component (p. 240)
• Describe the Recommended Monitoring Configuration of a Component (p. 240)
• Update the Monitoring Configurations for a Component (p. 241)
• Remove a Specified Resource Group from Application Insights Monitoring (p. 241)

List Problems with Your Application

List problems with your application using the AWS CLI

To use the AWS CLI to list problems with your application detected between 1,000 and 10,000 milliseconds since Unix Epoch for an application created on a resource group called my-resource-group, use the following command.

```bash
aws application-insights list-problems --resource-group-name my-resource-group --start-time 1000 --end-time 10000
```

List problems with your application using AWS Tools for Windows PowerShell

To use the AWS Tools for Windows PowerShell to list problems with your application detected between 1,000 and 10,000 milliseconds since Unix Epoch for an application created on a resource group called my-resource-group, use the following command.

```powershell
#startDate = "8/6/2019 3:33:00"
#endDate = "8/6/2019 3:34:00"
Get-CWAIProblemList -ResourceGroupName my-resource-group -StartTime $startDate -EndTime $endDate
```

Describe an Application Problem

Describe an application problem using the AWS CLI

To use the AWS CLI to describe a problem with problem id p-1234567890, use the following command.

```bash
aws application-insights describe-problem --problem-id p-1234567890
```

Describe an application problem using AWS Tools for Windows PowerShell

To use the AWS Tools for Windows PowerShell to describe a problem with problem id p-1234567890, use the following command.

```powershell
Get-CWAIProblem -ProblemId p-1234567890
```
Describe the Anomalies or Errors Associated with a Problem

Describe the anomalies or errors associated with a problem using the AWS CLI

To use the AWS CLI to describe the anomalies or errors associated with a problem with problem id p-1234567890, use the following command.

```
aws application-insights describe-problem-observations --problem-id p-1234567890
```

Describe the anomalies or errors associated with a problem using AWS Tools for Windows PowerShell

To use the AWS Tools for Windows PowerShell to describe the anomalies or errors associated with a problem with problem id p-1234567890, use the following command.

```
Get-CWAIProblemObservation -ProblemId p-1234567890
```

Describe an Anomaly or Error with the Application

Describe an anomaly or error with the application using the AWS CLI

To use the AWS CLI to describe an anomaly or error with the application with the observation id o-1234567890, use the following command.

```
aws application-insights describe-observation --observation-id o-1234567890
```

Describe an anomaly or error with the application using AWS Tools for Windows PowerShell

To use the AWS Tools for Windows PowerShell to describe an anomaly or error with the application with the observation id o-1234567890, use the following command.

```
Get-CWAIObservation -ObservationId o-1234567890
```

Describe the Monitoring Configurations of a Component

Describe the monitoring configurations of a component using the AWS CLI

To use the AWS CLI to describe the monitoring configuration of a component called my-component in an application created on the resource group my-resource-group, use the following command.

```
aws application-insights describe-component-configuration --resource-group-name my-resource-group --component-name my-component
```

Describe the monitoring configurations of a component using AWS Tools for Windows PowerShell

To use the AWS Tools for Windows PowerShell to describe the monitoring configuration of a component called my-component, in an application created on the resource group my-resource-group, use the following command.

```
Get-CWAIComponentConfiguration -ComponentName my-component -ResourceGroupName my-resource-group
```

For more information about component configuration and for example JSON files, see Component Configuration (p. 246).

Describe the Recommended Monitoring Configuration of a Component

Describe the recommended monitoring configuration of a component using the AWS CLI
When the component is part of a .NET Worker application, you can use the AWS CLI to describe the recommended monitoring configuration of a component called `my-component` in an application created on the resource group `my-resource-group`, by using the following command.

```bash
aws application-insights describe-component-configuration-recommendation --resource-group-name my-resource-group --component-name my-component --tier DOT_NET_WORKER
```

### Describe the recommended monitoring configuration of a component using AWS Tools for Windows PowerShell

When the component is part of a .NET Worker application, you can use the AWS Tools for Windows PowerShell to describe the recommended monitoring configuration of a component called `my-component` in an application created on the resource group `my-resource-group`, by using the following command.

```powershell
Get-CWAIComponentConfigurationRecommendation -ComponentName my-component -ResourceGroupName my-resource-group -Tier DOT_NET_WORKER
```

For more information about component configuration and for example JSON files, see Component Configuration (p. 246).

## Update the Monitoring Configurations for a Component

### Update the monitoring configurations for a component using the AWS CLI

To use the AWS CLI to update the component called `my-component` in an application created on the resource group `my-resource-group`, use the following command. The command includes these actions:

1. Enable monitoring for the component.
2. Set the tier of the component to .NET Worker.
3. Update the JSON configuration of the component to read from the local file `configuration.txt`.

```bash
aws application-insights update-component-configuration --resource-group-name my-resource-group --component-name my-component --tier DOT_NET_WORKER --monitor --component-configuration "file://configuration.txt"
```

### Update the monitoring configurations for a component using the AWS Tools for Windows PowerShell

To use the AWS Tools for Windows PowerShell to update the component called `my-component` in an application created on the resource group `my-resource-group`, use the following command. The command includes these actions:

1. Enable monitoring for the component.
2. Set the tier of the component to .NET Worker.
3. Update the JSON configuration of the component to read from the local file `configuration.txt`.

```powershell
[string]$config = Get-Content -Path configuration.txt
Update-CWAIComponentConfiguration -ComponentName my-component -ResourceGroupName my-resource-group -Tier DOT_NET_WORKER -Monitor 1 -ComponentConfiguration $config
```

For more information about component configuration and for example JSON files, see Component Configuration (p. 246).
Remove a Specified Resource Group from Application Insights Monitoring

Remove a specified resource group from Application Insights monitoring using the AWS CLI

To use the AWS CLI to remove an application created on the resource group called my-resource-group from monitoring, use the following command.

```
aws application-insights delete-application --resource-group-name my-resource-group
```

Remove a specified resource group from Application Insights monitoring using the AWS Tools for Windows PowerShell

To use the AWS Tools for Windows PowerShell to remove an application created on the resource group called my-resource-group from monitoring, use the following command.

```
Remove-CWAIApplication -ResourceGroupName my-resource-group
```

View and Troubleshoot Problems Detected by Amazon CloudWatch Application Insights for .NET and SQL Server

An overview of problems impacting your .NET and SQL Server applications is listed under the CloudWatch Application Insights for .NET and SQL Server widget in the default overview page of the CloudWatch console. For more information, see Getting Started with Amazon CloudWatch Application Insights for .NET and SQL Server (p. 231).

The CloudWatch Application Insights for .NET and SQL Server widget displays the following:

- The severity of the problems detected
- A summary of the problem
- The possible root cause of the problem
- The time the problem started
- The resolution status of the problem
- The affected Resource Group

To drill down into details of a specific problem, under Problem Summary, select the description of the problem. A detailed dashboard displays insights into the problem and related metric anomalies and snippets of log errors. From here, you can provide feedback on the relevance of the insight by selecting whether it is useful.

If a new, unconfigured resource is detected, the problem summary description takes you to the Edit configuration wizard to configure your new resource. If needed, you can view or edit your Resource Group configuration by choosing View/edit configuration in the upper right-hand corner of the detailed dashboard.

To return to the overview, choose Back to overview, which is next to the CloudWatch Application Insights for .NET and SQL Server detailed dashboard header.

Information Provided About Detected Problems

CloudWatch Application Insights for .NET and SQL Server provides the following information about detected problems:
• A short summary of the problem
• The start time and date of the problem
• The problem severity: High/Medium/Low
• The status of the detected problem: In-progress/Resolved
• Insights: Automatically generated insights on the detected problem and possible root cause
• Feedback on insights: Feedback you have provided about the usefulness of the insights generated by CloudWatch Application Insights for .NET and SQL Server
• Related observations: A detailed view of the metric anomalies and error snippets of relevant logs related to the problem across various application components

Feedback
You can provide feedback on the automatically generated insights on detected problems by designating them useful or not useful. Your feedback on the insights, along with your application diagnostics (metric anomalies and log exceptions), are used to improve the future detection of similar problems.

Configuration Errors
CloudWatch Application Insights for .NET and SQL Server uses your configuration to create monitoring telemetries for the components. When Application Insights detects an issue with your account or your configuration, information is provided in the Remarks field about how to resolve the configuration issue for your application.

The following table shows suggested resolutions for specific remarks.

<table>
<thead>
<tr>
<th>Remarks</th>
<th>Suggested Resolution</th>
<th>Additional notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>The quota for alarms has already been reached.</td>
<td>By default, each AWS account can have 5,000 CloudWatch alarms per AWS Region. See CloudWatch Limits. When throttled by this limit, CloudWatch Application Insights for .NET and SQL Server cannot create all of the required alarms to monitor your application. To resolve this, raise the account limit for CloudWatch alarms.</td>
<td>n/a</td>
</tr>
<tr>
<td>The quota for CloudFormation has already been reached.</td>
<td>Application Insights creates one CloudFormation stack for each application to manage CloudWatch agent installation and configuration for all application components. By default, each AWS account can have 200 stacks. See AWS CloudFormation Limits. To resolve this, raise the limit for CloudFormation stacks.</td>
<td>n/a</td>
</tr>
<tr>
<td>No SSM instance role on the following instances.</td>
<td>For Application Insights to be able to install and configure CloudWatch agent on application instances, Application Insights calls the SSM DescribeInstanceInformation API to get the list of instances with SSM permission. After</td>
<td></td>
</tr>
</tbody>
</table>
Set Up Notifications and Actions for Detected Problems

For each application that is added to Application Insights for .NET and SQL Server, a CloudWatch Event is published for the following events:

- **Problem Creation.** Emitted when CloudWatch Application Insights for .NET and SQL Server detects a new problem.
  - **Detail Type:** "Application Insights Problem Detected"
  - **Detail:**
    - `problemId`: The detected problem ID.
    - `region`: The AWS Region where the problem was created.
    - `resourceGroupName`: The Resource Group for the registered application for which the problem was detected.
    - `status`: The status of the problem.
    - `severity`: The severity of the problem.
    - `problemUrl`: The console URL for the problem.

- **Problem Update.** Emitted when the problem is updated with a new observation or when an existing observation is updated and the problem is subsequently updated; updates include a resolution or closure of the problem.
  - **Detail Type:** "Application Insights Problem Updated"
  - **Detail:**
    - `problemId`: The created problem ID.
    - `region`: The AWS Region where the problem was created.
    - `resourceGroupName`: The Resource Group for the registered application for which the problem was detected.
    - `status`: The status of the problem.
    - `severity`: The severity of the problem.
    - `problemUrl`: The console URL for the problem.

**Example:** How to receive notification for problem events generated by an application

<table>
<thead>
<tr>
<th>Remarks</th>
<th>Suggested Resolution</th>
<th>Additional notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>New components may need configuration.</td>
<td>AmazonEC2RoleforSSM and CloudWatchAgentServerPolicy policies must be attached to the instance role.</td>
<td>the role is attached to the instance, it takes time for SSM to include the instance in the DescribeInstancesInformation result. Until SSM includes the instance in the result, NO_SSM_INSTANCE_ROLE error remains present for the application.</td>
</tr>
<tr>
<td></td>
<td>Application Insights detects that there are new components in the application Resource Group. To resolve this, configure the new components accordingly.</td>
<td>n/a</td>
</tr>
</tbody>
</table>
To receive notifications for problem events generated by Application Insights for .NET and SQL Server, create a rule for Application Insights to receive problems for a specific application.

```bash
aws events put-rule \
  --name cwe-test \
  --event-pattern \
  '{
    "source": ["aws.applicationinsights"],
    "detail-type": ["Application Insights Problem Detected"],
    "detail": {
      "resourceGroupName": ["<RESOURCE_GROUP_NAME>"]
    }
  }
}
```

Then add the proper CloudWatch Event target, which should receive the events.

```bash
aws events put-targets \
  --rule cwe-test \
  --targets Id=1,Arn=<TARGET_ARN>
```

**Note**

You can create a rule from the CloudWatch console by choosing **Rules** under **Events** in the left navigation pane. Then choose **Create rule > Event pattern**, and then select **Custom event pattern** from the Build event pattern to match events by service dropdown.

