Comparing Memcached and Redis

Amazon ElastiCache supports the Memcached and Redis cache engines. Each engine provides some advantages. Use the information in this topic to help you choose the engine and version that best meets your requirements.

**Important**
After you create a cache cluster or replication group, you can upgrade to a newer engine version, but you cannot downgrade to an older engine version. If you want to use an older engine version, you must delete the existing cache cluster or replication group and create it again with the earlier engine version.

On the surface, the engines look similar. Each of them is an in-memory key-value store. However, in practice there are significant differences.

**Choose Memcached if the following apply for you:**

- You need the simplest model possible.
- You need to run large nodes with multiple cores or threads.
- You need the ability to scale out and in, adding and removing nodes as demand on your system increases and decreases.
- You need to cache objects.

**Choose Redis with a version of ElastiCache for Redis if the following apply for you:**

- **ElastiCache for Redis version 6.2 (Enhanced)**
  You want the ability to tier data between memory and SSD using the r6gd node type. For more information, see [Data tiering](#).

- **ElastiCache for Redis version 6.0 (Enhanced)**
  You want to authenticate users with role-based access control.
  For more information, see [Redis Version 6.0 (Enhanced)](#).

- **ElastiCache for Redis version 5.0.0 (Enhanced)**
  You want to use Redis streams, a log data structure that allows producers to append new items in real time and also allows consumers to consume messages either in a blocking or non-blocking fashion.
  For more information, see [Redis Version 5.0.0 (Enhanced)](#).

- **ElastiCache for Redis version 4.0.10 (Enhanced)**
  Supports both encryption and dynamically adding or removing shards from your Redis (cluster mode enabled) cluster.
  For more information, see [Redis Version 4.0.10 (Enhanced)](#).

- **ElastiCache for Redis version 3.2.10 (Enhanced)**
  Supports the ability to dynamically add or remove shards from your Redis (cluster mode enabled) cluster.
  **Important**
  Currently ElastiCache for Redis 3.2.10 doesn't support encryption.
For more information, see the following:

- **Redis Version 3.2.10 (Enhanced)**
- Online rehashing best practices for Redis, For more information, see the following:
  - Best Practices: Online Resharding
  - Online Resharding and Shard Rebalancing for Redis (Cluster Mode Enabled)
- For more information on scaling Redis clusters, see Scaling.

- **ElastiCache for Redis version 3.2.6 (Enhanced)**

  If you need the functionality of earlier Redis versions plus the following features, choose ElastiCache for Redis 3.2.6:
  - In-transit encryption. For more information, see Amazon ElastiCache for Redis In-Transit Encryption.
  - At-rest encryption. For more information, see Amazon ElastiCache for Redis At-Rest Encryption.
  - HIPAA eligibility certification. For more information, see HIPAA Eligibility for Amazon ElastiCache for Redis.

- **ElastiCache for Redis (Cluster mode enabled) version 3.2.4**

  If you need the functionality of Redis 2.8.x plus the following features, choose Redis 3.2.4 (clustered mode):
  - You need to partition your data across two to 500 node groups (clustered mode only).
  - You need geospatial indexing (clustered mode or non-clustered mode).
  - You don’t need to support multiple databases.

- **ElastiCache for Redis (non-clustered mode) 2.8.x and 3.2.4 (Enhanced)**

  If the following apply for you, choose Redis 2.8.x or Redis 3.2.4 (non-clustered mode):
  - You need complex data types, such as strings, hashes, lists, sets, sorted sets, and bitmaps.
  - You need to sort or rank in-memory datasets.
  - You need persistence of your key store.
  - You need to replicate your data from the primary to one or more read replicas for read intensive applications.
  - You need automatic failover if your primary node fails.
  - You need publish and subscribe (pub/sub) capabilities—to inform clients about events on the server.
  - You need backup and restore capabilities.
  - You need to support multiple databases.
## Comparison summary of Memcached, Redis (cluster mode disabled), and Redis (cluster mode enabled)

After you choose the engine for your cluster, we recommend that you use the most recent version of that engine. For more information, see Supported ElastiCache for Memcached Versions or Supported ElastiCache for Redis Versions.
What is Amazon ElastiCache for Redis?

Welcome to the Amazon ElastiCache for Redis User Guide. Amazon ElastiCache is a web service that makes it easy to set up, manage, and scale a distributed in-memory data store or cache environment in the cloud. It provides a high-performance, scalable, and cost-effective caching solution. At the same time, it helps remove the complexity associated with deploying and managing a distributed cache environment.

Note
Amazon ElastiCache works with both the Redis and Memcached engines. Use the guide for the engine that you're interested in. If you're unsure which engine you want to use, see Comparing Memcached and Redis (p. 1) in this guide.

Overview of ElastiCache for Redis

Existing applications that use Redis can use ElastiCache with almost no modification. Your applications simply need information about the host names and port numbers of the ElastiCache nodes that you have deployed.

ElastiCache for Redis has multiple features that help make the service more reliable for critical production deployments:

- Automatic detection of and recovery from cache node failures.
- Multi-AZ for a failed primary cluster to a read replica, in Redis clusters that support replication.
- Redis (cluster mode enabled) supports partitioning your data across up to 500 shards.
- For Redis version 3.2 and later, all versions support encryption in transit and encryption at rest with authentication. This support helps you build HIPAA-compliant applications.
- Flexible Availability Zone placement of nodes and clusters for increased fault tolerance.
- Integration with other AWS services such as Amazon EC2, Amazon CloudWatch, AWS CloudTrail, and Amazon SNS. This integration helps provide a managed in-memory caching solution that is high-performance and highly secure.
- ElastiCache for Redis manages backups, software patching, automatic failure detection, and recovery.
- You can have automated backups performed when you need them, or manually create your own backup snapshot. You can use these backups to restore a cluster. The ElastiCache for Redis restore process works reliably and efficiently.
- You can get high availability with a primary instance and a synchronous secondary instance that you can fail over to when problems occur. You can also use read replicas to increase read scaling.
- You can control access to your ElastiCache for Redis clusters by using AWS Identity and Access Management to define users and permissions. You can also help protect your clusters by putting them in a virtual private cloud (VPC).
- By using the Global Datastore for Redis feature, you can work with fully managed, fast, reliable, and secure replication across AWS Regions. Using this feature, you can create cross-Region read replica clusters for ElastiCache for Redis to enable low-latency reads and disaster recovery across AWS Regions.
- Data tiering provides a price-performance option for Redis workloads by utilizing lower-cost solid state drives (SSDs) in each cluster node in addition to storing data in memory. It is ideal for workloads...
that access up to 20 percent of their overall dataset regularly, and for applications that can tolerate additional latency when accessing data on SSD. For more information, see Data tiering (p. 121).

Clusters

The basic building block of ElastiCache for Redis is the cluster. A cluster is a collection of one or more cache nodes, all of which run an instance of the Redis cache engine software. When you create a cluster, you specify the engine and version for all of the nodes to use. Your ElastiCache for Redis instances are designed to be accessed through an Amazon EC2 instance. You can create and modify a cluster by using the AWS CLI, the ElastiCache for Redis API, or the AWS Management Console.

Each ElastiCache for Redis cluster runs a Redis engine version. Each Redis engine version has its own supported features. Additionally, each Redis engine version has a set of parameters in a parameter group that control the behavior of the clusters that it manages.

The computation and memory capacity of a cluster is determined by its instance, or node, class. You can select the node type that best meets your needs. If your needs change over time, you can change node types. For information, see Supported node types.

You can also leverage data-tiering when considering your node type needs. Data tiering is a feature where some least frequently used data is stored on disk to mitigate against memory limitations on applications that can tolerate additional latency when data on SSD (solid state drives) is accessed.

**Note**

For pricing information on ElastiCache instance classes, see Amazon ElastiCache pricing.

Cluster node storage comes in two types: Standard and memory-optimized. They differ in performance characteristics and price, allowing you to tailor your storage performance and cost to your needs. Each instance has minimum and maximum storage requirements depending on the storage type. It's important to have sufficient storage so that your clusters have room to grow. Also, sufficient storage makes sure that features have room to write content or log entries.

You can run a cluster on a virtual private cloud (VPC) using the Amazon Virtual Private Cloud (Amazon VPC) service. When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. ElastiCache manages backups, software patching, automatic failure detection, and recovery. There's no additional cost to run your cluster in a VPC. For more information on using Amazon VPC with ElastiCache for Redis, see Amazon VPCs and ElastiCache security.

AWS Regions and Availability Zones

Amazon cloud computing resources are housed in highly available data center facilities in different areas of the world (for example, North America, Europe, or Asia). Each data center location is called an AWS Region.

Each AWS Region contains multiple distinct locations called Availability Zones, or AZs. Each Availability Zone is engineered to be isolated from failures in other Availability Zones. Each is engineered to provide inexpensive, low-latency network connectivity to other Availability Zones in the same AWS Region. By launching instances in separate Availability Zones, you can protect your applications from the failure of a single location. For more information, see Choosing regions and availability zones. You can create your cluster in several Availability Zones, an option called a Multi-AZ deployment. When you choose this option, Amazon automatically provisions and maintains a secondary standby node instance in a different Availability Zone. Your primary node instance is asynchronously replicated across Availability Zones to the secondary instance. This approach helps provide data redundancy and failover support, eliminate
I/O freezes, and minimize latency spikes during system backups. For more information, see Minimizing downtime in ElastiCache for Redis with Multi-AZ.

Security

A security group controls the access to a cluster. It does so by allowing access to IP address ranges or Amazon EC2 instances that you specify. For more information about security groups, see Security in ElastiCache for Redis.

Monitoring an ElastiCache for Redis cluster

There are several ways that you can track the performance and health of a ElastiCache for Redis cluster. You can use the CloudWatch service to monitor the performance and health of a cluster. CloudWatch performance charts are shown in the ElastiCache for Redis console. You can also subscribe to ElastiCache for Redis events to be notified about changes to a cluster, snapshot, parameter group, or security group. For more information, see Monitoring Use with CloudWatch metrics.
Amazon ElastiCache resources

We recommend that you begin by reading the following sections, and refer to them as you need them:

- **Service highlights and pricing** – The product detail page provides a general product overview of ElastiCache, service highlights, and pricing.
- **ElastiCache videos** – The ElastiCache Videos (p. 63) section has videos that introduce you to Amazon ElastiCache. The videos cover common use cases for ElastiCache and demo how to use ElastiCache to reduce latency and improve throughput for your applications.
- **Getting started** – The Getting started with Amazon ElastiCache for Redis (p. 41) section includes information on creating a cache cluster. It also includes how to authorize access to the cache cluster, connect to a cache node, and delete the cache cluster.
- **Performance at scale** – The Performance at scale with Amazon ElastiCache whitepaper addresses caching strategies that help your application to perform well at scale.

After you complete the preceding sections, read these sections:

- **Choosing your node size (p. 127)**
  You want your nodes to be large enough to accommodate all the data you want to cache. At the same time, you don't want to pay for more cache than you need. You can use this topic to help select the best node size.
- **Caching strategies and best practices (p. 215)**
  Identify and address issues that can impact the efficiency of your cluster.

If you want to use the AWS Command Line Interface (AWS CLI), you can use these documents to help you get started:

- **AWS Command Line Interface documentation**
  This section provides information on downloading the AWS CLI, getting the AWS CLI working on your system, and providing your AWS credentials.
- **AWS CLI documentation for ElastiCache**
  This separate document covers all of the AWS CLI for ElastiCache commands, including syntax and examples.

You can write application programs to use the ElastiCache API with a variety of popular programming languages. Here are some resources:

- **Tools for Amazon Web Services**
  Amazon Web Services provides a number of software development kits (SDKs) with support for ElastiCache. You can code for ElastiCache using Java,.NET, PHP, Ruby, and other languages. These SDKs can greatly simplify your application development by formatting your requests to ElastiCache, parsing responses, and providing retry logic and error handling.
- **Using the ElastiCache API (p. 650)**
  If you don't want to use the AWS SDKs, you can interact with ElastiCache directly using the Query API. You can find troubleshooting tips and information on creating and authenticating requests and handling responses in this section.
- **Amazon ElastiCache API Reference**
This separate document covers all of the ElastiCache API operations, including syntax and examples.
ElastiCache for Redis components and features

Following, you can find an overview of the major components of an Amazon ElastiCache deployment.

Topics
- ElastiCache nodes (p. 10)
- ElastiCache for Redis shards (p. 10)
- ElastiCache for Redis clusters (p. 11)
- ElastiCache for Redis replication (p. 12)
- AWS Regions and availability zones (p. 29)
- ElastiCache for Redis endpoints (p. 29)
- ElastiCache parameter groups (p. 30)
- ElastiCache for Redis security (p. 30)
- ElastiCache security groups (p. 30)
- ElastiCache subnet groups (p. 31)
- ElastiCache for Redis backups (p. 31)
- ElastiCache events (p. 31)

ElastiCache nodes

A node is the smallest building block of an ElastiCache deployment. A node can exist in isolation form or in some relationship to other nodes.

A node is a fixed-size chunk of secure, network-attached RAM. Each node runs an instance of the engine and version that was chosen when you created your cluster. If necessary, you can scale the nodes in a cluster up or down to a different instance type. For more information, see Scaling ElastiCache for Redis clusters (p. 345).

Every node within a cluster is the same instance type and runs the same cache engine. Each cache node has its own Domain Name Service (DNS) name and port. Multiple types of cache nodes are supported, each with varying amounts of associated memory. For a list of supported node instance types, see Supported node types (p. 99).

You can purchase nodes on a pay-as-you-go basis, where you only pay for your use of a node. Or you can purchase reserved nodes at a much-reduced hourly rate. If your usage rate is high, purchasing reserved nodes can save you money. Suppose that your cluster is almost always in use, and you occasionally add nodes to handle use spikes. In this case, you can purchase a number of reserved nodes to run most of the time. You can then purchase pay-as-you-go nodes for the times you occasionally need to add nodes. For more information on reserved nodes, see ElastiCache reserved nodes (p. 107).

For more information on nodes, see Managing nodes (p. 95).

ElastiCache for Redis shards

A Redis shard (called a node group in the API and CLI) is a grouping of one to six related nodes. A Redis (cluster mode disabled) cluster always has one shard.

Redis (cluster mode enabled) clusters can have up to 500 shards, with your data partitioned across the shards. The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and
no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526). For versions below 5.0.6, the limit is 250 per cluster.

To request a limit increase, see AWS Service Limits and choose the limit type **Nodes per cluster per instance type**.

A **multiple node shard** implements replication by having one read/write primary node and 1–5 replica nodes. For more information, see High availability using replication groups (p. 246).

For more information on shards, see Working with shards (p. 183).

### ElastiCache for Redis clusters

A Redis **cluster** is a logical grouping of one or more ElastiCache for Redis shards (p. 10). Data is partitioned across the shards in a Redis (cluster mode enabled) cluster.

Many ElastiCache operations are targeted at clusters:

- Creating a cluster
- Modifying a cluster
- Taking snapshots of a cluster (all versions of Redis)
- Deleting a cluster
- Viewing the elements in a cluster
- Adding or removing cost allocation tags to and from a cluster

For more detailed information, see the following related topics:

- Managing clusters (p. 120) and Managing nodes (p. 95)
  Information about clusters, nodes, and related operations.
- AWS service limits: Amazon ElastiCache
  Information about ElastiCache limits, such as the maximum number of nodes or clusters. To exceed certain of these limits, you can make a request using the Amazon ElastiCache cache node request form.
- Mitigating Failures (p. 623)
  Information about improving the fault tolerance of your clusters and replication groups.

### Typical cluster configurations

Following are typical cluster configurations.

#### Redis clusters

Redis (cluster mode enabled) clusters can have up to 500 shards, with your data partitioned across the shards. The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526). For versions below 5.0.6, the limit is 250 per cluster.
To request a limit increase, see AWS Service Limits and choose the limit type **Nodes per cluster per instance type**.

Redis (cluster mode disabled) clusters always contain just one shard (in the API and CLI, one node group). A Redis shard contains one to six nodes. If there is more than one node in a shard, the shard supports replication. In this case, one node is the read/write primary node and the others are read-only replica nodes.

For improved fault tolerance, we recommend having at least two nodes in a Redis cluster and enabling Multi-AZ. For more information, see Mitigating Failures (p. 623).

As demand upon your Redis (cluster mode disabled) cluster changes, you can scale up or down. To do this, you move your cluster to a different node instance type. If your application is read intensive, we recommend adding read-only replicas Redis (cluster mode disabled) cluster. By doing this, you can spread the reads across a more appropriate number of nodes.

You can also use data-tiering. More frequently accessed data is stored in memory and less frequently accessed data is stored on disk. The advantage of using data tiering is that it decreases memory needs. For more information, see Data tiering (p. 121).

ElastiCache supports changing a Redis (cluster mode disabled) cluster's node type to a larger node type dynamically. For information on scaling up or down, see Scaling single-node clusters for Redis (Cluster Mode Disabled) (p. 347) or Scaling Redis (Cluster Mode Disabled) clusters with replica nodes (p. 360).

### ElastiCache for Redis replication

Before you continue reading here, see Tools for managing your implementation (p. 34) to better understand the differences in terminology between the ElastiCache console and the ElastiCache API and AWS CLI.

Replication is implemented by grouping from two to six nodes in a shard (in the API and CLI, called a node group). One of these nodes is the read/write primary node. All the other nodes are read-only replica nodes.

Each replica node maintains a copy of the data from the primary node. Replica nodes use asynchronous replication mechanisms to keep synchronized with the primary node. Applications can read from any node in the cluster but can write only to primary nodes. Read replicas enhance scalability by spreading reads across multiple endpoints. Read replicas also improve fault tolerance by maintaining multiple copies of the data. Locating read replicas in multiple Availability Zones further improves fault tolerance. For more information on fault tolerance, see Mitigating Failures (p. 623).

Redis (cluster mode disabled) clusters support one shard (in the API and CLI, called a node group).

Redis (cluster mode enabled) clusters can have up to 500 shards, with your data partitioned across the shards. The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526). For versions below 5.0.6, the limit is 250 per cluster.

To request a limit increase, see AWS Service Limits and choose the limit type **Nodes per cluster per instance type**.

Replication from the API and CLI perspective uses different terminology to maintain compatibility with previous versions, but the results are the same. The following table shows the API and CLI terms for implementing replication.

| Comparing Replication: Redis (cluster mode disabled) and Redis (cluster mode enabled) | API Version 2015-02-02 | 12 |
In the following table, you can find a comparison of the features of Redis (cluster mode disabled) and Redis (cluster mode enabled) replication groups.

<td></td>
</tr>
</tbody>
</table>

All of the shards (in the API and CLI, node groups) and nodes must reside in the same AWS Region. However, you can provision the individual nodes in multiple Availability Zones within that AWS Region.

Read replicas guard against potential data loss because your data is replicated over two or more nodes—the primary and one or more read replicas. For greater reliability and faster recovery, we recommend that you create one or more read replicas in different Availability Zones. In addition, enable Multi-AZ instead of using Redis Append Only File (AOF). AOF is disabled when Multi-AZ is enabled. For more information, see Minimizing downtime in ElastiCache for Redis with Multi-AZ (p. 253).

You can also leverage Global datastores. By using the Global Datastore for Redis feature, you can work with fully managed, fast, reliable, and secure replication across AWS Regions. Using this feature, you can create cross-Region read replica clusters for ElastiCache for Redis to enable low-latency reads and disaster recovery across AWS Regions. For more information, see

By using the Global Datastore for Redis feature, you can work with fully managed, fast, reliable, and secure replication across AWS Regions. Using this feature, you can create cross-Region read replica clusters for ElastiCache for Redis to enable low-latency reads and disaster recovery across AWS Regions.

In the following sections, you can find a description of how to work with global datastores.

### Topics

- Overview (p. 232)
- Prerequisites and limitations (p. 233)
- Using global datastores (console) (p. 234)
- Using global datastores (CLI) (p. 242)

### Overview

Each *global datastore* is a collection of one or more clusters that replicate to one another.

A global datastore consists of the following:

- **Primary (active) cluster** – A primary cluster accepts writes that are replicated to all clusters within the global datastore. A primary cluster also accepts read requests.

- **Secondary (passive) cluster** – A secondary cluster only accepts read requests and replicates data updates from a primary cluster. A secondary cluster needs to be in a different AWS Region than the primary cluster.

When you create a global datastore in ElastiCache, ElastiCache for Redis automatically replicates your data from the primary cluster to the secondary cluster. You choose the AWS Region where the Redis data should be replicated and then create a secondary cluster in that AWS Region. ElastiCache then sets up and manages automatic, asynchronous replication of data between the two clusters.

Using a global datastore for Redis provides the following advantages:
Prerequisites and limitations

Before getting started with global datastores, be aware of the following:

- Global datastores are supported in the following AWS Regions: Asia Pacific (Seoul, Tokyo, Singapore, Sydney, Mumbai, and Osaka), Europe (Frankfurt, Paris, London, Ireland, and Stockholm), US East (N. Virginia and Ohio), US West (N. California and Oregon), South America (São Paulo), AWS GovCloud (US-West and US-East), Canada (Central) Region, China (Beijing and Ningxia)
- To use global datastores, use Redis engine version 5.0.6 or higher and R5, R6g, R6gd, M5 or M6g node types.
- All clusters—primary and secondary—in your global datastore should have the same number of primary nodes, node type, engine version, and number of shards (in case of cluster-mode enabled). Each cluster in your global datastore can have a different number of read replicas to accommodate the read traffic local to that cluster. Replication must be enabled if you plan to use an existing single-node cluster.
- You can set up replication for a primary cluster from one AWS Region to a secondary cluster in up to two other AWS Regions.

**Note**
The exception to this are China (Beijing) Region and China (Ningxia) regions, where replication can only occur between the two regions.
- You can work with global datastores only in VPC clusters. For more information, see Access Patterns for Accessing an ElastiCache Cluster in an Amazon VPC (p. 508). Global datastores aren't supported when you use EC2-Classic. For more information, see EC2-Classic in the *Amazon EC2 User Guide for Linux Instances*.

**Note**
At this time, you can't use global datastores in Using local zones with ElastiCache (p. 91).
• ElastiCache doesn't support autofailover from one AWS Region to another. When needed, you can promote a secondary cluster manually. For an example, see Promoting the secondary cluster to primary (p. 240).

• To bootstrap from existing data, use an existing cluster as primary to create a global datastore. We don't support adding an existing cluster as secondary. The process of adding the cluster as secondary wipes data, which may result in data loss.

• Parameter updates are applied to all clusters when you modify a local parameter group of a cluster belonging to a global datastore.

• You can scale regional clusters both vertically (scaling up and down) and horizontally (scaling in and out). You can scale the clusters by modifying the global datastore. All the regional clusters in the global datastore are then scaled without interruption. For more information, see Scaling ElastiCache for Redis clusters (p. 345).

• Global datastores support encryption at rest, encryption in transit, and Redis AUTH.

• Global datastores support AWS KMS keys. For more information, see AWS key management service concepts in the AWS Key Management Service Developer Guide.

• Security for cross-Region communication is provided through VPC peering. For more information, see What is VPC peering? in the Amazon VPC Peering Guide.

  **Note**

  Global datastores support pub/sub messaging with the following stipulations:

  • For cluster-mode disabled, pub/sub is fully supported. Events published on the primary cluster of the primary AWS Region are propagated to secondary AWS Regions.

  • For cluster mode enabled, the following applies:
    • For published events that aren't in a keyspace, only subscribers in the same AWS Region receive the events.
    • For published keyspace events, subscribers in all AWS Regions receive the events.

Using global datastores (console)

To create a global datastore using the console, follow this two-step process:

1. Create a primary cluster, either by using an existing cluster or creating a new cluster. The engine must be Redis 5.0.6 or later.

2. Add up to two secondary clusters in different AWS Regions, again using the Redis 5.0.6 engine or later.

The following procedures guide you on how to create a global datastore for Redis and perform other operations using the ElastiCache for Redis console.

**Topics**

• Creating a global datastore using an existing cluster (p. 234)
• Creating a new global datastore using a new primary cluster (p. 236)
• Viewing global datastore details (p. 237)
• Adding a Region to a global datastore (p. 238)
• Modifying a global datastore (p. 240)
• Promoting the secondary cluster to primary (p. 240)
Creating a global datastore using an existing cluster

In this scenario, you use an existing cluster to serve as the primary of the new global datastore. You then create a secondary, read-only cluster in a separate AWS Region. This secondary cluster receives automatic and asynchronous updates from the primary cluster.

Important
The existing cluster must use the Redis 5.0.6 engine or later.

To create a global datastore using an existing cluster

2. On the navigation pane, choose Redis and then choose a cluster.
3. For Actions, choose Setup Global Datastore.
4. On the Setup Global Datastore page, do the following:
   • Enter a value for Global Datastore Name suffix: This suffix is used to generate a unique name for the global datastore. You can search for the global datastore by using the suffix that you specify here.
   • (Optional) Enter a Description value.
5. Under Secondary cluster details, choose a different AWS Region where the cluster will be stored.
6. Under Redis settings, enter a value for Name and, optionally, for Description for the cluster.
7. Keep the following options as they are. They're prepopulated to match the primary cluster configuration, you can't change them.
   • Engine version
   • Node type
   • Parameter group
     Note
     ElastiCache autogenerates a new parameter group from values of the provided parameter group and applies the new parameter group to the cluster. Use this new parameter group to modify parameters on a global datastore. Each autogenerated parameter group is associated with one and only one cluster and, therefore, only one global datastore.
   • Number of shards
   • Encryption at rest – Enables encryption of data stored on disk. For more information, see Encryption at rest.
     Note
     You can supply a different encryption key by choosing Customer Managed AWS KMS key and choosing the key. For more information, see Using Customer Managed AWS KMS keys.
   • Encryption in-transit – Enables encryption of data on the wire. For more information, see Encryption in transit. For Redis engine version 6.0 onwards, if you enable encryption in-transit you are prompted to specify one of the following Access Control options:
     • No Access Control – This is the default setting. This indicates no restrictions.
Using global datastores (console)

- **User Group Access Control List** – Choose a user group with a defined set of users and permissions on available operations. For more information, see Managing User Groups with the Console and CLI (p. 496).

- **Redis AUTH Default User** – An authentication mechanism for Redis server. For more information, see Redis AUTH.

8. (Optional) As needed, update the remaining secondary cluster settings. These are prepopulated with the same values as the primary cluster, but you can update them to meet specific requirements for that cluster.
   - Port
   - Number of replicas
   - Subnet group
   - Preferred Availability Zone(s)
   - Security groups
   - Customer Managed (AWS KMS key)
   - Redis AUTH Token
   - Enable automatic backups
   - Backup retention period
   - Backup window
   - Maintenance window
   - Topic for SNS notification

9. Choose Create. Doing this sets the status of the global datastore to Creating. The status transitions to Modifying after the primary cluster is associated to the global datastore and the secondary cluster is in Associating status. After the primary cluster and secondary clusters are associated with the global datastore, the status changes to Available. At this point, you have a primary cluster that accepts reads and writes and secondary clusters that accept reads replicated from the primary cluster.

The Redis page is updated to indicate whether a cluster is part of a global datastore, including:
- **Global Datastore** – The name of the global datastore to which the cluster belongs.
- **Global Datastore Role** – The role of the cluster, either primary or secondary.

You can add up to one additional secondary cluster in a different AWS Region. For more information, see Adding a Region to a global datastore (p. 238).

**Creating a new global datastore using a new primary cluster**

If you choose to create a global datastore with a new cluster, use the following procedure.

2. On the navigation pane, choose Global Datastore and then choose Create.
3. Under Create Global Datastore, do the following:
   a. Enter a value for Global Datastore Name suffix. ElastiCache uses the suffix to generate a unique name for the global datastore. You can search for the global datastore by using the suffix that you specify here.
b. (Optional) Enter a value for **Global Datastore Description**.

4. **Under Primary cluster details**, for **Region**, choose an available AWS Region.
5. Follow the steps at Creating a Redis (cluster mode enabled) cluster (console).

   **Note**
   When you select a parameter group to set the engine configuration values, that parameter group is applied to all clusters in the global datastore. On the **Parameter Groups** page, the yes/no **Global** attribute indicates whether a parameter group is part of a global datastore.

6. After you have successfully created the cluster in the previous step, choose **Next** to configure your secondary cluster details, which are outlined in the previous section beginning with Step 5.

7. The following options are prepopulated to match the primary cluster configuration and cannot be changed:
   - Engine version
   - Instance type
   - Node type
   - Number of shards
   - Parameter group

   **Note**
   ElastiCache autogenerates a new parameter group from values of the provided parameter group and applies the new parameter group to the cluster. Use this new parameter group to modify parameters on a global datastore. Each autogenerated parameter group is associated with one and only one cluster and, therefore, only one global datastore.

   - Encryption at rest – Enables encryption of data stored on disk. For more information, see **Encryption at rest**.

   **Note**
   You can supply a different encryption key by choosing **Customer Managed AWS KMS key** and choosing the key. For more information, see Using Customer Managed AWS KMS keys.

   - Encryption in-transit – Enables encryption of data on the wire. For more information, see **Encryption in transit**. For Redis engine version 6.4 and above, if you enable encryption in-transit you are prompted to specify one of the following **Access Control** options:

     - **No Access Control** – This is the default setting. This indicates no restrictions on user access to the cluster.
     - **User Group Access Control List** – Choose a user group with a defined set of users that can access the cluster. For more information, see Managing User Groups with the Console and CLI (p. 496).
     - **Redis AUTH Default User** – An authentication mechanism for Redis server. For more information, see **Redis AUTH**.

   **Note**
   For Redis versions between 4.0.2, when Encryption in-transit was first supported, and 6.0.4, Redis AUTH is the sole option.

The remaining secondary cluster settings are pre-populated with the same values as the primary cluster, but the following can be updated to meet specific requirements for that cluster:

- Port
• Number of replicas
  • Subnet group
  • Preferred Availability Zone(s)
  • Security groups
  • Customer Managed (AWS KMS key)
  • Redis AUTH Token
  • Enable automatic backups
  • Backup retention period
  • Backup window
  • Maintenance window
  • Topic for SNS notification

8. Choose Create. This sets the status of the global datastore to Creating. After the primary cluster and secondary clusters are associated with the global datastore, the status changes to Available. You have a primary cluster that accepts reads and writes and a secondary cluster that accepts reads replicated from the primary cluster. The Redis page is also updated to indicate whether a cluster is part of a global datastore, including the following:
  • Global Datastore – The name of the global datastore to which the cluster belongs.
  • Global Datastore Role – The role of the cluster, either primary or secondary.

You can add up to one additional secondary cluster in a different AWS Region. For more information, see Adding a Region to a global datastore (p. 238).

### Viewing global datastore details

You can view the details of existing global datastores and also modify them on the Global Datastore page.

#### To view global datastore details

2. On the navigation pane, choose Global Datastore and then choose an available global datastore.

You can then examine the following global datastore properties:

• **Global Datastore Name**: The name of the global datastore
• **Description**: A description of the global datastore
• **Status**: Options include:
  • Creating
  • Modifying
  • Available
  • Deleting
  • Primary-Only - This status indicates the global datastore contains only a primary cluster. Either all secondary clusters are deleted or not successfully created.
• **Cluster Mode**: Either enabled or disabled
• **Redis Engine Version**: The Redis engine version running the global datastore
Using global datastores (console)

- **Instance Node Type**: The node type used for the global datastore
- **Encryption at-rest**: Either enabled or disabled
- **Encryption in-transit**: Either enabled or disabled
- **Redis AUTH**: Either enabled or disabled

You can make the following changes to the global datastore:

- Adding a Region to a global datastore (p. 238)
- Removing a Region from a global datastore (p. 241)
- Promoting the secondary cluster to primary (p. 240)
- Modifying a global datastore (p. 240)

The Global Datastore page also lists the individual clusters that make up the global datastore and the following properties for each:

- **Region** - The AWS Region where the cluster is stored
- **Role** - Either primary or secondary
- **Cluster name** - The name of the cluster
- **Status** - Options include:
  - **Associating** - The cluster is in the process of being associated to the global datastore
  - **Associated** - The cluster is associated to the global datastore
  - **Disassociating** - The process of removing a secondary cluster from the global datastore using the global datastore name. After this, the secondary cluster no longer receives updates from the primary cluster but it remains as a standalone cluster in that AWS Region.
  - **Disassociated** - The secondary cluster has been removed from the global datastore and is now a standalone cluster in its AWS Region.
- **Global Datastore Replica lag** – Shows one value per secondary AWS Region in the global datastore. This is the lag between the secondary Region's primary node and the primary Region's primary node. For cluster mode enabled Redis, the lag indicates the maximum delay, in seconds, among the shards.

**Adding a Region to a global datastore**

You can add up to one additional AWS Region to an existing global datastore. In this scenario, you are creating a read-only cluster in a separate AWS Region that receives automatic and asynchronous updates from the primary cluster.

**To add an AWS Region to a global datastore**

2. On the navigation pane, choose **Global Datastore**, and then for **Global Datastore Name** choose a global datastore.
3. Choose **Add Region**, and choose the AWS Region where the secondary cluster is to reside.
4. Under **Redis settings**, enter a value for **Name** and, optionally, for **Description** for the cluster.
5. Keep the following options as they are. They're prepopulated to match the primary cluster configuration, and you can't change them.
• Engine version

• Instance type
• Node type
• Number of shards
• Parameter group

Note
ElastiCache autogenerates a new parameter group from values of the provided parameter group and applies the new parameter group to the cluster. Use this new parameter group to modify parameters on a global datastore. Each autogenerated parameter group is associated with one and only one cluster and, therefore, only one global datastore.

• Encryption at rest

Note
You can supply a different encryption key by choosing Customer Managed AWS KMS key and choosing the key.

• Encryption in transit
• Redis AUTH

6. (Optional) Update the remaining secondary cluster settings. These are prepopulated with the same values as the primary cluster, but you can update them to meet specific requirements for that cluster:
• Port
• Number of replicas
• Subnet group
• Preferred Availability Zone(s)
• Security groups
• Customer Managed AWS KMS key
• Redis AUTH Token
• Enable automatic backups
• Backup retention period
• Backup window
• Maintenance window
• Topic for SNS notification

7. Choose Add.

Modifying a global datastore

You can modify properties of regional clusters. Only one modify operation can be in progress on a global datastore, with the exception of promoting a secondary cluster to primary. For more information, see Promoting the secondary cluster to primary (p. 240).

To modify a global datastore

2. On the navigation pane, choose Global Datastore, and then for Global Datastore Name, choose a global datastore.

3. Choose Modify and choose among the following options:
• **Modify description** – Update the description of the global datastore

• **Modify engine version** – Only Redis engine version 5.0.6 or later is available.  
• **Modify node type** – Scale regional clusters both vertically (scaling up and down) and horizontally (scaling in and out). Options include the R5 and M5 node families. For more information on node types, see Supported node types (p. 99).
• **Modify Automatic Failover** – Enable or disable Automatic Failover. When you enable failover and primary nodes in regional clusters shut down unexpectedly, ElastiCache fails over to one of the regional replicas. For more information, see Auto failover.  
  For Redis clusters with cluster-mode enabled:
  • **Add shards** – Enter the number of shards to add and optionally specify one or more Availability Zones.
  • **Delete shards** – Choose shards to be deleted in each AWS Region.
  • **Rebalance shards** – Rebalance the slot distribution to ensure uniform distribution across existing shards in the cluster.

To modify a global datastore's parameters, modify the parameter group of any member cluster for the global datastore. ElastiCache applies this change to all clusters within that global datastore automatically. To modify the parameter group of that cluster, use the Redis console or the ModifyCacheCluster API operation. For more information, see Modifying a parameter group (p. 435). When you modify the parameter group of any cluster contained within a global datastore, it is applied to all the clusters within that global datastore.

To reset an entire parameter group or specific parameters, use the ResetCacheParameterGroup API operation.

**Promoting the secondary cluster to primary**

If the primary cluster or AWS Region becomes unavailable or is experiencing performance issues, you can promote a secondary cluster to primary. Promotion is allowed anytime, even if other modifications are in progress. You can also issue multiple promotions in parallel and the global datastore resolves to one primary eventually. If you promote multiple secondary clusters simultaneously, ElastiCache for Redis doesn't guarantee which one ultimately resolves to primary.

**To promote a secondary cluster to primary**

2. On the navigation pane, choose **Global Datastore** under **Redis**.
3. Choose the global datastore name to view the details.
4. Choose the **Secondary** cluster.
5. Choose **Promote to primary**.

You're then prompted to confirm your decision with the following warning:  
Promoting a region to primary will make the cluster in this region as read/writable. Are you sure you want to promote the secondary cluster to primary?  
The current primary cluster in **primary region** will become secondary and will stop accepting writes after this operation completes. Please ensure you update your application stack to direct traffic to the new primary region.
6. Choose **Confirm** if you want to continue the promotion or **Cancel** if you don’t.

If you choose to confirm, your global datastore moves to a **Modifying** state and is unavailable until the promotion is complete.

**Removing a Region from a global datastore**

You can remove an AWS Region from a global datastore by using the following procedure.

**To remove an AWS Region from a global datastore**

2. On the navigation pane, choose **Global Datastore** under Redis.
3. Choose a global datastore.
4. Choose the **Region** you want to remove.
5. Choose **Remove region**.
   
   **Note**
   
   This option is only available for secondary clusters.
   
   You're then be prompted to confirm your decision with the following warning:
   
   Removing the region will remove your only available cross region replica for the primary cluster. Your primary cluster will no longer be set up for disaster recovery and improved read latency in remote region. Are you sure you want to remove the selected region from the global datastore?

6. Choose **Confirm** if you want to continue the promotion or **Cancel** if you don’t.

If you choose confirm, the AWS Region is removed and the secondary cluster no longer receives replication updates.

**Deleting a global datastore**

To delete a global datastore, first remove all secondary clusters. For more information, see Removing a Region from a global datastore (p. 241). Doing this leaves the global datastore in **primary-only** status.

**To delete a global datastore**

2. On the navigation pane, choose **Global Datastore** under Redis.
3. Under **Global Datastore Name** choose the global datastore you want to delete and then choose **Delete**.
   
   You're then be prompted to confirm your decision with the following warning: **Are you sure you want to delete this Global Datastore?**

4. Choose **Delete**.

The global datastore transitions to **Deleting** status.
Using global datastores (CLI)

You can use the AWS Command Line Interface (AWS CLI) to control multiple AWS services from the command line and automate them through scripts. You can use the AWS CLI for ad hoc (one-time) operations.

Downloading and configuring the AWS CLI

The AWS CLI runs on Windows, macOS, or Linux. Use the following procedure to download and configure it.

To download, install, and configure the CLI

1. Download the AWS CLI on the AWS command line interface webpage.
2. Follow the instructions for Installing the AWS CLI and Configuring the AWS CLI in the AWS Command Line Interface User Guide.

Using the AWS CLI with global datastores

Use the following CLI operations to work with global datastores:

- `create-global-replication-group`

```bash
aws elasticache create-global-replication-group
   --global-replication-group-id-suffix my global datastore
   --primary-replication-group-id sample-repl-group
   --global-replication-group-description an optional description of the global datastore
```

Amazon ElastiCache automatically applies a prefix to the global datastore ID when it is created. Each AWS Region has its own prefix. For instance, a global datastore ID created in the US West (N. California) Region begins with "virxk" along with the suffix name that you provide. The suffix, combined with the autogenerated prefix, guarantees uniqueness of the global datastore name across multiple Regions.

The following table lists each AWS Region and its global datastore ID prefix.

<table>
<thead>
<tr>
<th>Region Name/Region</th>
<th>Prefix</th>

API Version 2015-02-02
Using global datastores (CLI)

- Create replication group – Use this operation to create secondary clusters for a global datastore by supplying the name of the global datastore to the `--global-replication-group-id` parameter.

```
aws elasticache create-replication-group
   --replication-group-id secondary replication group name
   --replication-group-description "Replication group description"
   --global-replication-group-id global datastore name
```

When calling this operation and passing in a `--global-replication-group-id` value, ElastiCache for Redis will infer the values from the primary replication group of the global replication group for the following parameters. Do not pass in values for these parameters:
- "PrimaryClusterId",
- "AutomaticFailoverEnabled",
- "NumNodeGroups",
- "CacheParameterGroupName",
- "Engine",
- "EngineVersion",
- "CacheSecurityGroupNames",
- "EnableTransitEncryption",
- "AtRestEncryptionEnabled",
- "SnapshotArns",
- "SnapshotName"

- Describe global replication groups

```
aws elasticache describe-global-replication-groups
   --global-replication-group-id my global datastore
   --show-member-info
```

This is an optional parameter that returns a list of the primary and secondary clusters that make up the global datastore.

- Modify global replication group

```
aws elasticache modify-global-replication-group
   --global-replication-group-id my global datastore
   --automatic-failover-enabled
   --cache-node-type node type
   --cache-parameter-group-name parameter group name
   --engine-version engine version
   --apply-immediately
```
Using global datastores (CLI)

- `delete-global-replication-group`
  ```bash
  aws elasticache delete-global-replication-group \\
  --global-replication-group-id my global datastore \\
  --retain-primary-replication-group defaults to true
  ```

- `disassociate-global-replication-group`
  ```bash
  aws elasticache disassociate-global-replication-group \\
  --global-replication-group-id my global datastore \\
  --replication-group-id my secondary cluster \\
  --replication-group-region the AWS Region in which the secondary cluster resides
  ```

- `failover-global-replication-group`
  ```bash
  aws elasticache failover-replication-group \\
  --global-replication-group-id my global datastore \\
  --primary-region The AWS Region of the primary cluster \\
  --primary-replication-group-id The name of the global datastore, including the suffix.
  ```

- `increase-node-groups-in-global-replication-group`
  ```bash
  aws elasticache increase-node-groups-in-global-replication-group \\
  --apply-immediately yes \\
  --global-replication-group-id global-replication-group-name \\
  --node-group-count 3
  ```

- `decrease-node-groups-in-global-replication-group`
  ```bash
  aws elasticache decrease-node-groups-in-global-replication-group \\
  --apply-immediately yes \\
  --global-replication-group-id global-replication-group-name \\
  --node-group-count 3
  ```

- `rebalance-shards-in-global-replication-group`
  ```bash
  aws elasticache rebalance-shards-in-global-replication-group \\
  --apply-immediately yes \\
  --global-replication-group-id global-replication-group-name
  ```

Use help to list all available commands ElastiCache for Redis.

```bash
aws elasticache help
```

You can also use help to describe a specific command and learn more about its usage:

```bash
aws elasticache create-global-replication-group help
```

(p. 231).
Replication: Limits and exclusions

- AOF is not supported on node type cache.t1.micro and cache.t2. For nodes of these types, the appendonly parameter value is ignored.
- Multi-AZ is not supported on node types T1.

For more information on AOF and Multi-AZ, see Mitigating Failures (p. 623).

AWS Regions and availability zones

Amazon ElastiCache is available in multiple AWS Regions around the world. Thus, you can launch ElastiCache clusters in the locations that meet your business requirements. For example, you can launch in the AWS Region closest to your customers or to meet certain legal requirements.

By default, the AWS SDKs, AWS CLI, ElastiCache API, and ElastiCache console reference the US West (Oregon) Region. As ElastiCache expands availability to new AWS Regions, new endpoints for these AWS Regions are also available. You can use these in your HTTP requests, the AWS SDKs, AWS CLI, and ElastiCache console.

Each AWS Region is designed to be completely isolated from the other AWS Regions. Within each are multiple Availability Zones. By launching your nodes in different Availability Zones, you can achieve the greatest possible fault tolerance. For more information about AWS Regions and Availability Zones, see Choosing regions and availability zones (p. 87). In the following diagram, you can see a high-level view of how AWS Regions and Availability Zones work.

For information on AWS Regions supported by ElastiCache and their endpoints, see Supported regions & endpoints (p. 88).

ElastiCache for Redis endpoints

An endpoint is the unique address your application uses to connect to an ElastiCache node or cluster.

Single node endpoints for Redis (Cluster Mode Disabled)

The endpoint for a single node Redis cluster is used to connect to the cluster for both reads and writes.

Multi-node endpoints for Redis (Cluster Mode Disabled)

A multiple node Redis (cluster mode disabled) cluster has two types of endpoints. The primary endpoint always connects to the primary node in the cluster, even if the specific node in the primary role changes. Use the primary endpoint for all writes to the cluster.

The read endpoint in a Redis (cluster mode disabled) cluster always points to a specific node. Whenever you add or remove a read replica, you must update the associated node endpoint in your application.
Redis (Cluster Mode Enabled) endpoints

A Redis (cluster mode enabled) cluster has a single configuration endpoint. By connecting to the configuration endpoint, your application is able to discover the primary and read endpoints for each shard in the cluster.

For more information, see Finding connection endpoints (p. 175).

ElastiCache parameter groups

Cache parameter groups are an easy way to manage runtime settings for supported engine software. Parameters are used to control memory usage, eviction policies, item sizes, and more. An ElastiCache parameter group is a named collection of engine-specific parameters that you can apply to a cluster. By doing this, you make sure that all of the nodes in that cluster are configured in exactly the same way.

For a list of supported parameters, their default values, and which ones can be modified, see DescribeEngineDefaultParameters (CLI: describe-engine-default-parameters).

For more detailed information on ElastiCache parameter groups, see Configuring engine parameters using parameter groups (p. 423).

ElastiCache for Redis security

For enhanced security, ElastiCache for Redis node access is restricted to applications running on the Amazon EC2 instances that you allow. You can control the Amazon EC2 instances that can access your cluster using security groups.

By default, all new ElastiCache for Redis clusters are launched in an Amazon Virtual Private Cloud (Amazon VPC) environment. You can use subnet groups to grant cluster access from Amazon EC2 instances running on specific subnets. If you choose to run your cluster outside of Amazon VPC, you can create security groups. These enable you to authorize Amazon EC2 instances running within specific Amazon EC2 security groups.