**Actions Through AWS Systems Manager.** CloudWatch Application Insights for .NET and SQL Server provides built-in integration with Systems Manager OpsCenter. If you choose to use this integration for your application, an OpsItem is created on the OpsCenter console for every problem detected with the application. From the OpsCenter console, you can view summarized information about the problem detected by CloudWatch Application Insights and pick a Systems Manager Automation runbook to take remedial actions or further identify Windows processes that are causing resource issues in your application.

### How Amazon CloudWatch Application Insights for .NET and SQL Server Works

**Application Discovery and Configuration**

The first time an application is added to Application Insights for .NET and SQL Server, it scans the application components to recommend key metrics, logs, and other data sources to monitor for your application. You can then configure your application based on these recommendations.

**Data Preprocessing**

Application Insights for .NET and SQL Server continuously analyzes the data sources being monitored across the application resources to discover metric anomalies and log errors (observations).

**Intelligent Problem Detection**

The Application Insights engine detects problems in your application by correlating observations using classification algorithms and built-in rules. To assist in troubleshooting, it creates automated CloudWatch dashboards, which include contextual information about the problems.

**Alert and Action**
When Application Insights detects a problem with your application, it generates CloudWatch Events to notify you of the problem. See Set Up Notifications and Actions for Detected Problems (p. 244) for more information about how to set up these Events.

**Example Scenario**

You have an ASP.NET application that is backed by a SQL Server database. Suddenly, your database begins to malfunction because of high memory pressure. This leads to application performance degradation and possibly HTTP 500 errors in your web servers and load balancer.

With CloudWatch Application Insights for .NET and SQL Server and its intelligent analytics, you can identify the application layer that is causing the problem by checking the dynamically created dashboard that shows the related metrics and log file snippets. In this case, the problem might be at the SQL database layer.

**Data Retention**

CloudWatch Application Insights for .NET and SQL Server retains problems for 55 days and observations for 60 days.

**Component Configuration**

A component configuration is a text file in JSON format that describes the configuration settings of the component. The following examples show a component configuration structure and its sections.

**JSON**

The following example shows a template fragment in JSON format.

```json
{
  "alarmMetrics" : [
    list of alarm metrics
  ],
  "logs" : [
    list of logs
  ],
  "instances" : {
    component nested instances configuration
  }
}
```

**Component Configuration Sections**

Component configuration includes several major sections. Sections in a component configuration can be in any order.

- **alarmMetrics (optional)**
  A list of metrics (p. 247) to monitor for the component. All component types can have an alarmMetrics section.

- **logs (optional)**
  A list of logs (p. 247) to monitor for the component. Only EC2 instances can have a logs section.

- **instances (optional)**
  Nested instance configuration for the component. The following types of component can have nested instances and an instances section: ELB, ASG, and custom-grouped EC2 instances.
The following example shows the instances section fragment in JSON format.

```
{
  "alarmMetrics" : [
    list of alarm metrics
  ],
  "logs" : [
    list of logs
  ]
}
```

**Metric**

Defines a metric to be monitored for the component.

**JSON**

```
{
  "alarmMetricName" : "monitoredMetricName",
  "monitor" : true/false
}
```

**Properties**

- **alarmMetricName (required)**
  
  The name of the metric to be monitored for the component. For metrics supported by Application Insights, see Logs and Metrics Supported by Amazon CloudWatch Application Insights for .NET and SQL Server (p. 251).

- **monitor (optional)**

  Boolean to indicate whether to monitor the metric. The default value is true.

**Log**

Defines a log to be monitored for the component.

**JSON**

```
{
  "logGroupName" : "logGroupName",
  "logPath" : "logPath",
  "logType" : "logType",
  "encoding" : "encodingType",
  "monitor" : true/false
}
```

**Properties**

- **logGroupName (required)**

  The CloudWatch log group name to be associated to the monitored log. For the log group name constraints, see CreateLogGroup.

- **logPath (required)**

  The path of the logs to be monitored. The log path must be an absolute Windows system file path. For more information, see CloudWatch Agent Configuration File: Logs Section.
- **logType (required)**
  The log type decides the log patterns against which Application Insights analyzes the log. The log type is selected from the following: SQL_SERVER/IIS/APPLICATION/DEFAULT.

- **encoding (optional)**
  The type of encoding of the logs to be monitored. The specified encoding should be included in the list of CloudWatch agent supported encodings. If not provided, Application Insights uses the default encoding type for the log type:
  - For APPLICATION/DEFAULT: utf-8 encoding
  - For SQL_SERVER: utf-16 encoding
  - For IIS: ascii encoding

- **monitor (optional)**
  Boolean that indicates whether to monitor the logs. The default value is true.

## Component Configuration Examples

The following examples show component configurations in JSON format for relevant AWS services.

### Amazon Elastic Cloud Compute (EC2) Instance

```
{
  "alarmMetrics" : [
    {
      "alarmMetricName" : "CPUUtilization",
      "monitor" : true
    },
    {
      "alarmMetricName" : "StatusCheckFailed"
    }
  ],
  "logs" : [
    {
      "logGroupName" : "my_log_group",
      "logPath" : "C:\LogFolder\**",
      "logType" : "APPLICATION",
      "monitor" : true
    },
    {
      "logGroupName" : "my_log_group_2",
      "logPath" : "C:\LogFolder2\**",
      "logType" : "IIS",
      "encoding" : "utf-8"
    }
  ]
}
```

### Amazon Relational Database (RDS) Instance

```
{
  "alarmMetrics" : [
    {
      "alarmMetricName" : "BurstBalance",
      "monitor" : true
    },
    {
      "alarmMetricName" : "WriteThroughput",
      "monitor" : false
    }
  ]
}
```
Elastic Load Balancing (ELB)

```json
{
    "alarmMetrics" : [
        {
            "alarmMetricName" : "EstimatedALBActiveConnectionCount",
        },
        {
            "alarmMetricName" : "HTTPCode_Backend_5XX"
        },
    ],
    "instances" : {

```
Amazon CloudWatch User Guide

Limits

The following table provides the default limits for CloudWatch Application Insights for .NET and SQL Server. Unless otherwise noted, each limit is per AWS Region. Please contact AWS Support to request an

```json
{
    "alarmMetricName" : "CPUCreditBalance",
},
{
    "alarmMetricName" : "EBSIOBalance%"
}
],
"instances" : {
    "alarmMetrics" : [
        {
            "alarmMetricName" : "CPUUtilization",
        },
        {
            "alarmMetricName" : "StatusCheckFailed"
        }
    ],
    "logs" : [
        {
            "logGroupName" : "my_log_group",
            "logPath" : "C:\\LogFolder\\*",
            "logType" : "APPLICATION",
        }
    ]
}
}

Amazon Simple Queue Service (SQS)

```json`
{
    "alarmMetrics" : [
        {
            "alarmMetricName" : "ApproximateAgeOfOldestMessage"
        },
        {
            "alarmMetricName" : "NumberOfEmptyReceives"
        }
    ]
}
```

Customer Grouped EC2 Instances

```json`
{
    "instances" : {
        "alarmMetrics" : [
            {
                "alarmMetricName" : "CPUUtilization",
            },
            {
                "alarmMetricName" : "StatusCheckFailed"
            }
        ],
        "logs" : [
            {
                "logGroupName" : "my_log_group",
                "logPath" : "C:\\LogFolder\\*",
                "logType" : "APPLICATION",
            }
        ]
    }
}
```

Limits
increase in your service limit. Many services contain limits that cannot be changed. For more information about the limits for a specific service, see the documentation for that service.

Logs and Metrics Supported by Amazon CloudWatch Application Insights for .NET and SQL Server

The following lists show the supported logs and metrics for CloudWatch Application Insights for .NET and SQL Server.

CloudWatch Application Insights for .NET and SQL Server supports the following logs:

- Microsoft Internet Information Services (IIS) logs
- Error log for SQL Server on EC2
- Custom .NET application logs, such as Log4Net

CloudWatch Application Insights for .NET and SQL Server supports metrics for the following application components:

- Amazon Elastic Cloud Compute (EC2) (p. 251)
- Elastic Load Balancer (ELB) (p. 253)
- Application ELB (p. 253)
- Amazon EC2 Auto Scaling Groups (p. 254)
- Amazon Simple Queue Server (SQS) (p. 254)
- Amazon Relational Database Service (RDS) (p. 254)
- Metrics With Datapoints Requirements (p. 255)
- Recommended Metrics (p. 259)

Metrics With Datapoints Requirements

For metrics without an obvious default threshold to alarm on, Application Insights waits until the metric has enough data points to predict a reasonable threshold to alarm on. The metric datapoints requirement that Application Insights checks before an alarm is created are:

- The metric has at least 100 datapoints from the past 15 to the past 2 days.
- The metric has at least 100 datapoints from the last day.

The following metrics follow these datapoint requirements. Note that CloudWatch agent metrics require up to one hour to create alarms.
**AWS/ApplicationELB**

- ActiveConnectionCount
- ConsumedLCUs
- HTTPCode_ELB_4XX_Count
- HTTPCode_Target_2XX_Count
- HTTPCode_Target_3XX_Count

Monitor Applications Using AWS SDK Metrics

Enterprise customers can use the CloudWatch agent with AWS SDK Metrics for Enterprise Support (SDK Metrics) to collect metrics from AWS SDKs on their hosts and clients. These metrics are shared with AWS Enterprise Support. SDK Metrics can help you collect relevant metrics and diagnostic data about your application’s connections to AWS services without adding custom instrumentation to your code, and reduces the manual work necessary to share logs and data with AWS Support.

Important
SDK Metrics is available only to customers with an Enterprise Support subscription. For more information, see Amazon CloudWatch Support Center.

You can use SDK Metrics with any application that directly calls AWS services and that was built using an AWS SDK that is one of the versions listed in the following section.

SDK Metrics monitors calls that are made by the AWS SDK and uses the CloudWatch agent running in the same environment as a client application. The following section explains the steps necessary to enable the CloudWatch agent to emit SDK Metrics data. For information about what you need to configure in your SDK, see your SDK documentation.

Topics
• Metrics and Data Collected by AWS SDK Metrics for Enterprise Support (p. 267)
• Set Up SDK Metrics (p. 269)

Supported Versions
To use SDK Metrics, you must be using version 1.207573.0 or later of the CloudWatch agent. If you are already running the CloudWatch agent, you can find the version in the following file.

• Linux: /opt/aws/amazon-cloudwatch-agent/bin/CWAGENT_VERSION
• Windows Server: C:\Program Files\Amazon\AmazonCloudWatchAgent\CWAGENT_VERSION

Additionally, you must be using one of the following versions of an AWS SDK.

<table>

Source IP Address | String
Destination IP Address | String

The following table lists the metrics generated by SDK Metrics, published in the AWS/SDKMetrics namespace. These metrics are available only to customers who have the Enterprise support plan. For these customers, the metrics can be accessed through AWS support personnel and technical account managers.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CallCount</strong></td>
<td>Total number of successful or failed API calls from your code to AWS services.</td>
<td>Use CallCount as a baseline to correlate with other metrics such as ServerErrorCount and ThrottleCount.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
<td></td>
</tr>
<tr>
<td><strong>ClientErrorCount</strong></td>
<td>The number of API calls that failed with client errors (4xx HTTP response codes). These can include throttling errors, access denied, S3 bucket does not exist, and invalid parameter value.</td>
<td>A high value for this metric usually indicates that something in your application needs to be fixed, unless the high value is a result of throttling caused by an AWS service limit. In this case, you should increase your service limit.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
<td></td>
</tr>
<tr>
<td><strong>EndToEndLatency</strong></td>
<td>The total time for your application to make a call using the AWS SDK, inclusive of retries.</td>
<td>Use EndToEndLatency to determine how AWS API calls contribute to your application's overall latency. Higher than expected latency might be caused by issues with your network, firewall, or other configuration settings. Latency can also result from SDK retries.</td>
</tr>
<tr>
<td></td>
<td>Unit: Milliseconds</td>
<td></td>
</tr>
<tr>
<td><strong>ConnectionErrorCount</strong></td>
<td>The number of API calls that fail because of errors connecting to the service. These can be caused by network issues between your application and AWS services, including load balancer issues, DNS failures, and transit provider issues. In some cases, AWS issues might result in this error.</td>
<td>Use this metric to determine whether problems are specific to your application or are caused by your infrastructure or network. A high value could also indicate short timeout values for API calls.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
<td></td>
</tr>
<tr>
<td><strong>ServerErrorCount</strong></td>
<td>The number of API calls that fail because of server errors (5xx HTTP response codes) from AWS services. These are typically caused by AWS services.</td>
<td>Use this metric to determine the cause of SDK retries or latency. This metric doesn't always indicate that AWS services are at fault because some AWS teams classify latency as an HTTP 503 response.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
<td></td>
</tr>
<tr>
<td><strong>ThrottleCount</strong></td>
<td>The number of API calls that fail because of throttling by AWS services.</td>
<td>Use this metric to assess if your application has reached throttle limits, as well as to</td>
</tr>
</tbody>
</table>
### Set Up SDK Metrics

To set up SDK Metrics, you perform some steps with your SDK and some with CloudWatch agent.

#### To set up SDK Metrics

1. Create an application with an AWS SDK that supports SDK Metrics.
2. Host your project on an Amazon EC2 instance or in your local environment.
3. Install and use the latest version of your SDK.
4. Install the CloudWatch agent on the EC2 instance or the local environment that is running an application that you want to receive metrics for. For more information, see [Installing the CloudWatch Agent](p. 142).
5. Configure the CloudWatch agent for SDK Metrics. For more information, see [Configure the CloudWatch Agent for SDK Metrics](p. 270).
6. Authorize SDK Metrics to collect and send metrics. For more information, see [Set IAM Permissions for SDK Metrics](p. 271).
7. Enable SDK Metrics. There are multiple methods to do this, depending on which SDK you’re using. One method that is universal for all SDKs is to add the following to your environment variables:

```bash
export AWS_CSM_ENABLED=true
```

For information about the other methods, see your SDK documentation as shown in the following table.

<table>
<thead>
<tr>
<th>Supported SDK</th>
<th>SDK Metrics documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS CLI 1.16.84 or later</td>
<td><a href="#">SDK Metrics</a></td>
</tr>
<tr>
<td></td>
<td>The instructions for the AWS CLI installation are the same as for SDK for Python (Boto 3).</td>
</tr>
<tr>
<td>AWS SDK for C++ 1.7.47 or later</td>
<td><a href="#">SDK Metrics</a></td>
</tr>
<tr>
<td>AWS SDK for Go 1.16.18 or later</td>
<td><a href="#">SDK Metrics in the AWS SDK for Go</a></td>
</tr>
</tbody>
</table>
Configure the CloudWatch Agent for SDK Metrics

After installing the CloudWatch agent, you need to configure it to work with SDK Metrics. The easiest way is to use AWS Systems Manager, but you can also do it manually.

Topics

- Configure the CloudWatch Agent for SDK Metrics Using AWS Systems Manager (p. 270)
- Configure the CloudWatch Agent for SDK Metrics Manually (p. 271)

Configure the CloudWatch Agent for SDK Metrics Using AWS Systems Manager

This section explains how to use SSM to configure the CloudWatch agent to work with SDK Metrics. For more information about SSM agents, see Installing and Configuring SSM Agent.

To configure SDK Metrics using SSM

2. In the navigation pane, choose Run Command.
3. In the Command document list, choose AWS-UpdateSSMAgent.
4. In the Targets area, choose the instance where you installed the CloudWatch agent.
5. In the navigation pane, choose Parameter Store.
6. Choose Create Parameter.
7. Do the following:
   a. Name the parameter AmazonCSM.
   b. Select type string.
   c. For Value, enter `{ "CSM": {"memory_limit_in_mb": 20, "port": 31000}}`.
8. Select Create Parameter.

To complete the configuration, see your SDK documentation.
Configure the CloudWatch Agent for SDK Metrics Manually

Create Your CloudWatch Agent Configuration File

If you don't already have a CloudWatch agent configuration file, create one. For more information, see Create the CloudWatch Agent Configuration File (p. 174).

Add the SDK Metrics Configuration

Add the following `csm` entry to the top-level JSON object in the CloudWatch agent configuration file.

```
"csm": {
   "memory_limit_in_mb": 20,
   "port": 31000
}
```

For example:

```
{
   "agent": {
      ...
   },
   "metrics": {
      ...
   },
   "csm": {
      "memory_limit_in_mb": 20,
      "port": 31000
   }
}
```

You can now start the CloudWatch agent using this configuration file. For more information, see Start the CloudWatch Agent (p. 160).

To complete the configuration, see your SDK documentation.

Set IAM Permissions for SDK Metrics

To configure permissions so you can use SDK Metrics, you must create an IAM policy to allow the SDK Metrics process and attach it to the role or user that is attached to the EC2 instance running the CloudWatch agent.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Policies.
3. Choose Create Policy, JSON.
4. Enter the following inline policy into the content window. Ignore the warning about the non-supported action.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "sdkmetrics:*"
         ]
      }
   ]
}
```
5. Name the policy AmazonSDKMetrics.
6. Attach the policy to the IAM user or role that is attached to the EC2 instance that is running the CloudWatch agent.
Monitoring CloudWatch Usage

CloudWatch collects metrics that track the usage of some AWS resources. These metrics correspond to AWS service limits. Tracking these metrics can help you make sure your use of AWS stays within your service limits.

Currently, the only metric in this namespace that CloudWatch uses is CallCount. This metric is published with the dimensions Resource, Service, and Type. The Resource dimension specifies the name of the API operation being tracked. For example, the CallCount metric with the dimensions "Service": "CloudWatch", "Type": "API" and "Resource": "PutMetricData" indicates the number of times the CloudWatch PutMetricData API operation has been called in your account.

Account-level usage metrics for supported AWS resources are in the AWS/Usage namespace and are collected every minute.

The CallCount metric does not have a specified unit. The most useful statistic for the metric is SUM, which represents the total operation count for the 1-minute period.

### Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CallCount</td>
<td>The number of specified operations performed in your account.</td>
</tr>
</tbody>
</table>

### Dimensions

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource</td>
<td>The name of the API operation. Valid values include the following:</td>
</tr>
<tr>
<td></td>
<td>DeleteAlarms, DeleteDashboards, DescribeAlarmHistory, DescribeAlarms,</td>

</table>
CloudWatch Tutorials

The following scenarios illustrate uses of Amazon CloudWatch. In the first scenario, you use the CloudWatch console to create a billing alarm that tracks your AWS usage and lets you know when you have exceeded a certain spending threshold. In the second, more advanced scenario, you use the AWS Command Line Interface (AWS CLI) to publish a single metric for a hypothetical application named GetStarted.

Scenarios

- Monitor Your Estimated Charges (p. 274)
- Publish Metrics (p. 277)

Scenario: Monitor Your Estimated Charges Using CloudWatch

In this scenario, you create an Amazon CloudWatch alarm to monitor your estimated charges. When you enable the monitoring of estimated charges for your AWS account, the estimated charges are calculated and sent several times daily to CloudWatch as metric data.

Billing metric data is stored in the US East (N. Virginia) Region and reflects worldwide charges. This data includes the estimated charges for every service in AWS that you use, as well as the estimated overall total of your AWS charges.

You can choose to receive alerts by email when charges have exceeded a certain threshold. These alerts are triggered by CloudWatch and messages are sent using Amazon Simple Notification Service (Amazon SNS).

Tasks

- Step 1: Enable Billing Alerts (p. 274)
- Step 2: Create a Billing Alarm (p. 275)
- Step 3: Check the Alarm Status (p. 276)
- Step 4: Edit a Billing Alarm (p. 276)
- Step 5: Delete a Billing Alarm (p. 276)

Step 1: Enable Billing Alerts

Before you can create an alarm for your estimated charges, you must enable billing alerts, so that you can monitor your estimated AWS charges and create an alarm using billing metric data. After you enable billing alerts, you cannot disable data collection, but you can delete any billing alarms that you created.

After you enable billing alerts for the first time, it takes about 15 minutes before you can view billing data and set billing alarms.

Requirements

- You must be signed in as either an AWS account root user or an IAM user whose access to the Billing and Cost Management console has been activated.
For consolidated billing accounts, billing data for each linked account can be found by logging in as the paying account. You can view billing data for total estimated charges and estimated charges by service for each linked account as well as for the consolidated account.

To enable monitoring of your estimated charges
2. In the navigation pane, choose Preferences.
4. Choose Save preferences.

Step 2: Create a Billing Alarm

After you've enabled billing alerts, you can create a billing alarm. In this scenario, you create an alarm that sends an email message when your estimated charges for AWS exceed a specified threshold.

Note
This procedure uses the simple options. To use the advanced options, see Creating a Billing Alarm (p. 90) in Create a Billing Alarm to Monitor Your Estimated AWS Charges.

To create a billing alarm
1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose Alarms, Create Alarm.
4. Choose Select metric, Billing, Total Estimated Charge.
5. Select the checkbox next to EstimatedCharges and choose Select metric
6. For Whenever my total AWS charges for the month exceed, specify the monetary amount (for example, 200) that must be exceeded to trigger the alarm and send an email notification.
   Tip
   The graph shows a current estimate of your charges that you can use to set an appropriate amount.
7. For send a notification to, choose an existing notification list or create a new one.
To create a list, choose **New list** and type a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state. Each email address is sent a subscription confirmation email. The recipient must confirm the subscription before notifications can be sent to the email address.

8. Choose **Create Alarm**.

**Step 3: Check the Alarm Status**

Now, check the status of the billing alarm that you just created.

**To check the alarm status**

2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**.
4. Select the check box next to the alarm. Until the subscription is confirmed, it is shown as "Pending confirmation". After the subscription is confirmed, refresh the console to show the updated status.

**Step 4: Edit a Billing Alarm**

For example, you may want to increase the amount of money you spend with AWS each month from $200 to $400. You can edit your existing billing alarm and increase the monetary amount that must be exceeded before the alarm is triggered.