In addition to restricting node access, ElastiCache for Redis supports TLS and in-place encryption for nodes running specified versions of ElastiCache for Redis. For more information, see the following:

- Data security in Amazon ElastiCache (p. 470)
- HIPAA eligibility (p. 620)
- Authenticating users with the Redis AUTH command (p. 478)

ElastiCache security groups

Note

ElastiCache security groups are only applicable to clusters that are not running in an Amazon Virtual Private Cloud (Amazon VPC) environment. If you run your ElastiCache nodes in a virtual private cloud (VPC) based on Amazon VPC, you control access to your cache clusters with Amazon VPC security groups. These are different from ElastiCache security groups. For more information on using ElastiCache with Amazon VPC, see Amazon VPCs and ElastiCache security (p. 502).

With ElastiCache, you can control access to your clusters using security groups. A security group acts like a firewall, controlling network access to your cluster. By default, network access to your clusters is turned off. If you want your applications to access your cluster, explicitly enable access from hosts in specific Amazon EC2 security groups. After ingress rules are configured, the same rules apply to all clusters associated with that security group.
To allow network access to your cluster, first create a security group. Then use the `AuthorizeCacheSecurityGroupIngress` API action or the `authorize-cache-security-group-ingress` AWS CLI command to authorize the desired Amazon EC2 security group. Doing this in turn specifies the Amazon EC2 instances allowed. You can associate the security group with your cluster at the time of creation. You can also do this by using the ElastiCache Management Console, the `ModifyCacheCluster` API operation, or the `modify-cache-cluster` AWS CLI command.

**Important**
Access control based on IP ranges is currently not enabled for clusters. All clients to a cluster must be within the Amazon EC2 network, and authorized by using security groups as described previously.

For more information about security groups, see Security groups: EC2-Classic (p. 533).

**ElastiCache subnet groups**

A subnet group is a collection of subnets (typically private) that you can designate for your clusters running in an Amazon VPC environment.

If you create a cluster in an Amazon VPC, then you must specify a cache subnet group. ElastiCache uses that cache subnet group to choose a subnet and IP addresses within that subnet to associate with your cache nodes.

For more information about cache subnet group usage in an Amazon VPC environment, see the following:
- Amazon VPCs and ElastiCache security (p. 502)
- Step 3: Authorize access to the cluster (p. 52)
- Subnets and subnet groups (p. 524)

**ElastiCache for Redis backups**

A backup is a point-in-time copy of a Redis cluster. Backups can be used to restore an existing cluster or to seed a new cluster. Backups consist of all the data in a cluster plus some metadata.

Depending upon the version of Redis running on your cluster, the backup process requires differing amounts of reserved memory to succeed. For more information, see the following:
- Backup and restore for ElastiCache for Redis (p. 310)
- How synchronization and backup are implemented (p. 265)
- Performance impact of backups (p. 312)
- Ensuring that you have enough memory to create a Redis snapshot (p. 221)

**ElastiCache events**

When important events happen on a cache cluster, ElastiCache sends notification to a specific Amazon SNS topic. These events can include such things as failure or success in adding a node, a security group modification, and others. By monitoring for key events, you can know the current state of your clusters and in many cases take corrective action.

For more information on ElastiCache events, see Monitoring ElastiCache events (p. 607).
ElastiCache for Redis terminology

In October 2016, Amazon ElastiCache launched support for Redis 3.2. At that point, we added support for partitioning your data across up to 500 shards (called node groups in the ElastiCache API and AWS CLI). To preserve compatibility with previous versions, we extended API version 2015-02-02 operations to include the new Redis functionality.

At the same time, we began using terminology in the ElastiCache console that is used in this new functionality and common across the industry. These changes mean that at some points, the terminology used in the API and CLI might be different from the terminology used in the console. The following list identifies terms that might differ between the API and CLI and the console.

**Cache cluster or node vs. node**

There is a one-to-one relationship between a node and a cache cluster when there are no replica nodes. Thus, the ElastiCache console often used the terms interchangeably. The console now uses the term *node* throughout. The one exception is the **Create Cluster** button, which launches the process to create a cluster with or without replica nodes.

The ElastiCache API and AWS CLI continue to use the terms as they have in the past.

**Cluster vs. replication group**

The console now uses the term *cluster* for all ElastiCache for Redis clusters. The console uses the term cluster in all these circumstances:

- When the cluster is a single node Redis cluster.
- When the cluster is a Redis (cluster mode disabled) cluster that supports replication within a single shard (in the API and CLI, called a *node group*).
- When the cluster is a Redis (cluster mode enabled) cluster that supports replication within 1-90 shards or up to 500 with a limit increase request. To request a limit increase, see AWS service limits and choose the limit type **Nodes per cluster per instance type**.

The following diagram illustrates the various topologies of ElastiCache for Redis clusters from the console's perspective.

### ElastiCache for Redis: Console View

The ElastiCache API and AWS CLI operations still distinguish single node ElastiCache for Redis clusters from multi-node replication groups. The following diagram illustrates the various ElastiCache for Redis topologies from the ElastiCache API and AWS CLI perspective.
Replication group vs. global datastore

A global datastore is a collection of one or more clusters that replicate to one another across Regions, whereas a replication group replicates data across a cluster mode enabled cluster with multiple shards. A global datastore consists of the following:

- **Primary (active) cluster** – A primary cluster accepts writes that are replicated to all clusters within the global datastore. A primary cluster also accepts read requests.
- **Secondary (passive) cluster** – A secondary cluster only accepts read requests and replicates data updates from a primary cluster. A secondary cluster needs to be in a different AWS Region than the primary cluster.

For information on global datastores, see [Replication across AWS Regions using global datastores (p. 231)](#).
Tools for managing your implementation

When you have granted your Amazon EC2 instance access to your ElastiCache cluster, you have four means by which you can manage your ElastiCache cluster: the AWS Management Console, the AWS CLI for ElastiCache, the AWS SDK for ElastiCache, and the ElastiCache API.

Using the AWS Management Console

The AWS Management Console is the easiest way to manage Amazon ElastiCache. The console lets you create cache clusters, add and remove cache nodes, and perform other administrative tasks without having to write any code. The console also provides cache node performance graphs from CloudWatch. These show cache engine activity, memory and CPU utilization, and other metrics. For more information, see specific topics in this User Guide.

Using the AWS CLI

You can also use the AWS Command Line Interface (AWS CLI) for ElastiCache. The AWS CLI makes it easy to perform one-at-a-time operations, such as starting or stopping your cache cluster. You can also invoke AWS CLI for ElastiCache commands from a scripting language of your choice, letting you automate repeating tasks. For more information about the AWS CLI, see the User Guide and the AWS CLI Command Reference.

Using the AWS SDK

If you want to access ElastiCache from an application, you can use one of the AWS software development kits (SDKs). The SDKs wrap the ElastiCache API calls, and insulate your application from the low-level details of the ElastiCache API. You provide your credentials, and the SDK libraries take care of authentication and request signing. For more information about using the AWS SDKs, see Tools for AWSlong;.

Using the ElastiCache API

You can also write application code directly against the ElastiCache web service API. When using the API, you must write the necessary code to construct and authenticate your HTTP requests. You also write code to parse results from ElastiCache and handle any errors. For more information about the API, see Using the ElastiCache API (p. 650).

Additional resources

For more detailed information on managing your Amazon ElastiCache for Redis deployment, see the following:

- Managing your ElastiCache for Redis implementation (p. 188)
- Internetwork traffic privacy (p. 502)
- Logging and monitoring in Elasticache (p. 578)
Common ElastiCache Use Cases and How ElastiCache Can Help

Whether serving the latest news, a top-10 leaderboard, a product catalog, or selling tickets to an event, speed is the name of the game. The success of your website and business is greatly affected by the speed at which you deliver content.

In "For Impatient Web Users, an Eye Blink Is Just Too Long to Wait," the New York Times noted that users can register a 250-millisecond (1/4 second) difference between competing sites. Users tend to opt out of the slower site in favor of the faster site. Tests done at Amazon, cited in How Webpage Load Time Is Related to Visitor Loss, revealed that for every 100-ms (1/10 second) increase in load time, sales decrease 1 percent.

If someone wants data, you can deliver that data much faster if it's cached. That's true whether it's for a webpage or a report that drives business decisions. Can your business afford to not cache your webpages so as to deliver them with the shortest latency possible?

It might seem intuitively obvious that you want to cache your most heavily requested items. But why not cache your less frequently requested items? Even the most optimized database query or remote API call is noticeably slower than retrieving a flat key from an in-memory cache. Noticeably slower tends to send customers elsewhere.

The following examples illustrate some of the ways using ElastiCache can improve overall performance of your application.

Topics
- In-Memory Data Store (p. 35)
- Gaming Leaderboards (Redis Sorted Sets) (p. 36)
- Messaging (Redis Pub/Sub) (p. 37)
- Recommendation Data (Redis Hashes) (p. 39)
- Other Redis Uses (p. 40)
- ElastiCache Customer Testimonials (p. 40)

In-Memory Data Store

The primary purpose of an in-memory key-value store is to provide ultrafast (submillisecond latency) and inexpensive access to copies of data. Most data stores have areas of data that are frequently accessed but seldom updated. Additionally, querying a database is always slower and more expensive than locating a key in a key-value pair cache. Some database queries are especially expensive to perform. An example is queries that involve joins across multiple tables or queries with intensive calculations. By caching such query results, you pay the price of the query only once. Then you can quickly retrieve the data multiple times without having to re-execute the query.

What Should I Cache?

When deciding what data to cache, consider these factors:

Speed and expense – It's always slower and more expensive to get data from a database than from a cache. Some database queries are inherently slower and more expensive than others. For example, queries that perform joins on multiple tables are much slower and more expensive than simple, single table queries. If the interesting data requires a slow and expensive query to get, it's a candidate for caching. If getting the data requires a relatively quick and simple query, it might still be a candidate for caching, depending on other factors.
Data and access pattern – Determining what to cache also involves understanding the data itself and its access patterns. For example, it doesn't make sense to cache data that changes quickly or is seldom accessed. For caching to provide a real benefit, the data should be relatively static and frequently accessed. An example is a personal profile on a social media site. On the other hand, you don’t want to cache data if caching it provides no speed or cost advantage. For example, it doesn’t make sense to cache webpages that return search results because the queries and results are usually unique.

Staleness – By definition, cached data is stale data. Even if in certain circumstances it isn’t stale, it should always be considered and treated as stale. To tell whether your data is a candidate for caching, determine your application's tolerance for stale data.

Your application might be able to tolerate stale data in one context, but not another. For example, suppose that your site serves a publicly traded stock price. Your customers might accept some staleness with a disclaimer that prices might be $n$ minutes delayed. But if you serve that stock price to a broker making a sale or purchase, you want real-time data.

Consider caching your data if the following is true:

• Your data is slow or expensive to get when compared to cache retrieval.
• Users access your data often.
• Your data stays relatively the same, or if it changes quickly staleness is not a large issue.

For more information, see the following:

• Caching Strategies in the ElastiCache for Redis User Guide

Gaming Leaderboards (Redis Sorted Sets)

Redis sorted sets move the computational complexity of leaderboards from your application to your Redis cluster.

Leaderboards, such as the top 10 scores for a game, are computationally complex. This is especially true when there is a large number of concurrent players and continually changing scores. Redis sorted sets guarantee both uniqueness and element ordering. Using Redis sorted sets, each time a new element is added to the sorted set it’s reranked in real time. It’s then added to the set in its correct numeric order.

In the following diagram, you can see how an ElastiCache for Redis gaming leaderboard works.
Example - Redis Leaderboard

In this example, four gamers and their scores are entered into a sorted list using `ZADD`. The command `ZREVRANGEBYSCORE` lists the players by their score, high to low. Next, `ZADD` is used to update June's score by overwriting the existing entry. Finally, `ZREVRANGEBYSCORE` lists the players by their score, high to low. The list shows that June has moved up in the rankings.

```
ZADD leaderboard 132 Robert
ZADD leaderboard 231 Sandra
ZADD leaderboard 32 June
ZADD leaderboard 381 Adam

ZREVRANGEBYSCORE leaderboard +inf -inf
1) Adam
2) Sandra
3) Robert
4) June

ZADD leaderboard 232 June

ZREVRANGEBYSCORE leaderboard +inf -inf
1) Adam
2) June
3) Sandra
4) Robert
```

The following command tells June where she ranks among all the players. Because ranking is zero-based, `ZREVRANK` returns a 1 for June, who is in second position.

```
ZREVRANK leaderboard June 1
```

For more information, see the Redis documentation about sorted sets.

Messaging (Redis Pub/Sub)

When you send an email message, you send it to one or more specified recipients. In the pub/sub paradigm, you send a message to a specific channel not knowing who, if anyone, receives it. The people who get the message are those who are subscribed to the channel. For example, suppose that you subscribe to the `news.sports.golf` channel. You and all others subscribed to the `news.sports.golf` channel get any messages published to `news.sports.golf`.

Redis pub/sub functionality has no relation to any key space. Therefore, it doesn't interfere on any level. In the following diagram, you can find an illustration of ElastiCache for Redis messaging.
Subscribing

To receive messages on a channel, you subscribe to the channel. You can subscribe to a single channel, multiple specified channels, or all channels that match a pattern. To cancel a subscription, you unsubscribe from the channel specified when you subscribed to it. Or, if you subscribed using pattern matching, you unsubscribe using the same pattern that you used before.

Example - Subscription to a Single Channel

To subscribe to a single channel, use the SUBSCRIBE command specifying the channel you want to subscribe to. In the following example, a client subscribes to the news.sports.golf channel.

```
SUBSCRIBE news.sports.golf
```

After a while, the client cancels their subscription to the channel using the UNSUBSCRIBE command specifying the channel to unsubscribe from.

```
UNSUBSCRIBE news.sports.golf
```

Example - Subscriptions to Multiple Specified Channels

To subscribe to multiple specific channels, list the channels with the SUBSCRIBE command. In the following example, a client subscribes to the news.sports.golf, news.sports.soccer, and news.sports.skiing channels.

```
SUBSCRIBE news.sports.golf news.sports.soccer news.sports.skiing
```

To cancel a subscription to a specific channel, use the UNSUBSCRIBE command and specify the channel to unsubscribe from.

```
UNSUBSCRIBE news.sports.golf
```

To cancel subscriptions to multiple channels, use the UNSUBSCRIBE command and specify the channels to unsubscribe from.
UNSUBSCRIBE news.sports.golf news.sports.soccer

To cancel all subscriptions, use UNSUBSCRIBE and specify each channel. Or use UNSUBSCRIBE and don't specify a channel.

UNSUBSCRIBE news.sports.golf news.sports.soccer news.sports.skiing

or

UNSUBSCRIBE

**Example - Subscriptions Using Pattern Matching**

Clients can subscribe to all channels that match a pattern by using the PSUBSCRIBE command.

In the following example, a client subscribes to all sports channels. You don’t list all the sports channels individually, as you do using SUBSCRIBE. Instead, with the PSUBSCRIBE command you use pattern matching.

PSUBSCRIBE news.sports.*

**Example Canceling Subscriptions**

To cancel subscriptions to these channels, use the PUNSUBSCRIBE command.

PUNSUBSCRIBE news.sports.*

**Important**

The channel string sent to a [P]SUBSCRIBE command and to the [P]UNSUBSCRIBE command must match. You can't PSUBSCRIBE to news.* and PUNSUBSCRIBE from news.sports.* or UNSUBSCRIBE from news.sports.golf.

**Publishing**

To send a message to all subscribers to a channel, use the PUBLISH command, specifying the channel and the message. The following example publishes the message, "It's Saturday and sunny. I'm headed to the links." to the news.sports.golf channel.

PUBLISH news.sports.golf "It's Saturday and sunny. I'm headed to the links."

A client can’t publish to a channel that it’s subscribed to.

For more information, see Pub/Sub in the Redis documentation.

**Recommendation Data (Redis Hashes)**

Using INCR or DECR in Redis makes compiling recommendations simple. Each time a user “likes” a product, you increment an `item:productID:like` counter. Each time a user “dislikes” a product, you increment an `item:productID:dislike` counter. Using Redis hashes, you can also maintain a list of everyone who has liked or disliked a product.

**Example - Likes and Dislikes**

INCR item:38923:likes
HSET item:38923:ratings Susan 1
INCR item:38923:dislikes
HSET item:38923:ratings Tommy -1

Other Redis Uses

The blog post How to take advantage of Redis just adding it to your stack by Salvatore Sanfilippo discusses a number of common database concerns and how they can be easily solved using Redis. This approach removes load from your database and improves performance.

ElastiCache Customer Testimonials

To learn about how businesses like Airbnb, PBS, Esri, and others use Amazon ElastiCache to grow their businesses with improved customer experience, see How Others Use Amazon ElastiCache.

You can also watch the ElastiCache Videos (p. 63) for additional ElastiCache customer use cases.
Getting started with Amazon ElastiCache for Redis

Following, you can find topics that lead you through creating, granting access to, connecting to, and finally deleting a Redis (cluster mode disabled) cluster using the ElastiCache Management Console. As part of this, the section starts by helping you determine the requirements for your cluster and create your own AWS account.

Amazon ElastiCache supports high availability through the use of Redis replication groups. For information about Redis replication groups and how to create them, see High availability using replication groups (p. 246).

Beginning with Redis version 3.2, ElastiCache Redis supports partitioning your data across multiple node groups, with each node group implementing a replication group. This exercise creates a standalone Redis cluster.

Topics
- Setting up (p. 41)
- Step 1: Create a subnet group (p. 44)
- Step 2: Create a cluster (p. 46)
- Step 3: Authorize access to the cluster (p. 52)
- Step 4: Connect to the cluster's node (p. 54)
- Step 5: Deleting a cluster (p. 61)
- ElastiCache tutorials and videos (p. 62)
- Where do I go from here? (p. 66)

Setting up

Following, you can find topics that describe the one-time actions you must take to start using ElastiCache.

Topics
- Create your AWS account (p. 41)
- Getting an AWS Access Key (p. 42)
- Configuring Your Credentials (p. 42)
- Downloading and Configuring the AWS CLI (p. 43)
- Set up your permissions (new ElastiCache users only) (p. 43)

Create your AWS account

To use Amazon ElastiCache, you must have an active AWS account and permissions to access ElastiCache and other AWS resources.

If you don't already have an AWS account, create one now. AWS accounts are free. You are not charged for signing up for an AWS service, only for using AWS services.
To create an AWS account

2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

Getting an AWS Access Key

Before you can access ElastiCache programmatically or through the AWS Command Line Interface (AWS CLI), you must have an AWS access key. You don't need an access key if you plan to use the ElastiCache console only. Access keys consist of an access key ID and secret access key, which are used to sign programmatic requests that you make to AWS. If you don't have access keys, you can create them from the AWS Management Console. As a best practice, do not use the AWS account root user access keys for any task where it's not required. Instead, create a new administrator IAM user with access keys for yourself. The only time that you can view or download the secret access key is when you create the keys. You cannot recover them later. However, you can create new access keys at any time. You must also have permissions to perform the required IAM actions. For more information, see Permissions Required to Access IAM Resources in the IAM User Guide.

To create access keys for an IAM user

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Users.
3. Choose the name of the user whose access keys you want to create, and then choose the Security credentials tab.
4. In the Access keys section, choose Create access key.
5. To view the new access key pair, choose Show. You will not have access to the secret access key again after this dialog box closes. Your credentials will look something like this:
   - Access key ID: AKIAIOSFODNN7EXAMPLE
   - Secret access key: wJalrXUtNfEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
6. To download the key pair, choose Download .csv file. Store the keys in a secure location. You will not have access to the secret access key again after this dialog box closes.
7. Keep the keys confidential in order to protect your AWS account and never email them. Do not share them outside your organization, even if an inquiry appears to come from Amazon or Amazon.com. No one who legitimately represents Amazon will ever ask you for your secret key.
8. After you download the .csv file, choose Close. When you create an access key, the key pair is active by default, and you can use the pair right away.

Related topics:
- What is IAM in the IAM User Guide.

Configuring Your Credentials

Before you can access ElastiCache programatically or through the AWS CLI, you must configure your credentials to enable authorization for your applications.
There are several ways to do this. For example, you can manually create the credentials file to store your access key ID and secret access key. You also can use the `aws configure` command of the AWS CLI to automatically create the file. Alternatively, you can use environment variables. For more information about configuring your credentials, see the programming-specific AWS SDK developer guide at Tools to Build on AWS.

**Downloading and Configuring the AWS CLI**

The AWS CLI is available at [http://aws.amazon.com/cli](http://aws.amazon.com/cli). It runs on Windows, MacOS and Linux. After you download the AWS CLI, follow these steps to install and configure it:

2. Follow the instructions for Installing the AWS CLI and Configuring the AWS CLI.

**Set up your permissions (new ElastiCache users only)**

Amazon ElastiCache creates and uses service-linked roles to provision resources and access other AWS resources and services on your behalf. For ElastiCache to create a service-linked role for you, use the AWS-managed policy named `AmazonElastiCacheFullAccess`. This role comes preprovisioned with permission that the service requires to create a service-linked role on your behalf.

You might decide not to use the default policy and instead to use a custom-managed policy. In this case, make sure that you have either permissions to call `iam:createServiceLinkedRole` or that you have created the ElastiCache service-linked role.

For more information, see the following:

- Creating a New Policy (IAM)
- AWS-managed (predefined) policies for Amazon ElastiCache (p. 547)
- Using Service-Linked Roles for Amazon ElastiCache (p. 567)
Step 1: Create a subnet group

Before you create a cluster, you first create a subnet group. A cache subnet group is a collection of subnets that you may want to designate for your cache clusters in a VPC. When launching a cache cluster in a VPC, you need to select a cache subnet group. Then ElastiCache uses that cache subnet group to assign IP addresses within that subnet to each cache node in the cluster.

When you create a new subnet group, note the number of available IP addresses. If the subnet has very few free IP addresses, you might be constrained as to how many more nodes you can add to the cluster. To resolve this issue, you can assign one or more subnets to a subnet group so that you have a sufficient number of IP addresses in your cluster’s Availability Zone. After that, you can add more nodes to your cluster.

The following procedures show you how to create a subnet group called mysubnetgroup (console), the AWS CLI, and the ElastiCache API.

Creating a subnet group (Console)

The following procedure shows how to create a subnet group (console).

To create a subnet group (Console)

2. In the navigation list, choose Subnet Groups.
3. Choose Create Subnet Group.
4. In the Create Subnet Group wizard, do the following. When all the settings are as you want them, choose Yes, Create.
   a. In the Name box, type a name for your subnet group.
   b. In the Description box, type a description for your subnet group.
   c. In the VPC ID box, choose the Amazon VPC that you created.
   d. In the Availability Zone and Subnet ID lists, choose the Availability Zone or Local Zone and ID of your private subnet, and then choose Add.
5. In the confirmation message that appears, choose Close.

Your new subnet group appears in the Subnet Groups list of the ElastiCache console. At the bottom of the window you can choose the subnet group to see details, such as all of the subnets associated with this group.

Create a subnet group (AWS CLI)

At a command prompt, use the command `create-cache-subnet-group` to create a subnet group.

For Linux, macOS, or Unix:

```bash
aws elasticache create-cache-subnet-group \
  --cache-subnet-group-name mysubnetgroup \
  --cache-subnet-group-description "Testing" \
  --subnet-ids subnet-53df9c3a
```

For Windows:

```cmd
aws elasticache create-cache-subnet-group ^
  --cache-subnet-group-name mysubnetgroup ^
  --cache-subnet-group-description "Testing" ^
  --subnet-ids subnet-53df9c3a
```

This command should produce output similar to the following:

```json
{
    "CacheSubnetGroup": {
        "VpcId": "vpc-37c3cd17",
```
Step 2: Create a cluster

Before creating a cluster for production use, you obviously need to consider how you will configure the cluster to meet your business needs. Those issues are addressed in the Preparing a cluster (p. 125) section. For the purposes of this Getting Started exercise, you will create a cluster with cluster mode disabled and you can accept the default configuration values where they apply.

The cluster you create will be live, and not running in a sandbox. You will incur the standard ElastiCache usage fees for the instance until you delete it. The total charges will be minimal (typically less than a dollar) if you complete the exercise described here in one sitting and delete your cluster when you are finished. For more information about ElastiCache usage rates, see Amazon ElastiCache.

Your cluster is launched in a virtual private cloud (VPC) based on the Amazon VPC service.

Creating a subnet group (ElastiCache API)

Using the ElastiCache API, call CreateCacheSubnetGroup with the following parameters:

- CacheSubnetGroupName=mysubnetgroup
- CacheSubnetGroupDescription=Testing
- SubnetIds.member.1=subnet-53df9c3a

Example

https://elasticache.us-west-2.amazonaws.com/
?Action=CreateCacheSubnetGroup
&CacheSubnetGroupName=mysubnetgroup
&CacheSubnetGroupDescription=Testing
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SubnetIds.member.1=subnet-53df9c3a
&Timestamp=20141201T220302Z
&Version=2014-12-01
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=<credential>
&X-Amz-Date=20141201T220302Z
&X-Amz-Expires=20141201T220302Z
&X-Amz-Signature=<signature>
&X-Amz-SignedHeaders=Host
Creating a Redis (cluster mode disabled) cluster (Console)

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. From the list in the upper-right corner, choose the AWS Region that you want to launch this cluster in.
3. Choose Redis from the navigation pane.
4. Choose Create.
5. For Cluster engine, choose Redis. Make sure the Cluster Mode enabled check box is cleared.
6. Complete the Redis settings section.
   a. In Name, enter a name for your cluster.
   b. In the Description box, enter a description for this cluster.
   c. For Engine version compatibility, choose the ElastiCache for Redis engine version that you want to run on this cluster. Unless you have a specific reason to run an older version, we recommend that you choose the latest version.

   **Important**
   You can upgrade to newer engine versions. If you upgrade major engine versions, for example from 5.0.6 to 6.0, you need to select a parameter group family that is compatible with the new engine version. For more information on doing so, see Upgrading engine versions (p. 198). However, you can't downgrade to older engine versions except by deleting the existing cluster and creating it again.

   d. In Port, use the default port, 6379. If you have a reason to use a different port, enter the port number.
   e. For Parameter group, choose a parameter group or create a new one. Parameter groups control the runtime parameters of your cluster. For more information on parameter groups, see Redis-specific parameters (p. 441) and Creating a parameter group (p. 425).
   f. For Node type, click the down arrow (▼). In the Change node type dialog box, choose the Instance family of the node type that you want, choose the node type that you want to use for this cluster, and then choose Save.

If you choose a node type from the r6gd family, data tiering will automatically be enabled. For more information, see Data tiering.

For more information, see Choosing your node size (p. 127).

g. For Number of replicas, choose the number of read replicas that you want for this cluster.

If you choose to have one or more replicas, the Multi-AZ check box is available. For more information, see Mitigating Failures when Running Redis (p. 623). We strongly suggest that you enable Multi-AZ, which helps ensure your eligibility for service level agreement (SLA) compliance. For more information on SLA compliance, see Amazon ElastiCache Service Level Agreement on the AWS website.

If you enter 0, the Multi-AZ check box is not enabled. The cluster that you create looks like the following. This is a Redis (cluster mode disabled) cluster with no replica nodes.
If you choose one or more replicas, the cluster that you create looks something like the following. This is a Redis (cluster mode disabled) cluster with replica nodes.

7. Choose Advanced Redis settings and complete the section.

   a. For Subnet group, choose the subnet group you created in the previous section to apply to this cluster. If you enabled Multi-AZ, the subnet group must contain at least two subnets that reside in different availability zones.

      If you are using Using local zones with ElastiCache (p. 91), you must create or choose a subnet that is in the local zone. Multi-AZ is automatically disabled. Local Zones don't support global datastores at this time.

      For more information, see Subnets and subnet groups (p. 524).

   b. For Availability zone(s), you have two options:

      • No preference – ElastiCache chooses the Availability Zones for your cluster's nodes.

      • Specify availability zones – Under Under availability zones placement, a list of your nodes appears allowing you to specify the Availability Zone for each node in your cluster. You can choose a different Availability Zone from the list to the right of each node name.

      • If you have Multi-AZ enabled, you must place at least two nodes in different Availability Zones.

      For more information, see Choosing regions and availability zones (p. 87).

   c. For Security groups, choose the security groups that you want for this cluster. A security group acts as a firewall to control network access to your cluster. You can choose use the Default security group for your VPC or create a new one.

      For more information, see Security groups for your VPC.

   d. Encrypt your data; you have the following options:

      • Encryption at rest – Enables encryption of data stored on disk. For more information, see encryption at rest.

      Note

      You have the option to supply a different encryption key by choosing Customer Managed AWS KMS key and choosing the key. For more information, see Using Customer Managed AWS KMS keys

      • Encryption in-transit – Enables encryption of data on the wire. For more information, see encryption in transit. For Redis engine version 6.0 onward, if you enable encryption in transit you're prompted to specify one of the following Access Control options:
• **No Access Control** – This is the default setting. This indicates no restrictions on user access to the cluster.

• **User Group Access Control List** – Choose a user group with a defined set of users that can access the cluster. For more information, see Managing User Groups with the Console and CLI (p. 496).

• **Redis AUTH Default User** – An authentication mechanism for Redis server. For more information, see Redis AUTH.

  **Note**
  For Redis versions between 3.2.6 onward, excluding version 3.2.10, Redis AUTH is the sole option.

e. (Optional) For **Logs**:

  • Under **Log format**, choose either **Text** or **JSON**.
  
  • Under **Destination Type**, choose either **CloudWatch Logs** or **Kinesis Firehose**.
  
  • Under **Log destination**, choose either **Create new** and enter either your CloudWatch Logs log group name or your Kinesis Data Firehose stream name, or choose **Select existing** and then choose either your CloudWatch Logs log group name or your Kinesis Data Firehose stream name,

f. (Optional) If you are going to seed your cluster with data from a .rdb file, enter the Amazon S3 location of the .rdb file for **Seed RDB file S3 location**.

  For more information, see Seeding a new cluster with an externally created backup (p. 337).

g. (Optional) For regularly scheduled automatic backups, choose **Enable automatic backups**, and then enter the number of days that you want an automatic backup retained before it is automatically deleted. If you don't want regularly scheduled automatic backups, clear the **Enable automatic backups** check box. In either case, you always have the option to create manual backups, which must be deleted manually.

  For more information on Redis backup and restore, see Backup and restore for ElastiCache for Redis (p. 310).

h. For **Maintenance window**, choose a maintenance window. The **maintenance window** is the time, generally an hour in length, each week when ElastiCache schedules system maintenance for your cluster.

  You can enable ElastiCache to choose the day and time for your maintenance window (**No preference**). Or you can choose the day, time, and duration yourself (**Specify maintenance window**). If you choose **Specify maintenance window**, choose the **Start day**, **Start time**, and **Duration** (in hours) for your maintenance window. All times are UTC times.

  For more information, see Managing maintenance (p. 230).

i. For **Notifications**, choose an existing Amazon Simple Notification Service (Amazon SNS) topic, or choose manual ARN input and enter the topic Amazon Resource Name (ARN). If you use Amazon SNS, you can push notifications to internet-connected smart devices. The default is to disable notifications. For more information, see https://aws.amazon.com/sns/.

8. Review all your entries and choices, then go back and make any needed corrections. When you're ready, choose **Create** to launch your cluster.

As soon as your cluster’s status is **available**, you can grant Amazon EC2 access to it, connect to it, and begin using it. For more information, see Step 3: Authorize access to the cluster (p. 52) and Step 4: Connect to the cluster’s node (p. 54).
Important
As soon as your cluster becomes available, you're billed for each hour or partial hour that the cluster is active, even if you're not actively using it. To stop incurring charges for this cluster, you must delete it. See Deleting a cluster (p. 165).

Creating a Redis (cluster mode disabled) cluster (AWS CLI) (AWS CLI)

Example

The following CLI code creates a Redis (cluster mode disabled) cache cluster with no replicas.

For Linux, macOS, or Unix:

```bash
aws elasticache create-cache-cluster
--cache-cluster-id my-cluster
--cache-node-type cache.r4.large
--engine redis
--engine-version 3.2.4
--num-cache-nodes 1
--cache-parameter-group default.redis3.2
--snapshot-arns arn:aws:s3:::my_bucket/snapshot.rdb
```

For Windows:

```bash
aws elasticache create-cache-cluster
--cache-cluster-id my-cluster
--cache-node-type cache.r4.large
--engine redis
--engine-version 3.2.4
--num-cache-nodes 1
--cache-parameter-group default.redis3.2
--snapshot-arns arn:aws:s3:::my_bucket/snapshot.rdb
```

Creating a Redis (cluster mode disabled) cluster (ElastiCache API)

The following code creates a Redis (cluster mode disabled) cache cluster (ElastiCache API).

Line breaks are added for ease of reading.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=CreateCacheCluster
&CacheClusterId=my-cluster
&CacheNodeType=cache.r4.large
&CacheParameterGroup=default.redis3.2
&Engine=redis
&EngineVersion=3.2.4
&NumCacheNodes=1
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&SnapshotArms.member.1=arn%3Aaws%3As3%3A%3A%3AmyS3Bucket%2Fdump.rdb
&Timestamp=20150508T220302Z
&Version=2015-02-02
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
&X-Amz-Credential=<credential>
&X-Amz-Date=20150508T220302Z
&X-Amz-Expires=20150508T220302Z
```

API Version 2015-02-02
To work with cluster mode enabled, see the following topics:

- To use the console, see Creating a Redis (cluster mode enabled) cluster (Console) (p. 133).
- To use the AWS CLI, see Creating a Redis (cluster mode enabled) cluster (AWS CLI) (p. 137).
- To use the ElastiCache API, see Creating a cache cluster in Redis (cluster mode enabled) (ElastiCache API) (p. 138).
Step 3: Authorize access to the cluster

This section assumes that you are familiar with launching and connecting to Amazon EC2 instances. For more information, see the Amazon EC2 Getting Started Guide.

All ElastiCache clusters are designed to be accessed from an Amazon EC2 instance. The most common scenario is to access an ElastiCache cluster from an Amazon EC2 instance in the same Amazon Virtual Private Cloud (Amazon VPC), which will be the case for this exercise.

By default, network access to your cluster is limited to the user account that was used to create it. Before you can connect to a cluster from an EC2 instance, you must authorize the EC2 instance to access the cluster. The steps required depend upon whether you launched your cluster into EC2-VPC or EC2-Classic.

The most common use case is when an application deployed on an EC2 instance needs to connect to a cluster in the same VPC. The simplest way to manage access between EC2 instances and clusters in the same VPC is to do the following:

1. Create a VPC security group for your cluster. This security group can be used to restrict access to the cluster instances. For example, you can create a custom rule for this security group that allows TCP access using the port you assigned to the cluster when you created it and an IP address you will use to access the cluster.

   The default port for Redis clusters and replication groups is 6379.

   **Important**
   Amazon ElastiCache security groups are only applicable to clusters that are not running in an Amazon Virtual Private Cloud environment (VPC). If you are running in an Amazon Virtual Private Cloud, **Security Groups** is not available in the console navigation pane. If you are running your ElastiCache nodes in an Amazon VPC, you control access to your clusters with Amazon VPC security groups, which are different from ElastiCache security groups. For more information about using ElastiCache in an Amazon VPC, see Amazon VPCs and ElastiCache security (p. 502)

2. Create a VPC security group for your EC2 instances (web and application servers). This security group can, if needed, allow access to the EC2 instance from the Internet via the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.

3. Create custom rules in the security group for your Cluster that allow connections from the security group you created for your EC2 instances. This would allow any member of the security group to access the clusters.

   **Note**
   If you are planning to use Local Zones, ensure that you have enabled them. When you create a subnet group in that local zone, your VPC is extended to that Local Zone and your VPC will treat the subnet as any subnet in any other Availability Zone. All relevant gateways and route tables will be automatically adjusted.

   **To create a rule in a VPC security group that allows connections from another security group**

   1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
   2. In the navigation pane, choose **Security Groups**.
   3. Select or create a security group that you will use for your Cluster instances. Under **Inbound Rules**, select **Edit Inbound Rules** and then select **Add Rule**. This security group will allow access to members of another security group.
   4. From **Type** choose **Custom TCP Rule**.
Step 3: Authorize access to the cluster

a. For Port Range, specify the port you used when you created your cluster.

   The default port for Redis clusters and replication groups is 6379.

b. In the Source box, start typing the ID of the security group. From the list select the security group you will use for your Amazon EC2 instances.

5. Choose Save when you finish.

Once you have enabled access, you are now ready to connect to the node, as discussed in the next section.

For information on accessing your ElastiCache cluster from a different Amazon VPC, a different AWS Region, or even your corporate network, see the following:

- Access Patterns for Accessing an ElastiCache Cluster in an Amazon VPC (p. 508)
- Accessing ElastiCache resources from outside AWS (p. 171)
Step 4: Connect to the cluster's node

Before you continue, complete Step 3: Authorize access to the cluster (p. 52).

This section assumes that you've created an Amazon EC2 instance and can connect to it. For instructions on how to do this, see the Amazon EC2 Getting Started Guide.

An Amazon EC2 instance can connect to a cluster node only if you have authorized it to do so.

Find your node endpoints

When your cluster is in the available state and you've authorized access to it, you can log in to an Amazon EC2 instance and connect to the cluster. To do so, you must first determine the endpoint.

Finding a Redis (Cluster Mode Disabled) Cluster's Endpoints (Console)

If a Redis (cluster mode disabled) cluster has only one node, the node's endpoint is used for both reads and writes. If the cluster has multiple nodes, there are three types of endpoints; the primary endpoint, the reader endpoint and the node endpoints.

The primary endpoint is a DNS name that always resolves to the primary node in the cluster. The primary endpoint is immune to changes to your cluster, such as promoting a read replica to the primary role. For write activity, we recommend that your applications connect to the primary endpoint instead of connecting directly to the primary.

A reader endpoint will evenly split incoming connections to the endpoint between all read replicas in a ElastiCache for Redis cluster. Additional factors such as when the application creates the connections or how the application (re)-uses the connections will determine the traffic distribution. Reader endpoints keep up with cluster changes in real-time as replicas are added or removed. You can place your ElastiCache for Redis cluster's multiple read replicas in different AWS Availability Zones (AZ) to ensure high availability of reader endpoints.

Note
A reader endpoint is not a load balancer. It is a DNS record that will resolve to an IP address of one of the replica nodes in a round robin fashion.

For read activity, applications can also connect to any node in the cluster. Unlike the primary endpoint, node endpoints resolve to specific endpoints. If you make a change in your cluster, such as adding or deleting a replica, you must update the node endpoints in your application.

To find a Redis (cluster mode disabled) cluster's endpoints

2. From the navigation pane, choose Redis.

   The clusters screen will appear with a list of Redis (cluster mode disabled) and Redis (cluster mode enabled) clusters. Choose the cluster you created in the Creating a Redis (cluster mode disabled) cluster (Console) (p. 47) section.
3. To find the cluster's Primary and/or Reader endpoints, choose the box to the left of cluster's name.
Find your node endpoints

Primary and Reader endpoints for a Redis (cluster mode disabled) cluster

If there is only one node in the cluster, there is no primary endpoint and you can continue at the next step.

4. If the Redis (cluster mode disabled) cluster has replica nodes, you can find the cluster's replica node endpoints by choosing the cluster's name.

The nodes screen appears with each node in the cluster, primary and replicas, listed with its endpoint.

Node endpoints for a Redis (cluster mode disabled) cluster

5. To copy an endpoint to your clipboard:
   a. One endpoint at a time, find then highlight the endpoint you want to copy.
   b. Right-click the highlighted endpoint, then choose Copy from the context menu.

The highlighted endpoint is now copied to your clipboard. For information on using the endpoint to connect to a node, see Connecting to nodes (p. 97).

A Redis (cluster mode disabled) primary endpoint looks something like the following. There is a difference depending upon whether or not In-Transit encryption is enabled.

In-transit encryption not enabled

```
clusterName.xxxxxx.nodeId.regionAndAz.cache.amazonaws.com:port
redis-01.7abc2d.0001.usw2.cache.amazonaws.com:6379
```
In-transit encryption enabled

```
master.clusterName.xxxxxx.regionAndAz.cache.amazonaws.com:port
master.ncit.ameaqx.use1.cache.amazonaws.com:6379
```

Now that you have the endpoint you need, copy it to your clipboard for use in connecting to the cluster in the next step.

To further explore how to find your endpoints, see the relevant topics for the engine and cluster type you’re running.

- Finding connection endpoints (p. 175)
- Finding Endpoints for a Redis (Cluster Mode Enabled) Cluster (Console) (p. 178)—You need the cluster's Configuration endpoint.
- Finding Endpoints (AWS CLI) (p. 180)
- Finding Endpoints (ElastiCache API) (p. 183)

## Connect to a Redis cluster or replication group (Linux)

Now that you have the endpoint you need, you can log in to an EC2 instance and connect to the cluster or replication group. In the following example, you use the `redis-cli` utility to connect to a cluster. The latest version of redis-cli also supports SSL/TLS for connecting encryption/authentication enabled clusters.

The following example uses Amazon EC2 instances running Amazon Linux and Amazon Linux 2. For details on installing and compiling redis-cli with other Linux distributions, see the documentation for your specific operating system.

**Note**
This process covers testing a connection using redis-cli utility for unplanned use only. For a list of supported Redis clients, see the Redis documentation. For examples of using the AWS SDKs with ElastiCache, see Getting Started with ElastiCache and AWS SDKs (p. 68).

### Download and install redis-cli

1. Connect to your Amazon EC2 instance using the connection utility of your choice. For instructions on how to connect to an Amazon EC2 instance, see the Amazon EC2 Getting Started Guide.
2. Download and install redis-cli utility by running following commands:

   **Amazon Linux 2**
   ```
sudo amazon-linux-extras install epel -y
sudo yum install gcc jemalloc-devel openssl-devel tcl tcl-devel -y
sudo wget http://download.redis.io/redis-stable.tar.gz
sudo tar xvzf redis-stable.tar.gz
cd redis-stable
sudo make BUILD_TLS=yes
```

   **Amazon Linux**
   ```
sudo yum install gcc jemalloc-devel openssl-devel tcl tcl-devel clang wget
sudo wget http://download.redis.io/redis-stable.tar.gz
sudo tar xzvf redis-stable.tar.gz
sudo tar xvzf redis-stable.tar.gz
```

API Version 2015-02-02
sudo CC=clang make BUILD_TLS=yes

**Note**
If the cluster you are connecting to isn't encrypted, you don't need the `BUILD_TLS=yes` option.

## Connecting to a cluster mode disabled unencrypted-cluster

1. Run the following command to connect to the cluster and replace `cluster-endpoint` and `port number` with the endpoint of your cluster and your port number. (The default port for Redis is 6379.)

   ```bash
   src/redis-cli -h cluster-endpoint -c -p port number
   ```

   **Note**
   In the preceding command, option `-c` enables cluster mode following `-ASK` and `-MOVED` redirections.

   The result in a Redis command prompt looks similar to the following:

   ```
   cluster-endpoint:port number
   ```

2. You can now run Redis commands. Note that redirection occurs because you enabled it using the `-c` option. If redirection isn't enabled, the command returns the MOVED error. For more information on the MOVED error, see Redis cluster specification.

   ```
   set x Hi
   -> Redirected to slot [16287] located at 172.31.28.122:6379
   OK
   set y Hello
   OK
   get y
   "Hello"
   set z Bye
   -> Redirected to slot [8157] located at 172.31.9.201:6379
   OK
   get z
   "Bye"
   get x
   -> Redirected to slot [16287] located at 172.31.28.122:6379
   "Hi"
   ```

## Connecting to an Encryption/Authentication enabled cluster

By default, `redis-cli` uses an unencrypted TCP connection when connecting to Redis. The option `BUILD_TLS=yes` enables SSL/TLS at the time of `redis-cli` compilation as shown in the preceding Download and install `redis-cli` (p. 56) section. Enabling AUTH is optional. However, you must enable encryption in-transit in order to enable AUTH. For more details on ElastiCache encryption and authentication, see ElastiCache for Redis in-transit encryption (TLS) (p. 471).

**Note**
You can use the option `--tls` with `redis-cli` to connect to both cluster mode enabled and disabled encrypted clusters. If a cluster has an AUTH token set, then you can use the option `-a` to provide an AUTH password.

In the following examples, be sure to replace `cluster-endpoint` and `port number` with the endpoint of your cluster and your port number. (The default port for Redis is 6379.)
Connect to cluster mode disabled encrypted clusters

The following example connects to an encryption and authentication enabled cluster:

```bash
src/redis-cli -h cluster-endpoint --tls -a your-password -p port number
```

The following example connects to a cluster that has only encryption enabled:

```bash
src/redis-cli -h cluster-endpoint --tls -p port number
```

Connect to cluster mode enabled encrypted clusters

The following example connects to an encryption and authentication enabled cluster:

```bash
src/redis-cli -c -h cluster-endpoint --tls -a your-password -p port number
```

The following example connects to a cluster that has only encryption enabled:

```bash
src/redis-cli -c -h cluster-endpoint --tls -p port number
```

After you connect to the cluster, you can run the Redis commands as shown in the preceding examples for unencrypted clusters.

Redis-cli alternative

If the cluster isn't cluster mode enabled and you need to make a connection to the cluster for a short test but without going through the redis-cli compilation, you can use telnet or openssl. In the following example commands, be sure to replace `cluster-endpoint` and `port number` with the endpoint of your cluster and your port number. (The default port for Redis is 6379.)

The following example connects to an encryption and/or authentication enabled cluster mode disabled cluster:

```bash
openssl s_client -connect cluster-endpoint:port number
```

If the cluster has a password set, first connect to the cluster. After connecting, authenticate the cluster using the following command, then press the Enter key. In the following example, replace `your-password` with the password for your cluster.