**To edit a billing alarm**

2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**.
4. Select the check box next to the alarm and choose **Actions**,** Modify**.
5. For **Whenever my total AWS charges for the month exceed**, specify the new amount that must be exceeded to trigger the alarm and send an email notification.
6. Choose **Save Changes**.

**Step 5: Delete a Billing Alarm**

If you no longer need your billing alarm, you can delete it.

**To delete a billing alarm**

2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**.
4. Select the check box next to the alarm and choose **Actions**, **Delete**.
5. When prompted for confirmation, choose **Yes**, **Delete**.
Scenario: Publish Metrics to CloudWatch

In this scenario, you use the AWS Command Line Interface (AWS CLI) to publish a single metric for a hypothetical application named GetStarted. If you haven't already installed and configured the AWS CLI, see Getting Set Up with the AWS Command Line Interface in the AWS Command Line Interface User Guide.

Tasks

- Step 1: Define the Data Configuration (p. 277)
- Step 2: Add Metrics to CloudWatch (p. 277)
- Step 3: Get Statistics from CloudWatch (p. 278)
- Step 4: View Graphs with the Console (p. 278)

Step 1: Define the Data Configuration

In this scenario, you publish data points that track the request latency for the application. Choose names for your metric and namespace that make sense to you. For this example, name the metric RequestLatency and place all of the data points into the GetStarted namespace.

You publish several data points that collectively represent three hours of latency data. The raw data comprises 15 request latency readings distributed over three hours. Each reading is in milliseconds:

- Hour one: 87, 51, 125, 235
- Hour two: 121, 113, 189, 65, 89
- Hour three: 100, 47, 133, 98, 100, 328

You can publish data to CloudWatch as single data points or as an aggregated set of data points called a statistic set. You can aggregate metrics to a granularity as low as one minute. You can publish the aggregated data points to CloudWatch as a set of statistics with four predefined keys: Sum, Minimum, Maximum, and SampleCount.

You publish the data points from hour one as single data points. For the data from hours two and three, you aggregate the data points and publish a statistic set for each hour. The key values are shown in the following table.

<table>
<thead>
<tr>
<th>Hour</th>
<th>Raw Data</th>
<th>Sum</th>
<th>Minimum</th>
<th>Maximum</th>
<th>SampleCount</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>87</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>51</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>125</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>235</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>121, 113, 189, 65, 89</td>
<td>577</td>
<td>65</td>
<td>189</td>
<td>5</td>
</tr>
<tr>
<td>3</td>
<td>100, 47, 133, 98, 100, 328</td>
<td>806</td>
<td>47</td>
<td>328</td>
<td>6</td>
</tr>
</tbody>
</table>

Step 2: Add Metrics to CloudWatch

After you have defined your data configuration, you are ready to add data.
To publish data points to CloudWatch

1. At a command prompt, run the following `put-metric-data` commands to add data for the first hour. Replace the example timestamp with a timestamp that is two hours in the past, in Universal Coordinated Time (UTC).

   ```bash
   aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted --timestamp 2016-10-14T20:30:00Z --value 87 --unit Milliseconds
   aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted --timestamp 2016-10-14T20:30:00Z --value 51 --unit Milliseconds
   aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted --timestamp 2016-10-14T20:30:00Z --value 125 --unit Milliseconds
   aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted --timestamp 2016-10-14T20:30:00Z --value 235 --unit Milliseconds
   ```

2. Add data for the second hour, using a timestamp that is one hour later than the first hour.

   ```bash
   aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted --timestamp 2016-10-14T21:30:00Z --statistic-values Sum=577,Minimum=65,Maximum=189,SampleCount=5 --unit Milliseconds
   ```

3. Add data for the third hour, omitting the timestamp to default to the current time.

   ```bash
   aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted --statistic-values Sum=806,Minimum=47,Maximum=328,SampleCount=6 --unit Milliseconds
   ```

Step 3: Get Statistics from CloudWatch

Now that you have published metrics to CloudWatch, you can retrieve statistics based on those metrics using the `get-metric-statistics` command as follows. Be sure to specify `--start-time` and `--end-time` far enough in the past to cover the earliest timestamp that you published.

```bash
aws cloudwatch get-metric-statistics --namespace GetStarted --metric-name RequestLatency --statistics Average --start-time 2016-10-14T00:00:00Z --end-time 2016-10-15T00:00:00Z --period 60
```

The following is example output:

```json
{
    "Datapoints": [],
    "Label": "Request:Latency"
}
```

Step 4: View Graphs with the Console

After you have published metrics to CloudWatch, you can use the CloudWatch console to view statistical graphs.

To view graphs of your statistics on the console

2. In the Navigation pane, choose Metrics.
3. On the All metrics tab, in the search box, type `RequestLatency` and press Enter.
4. Select the check box for the `RequestLatency` metric. A graph of the metric data is displayed in the upper pane.
For more information, see Graphing Metrics (p. 38).
Using CloudWatch with Interface VPC Endpoints

If you use Amazon Virtual Private Cloud (Amazon VPC) to host your AWS resources, you can establish a private connection between your VPC and CloudWatch. You can use this connection to enable CloudWatch to communicate with your resources on your VPC without going through the public internet.

Amazon VPC is an AWS service that you can use to launch AWS resources in a virtual network that you define. With a VPC, you have control over your network settings, such as the IP address range, subnets, route tables, and network gateways. To connect your VPC to CloudWatch, you define an *interface VPC endpoint* for CloudWatch. This type of endpoint enables you to connect your VPC to AWS services. The endpoint provides reliable, scalable connectivity to CloudWatch without requiring an internet gateway, network address translation (NAT) instance, or VPN connection. For more information, see *What is Amazon VPC* in the *Amazon VPC User Guide*.

Interface VPC endpoints are powered by AWS PrivateLink, an AWS technology that enables private communication between AWS services using an elastic network interface with private IP addresses. For more information, see *New – AWS PrivateLink for AWS Services*.

The following steps are for users of Amazon VPC. For more information, see *Getting Started* in the *Amazon VPC User Guide*.

Availability

CloudWatch currently supports VPC endpoints in the following Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- EU (Frankfurt)
- EU (Ireland)
- EU (London)
- EU (Paris)
- South America (São Paulo)

Creating a VPC Endpoint for CloudWatch

To start using CloudWatch with your VPC, create an interface VPC endpoint for CloudWatch. The service name to choose is *com.amazonaws.Region.monitoring*. For more information, see *Creating an Interface Endpoint* in the *Amazon VPC User Guide*. 
You do not need to change the settings for CloudWatch. CloudWatch calls other AWS services using either public endpoints or private interface VPC endpoints, whichever are in use. For example, if you create an interface VPC endpoint for CloudWatch, and you already have metrics flowing to CloudWatch from resources located on your VPC, these metrics begin flowing through the interface VPC endpoint by default.

## Controlling Access to Your CloudWatch VPC Endpoint

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. If you don’t attach a policy when you create an endpoint, we attach a default policy for you that allows full access to the service. An endpoint policy doesn’t override or replace IAM user policies or service-specific policies. It’s a separate policy for controlling access from the endpoint to the specified service.

Endpoint policies must be written in JSON format.

For more information, see [Controlling Access to Services with VPC Endpoints](https://docs.aws.amazon.com/vpc/latest/userguide/vpc-endpoints-controlled-access.html) in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy for CloudWatch. This policy enables users connecting to CloudWatch through the VPC to send metric data to CloudWatch and prevents them from performing other CloudWatch actions.

```json
{
  "Statement": [
    {
      "Sid": "PutOnly",
      "Principal": "*",
      "Action": ["cloudwatch:PutMetricData"],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

**To modify the VPC endpoint policy for CloudWatch**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. If you have not already created the endpoint for CloudWatch, choose **Create Endpoint**. Then select `com.amazonaws.Region.monitoring` and choose **Create endpoint**.
4. Select the `com.amazonaws.Region.monitoring` endpoint and choose the **Policy** tab in the lower half of the screen.
5. Choose **Edit Policy** and make the changes to the policy.
Authentication and Access Control for Amazon CloudWatch

Access to Amazon CloudWatch requires credentials. Those credentials must have permissions to access AWS resources, such as retrieving CloudWatch metric data about your cloud resources. The following sections provide details about how you can use AWS Identity and Access Management (IAM) and CloudWatch to help secure your resources by controlling who can access them:

- Authentication (p. 282)
- Access Control (p. 283)

Authentication

You can access AWS as any of the following types of identities:

- **AWS account root user** – When you sign up for AWS, you provide an email address and password that is associated with your AWS account. These are your *AWS account user credentials* and they provide complete access to all of your AWS resources.

  **Important**
  
  For security reasons, we recommend that you use the AWS account user credentials *only* to create an *administrator*, which is an *IAM user* with full permissions to your AWS account. Then, you can use this administrator to create other IAM users and roles with limited permissions. For more information, see IAM Best Practices and Creating an Admin User and Group in the IAM User Guide.

- **IAM user** – An *IAM user* is an identity within your AWS account that has specific custom permissions (for example, permissions to view metrics in CloudWatch). You can use an IAM user name and password to sign in to secure AWS webpages like the AWS Management Console, AWS Discussion Forums, or the AWS Support Center.

  In addition to a user name and password, you can also generate access keys for each user. You can use these keys when you access AWS services programmatically, either through one of the several SDKs or by using the AWS Command Line Interface (CLI). The SDK and AWS CLI tools use the access keys to cryptographically sign your request. If you don’t use the AWS tools, you must sign the request yourself. CloudWatch supports Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 Signing Process in the AWS General Reference.

- **IAM role** – An *IAM role* is another IAM identity you can create in your account that has specific permissions. It is similar to an IAM user, but it is not associated with a specific person. An IAM role enables you to obtain temporary access keys that can be used to access AWS services and resources. IAM roles with temporary credentials are useful in the following situations:

  - **Federated user access** – Instead of creating an IAM user, you can use preexisting identities from AWS Directory Service, your enterprise user directory, or a web identity provider (IdP). These are known as
federated users. AWS assigns a role to a federated user when access is requested through an IdP. For more information, see Federated Users and Roles in the IAM User Guide.

- **Cross-account access** – You can use an IAM role in your account to grant another AWS account permissions to access your account's resources. For an example, see Tutorial: Delegate Access Across AWS Accounts Using IAM Roles in the IAM User Guide.

- **AWS service access** – You can use an IAM role in your account to grant an AWS service the permissions needed to access your account's resources. For example, you can create a role that allows Amazon Redshift to access an Amazon S3 bucket on your behalf and then load data stored in the bucket into an Amazon Redshift cluster. For more information, see Creating a Role to Delegate Permissions to an AWS Service in the IAM User Guide.

- **Applications running on Amazon EC2** – Instead of storing access keys within the EC2 instance for use by applications running on the instance and making API requests, you can use an IAM role to manage temporary credentials for these applications. To assign an AWS role to an EC2 instance and make it available to all of its applications, you can create an instance profile that is attached to the instance. An instance profile contains the role and enables programs running on the EC2 instance to get temporary credentials. For more information, see Using Roles for Applications on Amazon EC2 in the IAM User Guide.

## Access Control

You can have valid credentials to authenticate your requests, but unless you have permissions you cannot create or access CloudWatch resources. For example, you must have permissions to create CloudWatch dashboard widgets, view metrics, and so on.

The following sections describe how to manage permissions for CloudWatch. We recommend that you read the overview first.

- Overview of Managing Access Permissions to Your CloudWatch Resources (p. 284)
- Using Identity-Based Policies (IAM Policies) for CloudWatch (p. 287)
- Amazon CloudWatch Permissions Reference (p. 300)

## CloudWatch Dashboard Permissions Update

On May 1, 2018, AWS changed the permissions required to access CloudWatch dashboards. Dashboard access in the CloudWatch console now requires permissions that were introduced in 2017 to support dashboard API operations:

- `cloudwatch:GetDashboard`
- `cloudwatch:ListDashboards`
- `cloudwatch:PutDashboard`
- `cloudwatch:DeleteDashboards`

To access CloudWatch dashboards, you need one of the following:

- The **AdministratorAccess** policy.
• The **CloudWatchFullAccess** policy.
• A custom policy that includes one or more of these specific permissions:
  • `cloudwatch:GetDashboard` and `cloudwatch:ListDashboards` to be able to view dashboards
  • `cloudwatch:PutDashboard` to be able to create or modify dashboards
  • `cloudwatch:DeleteDashboards` to be able to delete dashboards

For more information for changing permissions for an IAM user using policies, see [Changing Permissions for an IAM User](#).

For more information about CloudWatch permissions, see [Amazon CloudWatch Permissions Reference](#) (p. 300).

For more information about dashboard API operations, see [PutDashboard](#) in the Amazon CloudWatch API Reference.

---

### Overview of Managing Access Permissions to Your CloudWatch Resources

Every AWS resource is owned by an AWS account, and permissions to create or access a resource are governed by permissions policies. An account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles), and some services (such as AWS Lambda) also support attaching permissions policies to resources.

**Note**

An **account administrator** (or administrator IAM user) is a user with administrator privileges. For more information, see [IAM Best Practices](#) in the [IAM User Guide](#).

When granting permissions, you decide who is getting the permissions, the resources they get permissions for, and the specific actions that you want to allow on those resources.

**Topics**

• [CloudWatch Resources and Operations](#) (p. 284)
• [Understanding Resource Ownership](#) (p. 285)
• [Managing Access to Resources](#) (p. 285)
• [Specifying Policy Elements: Actions, Effects, and Principals](#) (p. 286)
• [Specifying Conditions in a Policy](#) (p. 287)

### CloudWatch Resources and Operations

You can restrict access to specific alarms and dashboards by using their Amazon Resource Names (ARNs) in your policies. For more information, see [Actions, Resources, and Condition Keys for Amazon CloudWatch](#) in the [IAM User Guide](#).

You use an `*` (asterisk) as the resource when writing a policy to control access to CloudWatch actions. For example:

```json
{
  "Version": "2012-10-17",
  "Statement":[
    {
      "Effect":"Allow",
      "Action": ["cloudwatch:GetMetricStatistics","cloudwatch:ListMetrics"]
    }
  ]
}
```
Understanding Resource Ownership

The AWS account owns the resources that are created in the account, regardless of who created the resources. Specifically, the resource owner is the AWS account of the principal entity (that is, the AWS account root user, an IAM user, or an IAM role) that authenticates the resource creation request. CloudWatch does not have any resources that you can own.

Managing Access to Resources

A permissions policy describes who has access to what. The following section explains the available options for creating permissions policies.

Note
This section discusses using IAM in the context of CloudWatch. It doesn't provide detailed information about the IAM service. For complete IAM documentation, see What Is IAM? in the IAM User Guide. For information about IAM policy syntax and descriptions, see IAM Policy Reference in the IAM User Guide.

Policies attached to an IAM identity are referred to as identity-based policies (IAM policies) and policies attached to a resource are referred to as resource-based policies. CloudWatch supports only identity-based policies.
Identity-Based Policies (IAM Policies)

You can attach policies to IAM identities. For example, you can do the following:

- **Attach a permissions policy to a user or a group in your account** – To grant a user permissions to create an Amazon CloudWatch resource, such as metrics, you can attach a permissions policy to a user or group that the user belongs to.

- **Attach a permissions policy to a role (grant cross-account permissions)** – You can attach an identity-based permissions policy to an IAM role to grant cross-account permissions. For example, the administrator in account A can create a role to grant cross-account permissions to another AWS account (for example, account B) or an AWS service as follows:
  1. Account A administrator creates an IAM role and attaches a permissions policy to the role that grants permissions on resources in account A.
  2. Account A administrator attaches a trust policy to the role identifying account B as the principal who can assume the role.
  3. Account B administrator can then delegate permissions to assume the role to any users in account B. Doing this allows users in account B to create or access resources in account A. The principal in the trust policy can also be an AWS service principal if you want to grant an AWS service permissions to assume the role.

For more information about using IAM to delegate permissions, see Access Management in the IAM User Guide.

For more information about using identity-based policies with CloudWatch, see Using Identity-Based Policies (IAM Policies) for CloudWatch (p. 287). For more information about users, groups, roles, and permissions, see Identities (Users, Groups, and Roles) in the IAM User Guide.

Resource-Based Policies (IAM Policies)

Other services, such as Amazon S3, also support resource-based permissions policies. For example, you can attach a policy to an Amazon S3 bucket to manage access permissions to that bucket. CloudWatch doesn’t support resource-based policies.

Specifying Policy Elements: Actions, Effects, and Principals

For each CloudWatch resource, the service defines a set of API operations. To grant permissions for these API operations, CloudWatch defines a set of actions that you can specify in a policy. Some API operations can require permissions for more than one action in order to perform the API operation. For more information about resources and API operations, see CloudWatch Resources and Operations (p. 284) and CloudWatch Actions.

The following are the basic policy elements:

- **Resource** – Use an Amazon Resource Name (ARN) to identify the resource that the policy applies to. CloudWatch does not have any resources for you to control using policies resources, so use the wildcard character (*) in IAM policies. For more information, see CloudWatch Resources and Operations (p. 284).
• **Action** – Use action keywords to identify resource operations that you want to allow or deny. For example, the `cloudwatch:ListMetrics` permission allows the user permissions to perform the `ListMetrics` operation.

• **Effect** – You specify the effect, either allow or deny, when the user requests the specific action. If you don't explicitly grant access to (allow) a resource, access is implicitly denied. You can also explicitly deny access to a resource, which you might do to make sure that a user cannot access it, even if a different policy grants access.

• **Principal** – In identity-based policies (IAM policies), the user that the policy is attached to is the implicit principal. For resource-based policies, you specify the user, account, service, or other entity that you want to receive permissions (applies to resource-based policies only). CloudWatch doesn't support resource-based policies.

To learn more about IAM policy syntax and descriptions, see [AWS IAM JSON Policy Reference](https://docs.aws.amazon.com/IAM/latest/userguide/) in the IAM User Guide.

For a table showing all of the CloudWatch API actions and the resources that they apply to, see [Amazon CloudWatch Permissions Reference](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/CloudWatch-Permissions-Reference.html) (p. 300).

### Specifying Conditions in a Policy

When you grant permissions, you can use the access policy language to specify the conditions when a policy should take effect. For example, you might want a policy to be applied only after a specific date. For more information about specifying conditions in a policy language, see [Condition](https://docs.aws.amazon.com/IAM/latest/userguide/) in the IAM User Guide.

To express conditions, you use predefined condition keys. For a list of context keys supported by each AWS service and a list of AWS-wide policy keys, see [AWS Service Actions and Condition Context Keys](https://docs.aws.amazon.com/IAM/latest/userguide/) and [Global and IAM Condition Context Keys](https://docs.aws.amazon.com/IAM/latest/userguide/) in the IAM User Guide.

### Using Identity-Based Policies (IAM Policies) for CloudWatch

This topic provides examples of identity-based policies that demonstrate how an account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on CloudWatch resources.

**Important**

We recommend that you first review the introductory topics that explain the basic concepts and options available to manage access to your CloudWatch resources. For more information, see [Access Control](https://docs.aws.amazon.com/IAM/latest/userguide/).  

The sections in this topic cover the following:

- **Permissions Required to Use the CloudWatch Console** (p. 288)
- **AWS Managed (Predefined) Policies for CloudWatch** (p. 290)
- **Customer Managed Policy Examples** (p. 291)

The following shows an example of a permissions policy.

```json
{
  "Version": "2012-10-17",
```
This sample policy has one statement that grants permissions to a group for two CloudWatch actions (cloudwatch:GetMetricStatistics data, and cloudwatch:ListMetrics), but only if the group uses SSL with the request ("aws:SecureTransport":"true"). For more information about the elements within an IAM policy statement, see Specifying Policy Elements: Actions, Effects, and Principals (p. 286) and IAM Policy Elements Reference in IAM User Guide.

Permissions Required to Use the CloudWatch Console

For a user to work with the CloudWatch console, that user must have a minimum set of permissions that allow the user to describe other AWS resources in their AWS account. The CloudWatch console requires permissions from the following services:

- Amazon EC2 Auto Scaling
- CloudTrail
- CloudWatch
- CloudWatch Events
- CloudWatch Logs
- Amazon EC2
- Amazon ES
- IAM
- Kinesis
- Lambda
- Amazon S3
- Amazon SNS
- Amazon SQS
- Amazon SWF

If you create an IAM policy that is more restrictive than the minimum required permissions, the console won’t function as intended for users with that IAM policy. To ensure that those users can still use the CloudWatch console, also attach the CloudWatchReadOnlyAccess managed policy to the user, as described in AWS Managed (Predefined) Policies for CloudWatch (p. 290).

You don’t need to allow minimum console permissions for users that are making calls only to the AWS CLI or the CloudWatch API.

The full set of permissions required to work with the CloudWatch console are listed below:

- application-autoscaling:DescribeScalingPolicies
- autoscaling:DescribeAutoScalingGroups
- autoscaling:DescribePolicies
• cloudtrail:DescribeTrails
• cloudwatch:DeleteAlarms
• cloudwatch:DescribeAlarmHistory
• cloudwatch:DescribeAlarms
• cloudwatch:GetMetricData
• cloudwatch:GetMetricStatistics
• cloudwatch:ListMetrics
• cloudwatch:PutMetricAlarm
• cloudwatch:PutMetricData
• ec2:DescribeInstances
• ec2:DescribeTags
• ec2:DescribeVolumes
• es:DescribeElasticsearchDomain
• es:ListDomainNames
• events:DeleteRule
• events:DescribeRule
• events:DisableRule
• events:EnableRule
• events:ListRules
• events:PutRule
• iam:AttachRolePolicy
• iam:CreateRole
• iam:GetPolicy
• iam:GetPolicyVersion
• iam:GetRole
• iam:ListAttachedRolePolicies
• iam:ListRoles
• kinesis:DescribeStream
• kinesis:ListStreams
• lambda:AddPermission
• lambda:CreateFunction
• lambda:GetFunctionConfiguration
• lambda:ListAliases
• lambda:ListFunctions
• lambda:ListVersionsByFunction
• lambda:RemovePermission
• logs:CancelExportTask
• logs:CreateExportTask
• logs:CreateLogGroup
• logs:CreateLogStream
• logs:DeleteLogGroup
• logs:DeleteLogStream
AWS Managed (Predefined) Policies for CloudWatch

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases so that you can avoid having to investigate what permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

The following AWS managed policies, which you can attach to users in your account, are specific to CloudWatch:

- **CloudWatchFullAccess** – Grants full access to CloudWatch.
Customer Managed Policy Examples

In this section, you can find example user policies that grant permissions for various CloudWatch actions. These policies work when you are using the CloudWatch API, AWS SDKs, or the AWS CLI.

Examples

- Example 1: Allow User Full Access to CloudWatch (p. 291)
- Example 2: Allow Read-Only Access to CloudWatch (p. 291)
- Example 3: Stop or Terminate an Amazon EC2 Instance (p. 292)

Example 1: Allow User Full Access to CloudWatch

The following policy allows a user to access all CloudWatch actions, CloudWatch Logs actions, Amazon SNS actions, and read-only access to Amazon EC2 Auto Scaling.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": [
            "autoscaling:Describe*",
            "cloudwatch:*",
            "logs:*",
            "sns:*"
         ],
         "Effect": "Allow",
         "Resource": "*"
      }
   ]
}
```