```bash
Auth your-password
```

The following example connects to a cluster mode disabled cluster that doesn't have encryption or authentication enabled:

```bash
telnet cluster-endpoint port number
```

Connect to a Redis cluster or replication group (Windows)

In order to connect to the Redis Cluster from an EC2 Windows instance using the Redis CLI, you must download the `redis-cli` package and use `redis-cli.exe` to connect to the Redis Cluster from an EC2 Windows instance.
In the following example, you use the `redis-cli` utility to connect to a cluster that is not encryption enabled and running Redis. For more information about Redis and available Redis commands, see Redis commands on the Redis website.

**To connect to a Redis cluster that is not encryption-enabled using `redis-cli`**

1. Connect to your Amazon EC2 instance using the connection utility of your choice. For instructions on how to connect to an Amazon EC2 instance, see the Amazon EC2 Getting Started Guide.

2. Copy and paste the link [https://github.com/microsoftarchive/redis/releases/download/win-3.0.504/Redis-x64-3.0.504.zip](https://github.com/microsoftarchive/redis/releases/download/win-3.0.504/Redis-x64-3.0.504.zip) in an Internet browser to download the zip file for the Redis client from the available release at GitHub [https://github.com/microsoftarchive/redis/releases/tag/win-3.0.504](https://github.com/microsoftarchive/redis/releases/tag/win-3.0.504)

   Extract the zip file to your desired folder/path.

   Open the Command Prompt and change to the Redis directory and run the command:

   ```
c:\Redis>redis-cli -h Redis_Cluster_Endpoint -p 6379
   ```

   For example:

   ```
c:\Redis>redis-cli -h cmd.xxxxxxx.ng.0001.usw2.cache.amazonaws.com -p 6379
   ```

3. Run Redis commands.

   You are now connected to the cluster and can run Redis commands like the following.

   ```
   set a "hello"          // Set key "a" with a string value and no expiration
   OK
   get a                 // Get value for key "a"
   "hello"
   get b                 // Get value for key "b" results in miss
   (nil)
   set b "Good-bye" EX 5 // Set key "b" with a string value and a 5 second expiration
   "Good-bye"
   get b                 // Get value for key "b"
   "Good-bye"
   // wait >= 5 seconds
   get b                 // key has expired, nothing returned
   (nil)
   quit                  // Exit from redis-cli
   ```

**Connecting to a cluster mode disabled unencrypted-cluster**

1. Run the following command to connect to the cluster and replace `cluster-endpoint` and `port number` with the endpoint of your cluster and your port number. (The default port for Redis is 6379.)

   ```
src/redis-cli -h cluster-endpoint -c -p port number
   ```

   **Note**

   In the preceding command, option `-c` enables cluster mode following `-ASK` and `-MOVED` redirections.

   The result in a Redis command prompt looks similar to the following:

   ```
   cluster-endpoint:port number
   ```
2. You can now run Redis commands. Note that redirection occurs because you enabled it using the `-c` option. If redirection isn’t enabled, the command returns the MOVED error. For more information on the MOVED error, see Redis cluster specification.

```
set x Hi
  -> Redirected to slot [16287] located at 172.31.28.122:6379
OK
set y Hello
OK
get y
"Hello"
get z Bye
  -> Redirected to slot [8157] located at 172.31.9.201:6379
OK
get z
"Bye"
get x
  -> Redirected to slot [16287] located at 172.31.28.122:6379
"Hi"
```

Connecting to an Encryption/Authentication enabled cluster

By default, redis-cli uses an unencrypted TCP connection when connecting to Redis. The option `BUILD_TLS=yes` enables SSL/TLS at the time of redis-cli compilation as shown in the preceding Download and install redis-cli (p. 56) section. Enabling AUTH is optional. However, you must enable encryption in-transit in order to enable AUTH. For more details on ElastiCache encryption and authentication, see ElastiCache for Redis in-transit encryption (TLS) (p. 471).

**Note**

You can use the option `--tls` with redis-cli to connect to both cluster mode enabled and disabled encrypted clusters. If a cluster has an AUTH token set, then you can use the option `-a` to provide an AUTH password.

In the following examples, be sure to replace `cluster-endpoint` and `port number` with the endpoint of your cluster and your port number. (The default port for Redis is 6379.)

**Connect to cluster mode disabled encrypted clusters**

The following example connects to an encryption and authentication enabled cluster:

```
src/redis-cli -h cluster-endpoint --tls -a your-password -p port number
```

The following example connects to a cluster that has only encryption enabled:

```
src/redis-cli -h cluster-endpoint --tls -p port number
```

**Connect to cluster mode enabled encrypted clusters**

The following example connects to an encryption and authentication enabled cluster:

```
src/redis-cli -c -h cluster-endpoint --tls -a your-password -p port number
```

The following example connects to a cluster that has only encryption enabled:

```
src/redis-cli -c -h cluster-endpoint --tls -p port number
```
After you connect to the cluster, you can run the Redis commands as shown in the preceding examples for unencrypted clusters.

**Step 5: Deleting a cluster**

As long as a cluster is in the *available* state, you are being charged for it, whether or not you are actively using it. To stop incurring charges, delete the cluster.

**Warning**
When you delete an ElastiCache for Redis cluster, your manual snapshots are retained. You can also create a final snapshot before the cluster is deleted. Automatic cache snapshots are not retained. For more information, see Backup and restore for ElastiCache for Redis (p. 310).

**Using the AWS Management Console**

The following procedure deletes a single cluster from your deployment. To delete multiple clusters, repeat the procedure for each cluster that you want to delete. You do not need to wait for one cluster to finish deleting before starting the procedure to delete another cluster.

**To delete a cluster**

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. In the ElastiCache console dashboard, choose Redis.

   A list of all clusters running Redis appears.
3. To choose the cluster to delete, choose the cluster's name from the list of clusters. In this case, the name of the cluster you created at Step 2: Create a cluster (p. 46).

   **Important**
   You can only delete one cluster at a time from the ElastiCache console. Choosing multiple clusters disables the delete operation.
4. For Actions, choose Delete.
5. In the Delete Cluster confirmation screen, choose Delete to delete the cluster, or choose Cancel to keep the cluster.

   If you chose Delete, the status of the cluster changes to deleting.

As soon as your cluster is no longer listed in the list of clusters, you stop incurring charges for it.

**Using the AWS CLI**

The following code deletes the cache cluster *my-cluster*. In this case, substitute *my-cluster* with the name of the cluster you created at Step 2: Create a cluster (p. 46).

```
aws elasticache delete-cache-cluster --cache-cluster-id my-cluster
```

The `delete-cache-cluster` CLI action only deletes one cache cluster. To delete multiple cache clusters, call `delete-cache-cluster` for each cache cluster that you want to delete. You do not need to wait for one cache cluster to finish deleting before deleting another.

For Linux, macOS, or Unix:

```
aws elasticache delete-cache-cluster \n```
For Windows:

```
aws elasticache delete-cache-cluster ^
 --cache-cluster-id my-cluster ^
 --region us-east-2
```

For more information, see the AWS CLI for ElastiCache topic `delete-cache-cluster`.

### Using the ElastiCache API

The following code deletes the cluster `my-cluster`. In this case, substitute `my-cluster` with the name of the cluster you created at Step 2: Create a cluster (p. 46).

```text
https://elasticache.us-west-2.amazonaws.com/
    ?Action=DeleteCacheCluster
    &CacheClusterId=my-cluster
    &Region us-east-2
    &SignatureVersion=4
    &SignatureMethod=HmacSHA256
    &Timestamp=20150202T220302Z
    &X-Amz-Algorithm=AWS4-HMAC-SHA256
    &X-Amz-Date=20150202T220302Z
    &X-Amz-SignedHeaders=Host
    &X-Amz-Expires=20150202T220302Z
    &X-Amz-Credential=<credential>
    &X-Amz-Signature=<signature>
```

The `DeleteCacheCluster` API operation only deletes one cache cluster. To delete multiple cache clusters, call `DeleteCacheCluster` for each cache cluster that you want to delete. You do not need to wait for one cache cluster to finish deleting before deleting another.

For more information, see the ElastiCache API reference topic `DeleteCacheCluster`.

### ElastiCache tutorials and videos

The following tutorials address tasks of interest to the Amazon ElastiCache user.

- **ElastiCache Videos (p. 63)**
- **Tutorial: Configuring a Lambda Function to Access Amazon ElastiCache in an Amazon VPC**
ElastiCache Videos

Following, you can find videos to help you learn basic and advanced Amazon ElastiCache concepts. For information about AWS Training, see AWS Training & Certification.

Topics

- Introductory Videos (p. 63)
- Advanced Videos (p. 64)

Introductory Videos

The following videos introduce you to Amazon ElastiCache.

Topics

- AWS re:Invent 2020: What's new in Amazon ElastiCache (p. 63)
- AWS re:Invent 2019: What's new in Amazon ElastiCache (p. 63)

AWS re:Invent 2017: What’s new in Amazon ElastiCache

DAT204—Building Scalable Applications on AWS NoSQL Services (re:Invent 2015)

In this session, we discuss the benefits of NoSQL databases and take a tour of the main NoSQL services offered by AWS—Amazon DynamoDB and Amazon ElastiCache. Then, we hear from two leading customers, Expedia and Mapbox, about their use cases and architectural challenges, and how they addressed them using AWS NoSQL services, including design patterns and best practices. You should come out of this session having a better understanding of NoSQL and its powerful capabilities, ready to tackle your database challenges with confidence.

DAT204—Building Scalable Applications on AWS NoSQL Services (re:Invent 2015)

DAT207—Accelerating Application Performance with Amazon ElastiCache (AWS re:Invent 2013)

In this video, learn how you can use Amazon ElastiCache to easily deploy an in-memory caching system to speed up your application performance. We show you how to use Amazon ElastiCache to improve your application latency and reduce the load on your database servers. We’ll also show you how to build a caching layer that is easy to manage and scale as your application grows. During this session, we go over
various scenarios and use cases that can benefit by enabling caching, and discuss the features provided by Amazon ElastiCache.

**DAT207 - Accelerating Application Performance with Amazon ElastiCache (re:Invent 2013)**

### Advanced Videos

The following videos cover more advanced Amazon ElastiCache topics.

**Topics**

- Design for success with Amazon ElastiCache best practices (re:Invent 2020) (p. 64)
- Supercharge your real-time apps with Amazon ElastiCache (re:Invent 2019) (p. 64)
- Best practices: migrating Redis clusters from Amazon EC2 to ElastiCache (re:Invent 2019) (p. 64)

- DAT307—Deep Dive into Amazon ElastiCache Architecture and Design Patterns (re:Invent 2013) (p. 66)

**Design for success with Amazon ElastiCache best practices (re:Invent 2020)**

With the explosive growth of business-critical, real-time applications built on Redis, availability, scalability, and security have become top considerations. Learn best practices for setting up Amazon ElastiCache for success with online scaling, high availability across Multi-AZ deployments, and security configurations.

**Supercharge your real-time apps with Amazon ElastiCache (re:Invent 2019)**

With the rapid growth in cloud adoption and the new scenarios that it empowers, applications need microsecond latency and high throughput to support millions of requests per second. Developers have traditionally relied on specialized hardware and workarounds, such as disk-based databases combined with data reduction techniques, to manage data for real-time applications. These approaches can be expensive and not scalable. Learn how you can boost the performance of real-time applications by using the fully managed, in-memory Amazon ElastiCache for extreme performance, high scalability, availability, and security.

**Best practices: migrating Redis clusters from Amazon EC2 to ElastiCache (re:Invent 2019)**

Managing Redis clusters on your own can be hard. You have to provision hardware, patch software, back up data, and monitor workloads constantly. With the newly released Online Migration feature for Amazon ElastiCache, you can now easily move your data from self-hosted Redis on Amazon EC2 to fully managed Amazon ElastiCache, with cluster mode disabled. In this session, you learn about the new
Online Migration tool, see a demo, and, more importantly, learn hands-on best practices for a smooth migration to Amazon ElastiCache.

Best practices: migrating Redis clusters from Amazon EC2 to ElastiCache (re:Invent 2019)

Scaling a Fantasy Sports Platform with Amazon ElastiCache & Amazon Aurora STP11 (re:Invent 2018)

Dream11 is India's leading sports-tech startup. It has a growing base of 40 million+ users playing multiple sports, including fantasy cricket, football, and basketball, and it currently serves one million concurrent users, who produce three million requests per minute under a 50-millisecond response time. In this talk, Dream11 CTO Amit Sharma explains how the company uses Amazon Aurora and Amazon ElastiCache to handle flash traffic, which can triple within a 30-second response window. Sharma also talks about scaling transactions without locking, and he shares the steps for handling flash traffic—thereby serving five million daily active users. Complete Title: AWS re:Invent 2018: Scaling a Fantasy Sports Platform with Amazon ElastiCache & Amazon Aurora (STP11)

Reliable & Scalable Redis in the Cloud with Amazon ElastiCache (re:Invent 2018)

This session covers the features and enhancements in our Redis-compatible service, Amazon ElastiCache for Redis. We cover key features, such as Redis 5, scalability and performance improvements, security and compliance, and much more. We also discuss upcoming features and customer case studies.

ElastiCache Deep Dive: Design Patterns for In-Memory Data Stores (re:Invent 2018)

In this session, we provide a behind the scenes peek to learn about the design and architecture of Amazon ElastiCache. See common design patterns with our Redis and Memcached offerings and how customers use them for in-memory data processing to reduce latency and improve application throughput. We review ElastiCache best practices, design patterns, and anti-patterns.

DAT305—Amazon ElastiCache Deep Dive (re:Invent 2017)

Look behind the scenes to learn about Amazon ElastiCache's design and architecture. See common design patterns with our Memcached and Redis offerings and how customers have used them for in-memory operations to reduce latency and improve application throughput. During this video, we review ElastiCache best practices, design patterns, and anti-patterns.

The video introduces the following:

- ElastiCache for Redis online resharding
- ElastiCache security and encryption
- ElastiCache for Redis version 3.2.10

DAT305—Amazon ElastiCache Deep Dive (re:Invent 2016)

DAT306—Amazon ElastiCache Deep Dive (re:Invent 2016)

Look behind the scenes to learn about Amazon ElastiCache's design and architecture. See common design patterns with our Memcached and Redis offerings and how customers have used them for in-
memory operations to reduce latency and improve application throughput. During this session, we review ElastiCache best practices, design patterns, and anti-patterns.

DAT306—Amazon ElastiCache Deep Dive (re:Invent 2016)

DAT317—How IFTTT uses ElastiCache for Redis to Predict Events (re:Invent 2016)

IFTTT is a free service that empowers people to do more with the services they love, from automating simple tasks to transforming how someone interacts with and controls their home. IFTTT uses ElastiCache for Redis to store transaction run history and schedule predictions as well as indexes for log documents on Amazon S3. View this session to learn how the scripting power of Lua and the data types of Redis allowed people to accomplish something they wouldn't have been able to elsewhere.

DAT317—How IFTTT uses ElastiCache for Redis to Predict Events (re:Invent 2016)

DAT407—Amazon ElastiCache Deep Dive (re:Invent 2015)

Peek behind the scenes to learn about Amazon ElastiCache's design and architecture. See common design patterns of our Memcached and Redis offerings and how customers have used them for in-memory operations and achieved improved latency and throughput for applications. During this session, we review best practices, design patterns, and anti-patterns related to Amazon ElastiCache.

DAT407—Amazon ElastiCache Deep Dive (re:Invent 2015)

SDD402—Amazon ElastiCache Deep Dive (re:Invent 2014)

In this video, we examine common caching use cases, the Memcached and Redis engines, patterns that help you determine which engine is better for your needs, consistent hashing, and more as means to building fast, scalable applications. Frank Wiebe, Principal Scientist at Adobe, details how Adobe uses Amazon ElastiCache to improve customer experience and scale their business.

DAT402—Amazon ElastiCache Deep Dive (re:Invent 2014)

DAT307—Deep Dive into Amazon ElastiCache Architecture and Design Patterns (re:Invent 2013)

In this video, we examine caching, caching strategies, scaling out, monitoring. We also compare the Memcached and Redis engines. During this session, also we review best practices and design patterns related to Amazon ElastiCache.

Where do I go from here?

Now that you have tried the Getting Started exercise, you can explore the following sections to learn more about ElastiCache and available tools:

- Getting started with AWS
- Tools for Amazon Web Services
- AWS Command Line Interface
- Amazon ElastiCache API reference

After you complete the Getting Started exercise, you can read these sections to learn more about ElastiCache administration:
• **Choosing your node size (p. 127)**

You want your cache to be large enough to accommodate all the data you want to cache. At the same time, you don't want to pay for more cache than you need. Use this topic to help you choose the best node size.

• **Caching strategies and best practices (p. 215)**

Identify and address issues that can affect the efficiency of your cluster.
Getting Started with ElastiCache and AWS SDKs

This section contains hands-on tutorials to help you learn about Amazon ElastiCache. We encourage you to work through one of the language-specific tutorials.

**Note**
AWS SDKs are available for a wide variety of languages. For a complete list, see Tools for Amazon Web Services.

Python and ElastiCache

In this tutorial, you use the AWS SDK for Python (Boto3) to write simple programs to perform the following ElastiCache operations:

- Create ElastiCache clusters (cluster mode enabled and cluster mode disabled)
- Check if users or user groups exist, otherwise create them (Redis 6.0 onwards only)
- Connect to ElastiCache
- Perform operations such as setting and getting strings, reading from and writing to streams and publishing and subscribing from Pub/Sub channel.

As you work through this tutorial, you can refer to the AWS SDK for Python (Boto) documentation. The following section is specific to ElastiCache:

ElastiCache low-level client

**Tutorial Prerequisites**

- Set up an AWS access key to use the AWS SDKs. For more information, see Setting up (p. 41).
- Install Python 3.0 or later. For more information, see https://www.python.org/downloads. For instructions, see Quickstart in the Boto 3 documentation.

**Creating Elasticache clusters and users**

The following examples use the boto3 SDK for ElastiCache management operations (cluster or user creation) and redis-py/redis-py-cluster for data handling.

**Topics**

- Create a cluster mode disabled cluster (p. 69)
- Create a cluster mode disabled cluster with TLS and RBAC (p. 70)
- Create a cluster mode enabled cluster (p. 71)
- Create a cluster mode enabled cluster with TLS and RBAC (p. 72)
Create a cluster mode disabled cluster

Copy the following program and paste it into a file named `CreateClusterModeDisabledCluster.py`.

```python
import boto3
import logging

logging.basicConfig(level=logging.INFO)
client = boto3.client('elasticache')

def create_cluster_mode_disabled(CacheNodeType='cache.t3.small', EngineVersion='6.0', NumCacheClusters=2, ReplicationGroupDescription='Sample cache cluster', ReplicationGroupId=None):
    """Creates an Elasticache Cluster with cluster mode disabled
    Returns a dictionary with the API response
    :param CacheNodeType: Node type used on the cluster. If not specified, cache.t3.small will be used
    Refer to https://docs.aws.amazon.com/AmazonElastiCache/latest/red-ug/CacheNodes.SupportedTypes.html for supported node types
    :param EngineVersion: Engine version to be used. If not specified, latest will be used.
    :param NumCacheClusters: Number of nodes in the cluster. Minimum 1 (just a primary node) and maximum 6 (1 primary and 5 replicas).
    If not specified, cluster will be created with 1 primary and 1 replica.
    :param ReplicationGroupDescription: Description for the cluster.
    :param ReplicationGroupId: Name for the cluster
    :return: dictionary with the API results"

    if not ReplicationGroupId:
        return 'ReplicationGroupId parameter is required'

    response = client.create_replication_group(  
        AutomaticFailoverEnabled=True,  
        CacheNodeType=CacheNodeType,  
        Engine='redis',  
        EngineVersion=EngineVersion,  
        NumCacheClusters=NumCacheClusters,  
        ReplicationGroupDescription=ReplicationGroupDescription,  
        ReplicationGroupId=ReplicationGroupId,  
        SnapshotRetentionLimit=30,
    )
    return response

if __name__ == '__main__':
    # Creates an Elasticache Cluster mode disabled cluster, based on cache.m6g.large nodes, Redis 6, one primary and two replicas
    elasticacheResponse = create_cluster_mode_disabled(  
        CacheNodeType='cache.m6g.large',  
        EngineVersion='6.0',  
        NumCacheClusters=3,  
        ReplicationGroupDescription='Redis cluster mode disabled with replicas',  
        ReplicationGroupId='redis202104053'
    )
    logging.info(elasticacheResponse)
```

To run the program, enter the following command:

```
API Version 2015-02-02
```
python CreateClusterModeDisabledCluster.py

For more information, see Managing clusters (p. 120).

Create a cluster mode disabled cluster with TLS and RBAC

To ensure security, you can use Transport Layer Security (TLS) and Role-Based Access Control (RBAC) when creating a cluster mode disabled cluster. Unlike Redis AUTH, where all authenticated clients have full replication group access if their token is authenticated, RBAC enables you to control cluster access through user groups. These user groups are designed as a way to organize access to replication groups. For more information, see Authenticating users with Role-Based Access Control (RBAC) (p. 490).

Copy the following program and paste it into a file named ClusterModeDisabledWithRBAC.py.

```python
import boto3
import logging
logging.basicConfig(level=logging.INFO)
client = boto3.client('elasticache')

def create_cluster_mode_disabled_rbac(CacheNodeType='cache.t3.small', EngineVersion='6.0', NumCacheClusters=2, ReplicationGroupDescription='Sample cache cluster', ReplicationGroupId=None, UserGroupIds=None, SecurityGroupIds=None, CacheSubnetGroupName=None):
    """Creates an Elasticache Cluster with cluster mode disabled and RBAC

    Arguments:
    :param CacheNodeType: Node type used on the cluster. If not specified, cache.t3.small will be used
    Refer to https://docs.amazonaws.amazon.com/AmazonElastiCache/latest/red-ug/CacheNodes.SupportedTypes.html for supported node types
    :param EngineVersion: Engine version to be used. If not specified, latest will be used.
    :param NumCacheClusters: Number of nodes in the cluster. Minimum 1 (just a primary node) and maximum 6 (1 primary and 5 replicas).
    If not specified, cluster will be created with 1 primary and 1 replica.
    :param ReplicationGroupDescription: Description for the cluster.
    :param ReplicationGroupId: Mandatory name for the cluster.
    :param UserGroupIds: Mandatory list of user groups to be assigned to the cluster.
    :param SecurityGroupIds: List of security groups to be assigned. If not defined, default will be used
    :param CacheSubnetGroupName: subnet group where the cluster will be placed. If not defined, default will be used.
    :return: dictionary with the API results
    """
    if not ReplicationGroupId:
        return {'Error': 'ReplicationGroupId parameter is required'}
    elif not isinstance(UserGroupIds,(list)):
        return {'Error': 'UserGroupIds parameter is required and must be a list'}
    params={'AutomaticFailoverEnabled': True,
            'CacheNodeType': CacheNodeType,
            'Engine': 'redis',
            'EngineVersion': EngineVersion,
            'NumCacheClusters': NumCacheClusters,
            'ReplicationGroupDescription': ReplicationGroupDescription,
            'ReplicationGroupId': ReplicationGroupId,
            'SnapshotRetentionLimit': 30,
            'TransitEncryptionEnabled': True,
            'UserGroupIds':UserGroupIds
            }
    # defaults will be used if CacheSubnetGroupName or SecurityGroups are not explicit.
```

API Version 2015-02-02
if isinstance(SecurityGroupIds,(list)):
    params.update({'SecurityGroupIds':SecurityGroupIds})
if CacheSubnetGroupName:
    params.update({'CacheSubnetGroupName':CacheSubnetGroupName})

response = client.create_replication_group(**params)
return response

if __name__ == '__main__':
    # Creates an Elasticache Cluster mode disabled cluster, based on cache.m6g.large nodes, Redis 6, one primary and two replicas.
    # Assigns the existent user group "mygroup" for RBAC authentication
    
    response=create_cluster_mode_disabled_rbac(
        CacheNodeType='cache.m6g.large',
        EngineVersion='6.0',
        NumCacheClusters=3,
        ReplicationGroupDescription='Redis cluster mode disabled with replicas',
        ReplicationGroupId='redis202104',
        UserGroupIds=[
            'mygroup'
        ],
        SecurityGroupIds=[
            'sg-7cc73803'
        ],
        CacheSubnetGroupName='default'
    )

logging.info(response)

To run the program, enter the following command:

    python ClusterModeDisabledWithRBAC.py

For more information, see Managing clusters (p. 120).

Create a cluster mode enabled cluster

Copy the following program and paste it into a file named ClusterModeEnabled.py.

```python
import boto3
import logging
logging.basicConfig(level=logging.INFO)
client = boto3.client('elasticache')

def create_cluster_mode_enabled(CacheNodeType='cache.t3.small',EngineVersion='6.0',NumNodeGroups=1,ReplicasPerNodeGroup=1,ReplicationGroupDescription='Sample cache with cluster mode enabled',ReplicationGroupId=None):
    """Creates an Elasticache Cluster with cluster mode enabled
    Returns a dictionary with the API response
    :param CacheNodeType: Node type used on the cluster. If not specified, cache.t3.small will be used
    Refer to https://docs..amazon.com/AmazonElastiCache/latest/red-ug/CacheNodes.SupportedTypes.html for supported node types
    :param EngineVersion: Engine version to be used. If not specified, latest will be used.
    :param NumNodeGroups: Number of shards in the cluster. Minimum 1 and maximun 90.
    If not specified, cluster will be created with 1 shard.
    :param ReplicasPerNodeGroup: Number of replicas per shard. If not specified 1 replica per shard will be created.
    """
```
Creating Elasticache clusters and users

```python
# param ReplicationGroupDescription: Description for the cluster.
# param ReplicationGroupId: Name for the cluster
# return: dictionary with the API results

if not ReplicationGroupId:
    return 'ReplicationGroupId parameter is required'

    ReplicationGroupId='redis20210',
    # Creates a cluster mode enabled cluster with 1 shard(NumNodeGroups), 1 primary (implicit) and 2 replicas (replicasPerNodeGroup)
    NumNodeGroups=2,
    ReplicasPerNodeGroup=1,
)

logging.info(response)
```

To run the program, enter the following command:

```bash
python ClusterModeEnabled.py
```

For more information, see Managing clusters (p. 120).

Create a cluster mode enabled cluster with TLS and RBAC

To ensure security, you can use Transport Layer Security (TLS) and Role-Based Access Control (RBAC) when creating a cluster mode enabled cluster. Unlike Redis AUTH, where all authenticated clients have full replication group access if their token is authenticated, RBAC enables you to control cluster access through user groups. These user groups are designed as a way to organize access to replication groups. For more information, see Authenticating users with Role-Based Access Control (RBAC) (p. 490).

Copy the following program and paste it into a file named `ClusterModeEnabledWithRBAC.py`.

```python
import boto3
import logging
logging.basicConfig(level=logging.INFO)
client = boto3.client('elasticache')

def create_cluster_mode_enabled(CacheNodeType='cache.t3.small', EngineVersion='6.0', NumNodeGroups=1, ReplicasPerNodeGroup=1): ...
```

API Version 2015-02-02

72
ReplicationGroupDescription='Sample cache with cluster mode enabled',ReplicationGroupId=None,UserGroupIds=None,SecurityGroupIds=None,CacheSubnetGroupName=None,CacheParameterGroupName='default.redis6.0.cluster.on')

"""Creates an ElastiCache Cluster with cluster mode enabled and RBAC

Returns a dictionary with the API response

:param CacheNodeType: Node type used on the cluster. If not specified, cache.t3.small will be used. Refer to https://docs.amazon.com/AmazonElastiCache/latest/red-ug/CacheNodes.SupportedTypes.html for supported node types
:param EngineVersion: Engine version to be used. If not specified, latest will be used.
:param NumNodeGroups: Number of shards in the cluster. Minimum 1 and maximum 90. If not specified, cluster will be created with 1 shard.
:param ReplicasPerNodeGroup: Number of replicas per shard. If not specified 1 replica per shard will be created.
:param ReplicationGroupDescription: Description for the cluster.
:param ReplicationGroupId: Name for the cluster.
:param CacheParameterGroupName: Parameter group to be used. Must be compatible with the engine version and cluster mode enabled.
:return: dictionary with the API results

"""

To run the program, enter the following command:

```bash
gp python ClusterModeEnabledWithRBAC.py
```

For more information, see Managing clusters (p. 120).

**Check if users/usergroup exists, otherwise create them**

With RBAC, you create users and assign them specific permissions by using an access string. You assign the users to user groups aligned with a specific role (administrators, human resources) that are then deployed to one or more ElastiCache for Redis replication groups. By doing this, you can establish security boundaries between clients using the same Redis replication group or groups and prevent clients from accessing each other’s data. For more information, see Authenticating users with Role-Based Access Control (RBAC) (p. 490).

Connecting to Elasticache

The following examples use the Redis client to connect to ElastiCache.

Topics
- Connecting to a cluster mode disabled cluster (p. 76)
- Connecting to a cluster mode enabled cluster (p. 76)

Connecting to a cluster mode disabled cluster

Copy the following program and paste it into a file named `ConnectClusterModeDisabled.py`.

```python
from redis import Redis
import logging
logging.basicConfig(level=logging.INFO)
redis = Redis(host='primary.xxx.yyyyyy.zzz1.cache.amazonaws.com', port=6379,
             decode_responses=True, ssl=True, username='myuser', password='MyPassword0123456789')
if redis.ping():
    logging.info("Connected to Redis")
```

To run the program, enter the following command:
```
python ConnectClusterModeDisabled.py
```

Connecting to a cluster mode enabled cluster

Copy the following program and paste it into a file named `ConnectClusterModeEnabled.py`.

```python
from rediscluster import RedisCluster
import logging
logging.basicConfig(level=logging.INFO)
redis = RedisCluster(startup_nodes=[{'host': 'xxx.yyy.clusterfg.zzz1.cache.amazonaws.com', 'port': '6379'}],
                     decode_responses=True, skip_full_coverage_check=True)
if redis.ping():
    logging.info("Connected to Redis")
```

To run the program, enter the following command:
```
python ConnectClusterModeEnabled.py
```
Usage examples

The following examples use the boto3 SDK for ElastiCache to work with ElastiCache.

Topics
- Set and Get strings (p. 77)
- Set and Get a hash with multiple items (p. 77)
- Publish (write) and subscribe (read) from a Pub/Sub channel (p. 78)
- Write and read from a stream (p. 78)

Set and Get strings

Copy the following program and paste it into a file named `SetAndGetStrings.py`.

```python
import time
import logging
logging.basicConfig(level=logging.INFO, format='%(asctime)s: %(message)s')

keyName = 'mykey'
currTime = time.ctime(time.time())

# Set the key 'mykey' with the current date and time as value.
# The Key will expire and removed from cache in 60 seconds.
redis.set(keyName, currTime, ex=60)

# Sleep just for better illustration of TTL (expiration) value
time.sleep(5)

# Retrieve the key value and current TTL
keyValue = redis.get(keyName)
keyTTL = redis.ttl(keyName)

logging.info("Key {} was set at {} and has {} seconds until expired".format(keyName, keyValue, keyTTL))
```

To run the program, enter the following command:

```
python SetAndGetStrings.py
```

Set and Get a hash with multiple items

Copy the following program and paste it into a file named `SetAndGetHash.py`.

```python
import logging
import time
logging.basicConfig(level=logging.INFO, format='%(asctime)s: %(message)s')

keyName = 'mykey'
keyValues = {'datetime': time.ctime(time.time()), 'epochtime': time.time()}

# Set the hash 'mykey' with the current date and time in human readable format (datetime field) and epoch number (epochtime field).
redis.hset(keyName, mapping=keyValues)

# Set the key to expire and removed from cache in 60 seconds.
redis.expire(keyName, 60)
```
Usage examples

```python
# Sleep just for better illustration of TTL (expiration) value
time.sleep(5)

# Retrieves all the fields and current TTL
keyValues=redis.hgetall(keyName)
keyTTL=redis.ttl(keyName)
logging.info("Key {} was set at {} and has {} seconds until expired".format(keyName, keyValues, keyTTL))
```

To run the program, enter the following command:

```
python SetAndGetHash.py
```

Publish (write) and subscribe (read) from a Pub/Sub channel

Copy the following program and paste it into a file named `PubAndSub.py`.

```python
import logging
import time

def handlerFunction(message):
    """Prints message got from PubSub channel to the log output
    :param message: message to log
    """
    logging.info(message)
logging.basicConfig(level=logging.INFO)
redis = Redis(host="redis202104053.tihewd.ng.0001.use1.cache.amazonaws.com", port=6379,
              decode_responses=True)

# Creates the subscriber connection on "mychannel"
subscriber = redis.pubsub()
subscriber.subscribe(**{'mychannel': handlerFunction})

# Creates a new thread to watch for messages while the main process continues with its routines
thread = subscriber.run_in_thread(sleep_time=0.01)

# Creates publisher connection on "mychannel"
redis.publish('mychannel', 'My message')

# Publishes several messages. Subscriber thread will read and print on log.
while True:
    redis.publish('mychannel', time.ctime(time.time()))
    time.sleep(1)
```

To run the program, enter the following command:

```
python PubAndSub.py
```

Write and read from a stream

Copy the following program and paste it into a file named `ReadWriteStream.py`.

```python
from redis import Redis
import redis.exceptions as exceptions
import logging
```

API Version 2015-02-02
Amazon ElastiCache for Redis User Guide
Usage examples
import time
import threading
logging.basicConfig(level=logging.INFO)
def writeMessage(streamName):
"""Starts a loop writting the current time and thread name to 'streamName'
:param streamName: Stream (key) name to write messages.
"""
fieldsDict={'writerId':threading.currentThread().getName(),'myvalue':None}
while True:
fieldsDict['myvalue'] = time.ctime(time.time())
redis.xadd(streamName,fieldsDict)
time.sleep(1)

    readerThread.daemon = True
    readerThread.start()

# Keep the code running for 30 seconds
sleep(30)

To run the program, enter the following command:

python ReadWriteStream.py
Online migration to ElastiCache

By using Online Migration, you can migrate your data from self-hosted Redis on Amazon EC2 to Amazon ElastiCache.

Note
Online migration is not supported for clusters running on the r6gd node type.

Overview

To migrate your data from Redis running on Amazon EC2 to Amazon ElastiCache requires an existing or newly created Amazon ElastiCache deployment. The deployment must have a configuration that is ready for migration. It also should be in line with the configuration that you want, including attributes like instance type and number of replicas.

Online migration is designed for data migration from hosted Redis on Amazon EC2 to ElastiCache for Redis and not between ElastiCache for Redis clusters.

Important
We strongly recommend you read the following sections in their entirety before beginning the online migration process.

The migration begins when you call the `StartMigration` API operation or AWS CLI command. The migration process makes the primary node of the ElastiCache for Redis cluster a replica to your source Redis cluster on EC2. Using Redis replication, data is synced between your source Redis and ElastiCache. After the data is in sync, you are nearly ready to cut over to ElastiCache. At this point, you make changes on the application side so your application can call ElastiCache post-migration.

After the client-side changes are ready, call the `CompleteMigration` API operation. This API operation promotes your ElastiCache deployment to your primary Redis deployment with primary and replica nodes (as applicable). Now you can redirect your client application to start writing data to ElastiCache. Throughout the migration, you can check the status of replication by running the `redis-cli INFO` command on your Redis on EC2 nodes and on the ElastiCache primary node.

Migration steps

The following topics outline the process for migrating your data:

- Preparing your source and target Redis nodes for migration (p. 81)
- Starting migration (p. 82)
- Verifying the data migration progress (p. 83)
- Completing the data migration (p. 84)

Preparing your source and target Redis nodes for migration

You must ensure that all four of the prerequisites mentioned following are satisfied before you start the migration from ElastiCache console, API or AWS CLI.
To prepare your source and target Redis Nodes for migration

1. Identify the target ElastiCache deployment and make sure that you can migrate data to it.
   An existing or newly created ElastiCache deployment should meet the following requirements for migration:
   • It's cluster-mode disabled using Redis engine version 5.0.5 or higher.
   • It doesn't have either encryption in-transit or encryption at-rest enabled.
   • It has Multi-AZ enabled.
   • It has sufficient memory available to fit the data from your Redis on EC2 instance. To configure the right reserved memory settings, see Managing Reserved Memory (p. 223).
   • You can migrate directly from Redis versions 2.8.21 onward to Redis version 5.0.5 onward if are using the CLI or Redis versions 5.0.6 onward using the CLI or console. We don't recommend migrating to Redis version 5.0.5. Redis version 5.0.6 offers enhanced stability and security.

2. Make sure that the configurations of your Redis on EC2 and the ElastiCache for Redis deployment are compatible.
   At a minimum, all the following in the target ElastiCache deployment should be compatible with your Redis configuration for Redis replication:
   • Your Redis cluster should be in cluster-mode disabled configuration.
   • Your Redis on EC2 instance should not have Redis AUTH enabled.
   • Redis config protected-mode should be set to no.
   • If you have bind configuration in your Redis config, then it should be updated to allow requests from ElastiCache nodes.
   • The number of logical databases should be the same on the ElastiCache node and your Redis on EC2 instance. This value is set using databases in the Redis config.
   • Redis commands that perform data modification should not be renamed to allow replication of the data to succeed.
   • To replicate the data from your Redis cluster to ElastiCache, make sure that there is sufficient CPU and memory to handle this additional load. This load comes from the RDB file created by your Redis cluster and transferred over the network to ElastiCache node.

3. Make sure that your EC2 instance can connect with ElastiCache by doing the following:
   • Ensure that your EC2 instance's IP address is private.
   • Assign or create the ElastiCache deployment in the same virtual private cloud (VPC) as your Redis on your EC2 instance (recommended).
   • If the VPCs are different, set up VPC peering to allow access between the nodes. For more information on VPC peering, see Access Patterns for Accessing an ElastiCache Cluster in an Amazon VPC (p. 508).
   • The security group attached to your Redis on EC2 instance should allow inbound traffic from ElastiCache nodes.

4. Make sure that your application can direct traffic to ElastiCache nodes after migration of data is complete. For more information, see Access Patterns for Accessing an ElastiCache Cluster in an Amazon VPC (p. 508).

Starting migration

After all prerequisites are complete, you can begin data migration using the AWS Management Console, ElastiCache API, or AWS CLI. The following example shows using the CLI.

Start migration by calling the start-migration command with the following parameters:
Verifying the data migration progress

- `--replication-group-id` - Identifier of the target ElastiCache replication group
- `--customer-node-endpoint-list` - A list of endpoints with either DNS or IP addresses and the port where your source Redis on EC2 cluster is running. Because ElastiCache currently only supports cluster-mode disabled configuration, this list should contain one entry. If you have enabled chained replication, the endpoint can point to a replica instead of the primary node in your Redis cluster.

The following is an example using the CLI.

```
alws elasticache start-migration --replication-group-id test-cluster --customer-node-endpoint-list "Address='10.0.0.241',Port=6379"
```

As you run this command, the ElastiCache primary node configures itself to become a replica of your Redis on EC2 instance. The status of ElastiCache cluster changes to **migrating** and data starts migrating from your Redis on EC2 instance to the ElastiCache primary node. Depending on the size of the data and load on your Redis instance, the migration can take a while to complete. You can check the progress of the migration by running the `redis-cli INFO` command on your Redis on EC2 instance and ElastiCache primary node.

After successful replication, all writes to your Redis on EC2 instance propagate to the ElastiCache cluster. You can use ElastiCache nodes for reads. However, you can't write to the ElastiCache cluster. If the ElastiCache primary node has other replica nodes connected to it, these replica nodes continue to replicate from the ElastiCache primary node. This way, all the data from your Redis on EC2 instance gets replicated to all the nodes in ElastiCache cluster.

If the ElastiCache primary node can't become a replica of your Redis on EC2 instance, it retries several times before eventually promoting itself back to primary. The status of ElastiCache cluster then changes to **available**, and a replication group event about the failure to initiate the migration is sent. To troubleshoot such a failure, check the following:

- Look at the replication group event. Use any specific information from the event to fix the migration failure.
- If the event doesn't provide any specific information, make sure that you have followed the guidelines in **Preparing your source and target Redis nodes for migration (p. 81)**.
- Ensure that the routing configuration for your VPC and subnets allows traffic between ElastiCache nodes and your Redis on EC2 instance.
- Ensure the security group attached to your Redis on EC2 instance allows input bound traffic from ElastiCache nodes.
- Check Redis logs for your Redis on EC2 instance for more information about failures specific to replication.

### Verifying the data migration progress

After the migration has begun, you can do the following to track its progress:

- Verify that Redis `master_link_status` is up in the `INFO` command on ElastiCache primary node. You can also find this information in the ElastiCache console. Select the cluster and under **CloudWatch metrics**, observe **Master Link Health Status**. After the value reaches 1, the data is in sync.
- You can check that for the ElastiCache replica has an **online** state by running the `INFO` command on your Redis on EC2 instance. Doing this also provides information about replication lag.
- Verify low client output buffer by using the `CLIENT LIST` Redis command on your Redis on EC2 instance.
After the migration is complete, the ElastiCache cluster shows the status of **in-sync**. This status means that all data is now replicated. The data is in sync with any new writes coming to the primary node of your Redis instance.

## Completing the data migration

When you are ready to cut over to the ElastiCache cluster, use the `complete-migration` CLI command with the following parameters:

- `--replication-group-id` – The identifier for the replication group.
- `--force` – A value that forces the migration to stop without ensuring that data is in sync.

The following is an example.

```bash
aws elasticache complete-migration --replication-group-id test-cluster
```

As you run this command, the ElastiCache primary node stops replicating from your Redis instance and promotes it to primary. This promotion typically completes within minutes. To confirm the promotion to primary, check for the event `Complete Migration successful for test-cluster`. At this point, you can direct your application to ElastiCache writes and reads. ElastiCache cluster status should change from **migrating** to **available**.

If the promotion to primary fails, the ElastiCache primary node continues to replicate from your Redis on EC2 instance. The ElastiCache cluster continues to be in **migrating** status, and a replication group event message about the failure is sent. To troubleshoot this failure, look at the following:

- Check the replication group event. Use specific information from the event to fix the failure.
- You might get an event message about data not in sync. If so, make sure that the ElastiCache primary can replicate from your Redis on EC2 instance and both are in sync. If you still want to stop the migration, you can run the preceding command with the `--force` option.
- You might get an event message if one of the ElastiCache nodes is undergoing a replacement. You can retry the complete the migration step after the replacement is complete.

## Performing online data migration using the Console

You can use the AWS Management Console to migrate your data from the EC2 instance to your Redis cluster.

**To perform online data migration using the console**

2. Either create a new Redis cluster or choose an existing cluster. Make sure that the cluster meets the following requirements:
   - Your Redis engine version should be 5.0.5 or higher. We don't recommend migrating to Redis version 5.0.5. Redis version 5.0.6 offers enhanced stability and security.
   - Your Redis cluster should be in cluster-mode disabled configuration.
Performing online data migration using the Console

- Your Redis on EC2 instance should not have Redis AUTH enabled.
- Redis config protected-mode should be set to no.
- If you have bind configuration in your Redis config, then it should be updated to allow requests from ElastiCache nodes.
- The number of databases should be the same between the ElastiCache node and your Redis on EC2 instance. This value is set using databases in the Redis config.
- Redis commands that perform data modification should not be renamed to allow replication of the data to succeed.
- To replicate the data from your Redis cluster to ElastiCache, make sure that there is sufficient CPU and memory to handle this additional load. This load comes from the RDB file created by your Redis cluster and transferred over the network to ElastiCache node.
- The cluster is in available status.

3. With your cluster selected, choose Migrate Data from Endpoint for Actions.
4. In the Migrate Data from Endpoint dialog box, enter either the IP address or the name of the EC2 instance, and the port where your Redis on EC2 instance is available.
   
   **Important**
   The IP address must be exact. If you enter the address incorrectly, the migration fails.

5. Choose Start Migration.
   
   As the cluster begins migration, it changes to Modifying and then Migrating status.

6. Monitor the migration progress by choosing Events on the navigation pane.
At any point during the migration process, you can stop migration. To do so, choose your cluster and choose **Stop Data Migration** for **Actions**. The cluster then goes to **Available** status.

If the migration succeeds, the cluster goes to **Available** status and the event log shows the following:

Migration operation succeeded for replication group **ElastiCacheClusterName**.

If the migration fails, the cluster goes to **Available** status and the event log shows the following:

Migration operation failed for replication group **ElastiCacheClusterName**.
Choosing regions and availability zones

AWS Cloud computing resources are housed in highly available data center facilities. To provide additional scalability and reliability, these data center facilities are located in different physical locations. These locations are categorized by **regions** and **Availability Zones**.

AWS Regions are large and widely dispersed into separate geographic locations. Availability Zones are distinct locations within an AWS Region that are engineered to be isolated from failures in other Availability Zones. They provide inexpensive, low-latency network connectivity to other Availability Zones in the same AWS Region.

**Important**
Each region is completely independent. Any ElastiCache activity you initiate (for example, creating clusters) runs only in your current default region.

To create or work with a cluster in a specific region, use the corresponding regional service endpoint. For service endpoints, see **Supported regions & endpoints (p. 88)**.

Regions and Availability Zones

**Topics**
- Supported regions & endpoints (p. 88)
- Locating your nodes (p. 91)
- Using local zones with ElastiCache (p. 91)
- Using Outposts (p. 92)
Amazon ElastiCache is available in multiple AWS Regions. This means that you can launch ElastiCache clusters in locations that meet your requirements. For example, you can launch in the AWS Region closest to your customers, or launch in a particular AWS Region to meet certain legal requirements.

By default, the AWS SDKs, AWS CLI, ElastiCache API, and ElastiCache console reference the US-West (Oregon) region. As ElastiCache expands availability to new regions, new endpoints for these regions are also available to use in your HTTP requests, the AWS SDKs, AWS CLI, and the console.

Each region is designed to be completely isolated from the other regions. Within each region are multiple Availability Zones (AZ). By launching your nodes in different AZs you are able to achieve the greatest possible fault tolerance. For more information on regions and Availability Zones, see Choosing regions and availability zones (p. 87) at the top of this topic.

### Regions where ElastiCache is supported

<table>
<thead>

</tbody>
</table>

For information on using the AWS GovCloud (US) with ElastiCache, see Services in the AWS GovCloud (US) region: ElastiCache.

Some regions support a subset of node types. For a table of supported node types by AWS Region, see Supported node types by AWS Region (p. 101).

For a table of AWS products and services by region, see Products and Services by Region.
Locating your nodes

Amazon ElastiCache supports locating all of a cluster’s nodes in a single or multiple Availability Zones (AZs). Further, if you elect to locate your nodes in multiple AZs (recommended), ElastiCache enables you to either choose the AZ for each node, or allow ElastiCache to choose them for you.

By locating the nodes in different AZs, you eliminate the chance that a failure, such as a power outage, in one AZ will cause your entire system to fail. Testing has demonstrated that there is no significant latency difference between locating all nodes in one AZ or spreading them across multiple AZs.