Example 2: Allow Read-Only Access to CloudWatch

The following policy allows a user read-only access to CloudWatch and view Amazon EC2 Auto Scaling actions, CloudWatch metrics, CloudWatch Logs data, and alarm-related Amazon SNS data.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": [
            "autoscaling:Describe*",
            "cloudwatch:Get*",
            "logs:Get*",
            "sns:Get*"
         ],
         "Effect": "Allow",
         "Resource": "*"
      }
   ]
}
```
Using Service-Linked Roles for CloudWatch Alarms

Amazon CloudWatch uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch. Service-linked roles are predefined by CloudWatch and include all the permissions that the service requires to call other AWS services on your behalf.
The service-linked role in CloudWatch makes setting up CloudWatch alarms that can terminate, stop, or reboot Amazon EC2 instance easier because you don’t have to manually add the necessary permissions. CloudWatch defines the permissions of the service-linked role, and unless defined otherwise, only CloudWatch can assume the role. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your CloudWatch resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-Linked Role Permissions for CloudWatch Alarms

CloudWatch uses the service-linked role named AWSServiceRoleForCloudWatchEvents – CloudWatch uses this service-linked role to perform Amazon EC2 alarm actions.

The AWSServiceRoleForCloudWatchEvents service-linked role trusts the CloudWatch Events service to assume the role. CloudWatch Events invokes the terminate, stop, or reboot instance actions when called upon by the alarm.

The AWSServiceRoleForCloudWatchEvents service-linked role permissions policy allows CloudWatch Events to complete the following actions on Amazon EC2 instances:

- ec2:StopInstances
- ec2:TerminateInstances
- ec2:RecoverInstances
- ec2:DescribeInstanceRecoveryAttribute
- ec2:DescribeInstances
- ec2:DescribeInstanceStatus

Creating a Service-Linked Role for CloudWatch Alarms

You do not need to manually create a service-linked role. The first time you create an alarm in the AWS Management Console, the IAM CLI, or the IAM API, CloudWatch creates the service-linked role for you.

Important
This service-linked role can appear in your account if you completed an action in another service that uses the features supported by this role. Also, if you were using the CloudWatch service before January 1, 2017, when it began supporting service-linked roles, then CloudWatch created the AWSServiceRoleForCloudWatchEvents role in your account. To learn more, see A New Role Appeared in My IAM Account.

For more information, see Creating a Service-Linked Role in the IAM User Guide.

Editing a Service-Linked Role for CloudWatch Alarms

CloudWatch does not allow you to edit the AWSServiceRoleForCloudWatchEvents role. After you create the role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the AWSServiceRoleForCloudWatchEvents role using IAM.
Editing a Service-Linked Role Description (IAM Console)

You can use the IAM console to edit the description of a service-linked role.

To edit the description of a service-linked role (console)

1. In the navigation pane of the IAM console, choose Roles.
2. Choose the name of the role to modify.
3. To the far right of Role description, choose Edit.
4. Type a new description in the box and choose Save.

Editing a Service-Linked Role Description (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to edit the description of a service-linked role.

To change the description of a service-linked role (AWS CLI)

1. (Optional) To view the current description for a role, use the following commands:

   ```bash
   $ aws iam get-role --role-name role-name
   ```

   Use the role name, not the ARN, to refer to roles with the AWS CLI commands. For example, if a role has the following ARN: `arn:aws:iam::123456789012:role/myrole`, you refer to the role as `myrole`.

2. To update a service-linked role's description, use the following command:

   ```bash
   $ aws iam update-role-description --role-name role-name --description description
   ```

Editing a Service-Linked Role Description (IAM API)

You can use the IAM API to edit the description of a service-linked role.

To change the description of a service-linked role (API)

1. (Optional) To view the current description for a role, use the following command:

   ```bash
   GetRole
   ```

2. To update a role's description, use the following command:

   ```bash
   UpdateRoleDescription
   ```

Deleting a Service-Linked Role for CloudWatch Alarms

If you no longer have alarms that automatically stop, terminate, or reboot EC2 instances, we recommend that you delete the AWSServiceRoleForCloudWatchEvents role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can delete it.
Cleaning Up a Service-Linked Role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles. Choose the name (not the check box) of the AWSServiceRoleForCloudWatchEvents role.
3. On the Summary page for the selected role, choose Access Advisor and review the recent activity for the service-linked role.

   Note
   If you are unsure whether CloudWatch is using the AWSServiceRoleForCloudWatchEvents role, try to delete the role. If the service is using the role, then the deletion fails and you can view the regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

Deleting a Service-Linked Role (IAM Console)

You can use the IAM console to delete a service-linked role.

To delete a service-linked role (console)

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles. Select the check box next to AWSServiceRoleForCloudWatchEvents, not the name or row itself.
3. For Role actions, choose Delete role.
4. In the confirmation dialog box, review the service last accessed data, which shows when each of the selected roles last accessed an AWS service. This helps you to confirm whether the role is currently active. To proceed, choose Yes, Delete.
5. Watch the IAM console notifications to monitor the progress of the service-linked role deletion. Because the IAM service-linked role deletion is asynchronous, the deletion task can succeed or fail after you submit the role for deletion. If the task fails, choose View details or View Resources from the notifications to learn why the deletion failed. If the deletion fails because there are resources in the service that are being used by the role, then the reason for the failure includes a list of resources.

Deleting a Service-Linked Role (AWS CLI)

You can use IAM commands from the AWS Command Line Interface to delete a service-linked role.

To delete a service-linked role (AWS CLI)

1. Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the deletion-task-id from the response to check the status of the deletion task. Type the following command to submit a service-linked role deletion request:

   ```
   $ aws iam delete-service-linked-role --role-name AWSServiceRoleForCloudWatchEvents
   ```

2. Type the following command to check the status of the deletion task:
Deleting a Service-Linked Role (IAM API)

You can use the IAM API to delete a service-linked role.

**To delete a service-linked role (API)**

1. To submit a deletion request for a service-linked role, call `DeleteServiceLinkedRole`. In the request, specify the `AWSServiceRoleForCloudWatchEvents` role name.

   Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `DeletionTaskId` from the response to check the status of the deletion task.

2. To check the status of the deletion, call `GetServiceLinkedRoleDeletionStatus`. In the request, specify the `DeletionTaskId`.

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Using Service-Linked Roles for CloudWatch Application Insights for .NET and SQL Server

CloudWatch Application Insights uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch Application Insights for .NET and SQL Server. Service-linked roles are predefined by CloudWatch Application Insights for .NET and SQL Server and include all of the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up CloudWatch Application Insights for .NET and SQL Server easier because you don't have to manually add the necessary permissions. CloudWatch Application Insights for .NET and SQL Server defines the permissions of its service-linked roles, and unless defined otherwise, only CloudWatch Application Insights for .NET and SQL Server can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes link to view the service-linked role documentation for that service.

Service-Linked Role Permissions for CloudWatch Application Insights for .NET and SQL Server

CloudWatch Application Insights for .NET and SQL Server uses the service-linked role named ApplicationInsights-role. Application Insights uses this role to perform operations such as analyzing the Resource Groups of the customer, creating CloudFormation stacks to create alarms on metrics, and configuring the CloudWatch Agent on EC2 instances.

```bash
$ aws iam get-service-linked-role-deletion-status --deletion-task-id deletion-task-id
```

The status of the deletion task can be **NOT_STARTED**, **IN_PROGRESS**, **SUCCEEDED**, or **FAILED**. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.
The role permissions policy allows CloudWatch Application Insights for .NET and SQL Server to complete the following actions on all resources:

- cloudwatch:DescribeAlarmHistory
- cloudwatch:DescribeAlarms
- cloudwatch:GetMetricData
- cloudwatch:ListMetrics
- cloudwatch:PutMetricAlarm
- cloudwatch:DeleteAlarms
- logs:GetLogEvents
- logs:DescribeLogStreams
- logs:DescribeLogGroup
- events:DescribeRule
- tag:GetResources
- resource-groups:ListGroupResources
- resource-groups:GetGroupQuery
- elasticloadbalancing:DescribeLoadBalancers
- elasticloadbalancing:DescribeTargetGroups
- elasticloadbalancing:DescribeTargetHealth
- Autoscaling:DescribeAutoScalingGroups
- cloudFormation:DescribeStacks
- cloudFormation:ListStackResources
- ssm:GetOpsItem
- ssm:CreateOpsItem
- ssm:DescribeOpsItems
- ssm:UpdateOpsItem
- ssm:DescribeInstanceInformation
- ec2:DescribeInstances
- rds:DescribeDBInstances

The role permissions policy allows CloudWatch Application Insights for .NET and SQL Server to complete the following actions on specified resources. These policies are used to manage resources created by or related to CloudWatch Application Insights for .NET and SQL Server in your account.

```json
{
  "Effect": "Allow",
  "Action": [
    "cloudFormation:CreateStack",
    "cloudFormation:UpdateStack",
    "cloudFormation:DeleteStack"
  ],
  "Resource": [
    "arn:aws:cloudformation:*:*:stack/ApplicationInsights-*"
  ]
},
{
  "Effect": "Allow",
  "Action": [
    "ssm:PutParameter",
    "ssm:GetParameter",
    "ssm:DescribeParameters"
  ],
  "Resource": [
    "arn:aws:ssm:*:*:parameter/ApplicationInsights-*"
  ]
}
```
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

Creating a Service-Linked Role for CloudWatch Application Insights for .NET and SQL Server

You don't need to manually create a service-linked role. When you create a new Application Insights application in the AWS Management Console, CloudWatch Application Insights for .NET and SQL Server creates the service-linked role for you.

If you delete this service-linked role, and then want to create it again, you can use the same process to recreate the role in your account. When you create a new Application Insights application, CloudWatch Application Insights for .NET and SQL Server creates the service-linked role for you again.

Editing a Service-Linked Role for CloudWatch Application Insights for .NET and SQL Server

CloudWatch Application Insights for .NET and SQL Server does not allow you to edit the ApplicationInsights-role service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

Deleting a Service-Linked Role for CloudWatch Application Insights for .NET and SQL Server

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you avoid having an unused entity that is not actively monitored or
maintained. However, you must delete all applications in Application Insights before you can manually delete the role.

**Note**
If the CloudWatch Application Insights for .NET and SQL Server service is using the role when you try to delete the resources, the deletion might fail. If that happens, wait for a few minutes and try the operation again.

**To delete CloudWatch Application Insights for .NET and SQL Server resources used by the ApplicationInsights-role**

- Delete all of your CloudWatch Application Insights for .NET and SQL Server applications. For more information, see "Deleting Your Application(s)" in the CloudWatch Application Insights for .NET and SQL Server User Guide.

**To manually delete the service-linked role using IAM**

Use the IAM console, the AWS CLI, or the AWS API to delete the ApplicationInsights-role service-linked role. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

### Supported Regions for CloudWatch Application Insights for .NET and SQL Server Service-Linked Roles

CloudWatch Application Insights for .NET and SQL Server supports using service-linked roles in all of the AWS Regions where the service is available.

<table>
<thead>

Amazon CloudWatch Permissions Reference

When you are setting up Access Control (p. 283) and writing permissions policies that you can attach to an IAM identity (identity-based policies), you can use the following table as a reference. The table lists each CloudWatch API operation and the corresponding actions for which you can grant permissions to perform the action. You specify the actions in the policy's Action field, and you specify a wildcard character (*) as the resource value in the policy's Resource field.

You can use AWS-wide condition keys in your CloudWatch policies to express conditions. For a complete list of AWS-wide keys, see AWS Global and IAM Condition Context Keys in the IAM User Guide.

**Note**
To specify an action, use the `cloudwatch:` prefix followed by the API operation name. For example: `cloudwatch:GetMetricStatistics`, `cloudwatch:ListMetrics`, or `cloudwatch:*` (for all CloudWatch actions).

**Tables**
- CloudWatch API Operations and Required Permissions
- CloudWatch Events API Operations and Required Permissions
- CloudWatch Logs API Operations and Required Permissions
- Amazon EC2 API Operations and Required Permissions
- Amazon EC2 Auto Scaling API Operations and Required Permissions

Logging Amazon CloudWatch API Calls with AWS CloudTrail

Amazon CloudWatch is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in CloudWatch. CloudTrail captures API calls made by or on behalf of your AWS account. The calls captured include calls from the CloudWatch console and code calls to the CloudWatch API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for CloudWatch. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to CloudWatch, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, including how to configure and enable it, see the AWS CloudTrail User Guide.

Topics
- CloudWatch Information in CloudTrail (p. 306)
- Example: CloudWatch Log File Entries (p. 307)

CloudWatch Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in CloudWatch, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for CloudWatch, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

CloudWatch supports logging the following actions as events in CloudTrail log files:

- DeleteAlarms
- DeleteDashboards
- DescribeAlarmHistory
- DescribeAlarms
- DescribeAlarmsForMetric
- DisableAlarmActions
Additionally, you can log the following AWS SDK Metrics actions in CloudTrail log files. These actions are used only by SDK Metrics and are not available for use in your code. For more information, see Monitor Applications Using AWS SDK Metrics (p. 266).

- **GetPublishingConfiguration** – Used by SDK Metrics to determine how to publish metrics.
- **GetPublishingSchema** – Used by SDK Metrics to determine how to publish metrics.
- **PutPublishingMetrics** – Used by SDK Metrics to send CloudWatch Agent health metrics to AWS Support.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail `userIdentity` Element.

## Example: CloudWatch Log File Entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the **PutMetricAlarm** action.

```json
{
    "Records": [{
        "eventVersion": "1.01",
        "userIdentity": {
            "type": "Root",
            "principalId": "EX_PRINCIPAL_ID",
            "arn": "arn:aws:iam::123456789012:root",
            "accountId": "123456789012",
            "accessKeyId": "EXAMPLE_KEY_ID"
        },
        "eventTime": "2014-03-23T21:50:34Z",
        "eventSource": "monitoring.amazonaws.com",
        "eventName": "PutMetricAlarm",

# CloudWatch Limits

CloudWatch has the following limits:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Actions</td>
<td>5/alarm. This limit cannot be changed.</td>
</tr>
<tr>
<td>Alarms</td>
<td>10/month/customer for free. 5000 per region per account. Alarms based on metric math expressions can have up to 10 metrics.</td>
</tr>
<tr>
<td>API requests</td>
<td>1,000,000/month/customer for free.</td>
</tr>
<tr>
<td>Custom metrics</td>
<td>No limit.</td>
</tr>
</tbody>
</table>
| Dashboards                   | Up to 100 metrics per dashboard widget. Up to 500 metrics per dashboard, across all widgets.  
These limits includes all metrics retrieved for use in metric math functions, even if those metrics are not displayed on the graph.  
These limits cannot be changed. |
| DescribeAlarms               | 9 transactions per second (TPS). The maximum number of operation requests you can make per second without being throttled.  
You can request a limit increase. |
| DeleteAlarms request         | 3 transactions per second (TPS) for each of these operations. The maximum number of operation requests you can make per second without being throttled.  
These limits cannot be changed. |
| DescribeAlarmHistory request |                                                                 |
| DescribeAlarmsForMetric request |                                                                 |
| DisableAlarmActions request  |                                                                 |
| EnableAlarmActions request   |                                                                 |
| SetAlarmState request        |                                                                 |
| DeleteDashboards request     | 10 transactions per second (TPS) for each of these operations. The maximum number of operation requests you can make per second without being throttled.  
These limits cannot be changed. |
<p>| GetDashboard request         |                                                                 |
| ListDashboards request       |                                                                 |
| PutDashboard request         |                                                                 |
| Dimensions                  | 10/metric. This limit cannot be changed.                                      |
| GetMetricData                | 50 transactions per second (TPS). The maximum number of operation requests you can make per second without being throttled. You can request a limit increase. |</p>
<table>
<thead>
<tr>
<th>Resource</th>
<th>Default Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>180,000 Datapoints Per Second (DPS) if the <code>StartTime</code> used in the API request is less than or equal to three hours from current time. 90,000 DPS if the <code>StartTime</code> is more than three hours from current time. This is the maximum number of datapoints you can request per second using one or more API calls without being throttled. This limit cannot be changed.</td>
</tr>
<tr>
<td>GetMetricData</td>
<td>A single <code>GetMetricData</code> call can include as many as 100 <code>MetricDataQuery</code> structures. This limit cannot be changed.</td>
</tr>
<tr>
<td>GetMetricStatistics</td>
<td>400 transactions per second (TPS). The maximum number of operation requests you can make per second without being throttled. You can request a limit increase.</td>
</tr>
<tr>
<td>ListMetrics</td>
<td>25 transactions per second (TPS). The maximum number of operation requests you can make per second without being throttled. You can request a limit increase.</td>
</tr>
<tr>
<td>Metric data</td>
<td>15 months. This limit cannot be changed.</td>
</tr>
<tr>
<td>MetricDatum items</td>
<td>20/PutMetricData request. A MetricDatum object can contain a single value or a StatisticSet object representing many values. This limit cannot be changed.</td>
</tr>
<tr>

</tr>
<tr>
<td>Period</td>
<td>Maximum value is one day (86,400 seconds). This limit cannot be changed.</td>
</tr>
<tr>
<td>PutMetricAlarm request</td>
<td>3 transactions per second (TPS). The maximum number of operation requests you can make per second without being throttled. You can request a limit increase.</td>
</tr>
<tr>
<td>PutMetricData request</td>
<td>40 KB for HTTP POST requests. PutMetricData can handle 150 transactions per second (TPS), which is the maximum number of operation requests you can make per second without being throttled. You can request a limit increase.</td>
</tr>
<tr>
<td>Amazon SNS email notifications</td>
<td>1,000/month/customer for free.</td>
</tr>
</tbody>
</table>
## Document History

The following table describes important changes in each release of the *Amazon CloudWatch User Guide*, beginning in June 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

<table>
<thead>
<tr>
<th>update-history-change</th>
<th>update-history-description</th>
<th>update-history-date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Container Insights (p. 312)</td>
<td>CloudWatch Container Insights is now generally available. It enables you to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. For more information, see Using Container Insights in the Amazon CloudWatch User Guide.</td>
<td>August 30, 2019</td>
</tr>
<tr>
<td>Updates for Container Insights preview metrics on Amazon EKS and Kubernetes (p. 312)</td>
<td>The Container Insights on Amazon EKS and Kubernetes public preview has been updated. Instanceld is now included as a dimension to the cluster EC2 instances. This allows alarms that have been created on these metrics to trigger the following EC2 actions: Stop, Terminate, Reboot, or Recover. Additionally, pod and service metrics are now reported by Kubernetes namespace to simplify the monitoring and alarming on metrics by namespace.</td>
<td>August 19, 2019</td>
</tr>
<tr>
<td>Updates for AWS Systems Manager OpsCenter integration (p. 312)</td>
<td>Updates on how CloudWatch Application Insights integrates with Systems Manager OpsCenter.</td>
<td>August 7, 2019</td>
</tr>
<tr>
<td>CloudWatch usage metrics (p. 312)</td>
<td>CloudWatch usage metrics help you track the usage of your CloudWatch resources and stay within your service limits. For more information, see <a href="https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/CloudWatch-Usage-Metrics.html">https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/CloudWatch-Usage-Metrics.html</a>.</td>
<td>August 6, 2019</td>
</tr>
<tr>
<td>CloudWatch Container Insights public preview (p. 312)</td>
<td>CloudWatch Container Insights is now in public preview. It enables you to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices.</td>
<td>July 9, 2019</td>
</tr>
</tbody>
</table>
CloudWatch Anomaly Detection public preview (p. 312)

CloudWatch anomaly detection is now in public preview. CloudWatch applies machine-learning algorithms to a metric's past data to create a model of the metric's expected values. You can use this model for visualization and for setting alarms. For more information, see .

July 9, 2019

CloudWatch Application Insights for .NET and SQL Server (p. 312)

CloudWatch Application Insights for .NET and SQL Server facilitates observability for .NET and SQL Server applications. It can help you set up the best monitors for your application resources to continuously analyze data for signs of problems with your applications.

June 21, 2019

CloudWatch agent section re-organized (p. 312)

The CloudWatch agent documentation has been rewritten to improve clarity, especially for customers using the command line to install and configure the agent. For more information, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the Amazon CloudWatch User Guide.

March 28, 2019

SEARCH function added to metric math expressions (p. 312)

You can now use a SEARCH function in metric math expressions. This enables you to create dashboards that update automatically as new resources are created that match the search query. For more information, see Using Search Expressions in Graphs in the Amazon CloudWatch User Guide.

March 21, 2019

AWS SDK Metrics for Enterprise Support (p. 312)

SDK Metrics helps you assess the health of your AWS services and diagnose latency caused by reaching your account usage limits or by a service outage. For more information, see Monitor Applications Using AWS SDK Metrics in the Amazon CloudWatch User Guide.

December 11, 2018
<table>
<thead>
<tr>
<th>Change</th>

<th>Release Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alarms on math expressions (p. 312)</td>
<td>CloudWatch supports creating alarms based on metric math expressions. For more information, see Alarms on Math Expressions in the Amazon CloudWatch User Guide.</td>
<td>November 20, 2018</td>
</tr>
<tr>
<td>New CloudWatch console home page (p. 312)</td>
<td>Amazon has created a new home page in the CloudWatch console, which automatically displays key metrics and alarms for all the AWS services you are using. For more information, see Getting Started with Amazon CloudWatch in the Amazon CloudWatch User Guide.</td>
<td>November 19, 2018</td>
</tr>
<tr>
<td>AWS CloudFormation templates for the CloudWatch Agent (p. 312)</td>
<td>Amazon has uploaded AWS CloudFormation templates that you can use to install and update the CloudWatch agent. For more information, see Install the CloudWatch Agent on New Instances Using AWS CloudFormation in the Amazon CloudWatch User Guide.</td>
<td>November 9, 2018</td>
</tr>
<tr>
<td>Enhancements to the CloudWatch Agent (p. 312)</td>
<td>The CloudWatch agent has been updated to work with both the StatsD and collectd protocols. It also has improved cross-account support. For more information, see Retrieve Custom Metrics with StatsD, Retrieve Custom Metrics with collectd, and Sending Metrics and Logs to a Different AWS Account in the Amazon CloudWatch User Guide.</td>
<td>September 28, 2018</td>
</tr>
<tr>
<td>Support for Amazon VPC endpoints (p. 312)</td>
<td>You can now establish a private connection between your VPC and CloudWatch. For more information, see Using CloudWatch with Interface VPC Endpoints in the Amazon CloudWatch User Guide.</td>
<td>June 28, 2018</td>
</tr>
</tbody>
</table>

The following table describes important changes to the *Amazon CloudWatch User Guide* before June 2018.