You can specify an AZ for each node when you create a cluster or by adding nodes when you modify an existing cluster. For more information, see the following:

- Creating a cluster (p. 130)
- Modifying an ElastiCache cluster (p. 149)
- Adding nodes to a cluster (p. 152)

Using local zones with ElastiCache

A Local Zone is an extension of an AWS Region that is geographically close to your users. You can extend any virtual private cloud (VPC) from a parent AWS Region into a Local Zones by creating a new subnet and assigning it to the Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as other subnets in your VPC.

By using Local Zones, you can place resources such as an ElastiCache cluster in multiple locations close to your users.

When you create an ElastiCache cluster, you can choose a subnet in a Local Zone. Local Zones have their own connections to the internet and support AWS-DC-long. Thus, resources created in a Local Zone can serve local users with very low-latency communications. For more information, see AWS Local Zones.

A Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-west-2-lax-1a.

At this time, the available Local Zones are us-west-2-lax-1a and us-west-2-lax-1b.

The following limitations apply to ElastiCache for Local Zones:

- Global datastores aren't supported.
- Online migration isn't supported.
- The following node types are supported by Local Zones at this time:
  - Current generation:
    - **M5 node types**: cache.m5.large, cache.m5.xlarge, cache.m5.2xlarge, cache.m5.4xlarge, cache.m5.12xlarge, cache.m5.24xlarge
    - **R5 node types**: cache.r5.large, cache.r5.xlarge, cache.r5.2xlarge, cache.r5.4xlarge, cache.r5.12xlarge, cache.r5.24xlarge
    - **T3 node types**: cache.t3.micro, cache.t3.small, cache.t3.medium

Enabling a local zone

1. Enable the Local Zone in the Amazon EC2 console.
2. Create a subnet in the Local Zone.
   For more information, see Creating a subnet in your VPC in the Amazon VPC User Guide.
3. Create an ElastiCache subnet group in the Local Zone.
   When you create an ElastiCache subnet group, choose the Availability Zone group for the Local Zone.
   For more information, see Creating a subnet group in the ElastiCache User Guide.
4. Create an ElastiCache for Redis cluster that uses the ElastiCache subnet in the Local Zone. For more information, see one of the following topics:
   - Creating a Redis (cluster mode disabled) cluster (Console) (p. 47)
   - Creating a Redis (cluster mode enabled) cluster (Console) (p. 133)

Using Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs. An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region. You can create subnets on your Outpost and specify them when you create AWS resources such as ElastiCache clusters.

Note
In this version, the following limitations apply:
- ElastiCache for Outposts only supports M5 and R5 node families.
- Live migration is not supported.
- Multi-AZ (cross Outpost replication is not supported).
- Local snapshots are not supported.
- ElastiCache for Outposts is not supported in the following regions: cn-north-1, cn-northwest-1 and ap-northeast-3.

Using Outposts with the Redis console

2. On the navigation pane, choose Redis.
4. Under Location, select On-Premises - Create your ElastiCache instances on AWS Outposts.

Configure on-premises options

You can select either an available Outpost to add your cache cluster or, if there are no available Outposts, create a new one using the following steps:
Under On-Premises options:

1. Under Redis settings:
   
   a. **Name**: Enter a name for the Redis cluster
   
   b. **Description**: Enter a description for the Redis cluster.
   
   c. **Engine version compatibility**: Engine version is based on the AWS Outpost region
   
   d. **Port**: Accept the default port, 6379. If you have a reason to use a different port, type the port number.
   
   e. **Parameter group**: Use the drop-down to select a default or custom parameter group.
   
   f. **Node Type**: Available instances are based on Outposts availability. Porting Assistant for .NET for Outposts only supports M5 and R5 node families. From the drop down list, select Outposts and then select an available node type you want to use for this cluster. Then select Save.
   
   g. **Number of Replicas**: Enter the number of read replicas you want created for this replication group. You must have at least one and no more than five read replicas. The default value is 2.

   The autogenerated names of the read replicas follow the same pattern as that of the primary cluster's name, with a dash and sequential three-digit number added to the end, beginning with -002. For example, if your replication group is named MyGroup, then the names of the secondaries would be MyGroup-002, MyGroup-003, MyGroup-004, MyGroup-005, MyGroup-006.

2. Under Advanced Redis settings:
   
   a. **Subnet Group**: From the list, select Create new.

   • **Name**: Enter a name for the subnet group
   
   • **Description**: Enter a description for the subnet group
   
   • **VPC ID**: The VPC ID should match the Outpost VPC. If you select a VPC that has no subnet IDs on the Outposts, the list will return empty.

   • **Availability Zone or Outpost**: Select the Outpost you are using.

   • **Subnet ID**: Select a subnet ID that is available for the Outpost. If there are no subnet IDs available, you need to create them. For more information, see Create a Subnet.

   b. Select Create.

Viewing Outpost cluster details

On the Redis list page, select a cluster that belongs to an AWS Outpost and note the following when viewing the Cluster details:

- **Availability Zone**: This will represent the Outpost, using an ARN (Amazon Resource Name) and the AWS Resource Number.

- **Outpost name**: The name of the AWS Outpost.

Using Outposts with the AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to control multiple AWS services from the command line and automate them through scripts. You can use the AWS CLI for ad hoc (one-time) operations.
Downloading and configuring the AWS CLI

The AWS CLI runs on Windows, macOS, or Linux. Use the following procedure to download and configure it.

To download, install, and configure the CLI

1. Download the AWS CLI on the AWS Command Line Interface webpage.
2. Follow the instructions for Installing the AWS CLI and Configuring the AWS CLI in the AWS Command Line Interface User Guide.

Using the AWS CLI with Outposts

Use the following CLI operation to create a cache cluster that uses Outposts:

- **create-cache-cluster** — Using this operation, the `outpost-mode` parameter accepts a value that specifies whether the nodes in the cache cluster are created in a single Outpost or across multiple Outposts.

  **Note**
  At this time, only `single-outpost` mode is supported.

```bash
aws elasticache create-cache-cluster \
  --cache-cluster-id cache cluster id \
  --outpost-mode single-outpost \
```
Managing nodes

A node is the smallest building block of an Amazon ElastiCache deployment. It is a fixed-size chunk of secure, network-attached RAM. Each node runs the engine that was chosen when the cluster or replication group was created or last modified. Each node has its own Domain Name Service (DNS) name and port. Multiple types of ElastiCache nodes are supported, each with varying amounts of associated memory and computational power.

Generally speaking, due to its support for sharding, Redis (cluster mode enabled) deployments have a number of smaller nodes. In contrast, Redis (cluster mode disabled) deployments have fewer, larger nodes in a cluster. For a more detailed discussion of which node size to use, see Choosing your node size (p. 127).

Topics
- Redis nodes and shards (p. 95)
- Connecting to nodes (p. 97)
- Supported node types (p. 99)
- Rebooting nodes (cluster mode disabled only) (p. 102)
- Replacing nodes (p. 103)
- ElastiCache reserved nodes (p. 107)
- Migrating previous generation nodes (p. 117)

Some important operations involving nodes are the following:
- Adding nodes to a cluster (p. 152)
- Removing nodes from a cluster (p. 158)
- Scaling ElastiCache for Redis clusters (p. 345)
- Finding connection endpoints (p. 175)

Redis nodes and shards

A shard (in the API and CLI, a node group) is a hierarchical arrangement of nodes, each wrapped in a cluster. Shards support replication. Within a shard, one node functions as the read/write primary node. All the other nodes in a shard function as read-only replicas of the primary node. Redis version 3.2 and later support multiple shards within a cluster (in the API and CLI, a replication group). This support enables partitioning your data in a Redis (cluster mode enabled) cluster.

The following diagram illustrates the differences between a Redis (cluster mode disabled) cluster and a Redis (cluster mode enabled) cluster.
Both Redis (cluster mode disabled) and Redis (cluster mode enabled) support replication via shards. The API operation DescribeReplicationGroups (CLI: describe-replication-groups) lists the node groups with the member nodes, the node's role within the node group, and also other information.

When you create a Redis cluster, you specify whether you want to create a cluster with clustering enabled. Redis (cluster mode disabled) clusters never have more than one shard, which can be scaled horizontally by adding (up to a total of five) or deleting read replica nodes. For more information, see High availability using replication groups (p. 246), Adding a read replica, for Redis (Cluster Mode Disabled) replication groups (p. 306) or Deleting a read replica, for Redis (Cluster Mode Disabled) replication groups (p. 308). Redis (cluster mode disabled) clusters can also scale vertically by changing node types. For more information, see Scaling Redis (Cluster Mode Disabled) clusters with replica nodes (p. 360).

The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526).

For versions below 5.0.6, the limit is 250 per cluster.

To request a limit increase, see AWS Service Limits and choose the limit type Nodes per cluster per instance type.

After a Redis (cluster mode enabled) cluster is created, it can be altered (scaled in or out). For more information, see Scaling ElastiCache for Redis clusters (p. 345) and Replacing nodes (p. 103).

When you create a new cluster, you can seed it with data from the old cluster so it doesn't start out empty. This approach works only if the cluster group has the same number of shards as the old cluster. Doing this can be helpful if you need change your node type or engine version. For more information, see Making manual backups (p. 315) and Restoring from a backup with optional cluster resizing (p. 334).
Connecting to nodes

Before attempting to connect to the nodes in your Redis cluster, you must have the endpoints for the nodes. To find the endpoints, see the following:

- Finding a Redis (Cluster Mode Disabled) Cluster’s Endpoints (Console) (p. 176)
- Finding Endpoints for a Redis (Cluster Mode Enabled) Cluster (Console) (p. 178)
- Finding Endpoints (AWS CLI) (p. 180)
- Finding Endpoints (ElastiCache API) (p. 183)

In the following example, you use the `redis-cli` utility to connect to a cluster that is running Redis.

**Note**
For more information about Redis and available Redis commands, see the [http://redis.io/commands](http://redis.io/commands) webpage.

**To connect to a Redis cluster using the `redis-cli`**

1. Connect to your Amazon EC2 instance using the connection utility of your choice.

   **Note**
   For instructions on how to connect to an Amazon EC2 instance, see the Amazon EC2 Getting Started Guide.

2. To build `redis-cli`, download and install the GNU Compiler Collection (`gcc`). At the command prompt of your EC2 instance, enter the following command and enter `y` at the confirmation prompt.

   ```bash
   sudo yum install gcc
   ```

   Output similar to the following appears.

   ```
   Loaded plugins: priorities, security, update-motd, upgrade-helper
   Setting up Install Process
   Resolving Dependencies
   --> Running transaction check
   ... (output omitted) ...
   Total download size: 27 M
   Installed size: 53 M
   Is this ok [y/N]: y
   Downloading Packages:
   (1/11): binutils-2.22.52.0.1-10.36.amzn1.x86_64.rpm  |  5.2 MB  00:00
   (2/11): cpp46-4.6.3-2.67.amzn1.x86_64.rpm             |  4.8 MB  00:00
   (3/11): gcc-4.6.3-3.10.amzn1.noarch.rpm               |  2.8 kB  00:00
   ... (output omitted) ...
   Complete!
   ```

3. Download and compile the `redis-cli` utility. This utility is included in the Redis software distribution. At the command prompt of your EC2 instance, type the following commands:

   **Note**
   For Ubuntu systems, before running `make`, run `make distclean`.

   ```bash
   wget http://download.redis.io/redis-stable.tar.gz
   ```
4. At the command prompt of your EC2 instance, type the following command.

```
src/redis-cli -c -h mycachecluster.eaogs8.0001.usw2.cache.amazonaws.com -p 6379
```

A Redis command prompt similar to the following appears.

```
redis mycachecluster.eaogs8.0001.usw2.cache.amazonaws.com 6379>
```

5. Test the connection by running Redis commands.

You are now connected to the cluster and can run Redis commands. The following are some example commands with their Redis responses.

```
set a "hello"          // Set key "a" with a string value and no expiration
OK
get a                  // Get value for key "a"
"hello"
get b                  // Get value for key "b" results in miss
(nil)
set b "Good-bye" EX 5 // Set key "b" with a string value and a 5 second expiration
get b
"Good-bye"            // wait 5 seconds
get b
(nil)                 // key has expired, nothing returned
quit                   // Exit from redis-cli
```

For connecting to nodes or clusters which have Secure Sockets Layer (SSL) encryption (in-transit enabled), see ElastiCache for Redis in-transit encryption (TLS) (p. 471).
Supported node types

For information on which node size to use, see Choosing your node size (p. 127).

ElastiCache supports the following node types. Generally speaking, the current generation types provide more memory and computational power at lower cost when compared to their equivalent previous generation counterparts.

For more information on performance details for each node type, see Amazon EC2 Instance Types.

- General purpose:
  - Current generation:
    - **M6g node types** (available only for Redis engine version 5.0.6 onward).
      - cache.m6g.large, cache.m6g.xlarge, cache.m6g.2xlarge, cache.m6g.4xlarge, cache.m6g.8xlarge, cache.m6g.12xlarge, cache.m6g.16xlarge
      - **Note**
        - For region availability, see Supported node types by AWS Region (p. 101).
    - **M5 node types**: cache.m5.large, cache.m5.xlarge, cache.m5.2xlarge, cache.m5.4xlarge, cache.m5.8xlarge, cache.m5.12xlarge, cache.m5.24xlarge
    - **M4 node types**: cache.m4.large, cache.m4.xlarge, cache.m4.2xlarge, cache.m4.4xlarge, cache.m4.8xlarge, cache.m4.12xlarge
    - **T4g node types** (available only for Redis engine version 5.0.6 onward).
      - cache.t4g.micro, cache.t4g.small, cache.t4g.medium
    - **T3 node types**: cache.t3.micro, cache.t3.small, cache.t3.medium
    - **T2 node types**: cache.t2.micro, cache.t2.small, cache.t2.medium
      - Previous generation: (not recommended. Existing clusters are still supported but creation of new clusters is not supported for these types.)
    - **T1 node types**: cache.t1.micro
  - **Previous generation:** (not recommended. Existing clusters are still supported but creation of new clusters is not supported for these types.)
    - **M1 node types**: cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
    - **M3 node types**: cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
- Compute optimized:
  - **Previous generation: (not recommended)**
    - **C1 node types**: cache.c1.xlarge
- Memory optimized with data tiering:
  - Current generation:
    - **R6gd node types** (available only for Redis engine version 6.2 onward). For more information, see Data tiering (p. 121).
      - cache.r6gd.xlarge, cache.r6gd.2xlarge, cache.r6gd.4xlarge, cache.r6gd.8xlarge, cache.r6gd.12xlarge, cache.r6gd.16xlarge
    - **Memory optimized**: (R6g node types are available only for Redis engine version 5.0.6 onward.)
R6g node types: cache.r6g.large, cache.r6g.xlarge, cache.r6g.2xlarge, cache.r6g.4xlarge, cache.r6g.8xlarge, cache.r6g.12xlarge, cache.r6g.16xlarge, cache.r6g.24xlarge

Note
For region availability, see Supported node types by AWS Region (p. 101).

R5 node types: cache.r5.large, cache.r5.xlarge, cache.r5.2xlarge, cache.r5.4xlarge, cache.r5.12xlarge, cache.r5.24xlarge

R4 node types: cache.r4.large, cache.r4.xlarge, cache.r4.2xlarge, cache.r4.4xlarge, cache.r4.8xlarge, cache.r4.16xlarge
- Previous generation: (not recommended)

M2 node types: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

R3 node types: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge

You can launch general-purpose burstable T4g, T3-Standard and T2-Standard cache nodes in Amazon ElastiCache. These nodes provide a baseline level of CPU performance with the ability to burst CPU usage at any time until the accrued credits are exhausted. A CPU credit provides the performance of a full CPU core for one minute.

Amazon ElastiCache’s T4g, T3 and T2 nodes are configured as standard and suited for workloads with an average CPU utilization that is consistently below the baseline performance of the instance. To burst above the baseline, the node spends credits that it has accrued in its CPU credit balance. If the node is running low on accrued credits, performance is gradually lowered to the baseline performance level. This gradual lowering ensures the node doesn't experience a sharp performance drop-off when its accrued CPU credit balance is depleted. For more information, see CPU Credits and Baseline Performance for Burstable Performance Instances in the Amazon EC2 User Guide.

The following table lists the burstable performance node types, the rate at which CPU credits are earned per hour. It also shows the maximum number of earned CPU credits that a node can accrue and the number of vCPUs per node. In addition, it gives the baseline performance level as a percentage of a full core performance (using a single vCPU).

<table>
<thead>
<tr>
<th>CPU credits earned per hour</th>
<th>Maximum earned credits that can be accrued*</th>
<th>vCPUs</th>
<th>Baseline performance per vCPU</th>
<th>Memory (GiB)</th>
<th>Network performance</th>
</tr>
</thead>

</table>

* The number of credits that can be accrued is equivalent to the number of credits that can be earned in a 24-hour period.

** The baseline performance in the table is per vCPU. Some node sizes that have more than one vCPU. For these, calculate the baseline CPU utilization for the node by multiplying the vCPU percentage by the number of vCPUs.

The following CPU credit metrics are available for T3 burstable performance instances:

* **Note**: These metrics are not available for T2 burstable performance instances.
  - CPUCreditUsage
  - CPUCreditBalance

For more information on these metrics, see CPU Credit Metrics.

In addition, be aware of these details:

- All current generation node types are created in a virtual private cloud (VPC) based on Amazon VPC by default.
- Redis append-only files (AOF) aren't supported for T1 or T2 instances.
- Redis Multi-AZ isn't supported on T1 instances.
- Redis configuration variables appendonly and appendfsync aren't supported on Redis version 2.8.22 and later.

* **Note**: Supported engine versions vary by AWS Region. The latest engine versions are supported in all AWS Regions. To find the available engine versions in your AWS Region, see Supported ElastiCache for Redis versions (p. 189).

**Supported node types by AWS Region**

See Amazon ElastiCache pricing.

For a complete list of node types and specifications, see the following:

- Amazon ElastiCache Product Features and Details
Rebooting nodes (cluster mode disabled only)

Some changes require that cluster nodes be rebooted for the changes to be applied. For example, for some parameters, changing the parameter value in a parameter group is only applied after a reboot.

For Redis (cluster mode disabled) clusters, those parameters are:

- activerehashing
- databases

You are able to reboot a node using only the ElastiCache console. You can only reboot a single node at a time. To reboot multiple nodes you must repeat the process for each node.

**Redis (Cluster Mode Enabled) parameter changes**

If you make changes to the following parameters on a Redis (cluster mode enabled) cluster, follow the ensuing steps.

- activerehashing
- databases

2. Delete the Redis (cluster mode enabled) cluster. See Deleting a cluster (p. 165).
3. Restore the cluster using the altered parameter group and backup to seed the new cluster. See Restoring from a backup with optional cluster resizing (p. 334).

Changes to other parameters do not require this.

**Using the AWS Management Console**

You can reboot a node using the ElastiCache console.

**To reboot a node (console)**

2. From the list in the upper-right corner, choose the AWS Region that applies.
3. In the left navigation pane, choose Redis.
   
   A list of clusters running Redis appears.
4. Choose the cluster under Cluster Name.
5. Under Node name, choose the radio button next to the node you want to reboot.
6. Choose Actions, and then choose Reboot node.

To reboot multiple nodes, repeat steps 2 through 5 for each node that you want to reboot. You do not need to wait for one node to finish rebooting to reboot another.
Replacing nodes

Amazon ElastiCache for Redis frequently upgrades its fleet with patches and upgrades being applied to instances seamlessly. However, from time to time we need to relaunch your ElastiCache for Redis nodes to apply mandatory OS updates to the underlying host. These replacements are required to apply upgrades that strengthen security, reliability, and operational performance.

You have the option to manage these replacements yourself at any time before the scheduled node replacement window. When you manage a replacement yourself, your instance receives the OS update when you relaunch the node and your scheduled node replacement is canceled. You might continue to receive alerts indicating that the node replacement is to take place. If you've already manually mitigated the need for the maintenance, you can ignore these alerts.

Note
Replacement cache nodes automatically generated by Amazon ElastiCache may have different IP addresses. You are responsible for reviewing your application configuration to ensure that your cache nodes are associated with the appropriate IP addresses.

The following list identifies actions you can take when ElastiCache schedules one of your Redis nodes for replacement. To expedite finding the information you need for your situation, choose from the following menu.

- **Do nothing** (p. 103) – Let Amazon ElastiCache replace the node as scheduled.
- **Change your maintenance window** (p. 104) – Change your maintenance window to a better time.
- **Redis (cluster mode enabled) Configurations**
  - Replace the only node in any Redis cluster (p. 104) – A procedure to replace a node in a Redis cluster using backup and restore.
  - Replace a replica node in any Redis cluster (p. 105) – A procedure to replace a read-replica in any Redis cluster by increasing and decreasing the replica count with no cluster downtime.
  - Replace any node in a Redis (cluster mode enabled) shard (p. 105) – A dynamic procedure with no cluster downtime to replace a node in a Redis (cluster mode enabled) cluster by scaling out and scaling in.
- **Redis (cluster mode disabled) Configurations**
  - Replace the only node in any Redis cluster (p. 104) – Procedure to replace any node in a Redis cluster using backup and restore.
  - Replace a replica node in any Redis cluster (p. 105) – A procedure to replace a read-replica in any Redis cluster by increasing and decreasing the replica count with no cluster downtime.
  - Replace a node in a Redis (cluster mode disabled) cluster (p. 105) – Procedure to replace a node in a Redis (cluster mode disabled) cluster using replication.
  - Replace a Redis (cluster mode disabled) read-replica (p. 105) – A procedure to manually replace a read-replica in a Redis (cluster mode disabled) replication group.
  - Replace a Redis (cluster mode disabled) primary node (p. 106) – A procedure to manually replace the primary node in a Redis (cluster mode disabled) replication group.

Redis node replacement options

- **Do nothing** – If you do nothing, ElastiCache replaces the node as scheduled.

If the node is a member of an auto failover enabled cluster, ElastiCache for Redis provides improved availability during patching, updates, and other maintenance-related node replacements.
For ElastiCache for Redis Cluster configurations that are set up to use ElastiCache for Redis Cluster clients, replacement now completes while the cluster serves incoming write requests.

For non-Cluster configurations with autofailover enabled, clusters on Redis 5.0.5 and above complete replacement while the cluster continues to stay online and serve incoming write requests. For auto failover enabled clusters on Redis 5.0.4 or below, you might notice a brief write interruption of up to a few seconds associated with DNS updates.

If the node is standalone, Amazon ElastiCache first launches a replacement node and then syncs from the existing node. The existing node isn't available for service requests during this time. Once the sync is complete, the existing node is terminated and the new node takes its place. ElastiCache makes a best effort to retain your data during this operation.

- **Change your maintenance window** – For scheduled maintenance events, you receive an email or a notification event from ElastiCache. In these cases, if you change your maintenance window before the scheduled replacement time, your node now is replaced at the new time. For more information, see the following:
  - Modifying an ElastiCache cluster (p. 149)
  - Modifying a replication group (p. 294)

  **Note**
  The ability to change your replacement window by moving your maintenance window is only available when the ElastiCache notification includes a maintenance window. If the notification does not include a maintenance window, you cannot change your replacement window.

For example, let's say it's Thursday, November 9, at 15:00 and the next maintenance window is Friday, November 10, at 17:00. Following are three scenarios with their outcomes:

- You change your maintenance window to Fridays at 16:00, after the current date and time and before the next scheduled maintenance window. The node is replaced on Friday, November 10, at 16:00.

- You change your maintenance window to Saturday at 16:00, after the current date and time and after the next scheduled maintenance window. The node is replaced on Saturday, November 11, at 16:00.

- You change your maintenance window to Wednesday at 16:00, earlier in the week than the current date and time). The node is replaced next Wednesday, November 15, at 16:00.

For instructions, see Managing maintenance (p. 230).

- **Replace the only node in any Redis cluster** – If the cluster does not have any read replicas, you can use the following procedure to replace the node.

  **To replace the only node using backup and restore**

  1. Create a snapshot of the node's cluster. For instructions, see Making manual backups (p. 315).

  2. Create a new cluster seeding it from the snapshot. For instructions, see Restoring from a backup with optional cluster resizing (p. 334).

  3. Delete the cluster with the node scheduled for replacement. For instructions, see Deleting a cluster (p. 165).

  4. In your application, replace the old node's endpoint with the new node's endpoint.
• **Replace a replica node in any Redis cluster** – To replace a replica cluster, increase your replica count. To do this, add a replica then decrease the replica count by removing the replica that you want to replace. This process is dynamic and doesn’t have any cluster downtime.

  **Note**
  If your shard or replication group already has five replicas, reverse steps 1 and 2.

**To replace a replica in any Redis cluster**

1. Increase the replica count by adding a replica to the shard or replication group. For more information, see [Increasing the number of replicas in a shard](#).
2. Delete the replica you want to replace. For more information, see [Decreasing the number of replicas in a shard](#).
3. Update the endpoints in your application.

• **Replace any node in a Redis (cluster mode enabled) shard** – To replace the node in a cluster with no downtime, use online resharding. First add a shard by scaling out, and then delete the shard with the node to be replaced by scaling in.

**To replace any node in a Redis (cluster mode enabled) cluster**

1. Scale out: Add an additional shard with the same configuration as the existing shard with the node to be replaced. For more information, see [Adding shards with online resharding](#).
2. Scale in: Delete the shard with the node to be replaced. For more information, see [Removing shards with online resharding](#).
3. Update the endpoints in your application.

• **Replace a node in a Redis (cluster mode disabled) cluster** – If the cluster is a Redis (cluster mode disabled) cluster without any read replicas, use the following procedure to replace the node.

**To replace the node using replication (cluster mode disabled only)**

1. Add replication to the cluster with the node scheduled for replacement as the primary. Do not enable Multi-AZ on this cluster. For instructions, see [To add replication to a Redis cluster with no shards](#).
2. Add a read-replica to the cluster. For instructions, see [To add nodes to a cluster (console)](#).
3. Promote the newly created read-replica to primary. For instructions, see [Promoting a read replica to primary, for Redis (cluster mode disabled) replication groups](#).
4. Delete the node scheduled for replacement. For instructions, see [Removing nodes from a cluster](#).
5. In your application, replace the old node's endpoint with the new node's endpoint.

• **Replace a Redis (cluster mode disabled) read-replica** – If the node is a read-replica, replace the node.

  If your cluster has only one replica node and Multi-AZ is enabled, you must disable Multi-AZ before you can delete the replica. For instructions, see [Modifying a replication group](#).
To replace a Redis (cluster mode disabled) read replica

1. Delete the replica that is scheduled for replacement. For instructions, see the following:
   - Decreasing the number of replicas in a shard (p. 302)
   - Removing nodes from a cluster (p. 158)
2. Add a new replica to replace the one that is scheduled for replacement. If you use the same name as the replica you just deleted, you can skip step 3. For instructions, see the following:
   - Increasing the number of replicas in a shard (p. 298)
   - Adding a read replica, for Redis (Cluster Mode Disabled) replication groups (p. 306)
3. In your application, replace the old replica's endpoint with the new replica's endpoint.
4. If you disabled Multi-AZ at the start, re-enable it now. For instructions, see Enabling Multi-AZ (p. 253).

- Replace a Redis (cluster mode disabled) primary node – If the node is the primary node, first promote a read-replica to primary. Then delete the replica that used to be the primary node.

   If your cluster has only one replica and Multi-AZ is enabled, you must disable Multi-AZ before you can delete the replica in step 2. For instructions, see Modifying a replication group (p. 294).

To replace a Redis (cluster mode disabled) primary node

1. Promote a read-replica to primary. For instructions, see Promoting a read replica to primary, for Redis (cluster mode disabled) replication groups (p. 309).
2. Delete the node that is scheduled for replacement (the old primary). For instructions, see Removing nodes from a cluster (p. 158).
3. Add a new replica to replace the one scheduled for replacement. If you use the same name as the node you just deleted, you can skip changing endpoints in your application.
   For instructions, see Adding a read replica, for Redis (Cluster Mode Disabled) replication groups (p. 306).
4. In your application, replace the old node's endpoint with the new node's endpoint.
5. If you disabled Multi-AZ at the start, re-enable it now. For instructions, see Enabling Multi-AZ (p. 253).
ElastiCache reserved nodes

Reserving one or more nodes might be a way for you to reduce costs. Reserved nodes are charged an up front fee that depends upon the node type and the length of reservation—one or three years.

To see if reserved nodes are a cost savings for your use cases, first determine the node size and number of nodes you need. Then estimate the usage of the node, and compare the total cost to you of using On-Demand nodes versus reserved nodes. You can mix and match reserved and On-Demand node usage in your clusters. For pricing information, see Amazon ElastiCache Pricing.

Managing costs with reserved nodes

Reserving one or more nodes may be a way for you to reduce costs. Reserved nodes are charged an up front fee that depends upon the node type and the length of reservation—one or three years. This charge is much less than the hourly usage charge that you incur with On-Demand nodes.

To see if reserved nodes are a cost savings for your use cases, first determine the node size and number of nodes you need. Then estimate the usage of the node, and compare the total cost to you using On-Demand nodes versus reserved nodes. You can mix and match reserved and On-Demand node usage in your clusters. For pricing information, see Amazon ElastiCache Pricing.

AWS Region, Cache Node Class, and term length must be chosen at purchase, and cannot be changed later.

You can use the AWS Management Console, the AWS CLI, or the ElastiCache API to list and purchase available reserved node offerings.

For more information on reserved nodes, see Amazon ElastiCache Reserved Cache Nodes.

Topics

• Standard reserved node cache offerings (p. 107)
• Legacy reserved node cache offerings (p. 108)
• Getting info about reserved node offerings (p. 110)
• Purchasing a reserved node (p. 113)
• Getting info about your reserved nodes (p. 116)

Standard reserved node cache offerings

When you purchase a standard reserved node instance (RI) in Amazon ElastiCache, you purchase a commitment to getting a discounted rate on a specific cache node instance type and AWS Region for the duration of the reserved node instance. To use an Amazon ElastiCache reserved node instance, you create a new ElastiCache node instance, just as you would for an on-demand instance.

The new node instance that you create must exactly match the specifications of the reserved node instance. If the specifications of the new node instance match an existing reserved node instance for your account, you are billed at the discounted rate offered for the reserved node instance. Otherwise, the node instance is billed at an on-demand rate. These standard RIs are available from R5 and M5 instance families onwards.

Note

All three offering types discussed next are available in one-year and three-year terms.

Offering Types
No Upfront RI provides access to a reserved ElastiCache instance without requiring an upfront payment. Your No Upfront reserved ElastiCache instance bills a discounted hourly rate for every hour within the term, regardless of usage.

Partial Upfront RI requires a part of the reserved ElasticCache instance to be paid upfront. The remaining hours in the term are billed at a discounted hourly rate, regardless of usage. This option is the replacement for the legacy Heavy Utilization option, which is explained in the next section.

All Upfront RI requires full payment to be made at the start of the RI term. You incur no other costs for the remainder of the term, regardless of the number of hours used.

Legacy reserved node cache offerings

There are three levels of legacy node reservations—Heavy Utilization, Medium Utilization, and Light Utilization. Nodes can be reserved at any utilization level for either one or three years. The node type, utilization level, and reservation term affect your total costs. Verify the savings that reserved nodes can provide your business by comparing various models before you purchase reserved nodes.

Nodes purchased at one utilization level or term cannot be converted to a different utilization level or term.

Utilization Levels

Heavy Utilization reserved nodes enable workloads that have a consistent baseline of capacity or run steady-state workloads. Heavy Utilization reserved nodes require a high up-front commitment, but if you plan to run more than 79 percent of the reserved node term you can earn the largest savings (up to 70 percent off of the On-Demand price). With Heavy Utilization reserved nodes, you pay a one-time fee. This is then followed by a lower hourly fee for the duration of the term regardless of whether your node is running.

Medium Utilization reserved nodes are the best option if you plan to use your reserved nodes a large amount of the time and you want either a lower one-time fee or to stop paying for your node when you shut it off. Medium Utilization reserved nodes are a more cost-effective option when you plan to run more than 40 percent of the reserved nodes term. This option can save you up to 64 percent off of the On-Demand price. With Medium Utilization reserved nodes, you pay a slightly higher one-time fee than with Light Utilization reserved nodes, and you receive lower hourly usage rates when you run a node.

Light Utilization reserved nodes are ideal for periodic workloads that run only a couple of hours a day or a few days per week. Using Light Utilization reserved nodes, you pay a one-time fee followed by a discounted hourly usage fee when your node is running. You can start saving when your node is running more than 17 percent of the reserved node term. You can save up to 56 percent off of the On-Demand rates over the entire term of your reserved node.

Legacy reserved cache node offerings

<table>
<thead>
<tr>
<th>Offering</th>
<th>Up-front cost</th>
<th>Usage fee</th>
<th>Advantage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Heavy Utilization</td>
<td>Highest</td>
<td>Lowest hourly fee. Applied to the whole term whether or not you're using the reserved node.</td>
<td>Lowest overall cost if you plan to run your reserved nodes more than 79 percent of a three-year term.</td>
</tr>
<tr>
<td>Medium Utilization</td>
<td>Medium</td>
<td>Hourly usage fee charged for each hour the node is running. No hourly charge when the node is not running.</td>
<td>Suitable for elastic workloads or when you expect moderate usage, more than 40 percent of a three-year term.</td>
</tr>
</tbody>
</table>
## Managing costs with reserved nodes

<table>

For more information, see [Amazon ElastiCache Pricing](https://aws.amazon.com/elasticyclecache/pricing/).
Getting info about reserved node offerings

Before you purchase reserved nodes, you can get information about available reserved node offerings.

The following examples show how to get pricing and information about available reserved node offerings using the AWS Management Console, AWS CLI, and ElastiCache API.

Topics
- Getting info about reserved node offerings (Console) (p. 110)
- Getting info about reserved node offerings (AWS CLI) (p. 110)
- Getting info about reserved node offerings (ElastiCache API) (p. 111)

Getting info about reserved node offerings (Console)

To get pricing and other information about available reserved cluster offerings using the AWS Management Console, use the following procedure.

To get information about available reserved node offerings

2. In the navigation pane, choose Reserved Cache Nodes.
4. For Product Description, choose Redis.
5. To determine the available offerings, make selections for the next three lists:
   - Cache Node Type
   - Term
   - Offering Type

After you make these selections, the cost per node and total cost of your selections is shows in the Purchase Reserved Cache Nodes wizard.
6. Choose Cancel to avoid purchasing these nodes and incurring charges.

Getting info about reserved node offerings (AWS CLI)

To get pricing and other information about available reserved node offerings, type the following command at a command prompt:

```
aws elasticache describe-reserved-cache-nodes-offerings
```

This operation produces output similar to the following (JSON format):

```
{
   "ReservedCacheNodesOfferings": [
      {
         "OfferingType": "Heavy Utilization",
         "FixedPrice": 4328.0,
         "ReservedCacheNodesOfferingId": "0192caa9-daf2-4159-b1e5-a79bb1916695",
         "UsagePrice": 0.0,
         "RecurringCharges": [
            "RecurringChargeAmount": 0.491,
            ...
```
"RecurringChargeFrequency": "Hourly"
],
"OfferingType": "Heavy Utilization",
"FixedPrice": 4132.0,
"ReservedCacheNodesOfferingId": "fb766e0a-79d7-4e8f-a780-a2a6ed5ed439",
"UsagePrice": 0.0,
"RecurringCharges": [
  {"RecurringChargeAmount": 0.182,
   "RecurringChargeFrequency": "Hourly"
  ],
"ProductDescription": "redis",
"Duration": 94608000,
"CacheNodeType": "cache.r3.2xlarge"
}
]
}
}

For more information, see describe-reserved-cache-nodes-offerings in the AWS CLI Reference.

### Getting info about reserved node offerings (ElastiCache API)

To get pricing and information about available reserved node offerings, call the DescribeReservedCacheNodesOfferings action.

**Example**

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=DescribeReservedCacheNodesOfferings
&Version=2014-12-01
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20141201T220302Z
&X-Amz-Algorithm
&X-Amz-SignedHeaders=Host
&X-Amz-Expires=20141201T220302Z
&X-Amz-Credential=<credential>
&X-Amz-Signature=<signature>
```

This call returns output similar to the following:

```
  <DescribeReservedCacheNodesOfferingsResult>
    <ReservedCacheNodesOfferings>
      <ReservedCacheNodesOffering>
        <Duration>31536000</Duration>
        <OfferingType>Medium Utilization</OfferingType>
        <CurrencyCode>USD</CurrencyCode>
      </ReservedCacheNodesOffering>
    </ReservedCacheNodesOfferings>
  </DescribeReservedCacheNodesOfferingsResult>
</DescribeReservedCacheNodesOfferingsResponse>
```

API Version 2015-02-02

111
Managing costs with reserved nodes

For more information, see DescribeReservedCacheNodesOfferings in the ElastiCache API Reference.
Purchasing a reserved node

The following examples show how to purchase a reserved node offering using the AWS Management Console, the AWS CLI, and the ElastiCache API.

Important
Following the examples in this section incurs charges on your AWS account that you can't reverse.

Topics
- Purchasing a reserved node (Console) (p. 113)
- Purchasing a reserved node (AWS CLI) (p. 113)
- Purchasing a reserved node (ElastiCache API) (p. 114)

Purchasing a reserved node (Console)

This example shows purchasing a specific reserved node offering, 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f, with a reserved node ID of myreservationID.

The following procedure uses the AWS Management Console to purchase the reserved node offering by offering id.

To purchase reserved nodes

2. In the navigation list, choose the Reserved Cache Nodes link.
3. Choose the Purchase Reserved Cache Node button.
4. Choose the node type from the Product Description drop-down list box.
5. Choose the node class from the Cache Node Class drop-down list box.
6. Choose length of time you want to reserve the node for from the Term drop-down list box.
7. Do either one of the following:
   - Choose the offering type from the Offering Type drop-down list box.
   - Enter a reserved node ID in the Reserved Cache Node ID text box.
     Note
     The Reserved Cache Node ID is a unique customer-specified identifier to track this reservation. If this box is left blank, ElastiCache automatically generates an identifier for the reservation.
8. Choose the Next button.

   The Purchase Reserved Cache Node dialog box shows a summary of the reserved node attributes that you've chosen and the payment due.
9. Choose the Yes, Purchase button to proceed and purchase the reserved node.

   Important
   When you choose Yes, Purchase you incur the charges for the reserved nodes you selected. To avoid incurring these charges, choose Cancel.

Purchasing a reserved node (AWS CLI)

The following example shows purchasing the specific reserved cluster offering, 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f, with a reserved node ID of myreservationID.
Type the following command at a command prompt:

For Linux, macOS, or Unix:

```
aws elasticache purchase-reserved-cache-nodes-offering \
  --reserved-cache-nodes-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f \
  --reserved-cache-node-id myreservationID
```

For Windows:

```
aws elasticache purchase-reserved-cache-nodes-offering ^
  --reserved-cache-nodes-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f ^
  --reserved-cache-node-id myreservationID
```

The command returns output similar to the following:

<table>
<thead>
<tr>
<th>Reservation</th>
<th>ReservationId</th>
<th>Class</th>
<th>Start Time</th>
<th>Duration</th>
<th>Fixed Price</th>
<th>Usage Price</th>
<th>Count</th>
<th>State</th>
<th>Description</th>
<th>Offering Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESERVATION</td>
<td>myreservationid</td>
<td>cache.m1.small</td>
<td>2013-12-19T00:30:23.247Z</td>
<td>1y</td>
<td>455.00 USD</td>
<td>0.092 USD</td>
<td>1</td>
<td>payment-pending</td>
<td>memcached</td>
<td>Medium Utilization</td>
</tr>
</tbody>
</table>

For more information, see `purchase-reserved-cache-nodes-offering` in the AWS CLI Reference.

**Purchasing a reserved node (ElastiCache API)**

The following example shows purchasing the specific reserved node offering, 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f, with a reserved cluster ID of myreservationID.

Call the `PurchaseReservedCacheNodesOffering` operation with the following parameters:

- `ReservedCacheNodesOfferingId = 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f`
- `ReservedCacheNodeID = myreservationID`
- `CacheNodeCount = 1`

**Example**

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=PurchaseReservedCacheNodesOffering
  &ReservedCacheNodesOfferingId=649fd0c8-cf6d-47a0-bfa6-060f8e75e95f
  &ReservedCacheNodeID=myreservationID
  &CacheNodeCount=1
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20141201T220302Z
  &X-Amz-Algorithm=AWS4-HMAC-SHA256
  &X-Amz-Date=20141201T220302Z
  &X-Amz-SignedHeaders=host
  &X-Amz-Expires=20141201T220302Z
  &X-Amz-Credential=<credential>
  &X-Amz-Signature=<signature>
```

This call returns output similar to the following:

```
  <PurchaseReservedCacheNodesOfferingResult>
    <ReservedCacheNode>
```

API Version 2015-02-02

114

Getting info about your reserved nodes

You can get information about the reserved nodes you’ve purchased using the AWS Management Console, the AWS CLI, and the ElastiCache API.

Topics

• Getting info about your reserved nodes (Console) (p. 116)
• Getting info about your reserved nodes (AWS CLI) (p. 116)
• Getting info about your reserved nodes (ElastiCache API) (p. 116)

Getting info about your reserved nodes (Console)

The following procedure describes how to use the AWS Management Console to get information about the reserved nodes you purchased.

To get information about your purchased reserved nodes

2. In the navigation list, choose the Reserved Cache Nodes link.
   The reserved nodes for your account appear in the Reserved Cache Nodes list. You can choose any of the reserved nodes in the list to see detailed information about the reserved node in the detail pane at the bottom of the console.

Getting info about your reserved nodes (AWS CLI)

To get information about reserved nodes for your AWS account, type the following command at a command prompt:

```
aws elasticache describe-reserved-cache-nodes
```

This operation produces output similar to the following (JSON format):

```
{
    "ReservedCacheNodeId": "myreservationid",
    "ReservedCacheNodesOfferingId": "649fd0c8-cf6d-47a0-bfa6-060f8e75e95f",
    "CacheNodeType": "cache.m1.small",
    "DataTiering": "disabled",
    "Duration": "31536000",
    "ProductDescription": "memcached",
    "OfferingType": "Medium Utilization",
    "MaxRecords": 0
}
```

For more information, see describe--reserved-cache-nodes in the AWS CLI Reference.

Getting info about your reserved nodes (ElastiCache API)

To get information about reserved nodes for your AWS account, call the DescribeReservedCacheNodes operation.

Example

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeReservedCacheNodes
```

API Version 2015-02-02
Migrating previous generation nodes

Previous generation nodes are node types that are being phased out. If you have no existing clusters using a previous generation node type, ElastiCache does not support the creation of new clusters with that node type. If you have existing clusters, you can continue to use them or create new clusters using the previous generation node type.

Due to the limited amount of previous generation node types, we cannot guarantee a successful replacement when a node becomes unhealthy in your cluster(s). In such a scenario, your cluster availability may be negatively impacted.

We recommend that you migrate your cluster(s) to a new node type for better availability and performance. For a recommended node type to migrate to, see Upgrade Paths. For a full list of
supported node types and previous generation node types in ElastiCache, see Supported node

types (p. 99).

Migrating nodes on a Redis cluster

The following procedure describes how to migrate your Redis cluster node type using the ElastiCache
Console. During this process, your Redis cluster will continue to serve requests with minimal downtime.
Depending on your cluster configuration you may see the following downtimes. The following are
estimates and may differ based on your specific configurations:

- Cluster mode disabled (single node) may see approximately 60 seconds, primarily due to DNS
  propagation.
- Cluster mode disabled (with replica node) may see approximately 1 second for clusters running Redis
  5.0.5 and above. All lower version can experience approximately 10 seconds.
- Cluster mode enabled may see approximately 1 second.

To modify a Redis cluster node type using the console:

1. Sign in to the Console and open the ElastiCache console at https://console.aws.amazon.com/
   elasticache/.
2. From the navigation pane, choose Redis.
3. From the list of clusters, choose the cluster you want to migrate.
4. Choose Actions and then choose Modify.
5. Choose the new node type from the node type list (if there is not a node type in the list, validate
   if you are running on EC2-Classic. For more information, see If nodes are running on EC2-
   Classic (p. 119).
6. If you want to perform the migration process right away, choose Apply immediately. If Apply
   immediately is not chosen, the migration process is performed during the cluster's next
   maintenance window.
7. Choose Modify. If you chose Apply immediately in the previous step, the cluster's status changes to
   modifying. When the status changes to available, the modification is complete and you can begin
   using the new cluster.

To modify a Redis cluster node type using the AWS CLI:

Use the modify-replication-group API as shown following:

For Linux, macOS, or Unix:

/aws elasticache modify-replication-group /
  --replication-group-id my-replication-group /
  --cache-node-type new-node-type /
  --apply-immediately

For Windows:

/aws elasticache modify-replication-group ^
  --replication-group-id my-replication-group ^
  --cache-node-type new-node-type ^
  --apply-immediately
In this scenario, the value of `new-node-type` is the node type you are migrating to. By passing the `--apply-immediately` parameter, the update will be applied immediately when the replication group transitions from modifying to available status. If `Apply immediately` is not chosen, the migration process is performed during the cluster’s next maintenance window.

**Note**

If you are unable to modify the cluster with an `InvalidCacheClusterState` error, you need to remove a restore-failed node first. For more information, see Remove restore-failed-node (p. 119). Once you have completed that process, you can then modify the node type using the previous steps.

**Remove restore-failed-node**

The following procedure describes how to remove restore-failed node from your Redis cluster. To remove restore-failed node (console):

2. From the navigation pane, choose Redis.
3. From the list of clusters, choose the cluster you want to remove a node from.
4. From the list of shards, choose the shard you want to remove a node from. Skip this step if cluster mode is disabled for the cluster.
5. From the list of nodes, choose the node with a status of `restore-failed`.
6. Choose Actions and then choose Delete node.

**If nodes are running on EC2-Classic**

Follow these steps to verify if your EC2 is running in EC2-Classic platform (console):

1. Sign in to the AWS Management Console and open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose Instances in the navigation pane.
3. Choose your instance and go to Description.
4. If VPC ID is blank, the instance is running on the EC2-Classic platform.

For information on migrating your EC2-Classic instance to a VPC, see Migrating an EC2-Classic cluster into a VPC (p. 514).
Managing clusters

A cluster is a collection of one or more cache nodes, all of which run an instance of the Redis cache engine software. When you create a cluster, you specify the engine and version for all of the nodes to use.

The following diagram illustrates a typical Redis cluster. Redis clusters can contain a single node or up to six nodes inside a shard (API/CLI: node group). A single-node Redis (cluster mode disabled) cluster has no shard, and a multi-node Redis (cluster mode disabled) cluster has a single shard. Redis (cluster mode enabled) clusters can have up to 500 shards, with your data partitioned across the shards. The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526). For versions below 5.0.6, the limit is 250 per cluster.

To request a limit increase, see AWS Service Limits and choose the limit type Nodes per cluster per instance type.

When you have multiple nodes in a shard, one of the nodes is a read/write primary node. All other nodes in the shard are read-only replicas.

Typical Redis clusters look as follows.

Most ElastiCache operations are performed at the cluster level. You can set up a cluster with a specific number of nodes and a parameter group that controls the properties for each node. All nodes within a cluster are designed to be of the same node type and have the same parameter and security group settings.

Every cluster must have a cluster identifier. The cluster identifier is a customer-supplied name for the cluster. This identifier specifies a particular cluster when interacting with the ElastiCache API and AWS CLI commands. The cluster identifier must be unique for that customer in an AWS Region.

ElastiCache supports multiple engine versions. Unless you have specific reasons, we recommend using the latest version.

ElastiCache clusters are designed to be accessed using an Amazon EC2 instance. If you launch your cluster in a virtual private cloud (VPC) based on the Amazon VPC service, you can access it from outside AWS. For more information, see Accessing ElastiCache resources from outside AWS (p. 171).

For a list of supported Redis versions, see Supported ElastiCache for Redis Versions.
Data tiering

Clusters that comprise a replication group and use a node type from the r6gd family have their data tiered between memory and local SSD (solid state drives) storage. Data tiering provides a new price-performance option for Redis workloads by utilizing lower-cost solid state drives (SSDs) in each cluster node in addition to storing data in memory. It is ideal for workloads that access up to 20 percent of their overall dataset regularly, and for applications that can tolerate additional latency when accessing data on SSD.

On clusters with data tiering, ElastiCache monitors the last access time of every item it stores. When available memory (DRAM) is fully consumed, ElastiCache uses a least-recently used (LRU) algorithm to automatically move infrequently accessed items from memory to SSD. When data on SSD is subsequently accessed, ElastiCache automatically and asynchronously moves it back to memory before processing the request. If you have a workload that accesses only a subset of its data regularly, data tiering is an optimal way to scale your capacity cost-effectively.

Note that when using data tiering, keys themselves always remain in memory, while the LRU governs the placement of values on memory vs. disk. In general, we recommend that your key sizes are smaller than your value sizes when using data tiering.

Data tiering is designed to have minimal performance impact to application workloads. For example, assuming 500-byte String values, you can expect an additional 300 microseconds of latency on average for requests to data stored on SSD compared to requests to data in memory.

With the largest data tiering node size (cache.r6gd.16xlarge), you can store up to 1 petabyte in a single 500-node cluster (500 TB when using 1 read replica). Data tiering is compatible with all Redis commands and data structures supported in ElastiCache. You don't need any client-side changes to use this feature.

Topics
- Best practices (p. 121)
- Limitations (p. 121)
- Pricing (p. 122)
- Monitoring (p. 122)
- Using data tiering (p. 122)
- Restoring data from backup into clusters with data tiering enabled (p. 123)

Best practices

We recommend the following best practices:

- Data tiering is ideal for workloads that access up to 20 percent of their overall dataset regularly, and for applications that can tolerate additional latency when accessing data on SSD.
- When using SSD capacity available on data-tiered nodes, we recommend that value size be larger than the key size. When items are moved between DRAM and SSD, keys will always remain in memory and only the values are moved to the SSD tier.

Limitations

Data tiering has the following limitations:

- You can only use data tiering on clusters that are part of a replication group.
• The node type you use must be from the r6gd family, which is available in the following regions: us-east-2, us-east-1, us-west-2, us-west-1, eu-west-1, eu-central-1, ap-northeast-1, ap-southeast-1, ap-southeast-2, ap-south-1, ca-central-1 and sa-east-1.
• You must use the Redis 6.2 or later engine.
• You cannot restore a backup of an r6gd cluster into another cluster unless it also uses r6gd.
• You cannot export a backup to Amazon S3 for data-tiering clusters.
• Online migration is not supported for clusters running on the r6gd node type.
• Scaling is not supported from a data tiering cluster (for example, a cluster using an r6gd node type) to a cluster that does not use data tiering (for example, a cluster using an r6g node type).
• Auto scaling is not supported for clusters running using data tiering.
• Data tiering only supports volatile-lru, allkeys-lru and noeviction maxmemory policies.
• Forkless save is not supported. For more information, see How synchronization and backup are implemented (p. 265).
• Items larger than 128 MiB are not moved to SSD.

**Pricing**

R6gd nodes have 4.8x more total capacity (memory + SSD) and can help you achieve over 60 percent savings when running at maximum utilization compared to R6g nodes (memory only). For more information, see ElastiCache pricing.

**Monitoring**

ElastiCache for Redis offers metrics designed specifically to monitor the performance clusters that use data tiering. To monitor the ratio of items in DRAM compared to SSD, you can use the CurItems metric at Metrics for Redis. You can calculate the percentage as: \((\text{CurItems with Dimension: Tier = Memory } \times 100) / (\text{CurItems with no dimension filter})\). When the percentage of items in memory decreases below 5 percent, we recommend that you consider scale out for Cluster Mode Enabled clusters or scale up for Cluster Mode disabled clusters. For more information, see Metrics for Redis clusters that use data tiering at Metrics for Redis (p. 590).

**Using data tiering**

**Using data tiering using the AWS Management Console**

When creating a cluster as part of a replication group, you use data tiering by selecting a node type from the r6gd family, such as `cache.r6gd.xlarge`. Selecting that node type automatically enables data tiering.

For more information on creating a cluster, see Creating a cluster (p. 130).

**Enabling data tiering using the AWS CLI**

When creating a replication group using the AWS CLI, you use data tiering by selecting a node type from the r6gd family, such as `cache.r6gd.xlarge` and setting the `--data-tiering-enabled` parameter.

You cannot opt out of data tiering when selecting a node type from the r6gd family. If you set the `--no-data-tiering-enabled` parameter, the operation will fail.

For Linux, macOS, or Unix:

```
aws elasticache create-replication-group \
  --replication-group-id redis-dt-cluster \
  --replication-group-description "Redis cluster with data tiering" \
  --num-node-groups 1 \
```

API Version 2015-02-02
122
Restoring data from backup into clusters with data tiering enabled

You can restore a backup to a new cluster with data tiering enabled using the (Console), (AWS CLI) or (ElastiCache API). When you create a cluster using node types in the r6gd family, data tiering is enabled.

To restore a backup to a new cluster with data tiering enabled (console)

2. From the navigation pane, choose Backups.
3. In the list of backups, choose the box to the left of the backup name you want to restore from.
4. Choose **Restore**.

5. Complete the **Restore Cluster** dialog box. Be sure to complete all the **Required** fields and any of the others you want to change from the defaults.

   1. **Cluster ID** – Required. The name of the new cluster.
   2. **Cluster mode enabled (scale out)** – Choose this for a Redis (cluster mode enabled) cluster.
   3. **Node Type** – Specify `cache.r6gd.xlarge` or any other node type from the r6gd family.
   4. **Number of Shards** – Choose the number of shards you want in the new cluster (API/CLI: node groups).
   5. **Replicas per Shard** – Choose the number of read replica nodes you want in each shard.
   6. **Slots and keyspaces** – Choose how you want keys distributed among the shards. If you choose to specify the key distributions complete the table specifying the key ranges for each shard.
   7. **Availability zone(s)** – Specify how you want the cluster's Availability Zones selected.
   8. **Port** – Change this only if you want the new cluster to use a different port.
   9. **Choose a VPC** – Choose the VPC in which to create this cluster.
   10. **Parameter Group** – Choose a parameter group that reserves sufficient memory for Redis overhead for the node type you selected.

6. When the settings are as you want them, choose **Create**.

   For more information on creating a cluster, see Creating a cluster (p. 130).

**Restoring data from backup into clusters with data tiering enabled (AWS CLI)**

When creating a replication group using the AWS CLI, data tiering is by default used by selecting a node type from the r6gd family, such as `cache.r6gd.xlarge` and setting the `--data-tiering-enabled` parameter.

You cannot opt out of data tiering when selecting a node type from the r6gd family. If you set the `--no-data-tiering-enabled` parameter, the operation will fail.

**For Linux, macOS, or Unix:**

```bash
aws elasticache create-replication-group
   --replication-group-id redis-dt-cluster
   --replication-group-description "Redis cluster with data tiering"
   --num-node-groups 1
   --replicas-per-node-group 1
   --cache-node-type cache.r6gd.xlarge
   --engine redis
   --engine-version 6.2
   --cache-subnet-group-name default
   --automatic-failover-enabled
   --data-tiering-enabled
   --snapshot-name my-snapshot
```

**For Linux, macOS, or Unix:**

```bash
aws elasticache create-replication-group ^
   --replication-group-id redis-dt-cluster ^
   --replication-group-description "Redis cluster with data tiering" ^
   --num-node-groups 1 ^
   --replicas-per-node-group 1 ^
   --cache-node-type cache.r6gd.xlarge ^
   --engine redis ^
   --engine-version 6.2 ^
   --cache-subnet-group-name default ^
```

API Version 2015-02-02

124
Preparing a cluster

Following, you can find instructions on creating a cluster using the ElastiCache console, the AWS CLI, or the ElastiCache API.

You can also create an ElastiCache cluster using AWS CloudFormation. For more information, see AWS::ElastiCache::CacheCluster in the AWS Cloud Formation User Guide, which includes guidance on how to implement that approach.

Whenever you create a cluster or replication group, it is a good idea to do some preparatory work so you won't need to upgrade or make changes right away.

Topics
- Determining your requirements (p. 125)
- Choosing your node size (p. 127)

Determining your requirements

Preparation

Knowing the answers to the following questions helps make creating your cluster go smoother:

- Which node instance type do you need?
- Will you launch your cluster in a virtual private cloud (VPC) based on Amazon VPC?

Important
If you're going to launch your cluster in a VPC, make sure to create a subnet group in the same VPC before you start creating a cluster. For more information, see Subnets and subnet groups (p. 524).
ElastiCache is designed to be accessed from within AWS using Amazon EC2. However, if you launch in a VPC based on Amazon VPC and your cluster is in an VPC, you can provide access from outside AWS. For more information, see Accessing ElastiCache resources from outside AWS (p. 171).

- **Do you need to customize any parameter values?**

  If you do, create a custom parameter group. For more information, see Creating a parameter group (p. 425).

  If you're running Redis, consider setting reserved-memory or reserved-memory-percent. For more information, see Managing Reserved Memory (p. 223).

- **Do you need to create your own security group or VPC security group?**

  For more information, see Security groups: EC2-Classic (p. 533) and Security in Your VPC.

- **How do you intend to implement fault tolerance?**

  For more information, see Mitigating Failures (p. 623).

**Topics**

- Memory and processor requirements (p. 126)
- Redis cluster configuration (p. 126)
- Scaling requirements (p. 127)
- Access requirements (p. 127)
- Region, Availability Zone and Local Zone requirements (p. 127)

**Memory and processor requirements**

The basic building block of Amazon ElastiCache is the node. Nodes are configured singularly or in groupings to form clusters. When determining the node type to use for your cluster, take the cluster’s node configuration and the amount of data you have to store into consideration.

**Redis cluster configuration**

ElastiCache for Redis clusters are comprised of from 0 to 500 shards (also called node groups). The data in a Redis cluster is partitioned across the shards in the cluster. Your application connects with a Redis cluster using a network address called an Endpoint. The nodes in a Redis shard fulfill one of two roles: one read/write primary and all other nodes read-only secondaries (also called read replicas). In addition to the node endpoints, the Redis cluster itself has an endpoint called the **configuration endpoint**. Your application can use this endpoint to read from or write to the cluster, leaving the determination of which node to read from or write to up to ElastiCache for Redis.
Choosing your node size

The node size you select for your cluster impacts costs, performance, and fault tolerance.

Answering the following questions can help you determine the minimum node type you need for your Redis implementation:

- Do you have workloads that access a small percentage of their data regularly?
  
  If this is the case and you are running on Redis engine version 6.2 or later, you can leverage data tiering by choosing the r6gd node type. With data tiering, least-recently used data is stored in SSD. When it is retrieved there is a small latency cost, which is balanced by cost savings. For more information, see Data tiering (p. 121).

  For more information, see Supported node types (p. 99).

- How much total memory do you need for your data?
  
  To get a general estimate, take the size of the items that you want to cache. Multiply this size by the number of items that you want to keep in the cache at the same time. To get a reasonable estimation of the item size, first serialize your cache items, then count the characters. Then divide this over the number of shards in your cluster.
Choosing your node size

For more information, see Supported node types (p. 99).

- What version of Redis are you running?

Redis versions before 2.8.22 require you to reserve more memory for failover, snapshot, synchronizing, and promoting a replica to primary operations. This requirement occurs because you must have sufficient memory available for all writes that occur during the process.

Redis version 2.8.22 and later use a forkless save process that requires less available memory than the earlier process.

For more information, see the following:
- How synchronization and backup are implemented (p. 265)
- Ensuring that you have enough memory to create a Redis snapshot (p. 221)
- How write-heavy is your application?

Write heavy applications can require significantly more available memory, memory not used by data, when taking snapshots or failing over. Whenever the BGSAVE process is performed, you must have sufficient memory that is unused by data to accommodate all the writes that transpire during the BGSAVE process. Examples are when taking a snapshot, when syncing a primary cluster with a replica in a cluster, and when enabling the append-only file (AOF) feature. Another is when promoting a replica to primary (if you have Multi-AZ enabled). The worst case is when all of your data is rewritten during the process. In this case, you need a node instance size with twice as much memory as needed for data alone.

For more detailed information, see Ensuring that you have enough memory to create a Redis snapshot (p. 221).

- Will your implementation be a standalone Redis (cluster mode disabled) cluster or a Redis (cluster mode enabled) cluster with multiple shards?

**Redis (cluster mode disabled) cluster**

If you're implementing a Redis (cluster mode disabled) cluster, your node type must be able to accommodate all your data plus the necessary overhead as described in the previous bullet.

For example, suppose that you estimate that the total size of all your items is 12 GB. In this case, you can use a cache.m3.xlarge node with 13.3 GB of memory or a cache.r3.large node with 13.5 GB of memory. However, you might need more memory for BGSAVE operations. If your application is write-heavy, double the memory requirements to at least 24 GB. Thus, use either a cache.m3.2xlarge with 27.9 GB of memory or a cache.r3.xlarge with 30.5 GB of memory.

**Redis (cluster mode enabled) with multiple shards**

If you're implementing a Redis (cluster mode enabled) cluster with multiple shards, then the node type must be able to accommodate bytes-for-data-and-overhead / number-of-shards bytes of data.

For example, suppose that you estimate that the total size of all your items to be 12 GB and you have two shards. In this case, you can use a cache.m3.large node with 6.05 GB of memory (12 GB / 2). However, you might need more memory for BGSAVE operations. If your application is write-heavy, double the memory requirements to at least 12 GB per shard. Thus, use either a cache.m3.xlarge with 13.3 GB of memory or a cache.r3.large with 13.5 GB of memory.

- Are you using Local Zones?

**Local Zones** enable you to place resources such as an ElastiCache cluster in multiple locations close to your users. But when you choose your node size, be aware that the available node sizes are limited to the following at this time, regardless of capacity requirements:
Choosing your node size

- **Current generation:**
  
  **M5 node types:** cache.m5.large, cache.m5.xlarge, cache.m5.2xlarge, cache.m5.4xlarge, cache.m5.12xlarge, cache.m5.24xlarge
  
  **R5 node types:** cache.r5.large, cache.r5.xlarge, cache.r5.2xlarge, cache.r5.4xlarge, cache.r5.12xlarge, cache.r5.24xlarge
  
  **T3 node types:** cache.t3.micro, cache.t3.small, cache.t3.medium

While your cluster is running, you can monitor the memory usage, processor utilization, cache hits, and cache misses metrics that are published to CloudWatch. You might notice that your cluster doesn't have the hit rate that you want or that keys are being evicted too often. In these cases, you can choose a different node size with larger CPU and memory specifications.

When monitoring CPU usage, remember the Redis is single-threaded. Thus, multiply the reported CPU usage by the number of CPU cores to get that actual usage. For example, a four-core CPU reporting a 20-percent usage rate is actually the one core Redis is running at 80 percent utilization.
Creating a cluster

The following examples show how to create a Redis cluster using the AWS Management Console, AWS CLI and ElastiCache API.

Creating a Redis (cluster mode disabled) (Console)

ElastiCache supports replication when you use the Redis engine. To monitor the latency between when data is written to a Redis read/write primary cluster and when it is propagated to a read-only secondary cluster, ElastiCache adds to the cluster a special key, `ElastiCacheMasterReplicationTimestamp`. This key is the current Universal Time (UTC) time. Because a Redis cluster might be added to a replication group at a later time, this key is included in all Redis clusters, even if initially they are not members of a replication group. For more information on replication groups, see High availability using replication groups (p. 246).

To create a standalone Redis (cluster mode disabled) cluster

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. From the list in the upper-right corner, choose the AWS Region that you want to launch this cluster in.
3. Choose Redis from the navigation pane.
4. Choose Create.
5. For Cluster engine, choose Redis. Make sure the Cluster Mode enabled check box is cleared.
6. Complete the Redis settings section.
   a. In Name, enter a name for your cluster.
   b. In the Description box, enter a description for this cluster.
   c. For Engine version compatibility, choose the ElastiCache for Redis engine version that you want to run on this cluster. Unless you have a specific reason to run an older version, we recommend that you choose the latest version.

   **Important**
   You can upgrade to newer engine versions. If you upgrade major engine versions, for example from 5.0.6 to 6.0, you need to select a parameter group family that is compatible with the new engine version. For more information on doing so, see Upgrading engine versions (p. 198). However, you can't downgrade to older engine versions except by deleting the existing cluster and creating it again.

d. In Port, use the default port, 6379. If you have a reason to use a different port, enter the port number.

e. For Parameter group, choose a parameter group or create a new one. Parameter groups control the runtime parameters of your cluster. For more information on parameter groups, see Redis-specific parameters (p. 441) and Creating a parameter group (p. 425).

f. For Node type, click the down arrow (▼). In the Change node type dialog box, choose the Instance family of the node type that you want, choose the node type that you want to use for this cluster, and then choose Save.

   For more information, see Choosing your node size (p. 127).

If you choose a node type from the r6gd family, you will automatically enable data-tiering, which splits data storage between memory and SSD. For more information, see Data tiering (p. 121).

g. For Number of replicas, choose the number of read replicas that you want for this cluster.
If you choose to have one or more replicas, the Multi-AZ check box is available. For more information, see Mitigating Failures when Running Redis (p. 623). We strongly suggest that you enable Multi-AZ, which helps ensure your eligibility for service level agreement (SLA) compliance. For more information on SLA compliance, see Amazon ElastiCache Service Level Agreement on the AWS website.

If you enter 0, the Multi-AZ check box is not enabled. The cluster that you create looks like the following.

If you choose one or more replicas, the cluster that you create looks something like the following. This is a Redis (cluster mode disabled) cluster with replica nodes.

7. Choose Advanced Redis settings and complete the section.
   a. For Subnet group, create a new subnet group or choose an existing one that you want to apply to this cluster. If you enabled Multi-AZ, the subnet group must contain at least two subnets that reside in different availability zones.

   If you are using Using local zones with ElastiCache (p. 91), you must create or choose a subnet that is in the local zone. Multi-AZ is automatically disabled. Local Zones don't support global datastores at this time.

   For more information, see Subnets and subnet groups (p. 524).
   b. For Availability zone(s), you have two options:
      • No preference – ElastiCache chooses the Availability Zones for your cluster's nodes.
      • Specify availability zones – Under Under availability zones placement, a list of your nodes appears allowing you to specify the Availability Zone for each node in your cluster. You can choose a different Availability Zone from the list to the right of each node name.
      • If you have Multi-AZ enabled, you must place at least two nodes in different Availability Zones.

   For more information, see Choosing regions and availability zones (p. 87).
   c. For Security groups, choose the security groups that you want for this cluster. A security group acts as a firewall to control network access to your cluster. You can choose use the Default security group for your VPC or create a new one.

   For more information, see Security groups for your VPC.
   d. Encrypt your data; you have the following options:
      • Encryption at rest – Enables encryption of data stored on disk. For more information, see encryption at rest.

      Note
      You have the option to supply a different encryption key by choosing Customer Managed AWS KMS key and choosing the key. For more information, see Using customer managed keys from AWS KMS.
• **Encryption in-transit** – Enables encryption of data on the wire. For more information, see encryption in transit. For Redis engine version 6.0 onward, if you enable encryption in transit you're prompted to specify one of the following **Access Control** options:

• **No Access Control** – This is the default setting. This indicates no restrictions on user access to the cluster.

• **User Group Access Control List** – Choose a user group with a defined set of users that can access the cluster. For more information, see Managing User Groups with the Console and CLI (p. 496).

• **Redis AUTH Default User** – An authentication mechanism for Redis server. For more information, see Redis AUTH.

**Note**
For Redis versions between 3.2.6 onward, excluding version 3.2.10, Redis AUTH is the sole option.

e. (Optional) For **Logs**:

• Under **Log format**, choose either **Text** or **JSON**.

• Under **Destination Type**, choose either **CloudWatch Logs** or **Kinesis Firehose**.

• Under **Log destination**, choose either **Create new** and enter either your CloudWatch Logs log group name or your Kinesis Data Firehose stream name, or choose **Select existing** and then choose either your CloudWatch Logs log group name or your Kinesis Data Firehose stream name,

f. (Optional) If you are going to seed your cluster with data from a .rdb file, enter the Amazon S3 location of the .rdb file for **Seed RDB file S3 location**.

For more information, see Seeding a new cluster with an externally created backup (p. 337).

g. (Optional) For regularly scheduled automatic backups, choose **Enable automatic backups**, and then enter the number of days that you want an automatic backup retained before it is automatically deleted. If you don't want regularly scheduled automatic backups, clear the **Enable automatic backups** check box. In either case, you always have the option to create manual backups, which must be deleted manually.

For more information on Redis backup and restore, see Backup and restore for ElastiCache for Redis (p. 310).

h. For **Maintenance window**, choose a maintenance window. The **maintenance window** is the time, generally an hour in length, each week when ElastiCache schedules system maintenance for your cluster.

You can enable ElastiCache to choose the day and time for your maintenance window (**No preference**). Or you can choose the day, time, and duration yourself (**Specify maintenance window**). If you choose **Specify maintenance window**, choose the **Start day**, **Start time**, and **Duration** (in hours) for your maintenance window. All times are UTC times.

For more information, see Managing maintenance (p. 230).

i. For **Notifications**, choose an existing Amazon Simple Notification Service (Amazon SNS) topic, or choose manual ARN input and enter the topic Amazon Resource Name (ARN). If you use Amazon SNS, you can push notifications to internet-connected smart devices. The default is to disable notifications. For more information, see https://aws.amazon.com/sns/.

8. Review all your entries and choices, then go back and make any needed corrections. When you're ready, choose **Create** to launch your cluster.

As soon as your cluster's status is **available**, you can grant Amazon EC2 access to it, connect to it, and begin using it. For more information, see Step 3: Authorize access to the cluster (p. 52) and Step 4: Connect to the cluster's node (p. 54).
Important
As soon as your cluster becomes available, you're billed for each hour or partial hour that the cluster is active, even if you're not actively using it. To stop incurring charges for this cluster, you must delete it. See Deleting a cluster (p. 165).

Creating a Redis (cluster mode enabled) cluster (Console)

If you are running Redis 3.2.4 or later, you can create a Redis (cluster mode enabled) cluster. Redis (cluster mode enabled) clusters support partitioning your data across 1 to 500 shards (API/CLI: node groups) but with some limitations. For a comparison of Redis (cluster mode disabled) and Redis (cluster mode enabled), see Supported ElastiCache for Redis versions (p. 189).

You can create a Redis (cluster mode enabled) cluster (API/CLI: replication group) using the ElastiCache management console, the AWS CLI for ElastiCache, and the ElastiCache API.

To create a Redis (cluster mode enabled) cluster using the ElastiCache console

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. From the list in the upper-right corner, choose the AWS Region that you want to launch this cluster in.
3. Choose Redis from the navigation pane.
4. Choose Create.
5. For Cluster engine, choose Redis, and then choose Cluster Mode enabled. These choices create a Redis (cluster mode enabled) cluster that looks something like the following.

![Redis (cluster mode enabled) Cluster created with replication and partitioning](image)

6. Complete the Redis settings section.
   a. In Name, enter a name for your cluster.
   b. In the Description box, enter a description for this cluster.
   c. For Engine version compatibility, choose the ElastiCache for Redis engine version that you want to run on this cluster. Unless you have a specific reason to run an older version, we recommend that you choose the latest version.
      Important
      For more information on doing so, see Upgrading engine versions (p. 198). However, you can't downgrade to older engine versions except by deleting the existing cluster and creating it again.
   d. In Port, use the default port, 6379. If you have a reason to use a different port, enter the port number.
   e. For Parameter group, choose a parameter group or create a new one. Parameter groups control the runtime parameters of your cluster. For more information on parameter groups, see Redis-specific parameters (p. 441) and Creating a parameter group (p. 425).
   f. For Node type, choose the down arrow ('). In the Change node type dialog box, choose a value for Instance family for the node type that you want. Then choose the node type that you want to use for this cluster, and then choose Save.
For more information, see Choosing your node size (p. 127).

If you choose an r6gd node type, data-tiering is automatically enabled. For more information, see Data tiering (p. 121).

g. For Number of shards, choose the number of shards (partitions/node groups) that you want for this Redis (cluster mode enabled) cluster.

For some versions of Redis (cluster mode enabled), you can change the number of shards in your cluster dynamically:

- **Redis 3.2.10 and later** – If your cluster is running Redis 3.2.10 or later versions, you can change the number of shards in your cluster dynamically. For more information, see Scaling clusters in Redis (Cluster Mode Enabled) (p. 375).

- **Other Redis versions** – If your cluster is running a version of Redis before version 3.2.10, there's another approach. To change the number of shards in your cluster in this case, create a new cluster with the new number of shards. For more information, see Restoring from a backup with optional cluster resizing (p. 334).

h. For Replicas per shard, choose the number of read replica nodes that you want in each shard.

The following restrictions exist for Redis (cluster mode enabled).

- If you have Multi-AZ enabled, make sure that you have at least one replica per shard.
- The number of replicas is the same for each shard when creating the cluster using the console.
- The number of read replicas per shard is fixed and cannot be changed. If you find you need more or fewer replicas per shard (API/CLI: node group), you must create a new cluster with the new number of replicas. For more information, see Seeding a new cluster with an externally created backup (p. 337).

i. For Subnet group, create a new subnet group or choose an existing one that you want to apply to this cluster. If you enabled Multi-AZ, the subnet group must contain at least two subnets that reside in different availability zones.

If you are using Using local zones with ElastiCache (p. 91), you must create or choose a subnet that is in the local zone. Multi-AZ is automatically disabled. Local Zones don't support global datastores at this time.

For more information, see Subnets and subnet groups (p. 524).

7. Click Advanced Redis settings and complete the section.

a. For Slots and keyspaces, choose how you want your keys distributed over your shards (partitions). There are 16,384 keys to be distributed (numbered 0 through 16383).

- **Equal distribution** – ElastiCache distributes your keyspace as equally as possible over your shards.

- **Custom distribution** – You specify the range of keys for each shard in the table below Availability zone(s).

b. For Availability zone(s), you have two options:

- **No preference** – ElastiCache chooses the Availability Zone.

- **Specify availability zones** – You specify the Availability Zone for each cluster.
If you chose to specify the Availability Zones, for each cluster in each shard, choose the Availability Zone from the list.

For more information, see Choosing regions and availability zones (p. 87).

Specifying Keyspaces and Availability Zones

c. For Security groups, choose the security groups that you want for this cluster. A security group acts as a firewall to control network access to your cluster. You can use the default security group for your VPC or create a new one.

For more information on security groups, see Security groups for your VPC in the Amazon VPC User Guide.

d. Encrypt your data, you have the following options:

- **Encryption at rest** – Enables encryption of data stored on disk. For more information, see Encryption at Rest.

  **Note**
  You have the option to supply a different encryption key by choosing Customer Managed AWS KMS key and choosing the key. For more information, see Using customer managed keys from AWS KMS.

- **Encryption in-transit** – Enables encryption of data on the wire. For more information, see encryption in transit. For Redis engine version 6.0 and above, if you enable Encryption in-transit you will be prompted to specify one of the following Access Control options:

  - **No Access Control** – This is the default setting. This indicates no restrictions on user access to the cluster.

  - **User Group Access Control List** – Select a user group with a defined set of users that can access the cluster. For more information, see Managing User Groups with the Console and CLI (p. 496).

  - **Redis AUTH Default User** – An authentication mechanism for Redis server. For more information, see Redis AUTH.

  - **Redis AUTH** – An authentication mechanism for Redis server. For more information, see Redis AUTH.

  **Note**
  For Redis versions between 3.2.6 onward, excluding version 3.2.10, Redis AUTH is the sole option.
Creating a cluster

e. (Optional) For Logs:
   • Under Log format, choose either Text or JSON.
   • Under Destination Type, choose either CloudWatch Logs or Kinesis Firehose.
   • Under Log destination, choose either Create new and enter either your CloudWatch Logs log group name or your Kinesis Data Firehose stream name, or choose Select existing and then choose either your CloudWatch Logs log group name or your Kinesis Data Firehose stream name.

f. (Optional) If you are going to seed your cluster with data from a .rdb file, enter the S3 location of the .rdb file for Seed RDB file S3 location.

For more information, see Seeding a new cluster with an externally created backup (p. 337).

For Redis (cluster mode enabled), make sure that you have a separate .rdb file for each node group.

g. For regularly scheduled automatic backups, select Enable automatic backups and then enter the number of days that you want each automatic backup retained before it is automatically deleted. If you don't want regularly scheduled automatic backups, clear the Enable automatic backups check box. In either case, you always have the option to create manual backups.

For more information on Redis backup and restore, see Backup and restore for ElastiCache for Redis (p. 310).

h. (Optional) Specify a maintenance window. The maintenance window is the time, generally an hour in length, each week when ElastiCache schedules system maintenance for your cluster. You can allow ElastiCache to choose the day and time for your maintenance window (No preference), or you can choose the day, time, and duration yourself (Specify maintenance window). If you choose Specify maintenance window from the lists, choose the Start day, Start time, and Duration (in hours) for your maintenance window. All times are UCT times.

For more information, see Managing maintenance (p. 230).

i. For Notifications, choose an existing Amazon Simple Notification Service (Amazon SNS) topic, or choose Manual ARN input and enter the topic's Amazon Resource Name (ARN). Amazon SNS allows you to push notifications to Internet-connected smart devices. The default is to disable notifications. For more information, see https://aws.amazon.com/sns/.

8. Review all your entries and choices, then make any needed corrections. When you're ready, choose Create cluster to launch your cluster, or Cancel to cancel the operation.

To create the equivalent using the ElastiCache API or AWS CLI instead of the ElastiCache console, see the following:

• API: CreateReplicationGroup
• CLI: create-replication-group

As soon as your cluster's status is available, you can grant EC2 access to it, connect to it, and begin using it. For more information, see Step 3: Authorize access to the cluster (p. 52) and Step 4: Connect to the cluster's node (p. 54).

Important
As soon as your cluster becomes available, you're billed for each hour or partial hour that the cluster is active, even if you're not actively using it. To stop incurring charges for this cluster, you must delete it. See Deleting a cluster (p. 165).
Creating a cluster (AWS CLI)

To create a cluster using the AWS CLI, use the `create-cache-cluster` command.

**Important**

As soon as your cluster becomes available, you're billed for each hour or partial hour that the cluster is active, even if you're not actively using it. To stop incurring charges for this cluster, you must delete it. See Deleting a cluster (p. 165).

Creating a cache cluster for Redis (cluster mode disabled) (AWS CLI)

**Example – A Redis (cluster mode disabled) Cluster with no read replicas**

The following CLI code creates a Redis (cluster mode disabled) cache cluster with no replicas.

**Note**

When creating cluster using a node type from the r6gd family, you must pass the `data-tiering-enabled` parameter.

For Linux, macOS, or Unix:

```
aws elasticache create-cache-cluster \
  --cache-cluster-id my-cluster \
  --cache-node-type cache.r4.large \
  --engine redis \
  --engine-version 3.2.4 \
  --num-cache-nodes 1 \
  --cache-parameter-group default.redis3.2 \
  --snapshot-arns arn:aws:s3:::my_bucket/snapshot.rdb
```

For Windows:

```
aws elasticache create-cache-cluster ^
  --cache-cluster-id my-cluster ^
  --cache-node-type cache.r4.large ^
  --engine redis ^
  --engine-version 3.2.4 ^
  --num-cache-nodes 1 ^
  --cache-parameter-group default.redis3.2 ^
  --snapshot-arns arn:aws:s3:::my_bucket/snapshot.rdb
```

Creating a Redis (cluster mode enabled) cluster (AWS CLI)

Redis (cluster mode enabled) clusters (API/CLI: replication groups) cannot be created using the `create-cache-cluster` operation. To create a Redis (cluster mode enabled) cluster (API/CLI: replication group), see Creating a Redis (Cluster Mode Enabled) replication group from scratch (AWS CLI) (p. 280).

For more information, see the AWS CLI for ElastiCache reference topic `create-replication-group`.

Creating a cluster (ElastiCache API)

To create a cluster using the ElastiCache API, use the `CreateCacheCluster` action.

**Important**

As soon as your cluster becomes available, you're billed for each hour or partial hour that the cluster is active, even if you're not using it. To stop incurring charges for this cluster, you must delete it. See Deleting a cluster (p. 165).

**Topics**
Creating a Redis (cluster mode disabled) cache cluster (ElastiCache API)

The following code creates a Redis (cluster mode disabled) cache cluster (ElastiCache API).

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=CreateCacheCluster
  &CacheClusterId=my-cluster
  &CacheNodeType=cache.r4.large
  &CacheParameterGroup=default.redis3.2
  &Engine=redis
  &EngineVersion=3.2.4
  &NumCacheNodes=1
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &SnapshotArns.member.1=arn%3Aaws%3As3%3A%3A%3A%3A%3A%3As3Bucket%2Fdump.rdb
  &Timestamp=20150508T220302Z
  &Version=2015-02-02
  &X-Amz-Credential=<credential>
  &X-Amz-Algorithm=&AWS;4-HMAC-SHA256
  &X-Amz-Credential=<credential>
  &X-Amz-Date=20150508T220302Z
  &X-Amz-Expires=20150508T220302Z
  &X-Amz-SignedHeaders=Host
  &X-Amz-Signature=<signature>
```

Creating a cache cluster in Redis (cluster mode enabled) (ElastiCache API)

Redis (cluster mode enabled) clusters (API/CLI: replication groups) cannot be created using the CreateCacheCluster operation. To create a Redis (cluster mode enabled) cluster (API/CLI: replication group), see Creating a replication group in Redis (Cluster Mode Enabled) from scratch (ElastiCache API) (p. 285).

For more information, see the ElastiCache API reference topic CreateReplicationGroup.
Viewing a cluster's details

You can view detail information about one or more clusters using the ElastiCache console, AWS CLI, or ElastiCache API.

**Viewing details of a Redis (Cluster Mode Disabled) cluster (Console)**

You can view the details of a Redis (cluster mode disabled) cluster using the ElastiCache console, the AWS CLI for ElastiCache, or the ElastiCache API.

The following procedure details how to view the details of a Redis (cluster mode disabled) cluster using the ElastiCache console.

**To view a Redis (cluster mode disabled) cluster's details**

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. In the ElastiCache console dashboard, choose **Redis** to display a list of all your clusters that are running any version of Redis.
3. To see details of a cluster, select the check box to the left of the cluster's name. Make sure that you select a cluster running the Redis engine, not Clustered Redis. Doing this displays details about the cluster, including the cluster's primary endpoint.
4. To view node information:
   a. Choose the cluster's name.
   b. Choose the **Nodes** tab. Doing this displays details about each node, including the node's endpoint which you need to use to read from the cluster.
   c. To view metrics on one or more nodes, select the box to the left of the node ID, then choose the time range for the metrics from the **Time range** list. If you choose multiple nodes, you can see overlay graphs.
Viewing details for a Redis (Cluster Mode Enabled) cluster (Console)

You can view the details of a Redis (cluster mode enabled) cluster using the ElastiCache console, the AWS CLI for ElastiCache, or the ElastiCache API.

The following procedure details how to view the details of a Redis (cluster mode enabled) cluster using the ElastiCache console.

To view a Redis (cluster mode enabled) cluster's details

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. From the list in the upper-right corner, choose the AWS Region you are interested in.
3. In the ElastiCache console dashboard, choose Redis to display a list of all your clusters that are running any version of Redis.
4. To see details of a Redis (cluster mode enabled) cluster, choose the box to the left of the cluster's name. Make sure you choose a cluster running the Clustered Redis engine, not just Redis.

   The screen expands below the cluster and display details about the cluster, including the cluster's configuration endpoint.
5. To see a listing of the cluster's shards and the number of nodes in each shard, choose the cluster's name.
6. To view specific information on a node:
   a. Choose the shard's ID.
   b. Choose the Nodes tab.

   Doing this displays information about each node, including each node's endpoint that you need to use to read data from the cluster.
   c. To view metrics on one or more nodes, choose the box by the node's ID, and then choose a time range for the metrics for Time range. Choosing multiple nodes generates overlay graphs.

   ![Node Information and Metrics]

   Metrics over the last hour for two Redis nodes

**Viewing a cluster's details (AWS CLI)**

You can view the details for a cluster using the AWS CLI describe-cache-clusters command. If the --cache-cluster-id parameter is omitted, details for multiple clusters, up to --max-items, are returned. If the --cache-cluster-id parameter is included, details for the specified cluster are returned. You can limit the number of records returned with the --max-items parameter.

The following code lists the details for my-cluster.

```
aws elasticache describe-cache-clusters --cache-cluster-id my-cluster
```

The following code list the details for up to 25 clusters.

```
aws elasticache describe-cache-clusters --max-items 25
```
Example

For Linux, macOS, or Unix:

```
aws elasticache describe-cache-clusters \
  --cache-cluster-id my-cluster \
  --show-cache-node-info
```

For Windows:

```
aws elasticache describe-cache-clusters ^
  --cache-cluster-id my-cluster ^
  --show-cache-node-info
```

This operation produces output similar to the following (JSON format):

The following JSON output is for three different Redis clusters:

- **my-cluster1** – a Redis (cluster mode disabled) cluster with 1 node.
- **my-cluster2** – a Redis (cluster mode disabled) cluster with 2 nodes, a primary and 1 read replica.
- **my-cluster3** – a Redis (cluster mode enabled) cluster with 2 shards, each shard having a primary node and 2 read replicas. This cluster has encryption enabled.

API Version 2015-02-02

146
For more information, see the AWS CLI for ElastiCache topic `describe-cache-clusters`.
Viewing a cluster's details (ElastiCache API)

You can view the details for a cluster using the ElastiCache API DescribeCacheClusters action. If the CacheClusterId parameter is included, details for the specified cluster are returned. If the CacheClusterId parameter is omitted, details for up to MaxRecords (default 100) clusters are returned. The value for MaxRecords cannot be less than 20 or greater than 100.

The following code lists the details for my-cluster.

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=DescribeCacheClusters
  &CacheClusterId=my-cluster
  &Version=2015-02-02
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20150202T192317Z
  &X-Amz-Credential=<credential>
```

The following code list the details for up to 25 clusters.

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=DescribeCacheClusters
  &MaxRecords=25
  &Version=2015-02-02
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20150202T192317Z
  &X-Amz-Credential=<credential>
```

For more information, see the ElastiCache API reference topic DescribeCacheClusters.
Modifying an ElastiCache cluster

In addition to adding or removing nodes from a cluster, there can be times where you need to make other changes to an existing cluster, such as, adding a security group, changing the maintenance window or a parameter group.

We recommend that you have your maintenance window fall at the time of lowest usage. Thus it might need modification from time to time.

When you change a cluster's parameters, the change is applied to the cluster either immediately or after the cluster is restarted. This is true whether you change the cluster's parameter group itself or a parameter value within the cluster's parameter group. To determine when a particular parameter change is applied, see the Changes Take Effect column in the tables for Redis-specific parameters (p. 441).

Using the AWS Management Console

To modify a cluster

2. From the list in the upper-right corner, choose the AWS Region where the cluster that you want to modify is located.
3. In the navigation pane, choose the engine running on the cluster that you want to modify.
   A list of the chosen engine's clusters appears.
4. In the list of clusters, for the cluster that you want to modify, choose its name.
5. Choose Actions and then choose Modify.
   The Modify Cluster window appears.
6. In the Modify Cluster window, make the modifications that you want. Options include:
   - Description
   - Engine Version Compatibility
     Important
     You can upgrade to newer engine versions. If you upgrade major engine versions, for example from 5.0.6 to 6.0, you need to select a parameter group family that is compatible with the new engine version. For more information on doing so, see Upgrading engine versions (p. 198). However, you can't downgrade to older engine versions except by deleting the existing cluster and creating it again.
   - VPC Security Group(s)
   - Parameter Group
   - Node Type
     Note
     If the cluster is using a node type from the r6gd family, you can only choose a different node size from within that family. If you choose a node type from the r6gd family, data tiering will automatically be enabled. For more information, see Data tiering.
   - Multi-AZ
   - Auto failover (cluster mode disabled only)
   - Enable Automatic Backups
   - Backup Node Id
   - Backup Retention Period
   - Backup Window
Modifying a cluster

• Topic for SNS Notification

The **Apply Immediately** box applies only to node type and engine version modifications. To apply changes immediately, choose the **Apply Immediately** check box. If this box is not chosen, node type and engine version modifications are applied during the next maintenance window. Other modifications, such as changing the maintenance window, are applied immediately.

7. Choose **Modify**.

**To enable/disable log delivery, do the following:**

1. From the list of clusters, choose the cluster you want to modify. Choose the **Cluster name** and not the checkbox beside it.
2. On the **Cluster name** page, choose the **Logs** tab.
3. To enable/disable slow logs, choose either **Enable slow logs** or **Disable slow logs**.
4. To change your configuration, choose **Modify slow logs**: 
   - Under **Destination Type**, choose either **CloudWatch Logs** or **Kinesis Firehose**.
   - Under **Log destination**, choose either **Create new** and enter either your CloudWatchLogs log group name or your Kinesis Data Firehose stream name. Or choose **Select existing** and then choose either your CloudWatchLogs log group name or your Kinesis Data Firehose stream name.

**Using the AWS CLI**

You can modify an existing cluster using the AWS CLI `modify-cache-cluster` operation. To modify a cluster's configuration value, specify the cluster's ID, the parameter to change and the parameter's new value. The following example changes the maintenance window for a cluster named *my-cluster* and applies the change immediately.

**Important**

You can upgrade to newer engine versions. If you upgrade major engine versions, for example from 5.0.6 to 6.0, you need to select a parameter group family that is compatible with the new engine version. For more information on doing so, see [Upgrading engine versions](#). However, you can't downgrade to older engine versions except by deleting the existing cluster and creating it again.

For Linux, macOS, or Unix:

```
aws elasticache modify-cache-cluster \
  --cache-cluster-id my-cluster \
  --preferred-maintenance-window sun:23:00-mon:02:00
```

For Windows:

```
aws elasticache modify-cache-cluster ^
  --cache-cluster-id my-cluster ^
  --preferred-maintenance-window sun:23:00-mon:02:00
```

The **--apply-immediately** parameter applies only to modifications in node type, engine version, and changing the number of nodes in a cluster. If you want to apply any of these changes immediately, use the **--apply-immediately** parameter. If you prefer postponing these changes to your next maintenance window, use the **--no-apply-immediately** parameter. Other modifications, such as changing the maintenance window, are applied immediately.

For more information, see the AWS CLI for ElastiCache topic `modify-cache-cluster`. 

---

API Version 2015-02-02

150
Using the ElastiCache API

You can modify an existing cluster using the ElastiCache API `ModifyCacheCluster` operation. To modify a cluster's configuration value, specify the cluster's ID, the parameter to change and the parameter's new value. The following example changes the maintenance window for a cluster named `my-cluster` and applies the change immediately.

**Important**

You can upgrade to newer engine versions. If you upgrade major engine versions, for example from 5.0.6 to 6.0, you need to select a parameter group family that is compatible with the new engine version. For more information on doing so, see Upgrading engine versions (p. 198). However, you can't downgrade to older engine versions except by deleting the existing cluster and creating it again.

Line breaks are added for ease of reading.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=ModifyCacheCluster
&CacheClusterId=my-cluster
&PREFERREDMAINTENANCEWINDOW=sun:23:00-mon:02:00
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150901T220302Z
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Date=20150202T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Expires=20150901T220302Z
&X-Amz-Credential=<credential>
&X-Amz-Signature=<signature>
```

The `ApplyImmediately` parameter applies only to modifications in node type, engine version, and changing the number of nodes in a cluster. If you want to apply any of these changes immediately, set the `ApplyImmediately` parameter to `true`. If you prefer postponing these changes to your next maintenance window, set the `ApplyImmediately` parameter to `false`. Other modifications, such as changing the maintenance window, are applied immediately.

For more information, see the ElastiCache API reference topic `ModifyCacheCluster`.

API Version 2015-02-02

151
Adding nodes to a cluster

To reconfigure your Redis (cluster mode enabled) cluster, see Scaling clusters in Redis (Cluster Mode Enabled) (p. 375)

You can use the ElastiCache Management Console, the AWS CLI or ElastiCache API to add nodes to your cluster.

Using the AWS Management Console

If you want to add a node to a single-node Redis (cluster mode disabled) cluster (one without replication enabled), it's a two-step process: first add replication, and then add a replica node.

Topics

• To add replication to a Redis cluster with no shards (p. 152)
• To add nodes to a cluster (console) (p. 152)

The following procedure adds replication to a single-node Redis that does not have replication enabled. When you add replication, the existing node becomes the primary node in the replication-enabled cluster. After replication is added, you can add up to 5 replica nodes to the cluster.

To add replication to a Redis cluster with no shards

2. From the navigation pane, choose Redis.
   A list of clusters running the Redis engine is displayed.
3. Choose the name of a cluster, not the box to the left of the cluster's name, that you want to add nodes to.
   The following is true of a Redis cluster that does not have replication enabled:
   • It is running Redis, not Clustered Redis.
   • It has zero shards.
   If the cluster has any shards, replication is already enabled on it and you can continue at To add nodes to a cluster (console) (p. 152).
4. Choose Add replication.
5. In Add Replication, enter a description for this replication-enabled cluster.
6. Choose Add.
   As soon as the cluster's status returns to available you can continue at the next procedure and add replicas to the cluster.

To add nodes to a cluster (console)

The following procedure can be used to add nodes to a cluster.

2. In the navigation pane, choose the engine running on the cluster that you want to add nodes to.
Adding nodes to a cluster

A list of clusters running the chosen engine appears.

3. From the list of clusters, for the cluster that you want to add a node to, choose its name.

If your cluster is a Redis (cluster mode enabled) cluster, see Scaling clusters in Redis (Cluster Mode Enabled) (p. 375).

If your cluster is a Redis (cluster mode disabled) cluster with zero shards, first complete the steps at To add replication to a Redis cluster with no shards (p. 152).

4. Choose **Add node**.

5. Complete the information requested in the **Add Node** dialog box.

6. Choose the **Apply Immediately - Yes** button to add this node immediately, or choose **No** to add this node during the cluster's next maintenance window.

### Impact of New Add and Remove Requests on Pending Requests

<table>
<thead>
<tr>
<th>Scenarios</th>
<th>Pending Operation</th>
<th>New Request</th>
<th>Results</th>
</tr>
</thead>
</table>
| Scenario 1 | Delete             | Delete      | The new delete request, pending or immediate, replaces the pending delete request.  
For example, if nodes 0001, 0003, and 0007 are pending deletion and a new request to delete nodes 0002 and 0004 is issued, only nodes 0002 and 0004 will be deleted. Nodes 0001, 0003, and 0007 will not be deleted. |
| Scenario 2 | Delete             | Create      | The new create request, pending or immediate, replaces the pending delete request.  
For example, if nodes 0001, 0003, and 0007 are pending deletion and a new request to create a node is issued, a new node will be created and nodes 0001, 0003, and 0007 will not be deleted. |
| Scenario 3 | Create             | Delete      | The new delete request, pending or immediate, replaces the pending create request.  
For example, if there is a pending request to create two nodes and a new request is issued to delete node 0003, no new nodes will be created and node 0003 will be deleted. |
| Scenario 4 | Create             | Create      | The new create request is added to the pending create request.  
For example, if there is a pending request to create two nodes and a new request is issued to create three nodes, the new requests is added to the pending request and five nodes will be created.  
**Important**  
If the new create request is set to **Apply Immediately - Yes**, all create requests are performed immediately. If the new create request is set to **Apply Immediately - No**, all create requests are pending. |
To determine what operations are pending, choose the **Description** tab and check to see how many pending creations or deletions are shown. You cannot have both pending creations and pending deletions.

7. Choose the **Add** button.

After a few moments, the new nodes should appear in the nodes list with a status of **creating**. If they don't appear, refresh your browser page. When the node's status changes to **available** the new node is able to be used.

### Using the AWS CLI

If you want to add nodes to an existing Redis (cluster mode disabled) cluster that does not have replication enabled, you must first create the replication group specifying the existing cluster as the primary. For more information, see [Creating a replication group using an available Redis cache cluster (AWS CLI)](p. 267). After the replication group is **available**, you can continue with the following process.

To add nodes to a cluster using the AWS CLI, use the AWS CLI operation **increase-replica-count** with the following parameters:

- **--replication-group-id** The ID of the replication group that you want to add nodes to.
- **--new-replica-count** specifies the number of nodes that you want in this replication group after the modification is applied. To add nodes to this cluster, **--new-replica-count** must be greater than the current number of nodes in this cluster.
- **--apply-immediately** or **--no-apply-immediately** which specifies whether to add these nodes immediately or at the next maintenance window.

For Linux, macOS, or Unix:

```bash
aws elasticache increase-replica-count \
   --replication-group-id my-replication-group \
   --new-replica-count \n   --apply-immediately
```
For Windows:

```bash
aws elasticache increase-replica-count ^
   --replication-group-id my-replication-group ^
   --new-replica-count 4 ^
   --apply-immediately
```

This operation produces output similar to the following (JSON format):

```json
{
   "ReplicationGroup": {
      "ReplicationGroupId": "node-test",
      "Description": "node-test",
      "Status": "modifying",
      "PendingModifiedValues": {},
      "MemberClusters": [
         "node-test-001",
         "node-test-002",

}

For more information, see the AWS CLI topic increase-replica-count.

**Using the ElastiCache API**

If you want to add nodes to an existing Redis (cluster mode disabled) cluster that does not have replication enabled, you must first create the replication group specifying the existing cluster as the Primary. For more information, see Adding replicas to a standalone Redis (Cluster Mode Disabled) cluster (ElastiCache API) (p. 269). After the replication group is available, you can continue with the following process.

**To add nodes to a cluster (ElastiCache API)**

- Call the IncreaseReplicaCount API operation with the following parameters:
  - ReplicationGroupId The ID of the cluster that you want to add nodes to.
  - NewReplicaCount The NewReplicaCount parameter specifies the number of nodes that you want in this cluster after the modification is applied. To add nodes to this cluster, NewReplicaCount must be greater than the current number of nodes in this cluster. If this value is less than the current number of nodes, use the DecreaseReplicaCount API with the number of nodes to remove from the cluster.
  - ApplyImmediately Specifies whether to add these nodes immediately or at the next maintenance window.
  - Region Specifies the AWS Region of the cluster that you want to add nodes to.

The following example shows a call to add nodes to a cluster.

**Example**

```plaintext
https://elasticache.us-west-2.amazonaws.com/
?Action=IncreaseReplicaCount
&ApplyImmediately=true
&NumCacheNodes=4
&ReplicationGroupId=my-replication-group
&Region=us-east-2
&Version=2014-12-01
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20141201T220302Z
```

API Version 2015-02-02
For more information, see ElastiCache API topic IncreaseReplicaCount.
Removing nodes from a cluster

You can delete a node from a cluster using the AWS Management Console, the AWS CLI, or the ElastiCache API.

Using the AWS Management Console

To remove nodes from a cluster (console)

2. From the list in the upper-right corner, choose the AWS Region of the cluster that you want to remove nodes from.
3. In the navigation pane, choose the engine running on the cluster that you want to remove a node.
   A list of clusters running the chosen engine appears.
4. From the list of clusters, choose the cluster name from which you want to remove a node.
   A list of the cluster's nodes appears.
5. Choose the box to the left of the node ID for the node that you want to remove. Using the ElastiCache console, you can only delete one node at a time, so choosing multiple nodes means that you can't use the Delete node button.
   The Delete Node page appears.
6. To delete the node, complete the Delete Node page and choose Delete Node. To keep the node, choose Cancel.
   **Important**
   If deleting the node results in the cluster no longer being Multi-AZ compliant, make sure to first clear the Multi-AZ check box and then delete the node. If you clear the Multi-AZ check box, you can choose to enable Auto failover.

Impact of New Add and Remove Requests on Pending Requests

<table>
<thead>
<tr>
<th>Scenarios</th>
<th>Pending Operation</th>
<th>New Request</th>
<th>Results</th>
</tr>
</thead>
</table>
| Scenario 1   | Delete            | Delete      | The new delete request, pending or immediate, replaces the pending delete request.  
   For example, if nodes 0001, 0003, and 0007 are pending deletion and a new request to delete nodes 0002 and 0004 is issued, only nodes 0002 and 0004 will be deleted. Nodes 0001, 0003, and 0007 will not be deleted. |
| Scenario 2   | Delete            | Create      | The new create request, pending or immediate, replaces the pending delete request.  
   For example, if nodes 0001, 0003, and 0007 are pending deletion and a new request to create a node is issued, a new node will be created and nodes 0001, 0003, and 0007 will not be deleted. |
| Scenario 3   | Create            | Delete      | The new delete request, pending or immediate, replaces the pending create request. |
Removing nodes from a cluster

<table>
<thead>
<tr>
<th>Scenarios</th>
<th>Pending Operation</th>
<th>New Request</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>For example, if there is a pending request to create two nodes and a new request is issued to delete node 0003, no new nodes will be created and node 0003 will be deleted.</td>
</tr>
<tr>
<td>Scenario 4</td>
<td>Create</td>
<td>Create</td>
<td>The new create request is added to the pending create request. For example, if there is a pending request to create two nodes and a new request is issued to create three nodes, the new requests is added to the pending request and five nodes will be created.</td>
</tr>
</tbody>
</table>

**Important**
If the new create request is set to Apply Immediately - Yes, all create requests are performed immediately. If the new create request is set to Apply Immediately - No, all create requests are pending.

To determine what operations are pending, choose the Description tab and check to see how many pending creations or deletions are shown. You cannot have both pending creations and pending deletions.

Using the AWS CLI

1. Identify the IDs of the nodes that you want to remove. For more information, see Viewing a cluster’s details (p. 139).
2. Use the decrease-replica-count CLI operation with a list of the nodes to remove, as in the following example.
To remove nodes from a cluster using the command-line interface, use the command decrease-replica-count with the following parameters:

- `--replication-group-id` The ID of the replication group that you want to remove nodes from.
- `--new-replica-count` The `--new-replica-count` parameter specifies the number of nodes that you want in this cluster after the modification is applied.
- `--replicas-to-remove` A list of node IDs that you want removed from this cluster.
- `--apply-immediately` or `--no-apply-immediately` Specifies whether to remove these nodes immediately or at the next maintenance window.
- `--region` Specifies the AWS Region of the cluster that you want to remove nodes from.

**Note**
You can pass only one of `--replicas-to-remove` or `--new-replica-count` parameters when calling this operation.

For Linux, macOS, or Unix:

```bash
aws elasticache decrease-replica-count \
   --replication-group-id my-replication-group \
   --new-replica-count 2 \
   --region us-east-2 \
   --apply-immediately
```

For Windows:

```bash
aws elasticache decrease-replica-count ^
   --replication-group-id my-replication-group ^
   --new-replica-count 3 ^
   --region us-east-2 ^
   --apply-immediately
```

This operation produces output similar to the following (JSON format):

```
{
   "ReplicationGroup": {
      "ReplicationGroupId": "node-test",
      "Description": "node-test"
   },
   "Status": "modifying",
   "PendingModifiedValues": {},
   "MemberClusters": [
      "node-test-001",
      "node-test-002",
      "node-test-003",
      "node-test-004",
      "node-test-005",
      "node-test-006"
   ],
   "NodeGroups": [
      {
         "NodeGroupId": "0001",
         "Status": "modifying",
         "PrimaryEndpoint": { 
            "Address": "node-test.zzzzzz.ng.0001.usw2.cache.amazonaws.com",
            "Port": 6379
         },
         "ReaderEndpoint": 
```
"Address": "node-test-ro.zzzzzz.ng.0001.usw2.cache.amazonaws.com",
"Port": 6379
},
"NodeGroupMembers": [
{
"CacheClusterId": "node-test-001",
"CacheNodeId": "0001",
"ReadEndpoint": {
"Address": "node-test-001.zzzzzz.0001.usw2.cache.amazonaws.com",
"Port": 6379
},
"PreferredAvailabilityZone": "us-west-2a",
"CurrentRole": "primary"
},
{
"CacheClusterId": "node-test-002",
"CacheNodeId": "0001",
"ReadEndpoint": {
"Address": "node-test-002.zzzzzz.0001.usw2.cache.amazonaws.com",
"Port": 6379
},
"PreferredAvailabilityZone": "us-west-2c",
"CurrentRole": "replica"
},
{
"CacheClusterId": "node-test-003",
"CacheNodeId": "0001",
"ReadEndpoint": {
"Address": "node-test-003.zzzzzz.0001.usw2.cache.amazonaws.com",
"Port": 6379
},
"PreferredAvailabilityZone": "us-west-2b",
"CurrentRole": "replica"
},
{
"CacheClusterId": "node-test-004",
"CacheNodeId": "0001",
"ReadEndpoint": {
"Address": "node-test-004.zzzzzz.0001.usw2.cache.amazonaws.com",
"Port": 6379
},
"PreferredAvailabilityZone": "us-west-2c",
"CurrentRole": "replica"
},
{
"CacheClusterId": "node-test-005",
"CacheNodeId": "0001",
"ReadEndpoint": {
"Address": "node-test-005.zzzzzz.0001.usw2.cache.amazonaws.com",
"Port": 6379
},
"PreferredAvailabilityZone": "us-west-2b",
"CurrentRole": "replica"
},
{
"CacheClusterId": "node-test-006",
"CacheNodeId": "0001",
"ReadEndpoint": {
"Address": "node-test-006.zzzzzz.0001.usw2.cache.amazonaws.com",
"Port": 6379
}
Alternatively, you could call `decrease-replica-count` and instead of passing in the `--new-replica-count` parameter, you could pass the `--replicas-to-remove` parameter, as shown following:

For Linux, macOS, or Unix:

```bash
aws elasticsearch decrease-replica-count
   --replication-group-id my-replication-group
   --replicas-to-remove node-test-003
   --region us-east-2
   --apply-immediately
```

For Windows:

```bash
aws elasticsearch decrease-replica-count ^
   --replication-group-id my-replication-group ^
   --replicas-to-remove node-test-003 ^
   --region us-east-2 ^
   --apply-immediately
```

For more information, see the AWS CLI topics `decrease-replica-count`.

**Using the ElastiCache API**

To remove nodes using the ElastiCache API, call the `DecreaseReplicaCount` API operation with the replication group ID and a list of nodes to remove, as shown:

- **ReplicationGroupId** The ID of the replication group that you want to remove nodes from.
- **ReplicasToRemove** The `ReplicasToRemove` parameter specifies the number of nodes that you want in this cluster after the modification is applied.
- **ApplyImmediately** Specifies whether to remove these nodes immediately or at the next maintenance window.
- **Region** Specifies the AWS Region of the cluster that you want to remove a node from.

The following example immediately removes nodes 0004 and 0005 from the cluster my-cluster.
Removing nodes from a cluster

For more information, see ElastiCache API topic `DecreaseReplicaCount`.

```plaintext
https://elasticache.us-west-2.amazonaws.com/
?Action=DecreaseReplicaCount
&ReplicationGroupId=my-replication-group
&ApplyImmediately=true
&ReplicasToRemove=node-test-003
&Region us-east-2
&Version=2014-12-01
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20141201T220302Z
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
&X-Amz-Date=20141201T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Expires=20141201T220302Z
&X-Amz-Credential=<credential>
&X-Amz-Signature=<signature>
```
Canceling pending add or delete node operations

If you elected to not apply a change immediately, the operation has pending status until it is performed at your next maintenance window. You can cancel any pending operation.

**To cancel a pending operation**

2. From the list in the upper-right corner, choose the AWS Region that you want to cancel a pending add or delete node operation in.
3. In the navigation pane, choose the engine running on the cluster that has pending operations that you want to cancel. A list of clusters running the chosen engine appears.
4. In the list of clusters, choose the name of the cluster, not the box to the left of the cluster's name, that has pending operations that you want to cancel.
5. To determine what operations are pending, choose the Description tab and check to see how many pending creations or deletions are shown. You cannot have both pending creations and pending deletions.

6. Choose the Nodes tab.
7. To cancel all pending operations, click Cancel Pending. The Cancel Pending dialog box appears.
8. Confirm that you want to cancel all pending operations by choosing the Cancel Pending button, or to keep the operations, choose Cancel.
Deleting a cluster

As long as a cluster is in the *available* state, you are being charged for it, whether or not you are actively using it. To stop incurring charges, delete the cluster.

**Warning**
When you delete an ElastiCache for Redis cluster, your manual snapshots are retained. You can also create a final snapshot before the cluster is deleted. Automatic cache snapshots are not retained.

**Using the AWS Management Console**

The following procedure deletes a single cluster from your deployment. To delete multiple clusters, repeat the procedure for each cluster that you want to delete. You do not need to wait for one cluster to finish deleting before starting the procedure to delete another cluster.

**To delete a cluster**

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at [https://console.aws.amazon.com/elasticache/](https://console.aws.amazon.com/elasticache/).
2. In the ElastiCache console dashboard, choose the engine the cluster that you want to delete is running.

   A list of all clusters running that engine appears.
3. To choose the cluster to delete, choose the cluster's name from the list of clusters.

   **Important**
   You can only delete one cluster at a time from the ElastiCache console. Choosing multiple clusters disables the delete operation.
4. For *Actions*, choose *Delete*.
5. In the *Delete Cluster* confirmation screen, choose *Delete* to delete the cluster, or choose *Cancel* to keep the cluster.

   If you chose *Delete*, the status of the cluster changes to *deleting*.

As soon as your cluster is no longer listed in the list of clusters, you stop incurring charges for it.

**Using the AWS CLI**

The following code deletes the cache cluster *my-cluster*.

```
aws elasticache delete-cache-cluster --cache-cluster-id my-cluster
```

The `delete-cache-cluster` CLI action only deletes one cache cluster. To delete multiple cache clusters, call `delete-cache-cluster` for each cache cluster that you want to delete. You do not need to wait for one cache cluster to finish deleting before deleting another.

For Linux, macOS, or Unix:

```
aws elasticache delete-cache-cluster --cache-cluster-id my-cluster --region us-east-2
```

For Windows:
aws elasticache delete-cache-cluster
   --cache-cluster-id my-cluster
   --region us-east-2

For more information, see the AWS CLI for ElastiCache topic delete-cache-cluster.

Using the ElastiCache API

The following code deletes the cluster my-cluster.

https://elasticache.us-west-2.amazonaws.com/
   ?Action=DeleteCacheCluster
   &CacheClusterId=my-cluster
   &Region us-east-2
   &SignatureVersion=4
   &SignatureMethod=HmacSHA256
   &Timestamp=20150202T220302Z
   &X-Amz-Algorithm=&AWS;4-HMAC-SHA256
   &X-Amz-Date=20150202T220302Z
   &X-Amz-SignedHeaders=Host
   &X-Amz-Expires=20150202T220302Z
   &X-Amz-Credential=<credential>
   &X-Amz-Signature=<signature>

The DeleteCacheCluster API operation only deletes one cache cluster. To delete multiple cache clusters, call DeleteCacheCluster for each cache cluster that you want to delete. You do not need to wait for one cache cluster to finish deleting before deleting another.

For more information, see the ElastiCache API reference topic DeleteCacheCluster.
Accessing your cluster or replication group

Your Amazon ElastiCache instances are designed to be accessed through an Amazon EC2 instance. If you launched your ElastiCache instance in an Amazon Virtual Private Cloud (Amazon VPC), you can access your ElastiCache instance from an Amazon EC2 instance in the same Amazon VPC. Or, by using VPC peering, you can access your ElastiCache instance from an Amazon EC2 in a different Amazon VPC.

If you launched your ElastiCache instance in EC2 Classic, you allow the EC2 instance to access your cluster by granting the Amazon EC2 security group associated with the instance access to your cache security group. By default, access to a cluster is restricted to the account that launched the cluster.

Topics

- Determine the cluster's platform (p. 167)
- Grant access to your cluster or replication group (p. 169)

Determine the cluster's platform

Before you continue, determine whether you launched your cluster into EC2-VPC or EC2-Classic.

For more information, see Detecting Your Supported Platforms and Whether You Have a Default VPC.

Determining Your Cluster's Platform using the ElastiCache Console

The following procedure uses the ElastiCache console to determine whether you launched your cluster into EC2-VPC or EC2-Classic.

To determine a cluster's platform using the ElastiCache console

2. To see a list of your clusters running the Redis engine, in the left navigation pane, choose Redis.
3. In the list of clusters, expand the cluster you want to authorize access to by choosing the box to the left of the cluster name.
4. Locate Subnet group:

   - If the Subnet group has a name, as shown here, you launched your cluster in EC2-VPC and should continue at You launched your cluster into EC2-VPC (p. 169).
   - If there is a dash (-) instead of a Subnet group name, you launched your cluster in EC2-Classic and should continue at You launched your cluster running in EC2-Classic (p. 170).

For more information, see Detecting Your Supported Platforms and Whether You Have a Default VPC.
Determining Your Clusters Platform using the AWS CLI

The following procedure uses the AWS CLI to determine whether you launched your cluster into EC2-VPC or EC2-Classic.

To determine a cluster's platform using the AWS CLI

1. Open a command window.
2. At the command prompt, run the following command.

   For Linux, macOS, or Unix:

   ```bash
   aws elasticache describe-cache-clusters
   --show-cache-cluster-details
   --cache-cluster-id my-cluster
   ```

   For Windows:

   ```bash
   aws elasticache describe-cache-clusters
   --show-cache-cluster-details
   --cache-cluster-id my-cluster
   ```

   JSON output from this command will look something like this. Some of the output is omitted to save space.

   ```json
   {
     "CacheClusters": [
       {
         "Engine": "redis",
         "AuthTokenEnabled": false,
         "CacheParameterGroup": {
           "CacheNodeIdsToReboot": [],
           "CacheParameterGroupName": "default.redis3.2",
           "ParameterApplyStatus": "in-sync"
         },
         "CacheClusterId": "my-cluster-001",
         "CacheSecurityGroups": [],
         "NumCacheNodes": 1,
         "AtRestEncryptionEnabled": false,
         "CacheClusterCreateTime": "2018-01-16T20:09:34.449Z",
         "ReplicationGroupId": "my-cluster",
         "AutoMinorVersionUpgrade": true,
         "CacheClusterStatus": "available",
         "PreferredAvailabilityZone": "us-east-2a",
       },
       "SecurityGroups": [
         {  
           "Status": "active",
           "SecurityGroupId": "sg-e8c03081"
         }
       ],
       "TransitEncryptionEnabled": false,
       "CacheSubnetGroupName": "default",
       "EngineVersion": "3.2.10",
       "PendingModifiedValues": {},
       "PreferredMaintenanceWindow": "sat:05:30-sat:06:30",
       "CacheNodeType": "cache.t2.medium",
       "DataTiering": "disabled"
     }
   }
   ```
Grant access to your cluster or replication group

You launched your cluster into EC2-VPC

If you launched your cluster into an Amazon Virtual Private Cloud (Amazon VPC), you can connect to your ElastiCache cluster only from an Amazon EC2 instance that is running in the same Amazon VPC. In this case, you will need to grant network ingress to the cluster.

Note
If you are using Local Zones, make sure you have enabled it. For more information, see Enable Local Zones. By doing so, your VPC is extended to that Local Zone and your VPC will treat the subnet as any subnet in any other Availability Zone and relevant gateways, route tables and other security group considerations. will be automatically adjusted.

To grant network ingress from an Amazon VPC security group to a cluster

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. From the list of security groups, choose the security group for your Amazon VPC. Unless you created a security group for ElastiCache use, this security group will be named default.
4. Choose the Inbound tab, and then do the following:
   a. Choose Edit.
   b. Choose Add rule.
   c. In the Type column, choose Custom TCP rule.
   d. In the Port range box, type the port number for your cluster node. This number must be the same one that you specified when you launched the cluster. The default port for Redis is 6379.
   e. In the Source box, choose Anywhere which has the port range (0.0.0.0/0) so that any Amazon EC2 instance that you launch within your Amazon VPC can connect to your ElastiCache nodes.

Important
Opening up the ElastiCache cluster to 0.0.0.0/0 does not expose the cluster to the Internet because it has no public IP address and therefore cannot be accessed from outside the VPC. However, the default security group may be applied to other Amazon EC2 instances in the customer’s account, and those instances may have a public IP address. If they happen to be running something on the default port, then that service could be exposed unintentionally. Therefore, we recommend creating a VPC Security Group that will be used exclusively by ElastiCache. For more information, see Custom Security Groups.

f. Choose Save.

When you launch an Amazon EC2 instance into your Amazon VPC, that instance will be able to connect to your ElastiCache cluster.
You launched your cluster running in EC2-Classic

If you launched your cluster into EC2-Classic, to allow an Amazon EC2 instance to access your cluster you will need to grant the Amazon EC2 security group associated with the instance access to your cache security group.

To grant an Amazon EC2 security group access to a cluster

2. To see a list of security groups, from the left navigation pane, choose Security Groups.
   
   **Important**
   
   If Security Groups is not listed in the navigation pane, you launched your cluster in EC2-VPC rather than EC2-Classic and should follow the instructions at You launched your cluster into EC2-VPC (p. 169).
3. Choose the box to the left of default security group.
4. From the list at the bottom of the screen, choose the EC2 Security Group Name you want to authorize.
5. To authorize access, choose Add.

Amazon EC2 instances that are associated with the security group are now authorized to connect to your ElastiCache cluster.

To revoke a security group’s access, locate the security group in the list of authorized security groups, and then choose Remove.

For more information on ElastiCache Security Groups, see Security groups: EC2-Classic (p. 533).
Accessing ElastiCache resources from outside AWS

Elasticache is a service designed to be used internally to your VPC. External access is discouraged due to the latency of Internet traffic and security concerns. However, if external access to Elasticache is required for test or development purposes, it can be done through a VPN.

Using the AWS Client VPN, you allow external access to your Elasticache nodes with the following benefits:

- Restricted access to approved users or authentication keys;
- Encrypted traffic between the VPN Client and the AWS VPN endpoint;
- Limited access to specific subnets or nodes;
- Easy revocation of access from users or authentication keys;
- Audit connections;

The following procedures demonstrate how to:

Topics

- Create a certificate authority (p. 171)
- Configuring AWS client VPN components (p. 172)
- Configure the VPN client (p. 174)

Create a certificate authority

It is possible to create a Certificate Authority (CA) using different techniques or tools. We suggest the easy-rsa utility, provided by the OpenVPN project. Regardless of the option you choose, make sure to keep the keys secure. The following procedure downloads the easy-rsa scripts, creates the Certificate Authority and the keys to authenticate the first VPN client:

- To create the initial certificates, open a terminal and do the following:
  - git clone https://github.com/OpenVPN/easy-rsa
  - cd easy-rsa
  - ./easyrsa3/easyrsa init-pki
  - ./easyrsa3/easyrsa build-ca nopass
  - ./easyrsa3/easyrsa build-server-full server nopass
  - ./easyrsa3/easyrsa build-client-full client1.domain.tld nopass

  A pki subdirectory containing the certificates will be created under easy-rsa.

- Submit the server certificate to the AWS Certificate manager (ACM):
  - On the ACM console, select Certificate Manager.
  - Select Import Certificate.
  - Enter the public key certificate available in the easy-rsa/pki/issued/server.crt file in the Certificate body field.
  - Paste the private key available in the easy-rsa/pki/private/server.key in the Certificate private key field. Make sure to select all the lines between BEGIN AND END PRIVATE KEY (including the BEGIN and END lines).
  - Paste the CA public key available on the easy-rsa/pki/ca.crt file in the Certificate chain field.
  - Select Review and import.
  - Select Import.
To submit the server's certificates to ACM using the AWS CLI, run the following command:

```bash
aws acm import-certificate --certificate fileb://easy-rsa/pki/issued/server.crt
--private-key fileb://easy-rsa/pki/private/server.key --certificate-chain
file://easy-rsa/pki/ca.crt --region region
```

Note the Certificate ARN for future use.

### Configuring AWS client VPN components

#### Using the AWS Console

On the AWS console, select **Services** and then **VPC**.

Under **Virtual Private Network**, select **Client VPN Endpoints** and do the following:

**Configuring AWS Client VPN components**

- Select **Create Client VPN Endpoint**.
- Specify the following options:
  - **Client IPv4 CIDR**: use a private network with a netmask of at least /22 range. Make sure that the selected subnet does not conflict with the VPC networks' addresses. Example: 10.0.0.0/22.
  - In **Server certificate ARN**, select the ARN of the certificate previously imported.
  - Select **Use mutual authentication**.
  - In **Client certificate ARN**, select the ARN of the certificate previously imported.
  - Select **Create Client VPN Endpoint**.

#### Using the AWS CLI

Run the following command:

```bash
aws ec2 create-client-vpn-endpoint --client-cidr-block "10.0.0.0/22" --server-
certificate-arn arn:aws:acm:us-east-1:012345678912:certificate/0123abcd-
ab12-01a0-123a-123456abcdef --authentication-options Type=certificate-
authentication,,MutualAuthentication={ClientRootCertificateChainArn=arn:aws:acm:us-
east-1:012345678912:certificate/123abcd-ab12-01a0-123a-123456abcdef} --
connection-log-options Enabled=false
```

Example output:

```
"ClientVpnEndpointId": "cvpn-endpoint-0123456789abcdefg",
"Status": { "Code": "pending-associate" }, "DnsName": "cvpn-
endpoint-0123456789abcdefg.prod.clientvpn.us-east-1.amazonaws.com" }
```

### Associate the target networks to the VPN endpoint

- Select the new VPN endpoint, and then select the **Associations** tab.
- Select **Associate** and specify the following options.
  - **VPC**: Select the Elasticache Cluster's VPC.
  - Select one of the Elasticache cluster's networks. If in doubt, review the networks in the **Subnet Groups** on the Elasticache dashboard.
  - Select **Associate**. If necessary, repeat the steps for the remaining networks.

#### Using the AWS CLI

API Version 2015-02-02

172
Run the following command:

```
aws ec2 associate-client-vpn-target-network --client-vpn-endpoint-id cvpn-endpoint-0123456789abcdefg --subnet-id subnet-0123456789abdcdef
```

Example output:

```
"Status": { "Code": "associating" }, "AssociationId": "cvpn-assoc-0123456789abdcdef" }
```

**Review the VPN security group**

The VPN Endpoint will automatically adopt the VPC's default security group. Check the inbound and outbound rules and confirm if the security group allows the traffic from the VPN network (defined on the VPN Endpoint settings) to the Elasticache networks on the service ports (by default, 6379 for Redis and 11211 for Memcached).

If you need to change the security group assigned to the VPN Endpoint, proceed as follows:

- Select the current security group.
- Select **Apply Security Group**.
- Select the new Security Group.

**Using the AWS CLI**

Run the following command:

```
aws ec2 apply-security-groups-to-client-vpn-target-network --client-vpn-endpoint-id cvpn-endpoint-0123456789abcdefga --vpc-id vpc-0123456789abdcdef --security-group-ids sg-0123456789abdcdef
```

Example output:

```
"SecurityGroupIds": [ "sg-0123456789abdcdef" ]
```

**Note**

The ElastiCache security group also needs to allow traffic coming from the VPN clients. The clients' addresses will be masked with the VPN Endpoint address, according to the VPC Network. Therefore, consider the VPC network (not the VPN Clients' network) when creating the inbound rule on the Elasticache security group.

**Authorize the VPN access to the destination networks**

On the **Authorization** tab, select **Authorize Ingress** and specify the following:

- Destination network to enable access: Either use 0.0.0.0/0 to allow access to any network (including the Internet) or restrict the the Elasticache networks/hosts.
- Under **Grant access to:** select **Allow access to all users**.
- Select **Add Authorization Rules**.

**Using the AWS CLI**

Run the following command:

```
aws ec2 authorize-client-vpn-ingress --client-vpn-endpoint-id cvpn-endpoint-0123456789abcdefg --target-network-cidr 0.0.0.0/0 --authorize-all-groups
```

Example output:
Grant access to your cluster or replication group

{ "Status": { "Code": "authorizing" } }

Allowing access to the Internet from the VPN clients

If you need to browse the Internet through the VPN, you need to create an additional route. Select the Route Table tab and then select Create Route:

- Route destination: 0.0.0.0/0
- Target VPC Subnet ID: Select one of the associated subnets with access to the Internet.
- Select Create Route.

Using the AWS CLI

Run the following command:

```
aws ec2 create-client-vpn-route --client-vpn-endpoint-id cvpn-endpoint-0123456789abcdefg --destination-cidr-block 0.0.0.0/0 --target-vpc-subnet-id subnet-0123456789abdcdef
```

Example output:

{ "Status": { "Code": "creating" } }

Configure the VPN client

On the AWS Client VPN Dashboard, select the VPN endpoint recently created and select Download Client Configuration. Copy the configuration file, and the files easy-rsa/pki/issued/client1.domain.tld.crt and easy-rsa/pki/private/client1.domain.tld.key. Edit the configuration file and change or add the following parameters:

- cert: add a new line with the parameter cert pointing to the client1.domain.tld.crt file. Use the full path to the file. Example: cert /home/user/.cert/client1.domain.tld.crt
- cert: key: add a new line with the parameter key pointing to the client1.domain.tld.key file. Use the full path to the file. Example: key /home/user/.cert/client1.domain.tld.key

Establish the VPN connection with the command: `sudo openvpn --config downloaded-client-config.ovpn`

Revoking access

If you need to invalidate the access from a particular client key, the key needs to be revoked in the CA. Then submit the revocation list to AWS Client VPN.

Revoking the key with easy-rsa:

- cd easy-rsa
- ./easyrsa3/easyrsa revoke client1.domain.tld
- Enter "yes" to continue, or any other input to abort.

  Continue with revocation: `yes` ... * `./easyrsa3/easyrsa gen-crl
- An updated CRL has been created. CRL file: /home/user/easy-rsa/pki/crl.pem

Importing the revocation list to the AWS Client VPN:

- On the AWS Management Console, select Services and then VPC.
- Select Client VPN Endpoints.
Finding connection endpoints

Your application connects to your cluster using endpoints. An endpoint is a node or cluster's unique address.

Which endpoints to use

- **Redis standalone node**, use the node's endpoint for both read and write operations.

- **Redis (cluster mode disabled) clusters**, use the *Primary Endpoint* for all write operations. Use the *Reader Endpoint* to evenly split incoming connections to the endpoint between all read replicas. Use the individual *Node Endpoints* for read operations (In the API/CLI these are referred to as Read Endpoints).

- **Redis (cluster mode enabled) clusters**, use the cluster's *Configuration Endpoint* for all operations that support cluster mode enabled commands. You must use a client that supports Redis Cluster (Redis 3.2). You can still read from individual node endpoints (In the API/CLI these are referred to as Read Endpoints).

The following sections guide you through discovering the endpoints you'll need for the engine you're running.
Finding a Redis (Cluster Mode Disabled) Cluster's Endpoints (Console)

If a Redis (cluster mode disabled) cluster has only one node, the node's endpoint is used for both reads and writes. If a Redis (cluster mode disabled) cluster has multiple nodes, there are three types of endpoints: the primary endpoint, the reader endpoint and the node endpoints.

The primary endpoint is a DNS name that always resolves to the primary node in the cluster. The primary endpoint is immune to changes to your cluster, such as promoting a read replica to the primary role. For write activity, we recommend that your applications connect to the primary endpoint.

A reader endpoint will evenly split incoming connections to the endpoint between all read replicas in an ElastiCache for Redis cluster. Additional factors such as when the application creates the connections or how the application (re)-uses the connections will determine the traffic distribution. Reader endpoints keep up with cluster changes in real-time as replicas are added or removed. You can place your ElastiCache for Redis cluster's multiple read replicas in different AWS Availability Zones (AZ) to ensure high availability of reader endpoints.

**Note**

A reader endpoint is not a load balancer. It is a DNS record that will resolve to an IP address of one of the replica nodes in a round robin fashion.

For read activity, applications can also connect to any node in the cluster. Unlike the primary endpoint, node endpoints resolve to specific endpoints. If you make a change in your cluster, such as adding or deleting a replica, you must update the node endpoints in your application.

**To find a Redis (cluster mode disabled) cluster's endpoints**

2. From the navigation pane, choose Redis.

   The clusters screen will appear with a list of Redis (cluster mode disabled) and Redis (cluster mode enabled) clusters.
3. To find the cluster's Primary and/or Reader endpoints, choose the box to the left of cluster's name.

   ![Primary and Reader endpoints for a Redis (cluster mode disabled) cluster](image)

   If there is only one node in the cluster, there is no primary endpoint and you can continue at the next step.
4. If the Redis (cluster mode disabled) cluster has replica nodes, you can find the cluster's replica node endpoints by choosing the cluster's name.

The nodes screen appears with each node in the cluster, primary and replicas, listed with its endpoint.

Node endpoints for a Redis (cluster mode disabled) cluster

5. To copy an endpoint to your clipboard:
   a. One endpoint at a time, find then highlight the endpoint you want to copy.
   b. Right-click the highlighted endpoint, then choose **Copy** from the context menu.

The highlighted endpoint is now copied to your clipboard. For information on using the endpoint to connect to a node, see Connecting to nodes (p. 97).

A Redis (cluster mode disabled) primary endpoint looks something like the following. There is a difference depending upon whether or not In-Transit encryption is enabled.

**In-transit encryption not enabled**

```
clusterName.xxxxxx.nodeId.regionAndAz.cache.amazonaws.com:port
redis-01.7abc2d.0001.usw2.cache.amazonaws.com:6379
```

**In-transit encryption enabled**

```
master.clusterName.xxxxxx.regionAndAz.cache.amazonaws.com:port
master.ncit.ameaqx.usel.cache.amazonaws.com:6379
```
Finding Endpoints for a Redis (Cluster Mode Enabled) Cluster (Console)

Use the Configuration Endpoint for both read and write operations. Redis determines which of the cluster's node to access.

The following procedure demonstrates how to find and copy Redis (cluster mode enabled) cluster endpoints.

To find the configuration endpoint for a Redis (cluster mode enabled) cluster

2. From the navigation pane, choose Redis.

   A list of clusters running any version of Redis appears.
3. From the list of clusters, choose the box to the left of a cluster running "Clustered Redis".

   The screen expands showing details about the selected cluster.
4. Locate the Configuration endpoint.

   Configuration endpoint for a Redis (cluster mode enabled) cluster

To find the node endpoints for a Redis (cluster mode enabled) cluster

2. From the navigation pane, choose Redis.

   A list of clusters running any version of Redis appears.
3. From the list of clusters, choose the cluster name of a cluster running "Clustered Redis".

   The shards page opens.
4. Choose the name of the shard you want node endpoint for.

   A list of the shard's nodes appears with each node's endpoint.
5. Locate the Endpoint column and read the endpoint for each node.
Node endpoints for a Redis (cluster mode enabled) cluster

To copy an endpoint to your clipboard

1. Find the endpoint you want to copy using one of the preceding procedures.
2. Highlight the endpoint that you want to copy.
3. Right-click the highlighted endpoint and choose Copy from the context menu.

   The highlighted endpoint is now copied to your clipboard. For information on using the endpoint to connect to a node, see Connecting to nodes (p. 97).

A Redis (cluster mode enabled) configuration endpoint looks something like the following.

In-transit encryption not enabled

```
clusterName.xxxxxx.regionAndAz.cache.amazonaws.com:port
rce.ameaqx.use1.cache.amazonaws.com:6379
```

In-transit encryption enabled

```
clustercfg.clusterName.xxxxxx.regionAndAz.cache.amazonaws.com:port
clustercfg.rce.ameaqx.use1.cache.amazonaws.com:6379
```
Finding Endpoints (AWS CLI)

You can use the AWS CLI for Amazon ElastiCache to discover the endpoints for nodes, clusters, and replication groups.

Topics
- Finding Endpoints for Nodes and Clusters (AWS CLI) (p. 180)
- Finding the Endpoints for Replication Groups (AWS CLI) (p. 181)

Finding Endpoints for Nodes and Clusters (AWS CLI)

You can use the AWS CLI to discover the endpoints for a cluster and its nodes with the `describe-cache-clusters` command. For Redis clusters, the command returns the cluster endpoint. If you include the optional parameter `--show-cache-node-info`, the command will also return the endpoints of the individual nodes in the cluster.

Example

The following command retrieves the cluster information for the single-node Redis (cluster mode disabled) cluster `mycluster`.

```
aws elasticache describe-cache-clusters \
--cache-cluster-id redis-cluster \
--show-cache-node-info
```

Output from the above operation should look something like this (JSON format).

```json
{
  "CacheClusters": [
    {
      "CacheClusterStatus": "available",
      "SecurityGroups": [
        {
          "SecurityGroupId": "sg-77186e0d",
          "Status": "active"
        }
      ],
      "CacheNodes": [
        {
          "CustomerAvailabilityZone": "us-east-1b",
          "CacheNodeStatus": "available",
          "CacheNodeId": "0001",
          "CacheNode": {
            "SecurityGroups": [
              {
                "SecurityGroupId": "sg-77186e0d",
                "Status": "active"
              }
            ],
            "CacheMode": "cache-only",
            "RoutingPolicy": "consistentHash",
            "Address": "cluster0001.redis.cluster"
          }
        }
      ]
    }
  ]
}
```
"Endpoint": {
  "Address": "redis-cluster.amea9x.0001.use1.cache.amazonaws.com",
  "Port": 6379
},
"ParameterGroupStatus": "in-sync"
},

"DataTiering": "disabled"
"EngineVersion": "3.2.10",
]
]

For more information, see the topic describe-cache-clusters.

Finding the Endpoints for Replication Groups (AWS CLI)

You can use the AWS CLI to discover the endpoints for a replication group and its clusters with the describe-replication-groups command. The command returns the replication group's primary endpoint and a list of all the clusters (nodes) in the replication group with their endpoints, along with the reader endpoint.

The following operation retrieves the primary endpoint and reader endpoint for the replication group myreplgroup. Use the primary endpoint for all write operations.

```bash
aws elasticache describe-replication-groups --replication-group-id myreplgroup
```

For Windows:

```bash
aws elasticache describe-replication-groups ^
  --replication-group-id myreplgroup
```

Output from this operation should look something like this (JSON format).

```json
{
  "ReplicationGroups": [
  {
    "Status": "available",
    "Description": "test",
```

API Version 2015-02-02

181
"NodeGroups": [

For more information, see describe-replication-groups in the AWS CLI Command Reference.
Finding Endpoints (ElastiCache API)

You can use the Amazon ElastiCache API to discover the endpoints for nodes, clusters, and replication groups.

Topics

- Finding Endpoints for Nodes and Clusters (ElastiCache API) (p. 183)
- Finding Endpoints for Replication Groups (ElastiCache API) (p. 183)

Finding Endpoints for Nodes and Clusters (ElastiCache API)

You can use the ElastiCache API to discover the endpoints for a cluster and its nodes with the DescribeCacheClusters action. For Redis clusters, the command returns the cluster endpoint. If you include the optional parameter ShowCacheNodeInfo, the action also returns the endpoints of the individual nodes in the cluster.

Example

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=DescribeCacheClusters
  &CacheClusterId=mycluster
  &ShowCacheNodeInfo=true
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20150202T192317Z
  &Version=2015-02-02
  &X-Amz-Credential=<credential>
```

Finding Endpoints for Replication Groups (ElastiCache API)

You can use the ElastiCache API to discover the endpoints for a replication group and its clusters with the DescribeReplicationGroups action. The action returns the replication group's primary endpoint and a list of all the clusters in the replication group with their endpoints, along with the reader endpoint.

The following operation retrieves the primary endpoint (PrimaryEndpoint), reader endpoint (ReaderEndpoint) and individual node endpoints (ReadEndpoint) for the replication group myreplgroup. Use the primary endpoint for all write operations.

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=DescribeReplicationGroups
  &ReplicationGroupId=myreplgroup
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20150202T192317Z
  &Version=2015-02-02
  &X-Amz-Credential=<credential>
```

For more information, see DescribeReplicationGroups.

Working with shards

A shard (API/CLI: node group) is a collection of one to six Redis nodes. A Redis (cluster mode disabled) cluster will never have more than one shard. You can create a cluster with higher number of shards and lower number of replicas totaling up to 90 nodes per cluster. This cluster configuration can range from 90 shards and 0 replicas to 15 shards and 5 replicas, which is the maximum number of replicas allowed.
The cluster’s data is partitioned across the cluster’s shards. If there is more than one node in a shard, the shard implements replication with one node being the read/write primary node and the other nodes read-only replica nodes.

The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526).

For versions below 5.0.6, the limit is 250 per cluster.

To request a limit increase, see AWS service limits and choose the limit type **Nodes per cluster per instance type**.

When you create a Redis (cluster mode enabled) cluster using the ElastiCache console, you specify the number of shards in the cluster and the number of nodes in the shards. For more information, see Creating a Redis (cluster mode enabled) cluster (Console) (p. 133). If you use the ElastiCache API or AWS CLI to create a cluster (called replication group in the API/CLI), you can configure the number of nodes in a shard (API/CLI: node group) independently. For more information, see the following:

- API: CreateReplicationGroup
- CLI: create-replication-group

Each node in a shard has the same compute, storage and memory specifications. The ElastiCache API lets you control shard-wide attributes, such as the number of nodes, security settings, and system maintenance windows.

**Redis shard configurations**

For more information, see Offline resharding and shard rebalancing for Redis (cluster mode enabled) (p. 376) and Online resharding and shard rebalancing for Redis (cluster mode enabled) (p. 377).

**Finding a shard's ID**

You can find a shard's ID using the AWS Management Console, the AWS CLI or the ElastiCache API.

**Using the AWS Management Console**

**Topics**
Finding a shard's ID

For Redis (Cluster Mode Disabled) (p. 185)
For Redis (Cluster Mode Enabled) (p. 185)

Redis (cluster mode disabled) replication group shard IDs are always 0001.

For Redis (Cluster Mode Enabled)

The following procedure uses the AWS Management Console to find a Redis (cluster mode enabled)'s replication group's shard ID.

To find the shard ID in a Redis (cluster mode enabled) replication group

2. On the navigation pane, choose Redis, then choose the name of the Redis (cluster mode enabled) replication group you want to find the shard IDs for.
3. In the Shard Name column, the shard ID is the last four digits of the shard name.

Using the AWS CLI

To find shard (node group) ids for either Redis (cluster mode disabled) or Redis (cluster mode enabled) replication groups use the AWS CLI operation describe-replication-groups with the following optional parameter.

• --replication-group-id—An optional parameter which when used limits the output to the details of the specified replication group. If this parameter is omitted, the details of up to 100 replication groups is returned.

Example

This command returns the details for sample-repl-group.

For Linux, macOS, or Unix:

```
aws elasticache describe-replication-groups \
   --replication-group-id sample-repl-group
```

For Windows:

```
aws elasticache describe-replication-groups ^
   --replication-group-id sample-repl-group
```

Output from this command looks something like this. The shard (node group) ids are highlighted here to make finding them easier.

```
{
   "ReplicationGroups": [
    {
      "Status": "available",
      "Description": "2 shards, 2 nodes (1 + 1 replica)",
      "NodeGroups": [
      {
        "Status": "available",
```
Using the ElastiCache API

To find shard (node group) ids for either Redis (cluster mode disabled) or Redis (cluster mode enabled) replication groups use the AWS CLI operation `describe-replication-groups` with the following optional parameter.

- **ReplicationGroupId**—An optional parameter which when used limits the output to the details of the specified replication group. If this parameter is omitted, the details of up to **xxx** replication groups is returned.
Example

This command returns the details for `sample-repl-group`.

For Linux, macOS, or Unix:

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeReplicationGroup
&ReplicationGroupId=sample-repl-group
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>
```
Managing your ElastiCache for Redis implementation

In this section, you can find details about how to manage the various components of your ElastiCache implementation. These include tasks such as creating, updating, and deleting nodes or clusters, and many more.

**Topics**
- Engine versions and upgrading (p. 188)
- Tagging your ElastiCache resources (p. 204)
- Caching strategies and best practices (p. 215)
- Managing maintenance (p. 230)
- Replication across AWS Regions using global datastores (p. 231)
- High availability using replication groups (p. 246)
- Backup and restore for ElastiCache for Redis (p. 310)
- Scaling ElastiCache for Redis clusters (p. 345)
- Auto Scaling ElastiCache for Redis clusters (p. 394)
- Configuring engine parameters using parameter groups (p. 423)

Engine versions and upgrading

This section covers the supported Redis engine versions and how to upgrade.

**Topics**
- Supported ElastiCache for Redis versions (p. 189)
- Redis versions end of life schedule (p. 197)
- Upgrading engine versions (p. 198)
- Major version behavior and compatibility differences (p. 200)
Supported ElastiCache for Redis versions

Supported ElastiCache for Redis versions

- ElastiCache for Redis version 6.2 (enhanced) (p. 190)
- ElastiCache for Redis version 6.0 (enhanced) (p. 190)
- ElastiCache for Redis version 5.0.6 (enhanced) (p. 191)
- ElastiCache for Redis version 5.0.5 (enhanced) (p. 191)
- ElastiCache for Redis version 5.0.4 (enhanced) (p. 191)
- ElastiCache for Redis version 5.0.3 (enhanced) (p. 191)
- ElastiCache for Redis version 5.0.0 (enhanced) (p. 192)
- ElastiCache for Redis version 4.0.10 (enhanced) (p. 193)
- ElastiCache for Redis version 3.2.10 (enhanced) (p. 194)
- ElastiCache for Redis version 3.2.6 (enhanced) (p. 194)
- ElastiCache for Redis version 3.2.4 (enhanced) (p. 194)
- ElastiCache for Redis version 2.8.24 (enhanced) (p. 195)
- ElastiCache for Redis version 2.8.23 (enhanced) (p. 196)
- ElastiCache for Redis version 2.8.22 (enhanced) (p. 196)
- ElastiCache for Redis version 2.8.21 (p. 196)
- ElastiCache for Redis version 2.8.19 (p. 196)
- ElastiCache for Redis version 2.8.6 (p. 197)
- ElastiCache for Redis version 2.6.13 (p. 197)

Note
Because the newer Redis versions provide a better and more stable user experience, Redis versions 5.0.0, 5.0.3, 5.0.4 and 5.0.5 as well as 2.6.13, 2.8.6, and 2.8.19 are deprecated when using the ElastiCache console. We recommend against using these Redis versions. If you need to use one of them, work with the AWS CLI or ElastiCache API.

For more information, see the following topics:

</table>
ElastiCache for Redis version 6.2 (enhanced)

ElastiCache for Redis 6.2 includes performance improvements for TLS-enabled clusters using x86 node types with 8 vCPUs or more or Graviton2 node types with 4 vCPUs or more. These enhancements improve throughput and reduce client connection establishment time by offloading encryption to other vCPUs. With Redis 6.2, you can also manage access to Pub/Sub channels with Access Control List (ACL) rules.

With this version, we also introduce support for data tiering on cluster nodes containing locally attached NVMe SSD. For more information, see Data tiering (p. 121).

You specify the engine version by using 6.2. ElastiCache for Redis will automatically invoke the preferred patch version of Redis 6.2 that is available. For example, when you create/modify a cache cluster, you set the --engine-version parameter to 6.2. The cluster will be launched with the current available preferred patch version of Redis 6.2 at the creation/modification time. Specifying engine version 6.x in the API will result in the latest minor version of Redis 6.

For existing 6.0 clusters, you can opt-in to the next auto minor version upgrade by setting the AutoMinorVersionUpgrade parameter to yes in the CreateCacheCluster, ModifyCacheCluster, CreateReplicationGroup or ModifyReplicationGroup APIs. ElastiCache for Redis will upgrade the minor version of your existing 6.0 clusters to 6.2 using self-service updates. For more information, see Self-service updates in Amazon ElastiCache.

When calling the DescribeCacheEngineVersions API, the EngineVersion parameter value will be set to 6.2 and the actual engine version with the patch version will be returned in the CacheEngineVersionDescription field.

For more information on the Redis 6.2 release, see Redis 6.2 Release Notes at Redis on GitHub.

ElastiCache for Redis version 6.0 (enhanced)

Amazon ElastiCache for Redis introduces the next version of the Redis engine, which includes Authenticating Users with Role Based Access Control, client-side caching and significant operational improvements.

Beginning with Redis 6.0, ElastiCache for Redis will offer a single version for each Redis OSS minor release, rather than offering multiple patch versions. ElastiCache for Redis will automatically manage the patch version of your running cache clusters, ensuring improved performance and enhanced security.

You can also opt-in to the next auto minor version upgrade by setting the AutoMinorVersionUpgrade parameter to yes and ElastiCache for Redis will manage the minor version upgrade, through self-service updates. For more information, see Self-service updates in Amazon ElastiCache (p. 626).

You specify the engine version by using 6.0. ElastiCache for Redis will automatically invoke the preferred patch version of Redis 6.0 that is available. For example, when you create/modify a cache cluster, you set the --engine-version parameter to 6.0. The cluster will be launched with the current available
preferred patch version of Redis 6.0 at the creation/modification time. Any request with a specific patch
version value will be rejected, an exception will be thrown and the process will fail.

When calling the DescribeCacheEngineVersions API, the EngineVersion parameter value
will be set to 6.0 and the actual engine version with the patch version will be returned in the
CacheEngineVersionDescription field.

For more information on the Redis 6.0 release, see Redis 6.0 Release Notes at Redis on GitHub.

ElastiCache for Redis version 5.0.6 (enhanced)

Amazon ElastiCache for Redis introduces the next version of the Redis engine, which includes bug fixes.

For more information, see Redis 5.0.6 Release Notes at Redis on GitHub.

ElastiCache for Redis version 5.0.5 (enhanced)

Amazon ElastiCache for Redis introduces the next version of the Redis engine;. It includes online
configuration changes for ElastiCache for Redis of auto-failover clusters during all planned operations.
You can now scale your cluster, upgrade the Redis engine version and apply patches and maintenance
updates while the cluster stays online and continues serving incoming requests. It also includes bug fixes.

For more information, see Redis 5.0.5 Release Notes at Redis on GitHub.

ElastiCache for Redis version 5.0.4 (enhanced)

Amazon ElastiCache for Redis introduces the next version of the Redis engine supported by Amazon
ElastiCache. It includes the following enhancements:

• Engine stability guarantee in special conditions.
• Improved Hyperloglog error handling.
• Enhanced handshake commands for reliable replication.
• Consistent message delivery tracking via \texttt{XCLAIM} command.
• Improved \texttt{LFU} field management in objects.
• Enhanced transaction management when using \texttt{ZPOP}.

For more information, see Redis 5.0.4 Release Notes at Redis on GitHub.

ElastiCache for Redis version 5.0.3 (enhanced)

Amazon ElastiCache for Redis introduces the next version of the Redis engine supported by Amazon
ElastiCache. It includes the following enhancements:

• Bug fixes to improve sorted set edge cases, accurate memory usage and more. For more information,
  see Redis 5.0.3 release notes.
• Ability to rename commands: ElastiCache for Redis 5.0.3 includes a new parameter called \texttt{rename-}
  commands that allows you to rename potentially dangerous or expensive Redis commands that might
  cause accidental data loss, such as \texttt{FLUSHALL} or \texttt{FLUSHDB}. This is similar to the rename-command
  configuration in open source Redis. However, ElastiCache has improved the experience by providing
  a fully managed workflow. The command name changes are applied immediately, and automatically
  propagated across all nodes in the cluster that contain the command list. There is no intervention
  required on your part, such as rebooting nodes.

The following examples demonstrate how to modify existing parameter groups. They include the
\texttt{rename-commands} parameter, which is a space-separated list of commands you want to rename:
aws elasticache modify-cache-parameter-group --cache-parameter-group-name custom_param_group --parameter-name-values "ParameterName=rename-commands, ParameterValue='flushall restrictedflushall'" --region region

In this example, the rename-commands parameter is used to rename the flushall command to restrictedflushall.

To rename multiple commands, use the following:

aws elasticache modify-cache-parameter-group --cache-parameter-group-name custom_param_group --parameter-name-values "ParameterName=rename-commands, ParameterValue='flushall restrictedflushall flushdb restrictedflushdb'" --region region

To revert any change, re-run the command and exclude any renamed values from the ParameterValue list that you want to retain, as shown following:

aws elasticache modify-cache-parameter-group --cache-parameter-group-name custom_param_group --parameter-name-values "ParameterName=rename-commands, ParameterValue='flushall restrictedflushall'" --region region

In this case, the flushall command is renamed to restrictedflushall and any other renamed commands revert to their original command names.

**Note**
When renaming commands, you are restricted to the following limitations:
- All renamed commands should be alphanumeric.
- The maximum length of new command names is 20 alphanumeric characters.
- When renaming commands, ensure that you update the parameter group associated with your cluster.
- To prevent a command's use entirely, use the keyword blocked, as shown following:

aws elasticache modify-cache-parameter-group --cache-parameter-group-name custom_param_group --parameter-name-values "ParameterName=rename-commands, ParameterValue='flushall blocked'" --region region

For more information on the parameter changes and a list of what commands are eligible for renaming, see Redis 5.0.3 parameter changes (p. 444).

**ElastiCache for Redis version 5.0.0 (enhanced)**

Amazon ElastiCache for Redis introduces the next major version of the Redis engine supported by Amazon ElastiCache. ElastiCache for Redis 5.0.0 brings support for the following improvements:

- **Redis Streams**: This models a log data structure that allows producers to append new items in real time. It also allows consumers to consume messages either in a blocking or nonblocking fashion. Streams also allow consumer groups, which represent a group of clients to cooperatively consume different portions of the same stream of messages, similar to Apache Kafka. For more information, see [Introduction to Redis Streams](#).
- **Support for a family of stream commands**, such as **XADD**, **XRANGE** and **XREAD**. For more information, see [Redis Streams Commands](#).
• A number of new and renamed parameters. For more information, see Redis 5.0.0 parameter changes (p. 445).
• A new Redis metric, StreamBasedCmds.
• Slightly faster snapshot time for Redis nodes.

Important
Amazon ElastiCache for Redis has back-ported two critical bug fixes from Redis open source version 5.0.1. They are listed following:

• RESTORE mismatch reply when certain keys have already expired.
• The XCLAIM command can potentially return a wrong entry or desynchronize the protocol.

Both of these bug fixes are included in ElastiCache for Redis support for Redis engine version 5.0.0 and are consumed in future version updates.

ElastiCache for Redis version 4.0.10 (enhanced)

Amazon ElastiCache for Redis introduces the next major version of the Redis engine supported by Amazon ElastiCache. ElastiCache for Redis 4.0.10 brings support the following improvements:

• Both online cluster resizing and encryption in a single ElastiCache for Redis version. For more information, see the following:
  • Scaling clusters in Redis (Cluster Mode Enabled) (p. 375)
  • Online resharding and shard rebalancing for Redis (cluster mode enabled) (p. 377)
  • Data security in Amazon ElastiCache (p. 470)
• A number of new parameters. For more information, see Redis 4.0.10 parameter changes (p. 448).
• Support for family of memory commands, such as MEMORY. For more information, see Redis Commands (search on MEMO).
• Support for memory defragmentation while online thus allowing more efficient memory utilization and more memory available for your data.
• Support for asynchronous flushes and deletes. ElastiCache for Redis supports commands like UNLINK, FLUSHDB and FLUSHALL to run in a different thread from the main thread. Doing this helps improve performance and response times for your applications by freeing memory asynchronously.
• A new Redis metric, ActiveDefragHits. For more information, see Metrics for Redis.

Redis (cluster mode disabled) users running Redis version 3.2.10 can use the console to upgrade their clusters via online upgrade.

* Adding, removing, and rebalancing shards.

** Required for FedRAMP, HIPAA, and PCI DSS compliant applications. For more information, see ElastiCache for Redis compliance (p. 619).
ElastiCache for Redis version 3.2.10 (enhanced)

Amazon ElastiCache for Redis introduces the next major version of the Redis engine supported by Amazon ElastiCache. ElastiCache for Redis 3.2.10 introduces online cluster resizing to add or remove shards from the cluster while it continues to serve incoming I/O requests. ElastiCache for Redis 3.2.10 users have all the functionality of earlier Redis versions except the ability to encrypt their data. This ability is currently available only in version 3.2.6.

Comparing ElastiCache for Redis versions 3.2.6 and 3.2.10

<table>
<thead>
<tr>

* Adding, removing, and rebalancing shards.

** Required for FedRAMP, HIPAA, and PCI DSS compliant applications. For more information, see ElastiCache for Redis compliance (p. 619).

For more information, see the following:

- Online resharding and shard rebalancing for Redis (cluster mode enabled) (p. 377)
- Best practices: Online cluster resizing (p. 229)

ElastiCache for Redis version 3.2.6 (enhanced)

Amazon ElastiCache for Redis introduces the next major version of the Redis engine supported by Amazon ElastiCache. ElastiCache for Redis 3.2.6 users have all the functionality of earlier Redis versions plus the option to encrypt their data. For more information, see the following:

- ElastiCache for Redis in-transit encryption (TLS) (p. 471)
- At-Rest Encryption in ElastiCache for Redis (p. 483)
- HIPAA eligibility (p. 620)

ElastiCache for Redis version 3.2.4 (enhanced)

Amazon ElastiCache for Redis version 3.2.4 introduces the next major version of the Redis engine supported by Amazon ElastiCache. ElastiCache for Redis 3.2.4 users have all the functionality of earlier Redis versions available to them plus the option to run in cluster mode or non-cluster mode. The following table summarizes.

Comparing Redis 3.2.4 non-cluster mode and cluster mode

<table>
<thead>
<tr>
<th>Feature</th>
<th>Non-cluster mode</th>

* See [Restoring from a backup with optional cluster resizing (p. 334)](#)

** Or one derived from it.

### Notes:

- **Partitioning** – the ability to split your data across 2 to 500 node groups (shards) with replication support for each node group.

- **Geospatial indexing** – Redis 3.2.4 introduces support for geospatial indexing via six GEO commands. For more information, see the Redis GEO* command documentation [Redis Commands: GEO](#) on the [Redis Commands page](#) (filtered for GEO).

For information about additional Redis 3 features, see [Redis 3.2 release notes](#) and [Redis 3.0 release notes](#).

Currently ElastiCache managed Redis (cluster mode enabled) does not support the following Redis 3.2 features:

- Replica migration
- Cluster rebalancing
- Lua debugger

ElastiCache disables the following Redis 3.2 management commands:

- cluster meet
- cluster replicate
- cluster flushslots
- cluster addslots
- cluster delslots
- cluster setslot
- cluster saveconfig
- cluster forget
- cluster failover
- cluster bumpepoch
- cluster set-config-epoch
- cluster reset

For information about Redis 3.2.4 parameters, see [Redis 3.2.4 parameter changes (p. 451)](#).

**ElastiCache for Redis version 2.8.24 (enhanced)**

Redis improvements added since version 2.8.23 include bug fixes and logging of bad memory access addresses. For more information, see [Redis 2.8 release notes](#).
ElastiCache for Redis version 2.8.23 (enhanced)

Redis improvements added since version 2.8.22 include bug fixes. For more information, see Redis 2.8 release notes. This release also includes support for the new parameter close-on-slave-write which, if enabled, disconnects clients who attempt to write to a read-only replica.

For more information on Redis 2.8.23 parameters, see Redis 2.8.23 (enhanced) added parameters (p. 455) in the ElastiCache User Guide.

ElastiCache for Redis version 2.8.22 (enhanced)

Redis improvements added since version 2.8.21 include the following:

- Support for forkless backups and synchronizations, which allows you to allocate less memory for backup overhead and more for your application. For more information, see How synchronization and backup are implemented (p. 265). The forkless process can impact both latency and throughput. When there is high write throughput, when a replica re-syncs, it can be unreachable for the entire time it is syncing.
- If there is a failover, replication groups now recover faster because replicas perform partial syncs with the primary rather than full syncs whenever possible. Additionally, both the primary and replicas no longer use the disk during syncs, providing further speed gains.
- Support for two new CloudWatch metrics.
  - ReplicationBytes – The number of bytes a replication group's primary cluster is sending to the read replicas.
  - SaveInProgress – A binary value that indicates whether or not there is a background save process running.

For more information, see Monitoring use with CloudWatch Metrics (p. 588).
- A number of critical bug fixes in replication PSYNC behavior. For more information, see Redis 2.8 release notes.
- To maintain enhanced replication performance in Multi-AZ replication groups and for increased cluster stability, non-ElastiCache replicas are no longer supported.
- To improve data consistency between the primary cluster and replicas in a replication group, the replicas no longer evict keys independent of the primary cluster.
- Redis configuration variables appendonly and appendfsync are not supported on Redis version 2.8.22 and later.
- In low-memory situations, clients with a large output buffer might be disconnected from a replica cluster. If disconnected, the client needs to reconnect. Such situations are most likely to occur for PUBSUB clients.

ElastiCache for Redis version 2.8.21

Redis improvements added since version 2.8.19 include a number of bug fixes. For more information, see Redis 2.8 release notes.

ElastiCache for Redis version 2.8.19

Redis improvements added since version 2.8.6 include the following:

- Support for HyperLogLog. For more information, see Redis new data structure: HyperLogLog.
- The sorted set data type now has support for lexicographic range queries with the new commands ZRANGEBYLEX, ZLEXCOUNT, and ZREMRANGEBYLEX.
To prevent a primary node from sending stale data to replica nodes, the master SYNC fails if a background save (bgsave) child process is aborted.

Support for the HyperLogLogBasedCommands CloudWatch metric. For more information, see Metrics for Redis (p. 590).

ElastiCache for Redis version 2.8.6

Redis improvements added since version 2.6.13 include the following:

- Improved resiliency and fault tolerance for read replicas.
- Support for partial resynchronization.
- Support for user-defined minimum number of read replicas that must be available at all times.
- Full support for pub/sub—notifying clients of events on the server.
- Automatic detection of a primary node failure and failover of your primary node to a secondary node.

ElastiCache for Redis version 2.6.13

Redis version 2.6.13 was the initial version of Redis supported by Amazon ElastiCache for Redis. Multi-AZ is not supported on Redis 2.6.13.

Redis versions end of life schedule

This section defines end of life (EOL) dates for older major versions as they are announced. This allows you to make version and upgrade decisions for the future.

The following table summarizes each version and its announced EOL date, as well as the recommended upgrade target version.

<table>
<thead>
<tr>
<th>Source Minor Versions</th>
<th>Recommended Upgrade Target</th>
<th>EOL Date</th>
</tr>
</thead>
</table>
| Version 2.8.14, 2.8.23, 2.8.22, 2.8.21, 2.8.12, 2.8.6, 2.6.13 | Version 6.2 or higher  
  **Note**  
  For US-ISO-EAST-1, US-ISO-WEST-1, and US-ISOB-EAST-1 Regions, we recommend 5.0.6 or higher. | January 13, 2023 |
Upgrading engine versions

You can control if and when the protocol-compliant software powering your cache cluster is upgraded to new versions that are supported by ElastiCache. This level of control enables you to maintain compatibility with specific versions, test new versions with your application before deploying in production, and perform version upgrades on your own terms and timelines.

Because version upgrades might involve some compatibility risk, they don't occur automatically. You must initiate them.

You initiate engine version upgrades to your cluster or replication group by modifying it and specifying a new engine version. For more information, see the following:

- Modifying an ElastiCache cluster (p. 149)
- Modifying a replication group (p. 294)

Note the following:

- Engine version management is designed so that you can have as much control as possible over how patching occurs. However, ElastiCache reserves the right to patch your cluster on your behalf in the unlikely event of a critical security vulnerability in the system or cache software.
- Beginning with Redis 6.0, ElastiCache for Redis will offer a single version for each Redis OSS minor release, rather than offering multiple patch versions.
- Starting with Redis engine version 5.0.5, you can upgrade your cluster version with minimal downtime. The cluster is available for reads during the entire upgrade and is available for writes for most of the upgrade duration, except during the failover operation which lasts a few seconds.
- You can also upgrade your ElastiCache clusters with versions earlier than 5.0.5. The process involved is the same but may incur longer failover time during DNS propagation (30s-1m).
- ElastiCache for Redis doesn't support switching between Redis (cluster mode disabled) and Redis (cluster mode enabled).
- The Amazon ElastiCache for Redis engine upgrade process is designed to make a best effort to retain your existing data and requires successful Redis replication.
- You can't upgrade directly from Redis (cluster mode disabled) to Redis (cluster mode enabled) when you upgrade your engine. The following procedure shows you how to upgrade from Redis (cluster mode disabled) to Redis (cluster mode enabled).

To upgrade from a Redis (cluster mode disabled) to Redis (cluster mode enabled) engine version

1. Make a backup of your Redis (cluster mode disabled) cluster or replication group. For more information, see Making manual backups (p. 315).
2. Use the backup to create and seed a Redis (cluster mode enabled) cluster with one shard (node group). Specify the new engine version and enable cluster mode when creating the cluster or replication group. For more information, see Seeding a new cluster with an externally created backup (p. 337).
3. Delete the old Redis (cluster mode disabled) cluster or replication group. For more information, see Deleting a cluster (p. 165) or Deleting a replication group (p. 296).
4. Scale the new Redis (cluster mode enabled) cluster or replication group to the number of shards (node groups) that you need. For more information, see Scaling clusters in Redis (Cluster Mode Enabled) (p. 375)

When upgrading major engine versions, for example from 5.0.6 to 6.0, you need to also choose a new parameter group that is compatible with the new engine version.

For single Redis clusters and clusters with Multi-AZ disabled, we recommend that sufficient memory be made available to Redis as described in Ensuring that you have enough memory to create a Redis...
Upgrading engine versions

In these cases, the primary is unavailable to service requests during the upgrade process.

- For Redis clusters with Multi-AZ enabled, we also recommend that you schedule engine upgrades during periods of low incoming write traffic. When upgrading to Redis 5.0.6 or above, the primary cluster continues to be available to service requests during the upgrade process.

Clusters and replication groups with multiple shards are processed and patched as follows:

- All shards are processed in parallel. Only one upgrade operation is performed on a shard at any time.
- In each shard, all replicas are processed before the primary is processed. If there are fewer replicas in a shard, the primary in that shard might be processed before the replicas in other shards are finished processing.
- Across all the shards, primary nodes are processed in series. Only one primary node is upgraded at a time.
- If encryption is enabled on your current cluster or replication group, you cannot upgrade to an engine version that does not support encryption, such as from 3.2.6 to 3.2.10.

How to upgrade engine versions

You initiate version upgrades to your cluster or replication group by modifying it using the ElastiCache console, the AWS CLI, or the ElastiCache API and specifying a newer engine version. For more information, see the following topics.

### How to modify clusters and replication groups

<table>
<thead>
<tr>
<th>How to modify clusters and replication groups</th>
<th>How to modify clusters and replication groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Using the AWS Management Console (p. 149)</td>
<td>Using the AWS Management Console (p. 294)</td>
</tr>
<tr>
<td>Using the AWS CLI (p. 150)</td>
<td>Using the AWS CLI (p. 294)</td>
</tr>
<tr>
<td>Using the ElastiCache API (p. 151)</td>
<td>Using the ElastiCache API (p. 295)</td>
</tr>
</tbody>
</table>

Resolving blocked Redis engine upgrades

As shown in the following table, your Redis engine upgrade operation is blocked if you have a pending scale up operation.

<table>
<thead>
<tr>
<th>Pending operations</th>
<th>Blocked operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scale up</td>
<td>Immediate engine upgrade</td>
</tr>
<tr>
<td>Engine upgrade</td>
<td>Immediate scale up</td>
</tr>
<tr>
<td>Scale up and engine upgrade</td>
<td>Immediate scale up</td>
</tr>
<tr>
<td></td>
<td>Immediate engine upgrade</td>
</tr>
</tbody>
</table>

To resolve a blocked Redis engine upgrade

- Do one of the following:
  - Schedule your Redis engine upgrade operation for the next maintenance window by clearing the **Apply immediately** check box.
    
    With the CLI, use `--no-apply-immediately`. With the API, use `ApplyImmediately=false`.  

API Version 2015-02-02
199
• Wait until your next maintenance window (or after) to perform your Redis engine upgrade operation.

• Add the Redis scale up operation to this cluster modification with the Apply Immediately check box chosen.

With the CLI, use --apply-immediately. With the API, use ApplyImmediately=true.

This approach effectively cancels the engine upgrade during the next maintenance window by performing it immediately.

Major version behavior and compatibility differences

Redis versions are identified with a semantic version which comprise a MAJOR, MINOR, and PATCH component. For example, in Redis 4.0.10, the major version is 4, the minor version 0, and the patch version is 10. These values are generally incremented based off the following conventions:

• MAJOR versions are for API incompatible changes
• MINOR versions are for new functionality added in a backwards-compatible way
• PATCH versions are for backwards-compatible bug fixes and non-functional changes

We recommend always staying on the latest patch version within a given MAJOR.MINOR version in order to have the latest performance and stability improvements. Beginning with Redis 6.0, ElastiCache for Redis will offer a single version for each Redis OSS minor release, rather than offering multiple patch versions. ElastiCache for Redis will automatically manage the patch version of your running cache clusters, ensuring improved performance and enhanced security.

We also recommend periodically upgrading to the latest major version, since most major improvements are not back ported to older versions. When doing an upgrade that spans major or minor versions, please consider the following list which includes behavior and backwards incompatible changes released with Redis over time.

Redis 2.8 behavior and backwards incompatible changes

For a full list of changes, see Redis 2.8 release notes.

• Starting in Redis 2.8.22, Redis AOF is no longer supported in ElastiCache for Redis. We recommend using MemoryDB when data needs to be persisted durably.

• Starting in Redis 2.8.22, ElastiCache for Redis no longer supports attaching replicas to primaries hosted within ElastiCache. While upgrading, external replicas will be disconnected and they will be unable to reconnect. We recommend using client-side caching, made available in Redis 6.0 as an alternative to external replicas.

• The TTL and PTTL commands now return -2 if the key does not exist and -1 if it exists but has no associated expire. Redis 2.6 and previous versions used to return -1 for both the conditions.

• SORT with ALPHA now sorts according to local collation locale if no STORE option is used.

Redis 3.2 behavior and backwards incompatible changes

For a full list of changes, see Redis 3.2 release notes.

• There are no compatibility changes to call out for this version.
Redis 4.0 behavior and backwards incompatible changes

For a full list of changes, see Redis 4.0 release notes.

- Slow log now logs an additional two arguments, the client name and address. This change should be backwards compatible unless you are explicitly relying on each slow log entry containing 3 values.
- The CLUSTER NODES command now returns a slight different format, which is not backwards compatible. We recommend that clients don’t use this command for learning about the nodes present in a cluster, and instead they should use CLUSTER SLOTS.

Redis 5.0 behavior and backwards incompatible changes

For a full list of changes, see Redis 5.0 release notes.

- Scripts are by replicated by effects instead of re-executing the script on the replica. This generally improves performance but may increase the amount of data replicated between primaries and replicas. There is an option to revert back to the previous behavior that is only available in ElastiCache for Redis 5.0.
- If you are upgrading from Redis 4.0, some commands in LUA scripts will return arguments in a different order than they did in earlier versions. In Redis 4.0, Redis would order some responses lexicographically in order to make the responses deterministic, this ordering is not applied when scripts are replicated by effects.
- Starting in Redis 5.0.3, ElastiCache for Redis will offload some IO work to background cores on instance types with more than 4 VCPUs. This may change the performance characteristics Redis and change the values of some metrics. For more information, see

  The following CloudWatch metrics offer good insight into ElastiCache performance. In most cases, we recommend that you set CloudWatch alarms for these metrics so that you can take corrective action before performance issues occur.

  **Metrics to Monitor**

  - CPUUtilization (p. 598)
  - EngineCPUUtilization (p. 598)
  - SwapUsage (p. 599)
  - Evictions (p. 599)
  - CurrConnections (p. 599)
  - Memory (p. 599)
  - Network (p. 599)
  - Latency (p. 599)
  - Replication (p. 599)

  **CPUUtilization**

  This is a host-level metric reported as a percentage. For more information, see Host-Level Metrics (p. 588).

  For smaller node types with 2vCPUs or less, use the CPUUtilization metric to monitor your workload.

  Generally speaking, we suggest you set your threshold at 90% of your available CPU. Because Redis is single-threaded, the actual threshold value should be calculated as a fraction of the node's total capacity. For example, suppose you are using a node type that has two cores. In this case, the threshold for CPUUtilization would be 90/2, or 45%.
You will need to determine your own threshold, based on the number of cores in the cache node that you are using. If you exceed this threshold, and your main workload is from read requests, scale your cache cluster out by adding read replicas. If the main workload is from write requests, depending on your cluster configuration, we recommend that you:

- **Redis (cluster mode disabled) clusters**: scale up by using a larger cache instance type.

- **Redis (cluster mode enabled) clusters**: add more shards to distribute the write workload across more primary nodes.

  **Tip**
  Instead of using the Host-Level metric `CPUUtilization`, Redis users might be able to use the Redis metric `EngineCPUUtilization`, which reports the percentage of usage on the Redis engine core. To see if this metric is available on your nodes and for more information, see Metrics for Redis.

For larger node types with 4vCPUs or more, you may want to use the `EngineCPUUtilization` metric, which reports the percentage of usage on the Redis engine core. To see if this metric is available on your nodes and for more information, see Metrics for Redis.

**EngineCPUUtilization**

For larger node types with 4vCPUs or more, you may want to use the `EngineCPUUtilization` metric, which reports the percentage of usage on the Redis engine core. To see if this metric is available on your nodes and for more information, see Metrics for Redis.

For more information, see the CPUs section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

**SwapUsage**

This is a host-level metric reported in bytes. For more information, see Host-Level Metrics (p. 588).

This metric should not exceed 300 MB. If it does, see the following topics:

- Ensuring that you have enough memory to create a Redis snapshot (p. 221)

- Managing Reserved Memory (p. 223)

**Evictions**

This is a cache engine metric. We recommend that you determine your own alarm threshold for this metric based on your application needs.

**CurrConnections**

This is a cache engine metric. We recommend that you determine your own alarm threshold for this metric based on your application needs.

An increasing number of `CurrConnections` might indicate a problem with your application; you will need to investigate the application behavior to address this issue.
For more information, see the Connections section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

Memory

Memory is a core aspect of Redis. Understanding the memory utilization of your cluster is necessary to avoid data loss and accommodate future growth of your dataset. Statistics about the memory utilization of a node are available in the memory section of the Redis INFO command.

For more information, see the Memory section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

Network

One of the determining factors for the network bandwidth capacity of your cluster is the node type you have selected. For more information about the network capacity of your node, see Amazon ElastiCache pricing.

For more information, see the Network section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

Latency

You can measure a command's latency with a set of CloudWatch metrics that provide aggregated latencies per data structure. These latency metrics are calculated using the commandstats statistic from the Redis INFO command.

For more information, see the Latency section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

Replication

The volume of data being replicated is visible via the ReplicationBytes metric. Although this metric is representative of the write load on the replication group, it doesn't provide insights into replication health. For this purpose, you can use the ReplicationLag metric.

For more information, see the Replication section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

Redis 6.0 behavior and backwards incompatible changes

For a full list of changes, see Redis 6.0 release notes.

- The maximum number of allowed databases has been decreased from 1.2 million to 10 thousand. The default value is 16, and we discourage using values much larger than this as we've found performance and memory concerns.
- Set AutoMinorVersionUpgrade parameter to yes, and ElastiCache for Redis will manage the minor version upgrade through self-service updates. This will be handled through standard customer-notification channels via a self-service update campaign. For more information, see Self-service updates in ElastiCache.
Redis 6.2 behavior and backwards incompatible changes

For a full list of changes, see Redis 6.2 release notes.

- The ACL flags of the `TIME`, `ECHO`, `ROLE`, and `LASTSAVE` commands were changed. This may cause commands that were previously allowed to be rejected and vice versa.
  
  **Note**
  None of these commands modify or give access to data.

- When upgrading from Redis 6.0, the ordering of key/value pairs returned from a map response to a lua script are changed. If your scripts use `redis.setresp()` or return a map (new in Redis 6.0), consider the implications that the script may break on upgrades.

Tagging your ElastiCache resources

To help you manage your clusters and other ElastiCache resources, you can assign your own metadata to each resource in the form of tags. Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type—you can quickly identify a specific resource based on the tags that you’ve assigned to it. This topic describes tags and shows you how to create them.

**Warning**
As a best practice, we recommend that you do not include sensitive data in your tags.

Tag basics

A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define. Tags enable you to categorize your AWS resources in different ways, for example, by purpose or owner. For example, you could define a set of tags for your account’s ElastiCache clusters that helps you track each instance’s owner and user group.

We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the AWS whitepaper Tagging Best Practices.

Tags don’t have any semantic meaning to ElastiCache and are interpreted strictly as a string of characters. Also, tags are not automatically assigned to your resources. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to `null`. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. If you delete a resource, any tags for the resource are also deleted. Furthermore, if you add or delete tags on a replication group, all nodes in that replication group will also have their tags added or removed.

You can work with tags using the AWS Management Console, the AWS CLI, and the ElastiCache API.

If you’re using IAM, you can control which users in your AWS account have permission to create, edit, or delete tags. For more information, see Resource-level permissions (p. 550).

Resources you can tag

You can tag most ElastiCache resources that already exist in your account. The table below lists the resources that support tagging. If you’re using the AWS Management Console, you can apply tags to resources by using the Tag Editor. Some resource screens enable you to specify tags for a resource when you create the resource; for example, a tag with a key of Name and a value that you specify. In most cases, the console applies the tags immediately after the resource is created (rather than during resource
creation). The console may organize resources according to the Name tag, but this tag doesn't have any semantic meaning to the ElastiCache service.

Additionally, some resource-creating actions enable you to specify tags for a resource when the resource is created. If tags cannot be applied during resource creation, we roll back the resource creation process. This ensures that resources are either created with tags or not created at all, and that no resources are left untagged at any time. By tagging resources at the time of creation, you can eliminate the need to run custom tagging scripts after resource creation.

If you're using the Amazon ElastiCache API, the AWS CLI, or an AWS SDK, you can use the Tags parameter on the relevant ElastiCache API action to apply tags. They are:

- CreateCacheCluster
- CreateReplicationGroup
- CopySnapshot
- CreateCacheParameterGroup
- CreateCacheSecurityGroup
- CreateCacheSubnetGroup
- CreateSnapshot
- CreateUserGroup
- CreateUser
- PurchaseReservedCacheNodesOffering

The following table describes the ElastiCache resources that can be tagged, and the resources that can be tagged on creation using the ElastiCache API, the AWS CLI, or an AWS SDK.

**Tagging support for ElastiCache resources**

<table>
<thead>
<tr>
<th>Supports tags</th>
<th>Supports tagging on creation</th>
</tr>
</thead>
<tbody>
<tr>
<td>parametergroup</td>
<td>Yes</td>
</tr>
<tr>
<td>securitygroup</td>
<td>Yes</td>
</tr>
<tr>
<td>subnetgroup</td>
<td>Yes</td>
</tr>
<tr>
<td>replicationgroup</td>
<td>Yes</td>
</tr>
<tr>
<td>cluster</td>
<td>Yes</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>snapshot</td>
<td>Yes</td>
</tr>
<tr>
<td>user</td>
<td>Yes</td>
</tr>
<tr>
<td>usergroup</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Note**

You cannot tag Global Datastores.

You can apply tag-based resource-level permissions in your IAM policies to the ElastiCache API actions that support tagging on creation to implement granular control over the users and groups that can tag resources on creation. Your resources are properly secured from creation—tags that are applied
Tagging your ElastiCache resources immediately to your resources. Therefore any tag-based resource-level permissions controlling the use of resources are immediately effective. Your resources can be tracked and reported on more accurately. You can enforce the use of tagging on new resources, and control which tag keys and values are set on your resources.

For more information, see Tagging resources examples (p. 207).

For more information about tagging your resources for billing, see Monitoring costs with cost allocation tags (p. 210).

Tagging replication groups, clusters and snapshots

The following rules apply to tagging as part of request operations:

- **CreateReplicationGroup:**
  - If the --primary-cluster-id and --tags parameters are included in the request, the request tags will be added to the replication group and propagate to all cache clusters in the replication group. If the primary cache cluster has existing tags, these will be overwritten with the request tags to have consistent tags across all nodes.
  
  If there are no request tags, the primary cache cluster tags will be added to the replication group and propagated to all cache clusters.

- **CreateCacheCluster:**
  - If the --replication-group-id is supplied:
    
    If tags are included in the request, the cache cluster will be tagged only with those tags. If no tags are included in the request, the cache cluster will inherit the replication group tags instead of the primary cache cluster's tags.
  
  - If the --snapshot-name is supplied:
    
    If tags are included in the request, the cache cluster will be tagged only with those tags. If no tags are included in the request, the snapshot tags will be added to the cache cluster.
  
  - If the --global-replication-group-id is supplied:
    
    If tags are included in the request, the request tags will be added to the replication group and propagate to all nodes.

- **CreateSnapshot:**
  - If the --replication-group-id is supplied:
    
    If tags are included in the request, only the request tags will be added to the snapshot. If no tags are included in the request, the replication group tags will be added to the snapshot.
  
  - If the --cache-cluster-id is supplied:
    
    If tags are included in the request, only the request tags will be added to the snapshot. If no tags are included in the request, the cache cluster tags will be added to the snapshot.
  
    - For automatic snapshots:
      
      Tags will propagate from the replication group tags.

- **CopySnapshot:**
  
    If tags are included in the request, only the request tags will be added to the snapshot. If no tags are included in the request, the source snapshot tags will be added to the copied snapshot.

- **AddTagsToResource** and **RemoveTagsFromResource**:

  Tags will be added/removed from the replication group and the action will be propagated to all clusters in the replication group.
Tagging your ElastiCache resources

Note
AddTagsToResource and RemoveTagsFromResource cannot be used for default parameter and security groups.

- **IncreaseReplicaCount** and **ModifyReplicationGroupShardConfiguration**: All new nodes added to the replication group will have the same tags applied as the replication group.

Tag restrictions

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum value length – 256 Unicode characters in UTF-8.
- Although ElastiCache allows for any character in its tags, other services can be restrictive. The allowed characters across services are: letters, numbers, and spaces representable in UTF-8, and the following characters: + - = . _ : / @
- Tag keys and values are case-sensitive.
- The `aws:` prefix is reserved for AWS use. If a tag has a tag key with this prefix, then you can't edit or delete the tag's key or value. Tags with the `aws:` prefix do not count against your tags per resource limit.

You can't terminate, stop, or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete snapshots that you tagged with a tag key called `DeleteMe`, you must use the `DeleteSnapshot` action with the resource identifiers of the snapshots, such as `snap-1234567890abcdef0`.

For more information on ElastiCache resources you can tag, see Resources you can tag (p. 204).

Tagging resources examples

- Adding tags to a Replication Group.

  ```bash
  aws elasticache add-tags-to-resource \
  --resource-name arn:aws:elasticache:us-east-1:111111222233:replicationgroup:my-rg \
  --tags Key="project",Value="XYZ" Key="Elasticache",Value="Service"
  ```

- Creating a Cache Cluster using tags.

  ```bash
  aws elasticache create-cache-cluster \
  --cluster-id testing-tags \
  --cluster-description cluster-test \
  --cache-subnet-group-name test \
  --cache-node-type cache.t2.micro \
  --engine redis \
  --tags Key="project",Value="XYZ" Key="Elasticache",Value="Service"
  ```

- Creating a Snapshot with tags.

  For this case, if you add tags on request, even if the replication group contains tags, the snapshot will receive only the request tags.

  ```bash
  aws elasticache create-snapshot \
  ```

API Version 2015-02-02

207
Tag-Based access control policy examples

1. Allowing `AddTagsToResource` action to a cluster only if the cluster has the tag Project=XYZ.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": "elasticache:AddTagsToResource",
         "Resource": [
           "arn:aws:elasticache::*::*:cluster:*"
         ],
         "Condition": {
           "StringEquals": {
             "aws:ResourceTag/Project": "XYZ"
           }
         }
       }
     ]
   }
   ``

2. Allowing to `RemoveTagsFromResource` action from a replication group if it contains the tags Project and Service and keys are different from Project and Service.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": "elasticache:RemoveTagsFromResource",
         "Resource": [
           "arn:aws:elasticache::*::*:replicationgroup:*"
         ],
         "Condition": {
           "StringEquals": {
             "aws:ResourceTag/Service": "Elasticache",
             "aws:ResourceTag/Project": "XYZ"
           },
           "ForAnyValue:StringNotEqualsIgnoreCase": {
             "aws:TagKeys": [
               "Project",
               "Service"
             ]
           }
         }
       }
     ]
   }
   ``

3. Allowing `AddTagsToResource` to any resource only if tags are different from Project and Service.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": "elasticache:AddTagsToResource",
         "Resource": [
           "arn:aws:elasticache::*::*:instance:*"
         ],
         "Condition": {
           "StringNotEquals": {
             "aws:TagKeys": [
               "Project",
               "Service"
             ]
           }
         }
       }
     ]
   }
   ```
Tagging your ElastiCache resources

4. Denying `CreateReplicationGroup` action if request has Tag `Project=Foo`.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": "elasticache:CreateReplicationGroup",
         "Resource": [
            "arn:aws:elasticache::*::*:replicationgroup::*"
         ],
         "Condition": {
            "StringEquals": {
               "aws:RequestTag/Project": "Foo"
            }
         }
      }
   ]
}
```

5. Denying `CopySnapshot` action if source snapshot has tag `Project=XYZ` and request tag is `Service=Elasticache`.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": "elasticache:CopySnapshot",
         "Resource": [
            "arn:aws:elasticache::*::*:snapshot::*"
         ],
         "Condition": {
            "StringEquals": {
               "aws:ResourceTag/Project": "XYZ",
               "aws:RequestTag/Service": "Elasticache"
            }
         }
      }
   ]
}
```

For more information, see Using condition keys (p. 551).
Monitoring costs with cost allocation tags

When you add cost allocation tags to your resources in Amazon ElastiCache, you can track costs by grouping expenses on your invoices by resource tag values.

An ElastiCache cost allocation tag is a key-value pair that you define and associate with an ElastiCache resource. The key and value are case-sensitive. You can use a tag key to define a category, and the tag value can be an item in that category. For example, you might define a tag key of `CostCenter` and a tag value of `10010`, indicating that the resource is assigned to the 10010 cost center. You can also use tags to designate resources as being used for test or production by using a key such as `Environment` and values such as `test` or `production`. We recommend that you use a consistent set of tag keys to make it easier to track costs associated with your resources.

Use cost allocation tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of combined resources, organize your billing information according to resources with the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services.

You can also combine tags to track costs at a greater level of detail. For example, to track your service costs by region you might use the tag keys `Service` and `Region`. On one resource you might have the values `ElastiCache` and `Asia Pacific (Singapore)`, and on another resource the values `ElastiCache` and `Europe (Frankfurt)`. You can then see your total ElastiCache costs broken out by region. For more information, see Use Cost Allocation Tags in the AWS Billing User Guide.

You can add ElastiCache cost allocation tags to Redis nodes. When you add, list, modify, copy, or remove a tag, the operation is applied only to the specified node.

Characteristics of ElastiCache cost allocation tags

- Cost allocation tags are applied to ElastiCache resources which are specified in CLI and API operations as an ARN. The resource-type will be a "cluster".

  Sample ARN: `arn:aws:elasticache:<region>::<customer-id>::<resource-type>::<resource-name>`

- The tag key is the required name of the tag. The key's string value can be from 1 to 128 Unicode characters long and cannot be prefixed with `aws:`. The string can contain only the set of Unicode letters, digits, blank spaces, underscores (_), periods (.), colons (:), backslashes (\), equal signs (=), plus signs (+), hyphens (-), or at signs (@).

- The tag value is the optional value of the tag. The value's string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with `aws:`. The string can contain only the set of Unicode letters, digits, blank spaces, underscores (_), periods (.), colons (:), backslashes (\), equal signs (=), plus signs (+), hyphens (-), or at signs (@).

- An ElastiCache resource can have a maximum of 50 tags.

- Values do not have to be unique in a tag set. For example, you can have a tag set where the keys `Service` and `Application` both have the value `ElastiCache`.

  AWS does not apply any semantic meaning to your tags. Tags are interpreted strictly as character strings. AWS does not automatically set any tags on any ElastiCache resource.
Managing your cost allocation tags using the AWS CLI

You can use the AWS CLI to add, modify, or remove cost allocation tags.

Cost allocation tags are applied to ElastiCache for Redis nodes. The node to be tagged is specified using an ARN (Amazon Resource Name).

Topics

• Listing tags using the AWS CLI (p. 211)
• Adding tags using the AWS CLI (p. 212)
• Modifying tags using the AWS CLI (p. 212)
• Removing tags using the AWS CLI (p. 213)

Listing tags using the AWS CLI

You can use the AWS CLI to list tags on an existing ElastiCache resource by using the list-tags-for-resource operation.

The following code uses the AWS CLI to list the tags on the Redis node my-cluster-001 in the my-cluster cluster in region us-west-2.

For Linux, macOS, or Unix:

```bash
aws elasticache list-tags-for-resource \
```

For Windows:

```bash
aws elasticache list-tags-for-resource ^
```

Output from this operation will look something like the following, a list of all the tags on the resource.

```json
{
  "TagList": [
    {
      "Value": "10110",
      "Key": "CostCenter"
    },
    {
      "Value": "EC2",
      "Key": "Service"
    }
  ]
}
```

If there are no tags on the resource, the output will be an empty TagList.

```json
{
  "TagList": []
}
```
For more information, see the AWS CLI for ElastiCache list-tags-for-resource.

## Adding tags using the AWS CLI

You can use the AWS CLI to add tags to an existing ElastiCache resource by using the `add-tags-to-resource` CLI operation. If the tag key does not exist on the resource, the key and value are added to the resource. If the key already exists on the resource, the value associated with that key is updated to the new value.

The following code uses the AWS CLI to add the keys `Service` and `Region` with the values `elasticache` and `us-west-2` respectively to the node `my-cluster-001` in the cluster `my-cluster` in region us-west-2.

For Linux, macOS, or Unix:

```bash
aws elasticache add-tags-to-resource \
  --tags Key=Service,Value=elasticache \
      Key=Region,Value=us-west-2
```

For Windows:

```bash
aws elasticache add-tags-to-resource ^ \
  --tags Key=Service,Value=elasticache ^ \
      Key=Region,Value=us-west-2
```

Output from this operation will look something like the following, a list of all the tags on the resource following the operation.

```json
{
  "TagList": [
    {
      "Value": "elasticache",
      "Key": "Service"
    },
    {
      "Value": "us-west-2",
      "Key": "Region"
    }
  ]
}
```

For more information, see the AWS CLI for ElastiCache add-tags-to-resource.

You can also use the AWS CLI to add tags to a cluster when you create a new cluster by using the operation create-cache-cluster. You cannot add tags when creating a cluster using the ElastiCache management console. After the cluster is created, you can then use the console to add tags to the cluster.

## Modifying tags using the AWS CLI

You can use the AWS CLI to modify the tags on a node in an ElastiCache for Redis cluster.

To modify tags:

- Use `add-tags-to-resource` to either add a new tag and value or to change the value associated with an existing tag.
• Use `remove-tags-from-resource` to remove specified tags from the resource.

Output from either operation will be a list of tags and their values on the specified cluster.

**Removing tags using the AWS CLI**

You can use the AWS CLI to remove tags from an existing node in an ElastiCache for Redis cluster by using the `remove-tags-from-resource` operation.

The following code uses the AWS CLI to remove the tags with the keys `Service` and `Region` from the node `my-cluster-001` in the cluster `my-cluster` in the us-west-2 region.

For Linux, macOS, or Unix:

```bash
aws elasticache remove-tags-from-resource
    --tag-keys PM Service
```

For Windows:

```bash
aws elasticache remove-tags-from-resource
    --tag-keys PM Service
```

Output from this operation will look something like the following, a list of all the tags on the resource following the operation.

```json
{
    "TagList": []
}
```

For more information, see the AWS CLI for ElastiCache `remove-tags-from-resource`.

**Managing your cost allocation tags using the ElastiCache API**

You can use the ElastiCache API to add, modify, or remove cost allocation tags.

Cost allocation tags are applied to ElastiCache for Memcached clusters. The cluster to be tagged is specified using an ARN (Amazon Resource Name).

**Topics**

- Listing tags using the ElastiCache API (p. 213)
- Adding tags using the ElastiCache API (p. 214)
- Modifying tags using the ElastiCache API (p. 214)
- Removing tags using the ElastiCache API (p. 214)

**Listing tags using the ElastiCache API**

You can use the ElastiCache API to list tags on an existing resource by using the `ListTagsForResource` operation.
The following code uses the ElastiCache API to list the tags on the resource my-cluster-001 in the us-west-2 region.

https://elasticache.us-west-2.amazonaws.com/
?Action=ListTagsForResource
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Version=2015-02-02
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>

Adding tags using the ElastiCache API

You can use the ElastiCache API to add tags to an existing ElastiCache cluster by using the AddTagsToResource operation. If the tag key does not exist on the resource, the key and value are added to the resource. If the key already exists on the resource, the value associated with that key is updated to the new value.

The following code uses the ElastiCache API to add the keys Service and Region with the values elasticache and us-west-2 respectively to the resource my-cluster-001 in the us-west-2 region.

https://elasticache.us-west-2.amazonaws.com/
?Action=AddTagsToResource
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Tags.member.1.Key=Service
&Tags.member.1.Value=elasticache
&Tags.member.2.Key=Region
&Tags.member.2.Value=us-west-2
&Version=2015-02-02
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>

For more information, see AddTagsToResource in the Amazon ElastiCache API Reference.

Modifying tags using the ElastiCache API

You can use the ElastiCache API to modify the tags on an ElastiCache cluster.

To modify the value of a tag:

- Use AddTagsToResource operation to either add a new tag and value or to change the value of an existing tag.
- Use RemoveTagsFromResource to remove tags from the resource.

Output from either operation will be a list of tags and their values on the specified resource.

Use RemoveTagsFromResource to remove tags from the resource.

Removing tags using the ElastiCache API

You can use the ElastiCache API to remove tags from an existing ElastiCache for Redis node by using the RemoveTagsFromResource operation.

The following code uses the ElastiCache API to remove the tags with the keys Service and Region from the node my-cluster-001 in the cluster my-cluster in region us-west-2.
Caching strategies and best practices

Following, you can find recommended best practices for Amazon ElastiCache. Following these improves your cluster’s performance and reliability.

Topics
- Caching strategies (p. 215)
- Restricted Redis Commands (p. 220)
- Ensuring that you have enough memory to create a Redis snapshot (p. 221)
- Managing Reserved Memory (p. 223)
- Mitigating failure issues when using Redis AOF (p. 228)
- Best practices: Online cluster resizing (p. 229)
- Best practices: Minimizing downtime during maintenance (p. 230)
- Best practices: Redis clients and ElastiCache for Redis (p. 230)

Caching strategies

In the following topic, you can find strategies for populating and maintaining your cache.

What strategies to implement for populating and maintaining your cache depend upon what data you cache and the access patterns to that data. For example, you likely don’t want to use the same strategy for both a top-10 leaderboard on a gaming site and trending news stories. In the rest of this section, we discuss common cache maintenance strategies and their advantages and disadvantages.

Topics
- Lazy loading (p. 215)
- Write-through (p. 217)
- Adding TTL (p. 218)
- Related topics (p. 219)

Lazy loading

As the name implies, lazy loading is a caching strategy that loads data into the cache only when necessary. It works as described following.

Amazon ElastiCache is an in-memory key-value store that sits between your application and the data store (database) that it accesses. Whenever your application requests data, it first makes the request to the ElastiCache cache. If the data exists in the cache and is current, ElastiCache returns the data to your application. If the data doesn't exist in the cache or has expired, your application requests the data from
your data store. Your data store then returns the data to your application. Your application next writes
the data received from the store to the cache. This way, it can be more quickly retrieved the next time it's
requested.

_A cache hit_ occurs when data is in the cache and isn't expired:

1. Your application requests data from the cache.
2. The cache returns the data to the application.

_A cache miss_ occurs when data isn't in the cache or is expired:

1. Your application requests data from the cache.
2. The cache doesn't have the requested data, so returns a `null`.
3. Your application requests and receives the data from the database.
4. Your application updates the cache with the new data.

**Advantages and disadvantages of lazy loading**

The advantages of lazy loading are as follows:

- Only requested data is cached.

  Because most data is never requested, lazy loading avoids filling up the cache with data that isn't
  requested.

- Node failures aren't fatal for your application.

  When a node fails and is replaced by a new, empty node, your application continues to function,
  though with increased latency. As requests are made to the new node, each cache miss results in a
  query of the database. At the same time, the data copy is added to the cache so that subsequent
  requests are retrieved from the cache.

The disadvantages of lazy loading are as follows:

- There is a cache miss penalty. Each cache miss results in three trips:
  1. Initial request for data from the cache
  2. Query of the database for the data
  3. Writing the data to the cache

  These misses can cause a noticeable delay in data getting to the application.

- Stale data.

  If data is written to the cache only when there is a cache miss, data in the cache can become stale.
  This result occurs because there are no updates to the cache when data is changed in the database. To
  address this issue, you can use the [Write-through (p. 217)](https://example.com) and [Adding TTL (p. 218)](https://example.com) strategies.

**Lazy loading pseudocode example**

The following is a pseudocode example of lazy loading logic.

```java
// *****************************************
// function that returns a customer's record.
// Attempts to retrieve the record from the cache.
// If it is retrieved, the record is returned to the application.
// If the record is not retrieved from the cache, it is
```
Caching strategies

get_customer(customer_id)

customer_record = cache.get(customer_id)
if (customer_record == null)
    
    customer_record = db.query("SELECT * FROM Customers WHERE id = {0}", customer_id)
    cache.set(customer_id, customer_record)

return customer_record

For this example, the application code that gets the data is the following.

customer_record = get_customer(12345)

Write-through

The write-through strategy adds data or updates data in the cache whenever data is written to the database.

Advantages and disadvantages of write-through

The advantages of write-through are as follows:

- Data in the cache is never stale.

  Because the data in the cache is updated every time it’s written to the database, the data in the cache is always current.

- Write penalty vs. read penalty.

  Every write involves two trips:
  1. A write to the cache
  2. A write to the database

  Which adds latency to the process. That said, end users are generally more tolerant of latency when updating data than when retrieving data. There is an inherent sense that updates are more work and thus take longer.

The disadvantages of write-through are as follows:

- Missing data.

  If you spin up a new node, whether due to a node failure or scaling out, there is missing data. This data continues to be missing until it’s added or updated on the database. You can minimize this by implementing lazy loading (p. 215) with write-through.

- Cache churn.

  Most data is never read, which is a waste of resources. By adding a time to live (TTL) value (p. 218), you can minimize wasted space.

Write-through pseudocode example

The following is a pseudocode example of write-through logic.
Adding TTL

Lazy loading allows for stale data but doesn't fail with empty nodes. Write-through ensures that data is always fresh, but can fail with empty nodes and can populate the cache with superfluous data. By adding a time to live (TTL) value to each write, you can have the advantages of each strategy. At the same time, you can and largely avoid cluttering up the cache with extra data.

Time to live (TTL) is an integer value that specifies the number of seconds until the key expires. Redis can specify seconds or milliseconds for this value. When an application attempts to read an expired key, it is treated as though the key is not found. The database is queried for the key and the cache is updated. This approach doesn't guarantee that a value isn't stale. However, it keeps data from getting too stale and requires that values in the cache are occasionally refreshed from the database.

For more information, see the Redis set command.

TTL pseudocode examples

The following is a pseudocode example of write-through logic with TTL.

```plaintext
// *****************************************
// function that saves a customer's record.
// The TTL value of 300 means that the record expires
// 300 seconds (5 minutes) after the set command
// and future reads will have to query the database.
// *****************************************
save_customer(customer_id, values)
    customer_record = db.query("UPDATE Customers WHERE id = {0}", customer_id, values)
    cache.set(customer_id, customer_record, 300)
    return success
```

The following is a pseudocode example of lazy loading logic with TTL.

```plaintext
// *****************************************
// function that returns a customer's record.
// If it is retrieved, the record is returned to the application.
// If the record is not retrieved from the cache, it is
// retrieved from the database, added to the cache, and
// returned to the application.
// The TTL value of 300 means that the record expires
// 300 seconds (5 minutes) after the set command
// and subsequent reads will have to query the database.
```
get_customer(customer_id)

    customer_record = cache.get(customer_id)

    if (customer_record != null)
        if (customer_record.TTL < 300)
            return customer_record        // return the record and exit function

    // do this only if the record did not exist in the cache OR
    // the TTL was >= 300, i.e., the record in the cache had expired.
    customer_record = db.query("SELECT * FROM Customers WHERE id = {0}", customer_id)
    cache.set(customer_id, customer_record, 300)  // update the cache
    return customer_record                // return the newly retrieved record and exit function

For this example, the application code that gets the data is the following.

save_customer(12345,"address":"123 Main")

customer_record = get_customer(12345)

Restricted Redis Commands

To deliver a managed service experience, restricts access to certain cache engine-specific commands that require advanced privileges. For cache clusters running Redis, the following commands are unavailable:

- acl setuser
- acl load
- acl save
- acl deluser
- bgrewriteaof
- bgsave
- cluster addslot
- cluster delslot
- cluster setslot
- config
- debug
- migrate
- replicaof
- save
- slaveof
- shutdown
- sync
Ensuring that you have enough memory to create a Redis snapshot

Redis snapshots and synchronizations in version 2.8.22 and later

Redis 2.8.22 introduces a forkless save process that allows you to allocate more of your memory to your application's use without incurring increased swap usage during synchronizations and saves. For more information, see How synchronization and backup are implemented (p. 265).

Redis snapshots and synchronizations before version 2.8.22

When you work with Redis ElastiCache, Redis calls a background write command in a number of cases:

- When creating a snapshot for a backup.
- When synchronizing replicas with the primary in a replication group.
- When enabling the append-only file feature (AOF) for Redis.
- When promoting a replica to primary (which causes a primary/replica sync).

Whenever Redis executes a background write process, you must have sufficient available memory to accommodate the process overhead. Failure to have sufficient memory available causes the process to fail. Because of this, it is important to choose a node instance type that has sufficient memory when creating your Redis cluster.

Background Write Process and Memory Usage

Whenever a background write process is called, Redis forks its process (remember, Redis is single threaded). One fork persists your data to disk in a Redis .rdb snapshot file. The other fork services all read and write operations. To ensure that your snapshot is a point-in-time snapshot, all data updates and additions are written to an area of available memory separate from the data area.

As long as you have sufficient memory available to record all write operations while the data is being persisted to disk, you should have no insufficient memory issues. You are likely to experience insufficient memory issues if any of the following are true:

- Your application performs many write operations, thus requiring a large amount of available memory to accept the new or updated data.
- You have very little memory available in which to write new or updated data.
- You have a large dataset that takes a long time to persist to disk, thus requiring a large number of write operations.

The following diagram illustrates memory use when executing a background write process.
Memory use prior to a snapshot

| Memory for data | Reserved/available memory |

Memory use during a snapshot—sufficient memory

| Memory for data | Memory used by background write operations | Available memory |

Additional memory needed for background write operations

Memory use during a snapshot—insufficient memory

| Memory for data | Memory used by background write operations |

For information on the impact of doing a backup on performance, see Performance impact of backups (p. 312).

For more information on how Redis performs snapshots, see http://redis.io.

For more information on regions and Availability Zones, see Choosing regions and availability zones (p. 87).

Avoiding running out of memory when executing a background write

Whenever a background write process such as BGSAVE or BGREWRITEAOF is called, to keep the process from failing, you must have more memory available than will be consumed by write operations during the process. The worst-case scenario is that during the background write operation every Redis record is updated and some new records are added to the cache. Because of this, we recommend that you set reserved-memory-percent to 50 (50 percent) for Redis versions before 2.8.22 or 25 (25 percent) for Redis versions 2.8.22 and later.

The maxmemory value indicates the memory available to you for data and operational overhead. Because you cannot modify the reserved-memory parameter in the default parameter group, you must create a custom parameter group for the cluster. The default value for reserved-memory is 0, which allows Redis to consume all of maxmemory with data, potentially leaving too little memory for other uses, such as a background write process. For maxmemory values by node instance type, see Redis node-type specific parameters (p. 465).

You can also use reserved-memory parameter to reduce the amount of memory Redis uses on the box.

For more information on Redis-specific parameters in ElastiCache, see Redis-specific parameters (p. 441).

For information on creating and modifying parameter groups, see Creating a parameter group (p. 425) and Modifying a parameter group (p. 435).
Managing Reserved Memory

Reserved memory is memory set aside for nondata use. When performing a backup or failover, Redis uses available memory to record write operations to your cluster while the cluster's data is being written to the .rdb file. If you don't have sufficient memory available for all the writes, the process fails. Following, you can find information on options for managing reserved memory for ElastiCache for Redis and how to apply those options.

Topics
- How Much Reserved Memory Do You Need? (p. 223)
- Parameters to Manage Reserved Memory (p. 223)
- Specifying Your Reserved Memory Management Parameter (p. 226)

How Much Reserved Memory Do You Need?

If you are running a version of Redis before 2.8.22, reserve more memory for backups and failovers than if you are running Redis 2.8.22 or later. This requirement is due to the different ways that ElastiCache for Redis implements the backup process. The rule of thumb is to reserve half of a node type's maxmemory value for Redis overhead for versions before 2.8.22, and one-fourth for Redis versions 2.8.22 and later.

When using clusters with data tiering, we recommend increasing maxmemory to up to half your node's available memory if your workload is write-heavy.

For more information, see the following:
- Ensuring that you have enough memory to create a Redis snapshot (p. 221)
- How synchronization and backup are implemented (p. 265)
- Data tiering (p. 121)

Parameters to Manage Reserved Memory

As of March 16, 2017, Amazon ElastiCache for Redis provides two mutually exclusive parameters for managing your Redis memory, reserved-memory and reserved-memory-percent. Neither of these parameters is part of the Redis distribution.

Depending upon when you became an ElastiCache customer, one or the other of these parameters is the default memory management parameter. This parameter applies when you create a new Redis cluster or replication group and use a default parameter group.

- For customers who started before March 16, 2017 – When you create a Redis cluster or replication group using the default parameter group, your memory management parameter is reserved-memory. In this case, zero (0) bytes of memory are reserved.
- For customers who started on or after March 16, 2017 – When you create a Redis cluster or replication group using the default parameter group, your memory management parameter is reserved-memory-percent. In this case, 25 percent of your node's maxmemory value is reserved for nondata purposes.

After reading about the two Redis memory management parameters, you might prefer to use the one that isn't your default or with nondefault values. If so, you can change to the other reserved memory management parameter.

To change the value of that parameter, you can create a custom parameter group and modify it to use your preferred memory management parameter and value. You can then use the custom parameter...
group whenever you create a new Redis cluster or replication group. For existing clusters or replication
groups, you can modify them to use your custom parameter group.

For more information, see the following:

- Specifying Your Reserved Memory Management Parameter (p. 226)
- Creating a parameter group (p. 425)
- Modifying a parameter group (p. 435)
- Modifying an ElastiCache cluster (p. 149)
- Modifying a replication group (p. 294)

**The reserved-memory Parameter**

Before March 16, 2017, all ElastiCache for Redis reserved memory management was done using the
parameter `reserved-memory`. The default value of `reserved-memory` is 0. This default reserves no
memory for Redis overhead and allows Redis to consume all of a node's memory with data.

Changing `reserved-memory` so you have sufficient memory available for backups and failovers requires
you to create a custom parameter group. In this custom parameter group, you set `reserved-memory`
to a value appropriate for the Redis version running on your cluster and cluster's node type. For more
information, see How Much Reserved Memory Do You Need? (p. 223)

The ElastiCache for Redis parameter `reserved-memory` is specific to ElastiCache for Redis and isn't part
of the Redis distribution.

The following procedure shows how to use `reserved-memory` to manage the memory on your Redis
cluster.

**To reserve memory using reserved-memory**

1. Create a custom parameter group specifying the parameter group family matching the engine
   version you're running—for example, specifying the `redis2.8` parameter group family. For more
   information, see Creating a parameter group (p. 425).

   ```bash
   aws elasticache create-cache-parameter-group \
   --cache-parameter-group-name redis28-m3xl \
   --description "Redis 2.8.x for m3.xlarge node type" \
   --cache-parameter-group-family redis2.8
   ```

2. Calculate how many bytes of memory to reserve for Redis overhead. You can find the value of
   `maxmemory` for your node type at Redis node-type specific parameters (p. 465).

3. Modify the custom parameter group so that the parameter `reserved-memory` is the number of
   bytes you calculated in the previous step. The following AWS CLI example assumes you're running
   a version of Redis before 2.8.22 and need to reserve half of the node's `maxmemory`. For more
   information, see Modifying a parameter group (p. 435).

   ```bash
   aws elasticache modify-cache-parameter-group \
   --cache-parameter-group-name redis28-m3xl \
   --parameter-name-values ParameterName=reserved-memory, ParameterValue=7130316800
   ```

You need a separate custom parameter group for each node type that you use, because each node
type has a different `maxmemory` value. Thus, each node type needs a different value for `reserved-
memory`.

4. Modify your Redis cluster or replication group to use your custom parameter group.
The following CLI example modifies the cluster `my-redis-cluster` to use the custom parameter group `redis28-m3xl` beginning immediately. For more information, see Modifying an ElastiCache cluster (p. 149).

```bash
aws elasticache modify-cache-cluster \
  --cache-cluster-id my-redis-cluster \
  --cache-parameter-group-name redis28-m3xl \
  --apply-immediately
```

The following CLI example modifies the replication group `my-redis-repl-grp` to use the custom parameter group `redis28-m3xl` beginning immediately. For more information, Modifying a replication group (p. 294).

```bash
aws elasticache modify-replication-group \
  --replication-group-id my-redis-repl-grp \
  --cache-parameter-group-name redis28-m3xl \
  --apply-immediately
```

### The reserved-memory-percent parameter

On March 16, 2017, Amazon ElastiCache introduced the parameter `reserved-memory-percent` and made it available on all versions of ElastiCache for Redis. The purpose of `reserved-memory-percent` is to simplify reserved memory management across all your clusters. It does so by enabling you to have a single parameter group for each parameter group family (such as `redis2.8`) to manage your clusters' reserved memory, regardless of node type. The default value for `reserved-memory-percent` is 25 (25 percent).

The ElastiCache for Redis parameter `reserved-memory-percent` is specific to ElastiCache for Redis and isn't part of the Redis distribution.

If your cluster is using a node type from the r6gd family and your memory usage reaches 75 percent, data-tiering will automatically be triggered. For more information, see Data tiering (p. 121).

### To reserve memory using `reserved-memory-percent`

To use `reserved-memory-percent` to manage the memory on your ElastiCache for Redis cluster, do one of the following:

- If you are running Redis 2.8.22 or later, assign the default parameter group to your cluster. The default 25 percent should be adequate. If not, take the steps described following to change the value.
- If you are running a version of Redis before 2.8.22, you probably need to reserve more memory than `reserved-memory-percent`'s default 25 percent. To do so, use the following procedure.

### To change the percent value of `reserved-memory-percent`

1. Create a custom parameter group specifying the parameter group family matching the engine version you're running—for example, specifying the `redis2.8` parameter group family. A custom parameter group is necessary because you can't modify a default parameter group. For more information, see Creating a parameter group (p. 425).

```bash
aws elasticache create-cache-parameter-group \
  --cache-parameter-group-name redis28-50 \
  --description "Redis 2.8.x 50% reserved" \
  --cache-parameter-group-family redis2.8
```
Because reserved-memory-percent reserves memory as a percent of a node's maxmemory, you don't need a custom parameter group for each node type.

2. Modify the custom parameter group so that reserved-memory-percent is 50 (50 percent). For more information, see Modifying a parameter group (p. 435).

```
aws elasticache modify-cache-parameter-group \
--cache-parameter-group-name redis28-50 \
--parameter-name-values "ParameterName=reserved-memory-percent, ParameterValue=50"
```

3. Use this custom parameter group for any Redis clusters or replication groups running a version of Redis older than 2.8.22.

The following CLI example modifies the Redis cluster my-redis-cluster to use the custom parameter group redis28-50 beginning immediately. For more information, see Modifying an ElastiCache cluster (p. 149).

```
aws elasticache modify-cache-cluster \
--cache-cluster-id my-redis-cluster \
--cache-parameter-group-name redis28-50 \
--apply-immediately
```

The following CLI example modifies the Redis replication group my-redis-repl-grp to use the custom parameter group redis28-50 beginning immediately. For more information, see Modifying a replication group (p. 294).

```
aws elasticache modify-replication-group \
--replication-group-id my-redis-repl-grp \
--cache-parameter-group-name redis28-50 \
--apply-immediately
```

### Specifying Your Reserved Memory Management Parameter

If you were a current ElastiCache customer on March 16, 2017, your default reserved memory management parameter is reserved-memory with zero (0) bytes of reserved memory. If you became an ElastiCache customer after March 16, 2017, your default reserved memory management parameter is reserved-memory-percent with 25 percent of the node's memory reserved. This is true no matter when you created your ElastiCache for Redis cluster or replication group. However, you can change your reserved memory management parameter using either the AWS CLI or ElastiCache API.

The parameters reserved-memory and reserved-memory-percent are mutually exclusive. A parameter group always has one but never both. You can change which parameter a parameter group uses for reserved memory management by modifying the parameter group. The parameter group must be a custom parameter group, because you can't modify default parameter groups. For more information, see Creating a parameter group (p. 425).

**To specify reserved-memory-percent**

To use reserved-memory-percent as your reserved memory management parameter, modify a custom parameter group using the modify-cache-parameter-group command. Use the parameter-name-values parameter to specify reserved-memory-percent and a value for it.

The following CLI example modifies the custom parameter group redis32-cluster-on so that it uses reserved-memory-percent to manage reserved memory. A value must be assigned to ParameterValue for the parameter group to use the ParameterName parameter for reserved memory management. For more information, see Modifying a parameter group (p. 435).
To specify reserved-memory

To use reserved-memory as your reserved memory management parameter, modify a custom parameter group using the `modify-cache-parameter-group` command. Use the `parameter-name-values` parameter to specify `reserved-memory` and a value for it.

The following CLI example modifies the custom parameter group `redis32-m3xl` so that it uses reserved-memory to manage reserved memory. A value must be assigned to `ParameterValue` for the parameter group to use the `ParameterName` parameter for reserved memory management. Because the engine version is newer than 2.8.22, we set the value to 3565158400 which is 25 percent of a cache.m3.xlarge's `maxmemory`. For more information, see Modifying a parameter group (p. 435).

```
aws elasticache modify-cache-parameter-group \
  --cache-parameter-group-name redis32-m3xl \
  --parameter-name-values "ParameterName=reserved-memory, ParameterValue=3565158400"
```
Mitigating failure issues when using Redis AOF

When planning your Amazon ElastiCache implementation, you should plan so that failures have the least impact possible.

You enable AOF because an AOF file is useful in recovery scenarios. In case of a node restart or service crash, Redis replays the updates from an AOF file, thereby recovering the data lost due to the restart or crash.

**Warning**

AOF cannot protect against all failure scenarios. For example, if a node fails due to a hardware fault in an underlying physical server, ElastiCache provisions a new node on a different server. In this case, the AOF file is no longer available and cannot be used to recover the data. Thus, Redis restarts with a cold cache.

Enabling Redis Multi-AZ as a better approach to fault tolerance

If you are enabling AOF to protect against data loss, consider using a replication group with Multi-AZ enabled instead of AOF. When using a Redis replication group, if a replica fails, it is automatically replaced and synchronized with the primary cluster. If Multi-AZ is enabled on a Redis replication group and the primary fails, it fails over to a read replica. Generally, this functionality is much faster than rebuilding the primary from an AOF file. For greater reliability and faster recovery, we recommend that you create a replication group with one or more read replicas in different Availability Zones and enable Multi-AZ instead of using AOF. Because there is no need for AOF in this scenario, ElastiCache disables AOF on Multi-AZ replication groups.

For more information, see the following topics:

- Mitigating Failures (p. 623)
- High availability using replication groups (p. 246)
- Minimizing downtime in ElastiCache for Redis with Multi-AZ (p. 253)
Best practices: Online cluster resizing

Resharding involves adding and removing shards or nodes to your cluster and redistributing key spaces. As a result, multiple things have an impact on the resharding operation, such as the load on the cluster, memory utilization, and overall size of data. For the best experience, we recommend that you follow overall cluster best practices for uniform workload pattern distribution. In addition, we recommend taking the following steps.

Before initiating resharding, we recommend the following:

- **Test your application** – Test your application behavior during resharding in a staging environment if possible.
- **Get early notification for scaling issues** – Resharding is a compute-intensive operation. Because of this, we recommend keeping CPU utilization under 80 percent on multicore instances and less than 50 percent on single core instances during resharding. Monitor ElastiCache for Redis metrics and initiate resharding before your application starts observing scaling issues. Useful metrics to track are **CPUUtilization**, **NetworkBytesIn**, **NetworkBytesOut**, **CurrConnections**, **NewConnections**, **FreeableMemory**, **SwapUsage**, and **BytesUsedForCacheItems**.
- **Ensure sufficient free memory is available before scaling in** – If you're scaling in, ensure that free memory available on the shards to be retained is at least 1.5 times the memory used on the shards you plan to remove.
- **Initiate resharding during off-peak hours** – This practice helps to reduce the latency and throughput impact on the client during the resharding operation. It also helps to complete resharding faster as more resources can be used for slot redistribution.
- **Review client timeout behavior** – Some clients might observe higher latency during online cluster resizing. Configuring your client library with a higher timeout can help by giving the system time to connect even under higher load conditions on server. In some cases, you might open a large number of connections to the server. In these cases, consider adding exponential backoff to reconnect logic. Doing this can help prevent a burst of new connections hitting the server at the same time.

During resharding, we recommend the following:

- **Avoid expensive commands** – Avoid running any computationally and I/O intensive operations, such as the **KEYS** and **SMEMBERS** commands. We suggest this approach because these operations increase the load on the cluster and have an impact on the performance of the cluster. Instead, use the **SCAN** and **SSCAN** commands.
- **Follow Lua best practices** – Avoid long running Lua scripts, and always declare keys used in Lua scripts up front. We recommend this approach to determine that the Lua script is not using cross slot commands. Ensure that the keys used in Lua scripts belong to the same slot.

After resharding, note the following:

- Scale-in might be partially successful if insufficient memory is available on target shards. If such a result occurs, review available memory and retry the operation, if necessary. The data on the target shards will not be deleted.
- Slots with large items are not migrated. In particular, slots with items larger than 256 MB post-serialization are not migrated.
- The **BRPOPLPUSH** command is not supported if it operates on the slot being migrated. **FLUSHALL** and **FLUSHDB** commands are not supported inside Lua scripts during a resharding operation.
Best practices: Minimizing downtime during maintenance

Cluster mode configuration has the best availability during managed or unmanaged operations. We recommend that you use a cluster mode supported client that connects to the cluster discovery endpoint. For cluster mode disabled, we recommend that you use the primary endpoint for all write operations.

For read activity, applications can also connect to any node in the cluster. Unlike the primary endpoint, node endpoints resolve to specific endpoints. If you make a change in your cluster, such as adding or deleting a replica, you must update the node endpoints in your application.

If autofailover is enabled in the cluster, the primary node might change. Therefore, the application should confirm the role of the node and update all the read endpoints. Doing this helps ensure that you aren't causing a major load on the primary. With autofailover disabled, the role of the node doesn't change. However, the downtime in managed or unmanaged operations is higher as compared to clusters with auto failover enabled.

Avoid directing read requests to read replicas only. If you configure your client to direct read requests to read replicas only, ensure that you have at least two read replicas to avoid any read interruption during maintenance.

Best practices: Redis clients and ElastiCache for Redis

To learn more about best practices for interacting with ElastiCache for Redis resources with commonly used open-source Redis client libraries, see Best practices: Redis clients and Amazon ElastiCache for Redis.

Managing maintenance

Every cluster and replication group has a weekly maintenance window during which any system changes are applied. If you don't specify a preferred maintenance window when you create or modify a cluster or replication group, ElastiCache assigns a 60-minute maintenance window within your region's maintenance window on a randomly chosen day of the week.

The 60-minute maintenance window is chosen at random from an 8-hour block of time per region. The following table lists the time blocks for each region from which the default maintenance windows are assigned. You may choose a preferred maintenance window outside the region's maintenance window block.

### Changing your Cluster's or Replication Group's Maintenance Window

The maintenance window should fall at the time of lowest usage and thus might need modification from time to time. You can modify your cluster or replication group to specify a time range of up to 24 hours in duration during which any maintenance activities you have requested should occur. Any deferred or pending cluster modifications you requested occur during this time.

**More information**

For information on your maintenance window and node replacement, see the following:

- **ElastiCache Maintenance**—FAQ on maintenance and node replacement
- **Replacing nodes (p. 103)**—Managing node replacement
- **Modifying an ElastiCache cluster (p. 149)**—Changing a cluster's maintenance window
- **Modifying a replication group (p. 294)**—Changing a replication group's maintenance window

### Replication across AWS Regions using global datastores

By using the Global Datastore for Redis feature, you can work with fully managed, fast, reliable, and secure replication across AWS Regions. Using this feature, you can create cross-Region read replica clusters for ElastiCache for Redis to enable low-latency reads and disaster recovery across AWS Regions.
In the following sections, you can find a description of how to work with global datastores.

**Topics**
- Overview (p. 232)
- Prerequisites and limitations (p. 233)
- Using global datastores (console) (p. 234)
- Using global datastores (CLI) (p. 242)

**Overview**

Each *global datastore* is a collection of one or more clusters that replicate to one another.

A global datastore consists of the following:

- **Primary (active) cluster** – A primary cluster accepts writes that are replicated to all clusters within the global datastore. A primary cluster also accepts read requests.
- **Secondary (passive) cluster** – A secondary cluster only accepts read requests and replicates data updates from a primary cluster. A secondary cluster needs to be in a different AWS Region than the primary cluster.

When you create a global datastore in ElastiCache, ElastiCache for Redis automatically replicates your data from the primary cluster to the secondary cluster. You choose the AWS Region where the Redis data should be replicated and then create a secondary cluster in that AWS Region. ElastiCache then sets up and manages automatic, asynchronous replication of data between the two clusters.

Using a global datastore for Redis provides the following advantages:

- **Geolocal performance** – By setting up remote replica clusters in additional AWS Regions and synchronizing your data between them, you can reduce latency of data access in that AWS Region. A global datastore can help increase the responsiveness of your application by serving low-latency, geolocal reads across AWS Regions.
- **Disaster recovery** – If your primary cluster in a global datastore experiences degradation, you can promote a secondary cluster as your new primary cluster. You can do so by connecting to any AWS Region that contains a secondary cluster.

The following diagram shows how global datastores can work.
Prerequisites and limitations

Before getting started with global datastores, be aware of the following:

- Global datastores are supported in the following AWS Regions: Asia Pacific (Seoul, Tokyo, Singapore, Sydney, Mumbai, and Osaka), Europe (Frankfurt, Paris, London, Ireland, and Stockholm), US East (N. Virginia and Ohio), US West (N. California and Oregon), South America (São Paulo), AWS GovCloud (US-West and US-East), Canada (Central) Region, China (Beijing and Ningxia)
- To use global datastores, use Redis engine version 5.0.6 or higher and R5, R6g, R6gd, M5 or M6g node types.
- All clusters—primary and secondary—in your global datastore should have the same number of primary nodes, node type, engine version, and number of shards (in case of cluster-mode enabled). Each cluster in your global datastore can have a different number of read replicas to accommodate the read traffic local to that cluster.

Replication must be enabled if you plan to use an existing single-node cluster.

- You can set up replication for a primary cluster from one AWS Region to a secondary cluster in up to two other AWS Regions.

Note
The exception to this are China (Beijing) Region and China (Ningxia) regions, where replication can only occur between the two regions.

- You can work with global datastores only in VPC clusters. For more information, see Access Patterns for Accessing an ElastiCache Cluster in an Amazon VPC (p. 508). Global datastores aren't supported when you use EC2-Classic. For more information, see EC2-Classic in the Amazon EC2 User Guide for Linux Instances.

Note
At this time, you can't use global datastores in Using local zones with ElastiCache (p. 91).

- ElastiCache doesn't support autofailover from one AWS Region to another. When needed, you can promote a secondary cluster manually. For an example, see Promoting the secondary cluster to primary (p. 240).
- To bootstrap from existing data, use an existing cluster as primary to create a global datastore. We don't support adding an existing cluster as secondary. The process of adding the cluster as secondary wipes data, which may result in data loss.
- Parameter updates are applied to all clusters when you modify a local parameter group of a cluster belonging to a global datastore.
- You can scale regional clusters both vertically (scaling up and down) and horizontally (scaling in and out). You can scale the clusters by modifying the global datastore. All the regional clusters in the global datastore are then scaled without interruption. For more information, see Scaling ElastiCache for Redis clusters (p. 345).
- Global datastores support encryption at rest, encryption in transit, and Redis AUTH.
- Global datastores support AWS KMS keys. For more information, see AWS key management service concepts in the AWS Key Management Service Developer Guide.
- Security for cross-Region communication is provided through VPC peering. For more information, see What is VPC peering? in the Amazon VPC Peering Guide.

Note
Global datastores support pub/sub messaging with the following stipulations:

- For cluster-mode disabled, pub/sub is fully supported. Events published on the primary cluster of the primary AWS Region are propagated to secondary AWS Regions.
- For cluster mode enabled, the following applies:
• For published events that aren't in a keyspace, only subscribers in the same AWS Region receive the events.
• For published keyspace events, subscribers in all AWS Regions receive the events.

Using global datastores (console)

To create a global datastore using the console, follow this two-step process:

1. Create a primary cluster, either by using an existing cluster or creating a new cluster. The engine must be Redis 5.0.6 or later.
2. Add up to two secondary clusters in different AWS Regions, again using the Redis 5.0.6 engine or later.

The following procedures guide you on how to create a global datastore for Redis and perform other operations using the ElastiCache for Redis console.

Topics
• Creating a global datastore using an existing cluster (p. 234)
• Creating a new global datastore using a new primary cluster (p. 236)
• Viewing global datastore details (p. 237)
• Adding a Region to a global datastore (p. 238)
• Modifying a global datastore (p. 240)
• Promoting the secondary cluster to primary (p. 240)
• Removing a Region from a global datastore (p. 241)
• Deleting a global datastore (p. 241)

Creating a global datastore using an existing cluster

In this scenario, you use an existing cluster to serve as the primary of the new global datastore. You then create a secondary, read-only cluster in a separate AWS Region. This secondary cluster receives automatic and asynchronous updates from the primary cluster.

Important
The existing cluster must use the Redis 5.0.6 engine or later.

To create a global datastore using an existing cluster

2. On the navigation pane, choose Redis and then choose a cluster.
3. For Actions, choose Setup Global Datastore.
4. On the Setup Global Datastore page, do the following:
   • Enter a value for Global Datastore Name suffix: This suffix is used to generate a unique name for the global datastore. You can search for the global datastore by using the suffix that you specify here.
   • (Optional) Enter a Description value.
5. Under Secondary cluster details, choose a different AWS Region where the cluster will be stored.
6. Under Redis settings, enter a value for Name and, optionally, for Description for the cluster.
7. Keep the following options as they are. They're prepopulated to match the primary cluster configuration, you can't change them.
Using global datastores (console)

- Engine version
- Node type
- Parameter group

**Note**
ElastiCache autogenerates a new parameter group from values of the provided parameter group and applies the new parameter group to the cluster. Use this new parameter group to modify parameters on a global datastore. Each autogenerated parameter group is associated with one and only one cluster and, therefore, only one global datastore.

- Number of shards
- Encryption at rest – Enables encryption of data stored on disk. For more information, see Encryption at rest.

**Note**
You can supply a different encryption key by choosing Customer Managed AWS KMS key and choosing the key. For more information, see Using Customer Managed AWS KMS keys.

- Encryption in-transit – Enables encryption of data on the wire. For more information, see Encryption in transit. For Redis engine version 6.0 onwards, if you enable encryption in-transit you are prompted to specify one of the following Access Control options:
  - **No Access Control** – This is the default setting. This indicates no restrictions.
  - **User Group Access Control List** – Choose a user group with a defined set of users and permissions on available operations. For more information, see Managing User Groups with the Console and CLI (p. 496).
  - **Redis AUTH Default User** – An authentication mechanism for Redis server. For more information, see Redis AUTH.

8. (Optional) As needed, update the remaining secondary cluster settings. These are prepopulated with the same values as the primary cluster, but you can update them to meet specific requirements for that cluster.

- Port
- Number of replicas
- Subnet group
- Preferred Availability Zone(s)
- Security groups
- Customer Managed (AWS KMS key)
- Redis AUTH Token
- Enable automatic backups
- Backup retention period
- Backup window
- Maintenance window
- Topic for SNS notification

9. Choose Create. Doing this sets the status of the global datastore to Creating. The status transitions to Modifying after the primary cluster is associated to the global datastore and the secondary cluster is in Associating status.

After the primary cluster and secondary clusters are associated with the global datastore, the status changes to Available. At this point, you have a primary cluster that accepts reads and writes and secondary clusters that accept reads replicated from the primary cluster.

The Redis page is updated to indicate whether a cluster is part of a global datastore, including:
• **Global Datastore** – The name of the global datastore to which the cluster belongs.
• **Global Datastore Role** – The role of the cluster, either primary or secondary.

You can add up to one additional secondary cluster in a different AWS Region. For more information, see Adding a Region to a global datastore (p. 238).

**Creating a new global datastore using a new primary cluster**

If you choose to create a global datastore with a new cluster, use the following procedure.

2. On the navigation pane, choose **Global Datastore** and then choose **Create**.
3. Under **Create Global Datastore**, do the following:
   a. Enter a value for **Global Datastore Name suffix**. ElastiCache uses the suffix to generate a unique name for the global datastore. You can search for the global datastore by using the suffix that you specify here.
   b. (Optional) Enter a value for **Global Datastore Description**.
4. Under **Primary cluster details**, for **Region**, choose an available AWS Region.
5. Follow the steps at Creating a Redis (cluster mode enabled) cluster (console).

   **Note**
   When you select a parameter group to set the engine configuration values, that parameter group is applied to all clusters in the global datastore. On the **Parameter Groups** page, the yes/no **Global** attribute indicates whether a parameter group is part of a global datastore.

6. After you have successfully created the cluster in the previous step, choose **Next** to configure your secondary cluster details, which are outlined in the previous section beginning with Step 5.
7. The following options are prepopulated to match the primary cluster configuration and cannot be changed:
   • Engine version
   • Instance type
   • Node type
   • Number of shards
   • Parameter group

   **Note**
   ElastiCache autogenerates a new parameter group from values of the provided parameter group and applies the new parameter group to the cluster. Use this new parameter group to modify parameters on a global datastore. Each autogenerated parameter group is associated with one and only one cluster and, therefore, only one global datastore.

   • Encryption at rest – Enables encryption of data stored on disk. For more information, see Encryption at rest.

   **Note**
   You can supply a different encryption key by choosing **Customer Managed AWS KMS key** and choosing the key. For more information, see Using Customer Managed AWS KMS keys.

   • Encryption in-transit – Enables encryption of data on the wire. For more information, see Encryption in transit. For Redis engine version 6.4 and above, if you enable encryption in-transit you are prompted to specify one of the following **Access Control** options:

   • **No Access Control** – This is the default setting. This indicates no restrictions on user access to the cluster.
• **User Group Access Control List** – Choose a user group with a defined set of users that can access the cluster. For more information, see Managing User Groups with the Console and CLI (p. 496).

• **Redis AUTH Default User** – An authentication mechanism for Redis server. For more information, see Redis AUTH.

**Note**
For Redis versions between 4.0.2, when Encryption in-transit was first supported, and 6.0.4, Redis AUTH is the sole option.

The remaining secondary cluster settings are pre-populated with the same values as the primary cluster, but the following can be updated to meet specific requirements for that cluster:

• Port
• Number of replicas
• Subnet group
• Preferred Availability Zone(s)
• Security groups
• Customer Managed (AWS KMS key)
• Redis AUTH Token
• Enable automatic backups
• Backup retention period
• Backup window
• Maintenance window
• Topic for SNS notification

8. Choose **Create**. This sets the status of the global datastore to **Creating**. After the primary cluster and secondary clusters are associated with the global datastore, the status changes to **Available**. You have a primary cluster that accepts reads and writes and a secondary cluster that accepts reads replicated from the primary cluster.

The Redis page is also updated to indicate whether a cluster is part of a global datastore, including the following:

• **Global Datastore** – The name of the global datastore to which the cluster belongs.
• **Global Datastore Role** – The role of the cluster, either primary or secondary.

You can add up to one additional secondary cluster in a different AWS Region. For more information, see Adding a Region to a global datastore (p. 238).

**Viewing global datastore details**

You can view the details of existing global datastores and also modify them on the **Global Datastore** page.

**To view global datastore details**

2. On the navigation pane, choose **Global Datastore** and then choose an available global datastore.
• **Global Datastore Name**: The name of the global datastore
• **Description**: A description of the global datastore
• **Status**: Options include:
  • Creating
  • Modifying
  • Available
  • Deleting
  • Primary-Only - This status indicates the global datastore contains only a primary cluster. Either all secondary clusters are deleted or not successfully created.
• **Cluster Mode**: Either enabled or disabled
• **Redis Engine Version**: The Redis engine version running the global datastore
• **Instance Node Type**: The node type used for the global datastore
• **Encryption at-rest**: Either enabled or disabled
• **Encryption in-transit**: Either enabled or disabled
• **Redis AUTH**: Either enabled or disabled

You can make the following changes to the global datastore:
• Adding a Region to a global datastore (p. 238)
• Removing a Region from a global datastore (p. 241)
• Promoting the secondary cluster to primary (p. 240)
• Modifying a global datastore (p. 240)

The Global Datastore page also lists the individual clusters that make up the global datastore and the following properties for each:
• **Region** - The AWS Region where the cluster is stored
• **Role** - Either primary or secondary
• **Cluster name** - The name of the cluster
• **Status** - Options include:
  • **Associating** - The cluster is in the process of being associated to the global datastore
  • **Associated** - The cluster is associated to the global datastore
  • **Disassociating** - The process of removing a secondary cluster from the global datastore using the global datastore name. After this, the secondary cluster no longer receives updates from the primary cluster but it remains as a standalone cluster in that AWS