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Release Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metric math</td>
<td>You can now perform math expressions on CloudWatch metrics, producing new time series that you can add to graphs on your dashboard. For more information, see Using Metric Math (p. 47).</td>
<td>April 4, 2018</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Release Date</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>&quot;M out of N&quot; alarms</td>
<td>You can now configure an alarm to trigger based on &quot;M out of N&quot; datapoints in any alarm evaluation interval. For more information, see Evaluating an Alarm (p. 62).</td>
<td>December 8, 2017</td>
</tr>
<tr>
<td>CloudWatch agent</td>
<td>A new unified CloudWatch agent was released. You can use the unified multi-platform agent to collect custom both system metrics and log files from Amazon EC2 instances and on-premises servers. The new agent supports both Windows and Linux and enables customization of metrics collected, including sub-resource metrics such as per-CPU core. For more information, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent (p. 141).</td>
<td>September 7, 2017</td>
</tr>
<tr>
<td>NAT gateway metrics</td>
<td>Added metrics for Amazon VPC NAT gateway.</td>
<td>September 7, 2017</td>
</tr>
<tr>
<td>High-resolution metrics</td>
<td>You can now optionally set up custom metrics as high-resolution metrics, with a granularity of as low as one second. For more information, see High-Resolution Metrics (p. 45).</td>
<td>July 26, 2017</td>
</tr>
<tr>
<td>Dashboard APIs</td>
<td>You can now create, modify, and delete dashboards using APIs and the AWS CLI. For more information, see Creating a CloudWatch Dashboard (p. 16).</td>
<td>July 6, 2017</td>
</tr>
<tr>
<td>AWS Direct Connect metrics</td>
<td>Added metrics for AWS Direct Connect.</td>
<td>June 29, 2017</td>
</tr>
<tr>
<td>Amazon VPC VPN metrics</td>
<td>Added metrics for Amazon VPC VPN.</td>
<td>May 15, 2017</td>
</tr>
<tr>
<td>AppStream 2.0 metrics</td>
<td>Added metrics for AppStream 2.0.</td>
<td>March 8, 2017</td>
</tr>
<tr>
<td>CloudWatch console color picker</td>
<td>You can now choose the color for each metric on your dashboard widgets. For more information, see Edit a Graph on a CloudWatch Dashboard (p. 19).</td>
<td>February 27, 2017</td>
</tr>
<tr>
<td>Alarms on dashboards</td>
<td>Alarms can now be added to dashboards. For more information, see Add or Remove an Alarm from a CloudWatch Dashboard (p. 23).</td>
<td>February 15, 2017</td>
</tr>
<tr>
<td>Added metrics for Amazon Polly</td>
<td>Added metrics for Amazon Polly.</td>
<td>December 1, 2016</td>
</tr>
<tr>
<td>Added metrics for Amazon Kinesis Data Analytics</td>
<td>Added metrics for Amazon Kinesis Data Analytics.</td>
<td>December 1, 2016</td>
</tr>
<tr>
<td>Added support for percentile statistics</td>
<td>You can specify any percentile, using up to two decimal places (for example, p95.45). For more information, see Percentiles (p. 7).</td>
<td>November 17, 2016</td>
</tr>
<tr>
<td>Change</td>

</tr>
<tr>
<td>Added metrics for Amazon Simple Email Service</td>
<td>Added metrics for Amazon Simple Email Service.</td>
<td>November 2, 2016</td>
</tr>
<tr>
<td>Updated metrics retention</td>
<td>Amazon CloudWatch now retains metrics data for 15 months instead of 14 days.</td>
<td>November 1, 2016</td>
</tr>
<tr>
<td>Updated metrics console interface</td>
<td>The CloudWatch console is updated with improvements to existing functionality and new functionality.</td>
<td>November 1, 2016</td>
</tr>
<tr>
<td>Added metrics for Amazon Elastic Transcoder</td>
<td>Added metrics for Amazon Elastic Transcoder.</td>
<td>September 20, 2016</td>
</tr>
<tr>
<td>Added metrics for Amazon API Gateway</td>
<td>Added metrics for Amazon API Gateway.</td>
<td>September 9, 2016</td>
</tr>
<tr>
<td>Added metrics for AWS Key Management Service</td>
<td>Added metrics for AWS Key Management Service.</td>
<td>September 9, 2016</td>
</tr>
<tr>
<td>Added metrics for the new Application Load Balancers supported by Elastic Load Balancing</td>
<td>Added metrics for Application Load Balancers.</td>
<td>August 11, 2016</td>
</tr>
<tr>
<td>Added new metrics for Amazon EC2 Spot fleet</td>
<td>Added new metrics for Amazon EC2 Spot fleet.</td>
<td>March 21, 2016</td>
</tr>
<tr>
<td>Added new CloudWatch Logs metrics</td>
<td>Added new CloudWatch Logs metrics.</td>
<td>March 10, 2016</td>
</tr>
<tr>
<td>Added Amazon Elasticsearch Service and AWS WAF metrics and dimensions</td>
<td>Added Amazon Elasticsearch Service and AWS WAF metrics and dimensions.</td>
<td>October 14, 2015</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Release Date</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Added support for CloudWatch dashboards</td>
<td>Dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view, even those that are spread out across different regions. For more information, see Using Amazon CloudWatch Dashboards (p. 16).</td>
<td>October 8, 2015</td>
</tr>
<tr>
<td>Added AWS Lambda metrics and dimensions</td>
<td>Added AWS Lambda metrics and dimensions.</td>
<td>September 4, 2015</td>
</tr>
<tr>
<td>Added Amazon Elastic Container Service metrics and dimensions</td>
<td>Added Amazon Elastic Container Service metrics and dimensions.</td>
<td>August 17, 2015</td>
</tr>
<tr>
<td>Added Amazon Simple Storage Service metrics and dimensions</td>
<td>Added Amazon Simple Storage Service metrics and dimensions.</td>
<td>July 26, 2015</td>
</tr>
<tr>
<td>New feature: Reboot alarm action</td>
<td>Added the reboot alarm action and new IAM role for use with alarm actions. For more information, see Create Alarms to Stop, Terminate, Reboot, or Recover an Instance (p. 83).</td>
<td>July 23, 2015</td>
</tr>
<tr>
<td>Added Amazon WorkSpaces metrics and dimensions</td>
<td>Added Amazon WorkSpaces metrics and dimensions.</td>
<td>April 30, 2015</td>
</tr>
<tr>
<td>Added Amazon Machine Learning metrics and dimensions</td>
<td>Added Amazon Machine Learning metrics and dimensions.</td>
<td>April 9, 2015</td>
</tr>
<tr>
<td>New feature: Amazon EC2 instance recovery alarm actions</td>
<td>Updated alarm actions to include new EC2 instance recovery action. For more information, see Create Alarms to Stop, Terminate, Reboot, or Recover an Instance (p. 83).</td>
<td>March 12, 2015</td>
</tr>
<tr>
<td>Added Amazon CloudFront and Amazon CloudSearch metrics and dimensions</td>
<td>Added Amazon CloudFront and Amazon CloudSearch metrics and dimensions.</td>
<td>March 6, 2015</td>
</tr>
<tr>
<td>Added Amazon Simple Workflow Service metrics and dimensions</td>
<td>Added Amazon Simple Workflow Service metrics and dimensions.</td>
<td>May 9, 2014</td>
</tr>
<tr>
<td>Updated guide to add support for AWS CloudTrail</td>
<td>Added a new topic to explain how you can use AWS CloudTrail to log activity in Amazon CloudWatch. For more information, see Logging Amazon CloudWatch API Calls with AWS CloudTrail (p. 306).</td>
<td>April 30, 2014</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Release Date</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Updated guide to use the new AWS Command Line Interface (AWS CLI)</td>
<td>The AWS CLI is a cross-service CLI with a simplified installation, unified configuration, and consistent command line syntax. The AWS CLI is supported on Linux/Unix, Windows, and Mac. The CLI examples in this guide have been updated to use the new AWS CLI. For information about how to install and configure the new AWS CLI, see Getting Set Up with the AWS Command Line Interface in the AWS Command Line Interface User Guide.</td>
<td>February 21, 2014</td>
</tr>
<tr>
<td>Added Amazon Redshift and AWS OpsWorks metrics and dimensions</td>
<td>Added Amazon Redshift and AWS OpsWorks metrics and dimensions.</td>
<td>July 16, 2013</td>
</tr>
<tr>
<td>Added Amazon Route 53 metrics and dimensions</td>
<td>Added Amazon Route 53 metrics and dimensions.</td>
<td>June 26, 2013</td>
</tr>
<tr>
<td>New feature: Amazon CloudWatch Alarm Actions</td>
<td>Added a new section to document Amazon CloudWatch alarm actions, which you can use to stop or terminate an Amazon Elastic Compute Cloud instance. For more information, see Create Alarms to Stop, Terminate, Reboot, or Recover an Instance (p. 83).</td>
<td>January 8, 2013</td>
</tr>
<tr>
<td>Updated EBS metrics</td>
<td>Updated the EBS metrics to include two new metrics for Provisioned IOPS volumes.</td>
<td>November 20, 2012</td>
</tr>
<tr>
<td>New billing alerts</td>
<td>You can now monitor your AWS charges using Amazon CloudWatch metrics and create alarms to notify you when you have exceeded the specified threshold. For more information, see Creating a Billing Alarm to Monitor Your Estimated AWS Charges (p. 89).</td>
<td>May 10, 2012</td>
</tr>
<tr>
<td>New metrics</td>
<td>You can now access six new Elastic Load Balancing metrics that provide counts of various HTTP response codes.</td>
<td>October 19, 2011</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now access metrics from Amazon EMR.</td>
<td>June 30, 2011</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now access metrics from Amazon Simple Notification Service and Amazon Simple Queue Service.</td>
<td>July 14, 2011</td>
</tr>
<tr>
<td>New Feature</td>
<td>Added information about using the <code>PutMetricData</code> API to publish custom metrics. For more information, see Publishing Custom Metrics (p. 45).</td>
<td>May 10, 2011</td>
</tr>
<tr>
<td>Updated metrics retention</td>
<td>Amazon CloudWatch now retains the history of an alarm for two weeks rather than six weeks. With this change, the retention period for alarms matches the retention period for metrics data.</td>
<td>April 7, 2011</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Release Date</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Added ability to send Amazon Simple Notification Service or Auto Scaling notifications when a metric has crossed a threshold. For more information, see Alarms (p. 7).</td>
<td>December 2, 2010</td>
</tr>
<tr>
<td>New feature</td>
<td>A number of CloudWatch actions now include the MaxRecords and NextToken parameters, which enable you to control pages of results to display.</td>
<td>December 2, 2010</td>
</tr>
<tr>
<td>New feature</td>
<td>This service now integrates with AWS Identity and Access Management (IAM).</td>
<td>December 2, 2010</td>
</tr>
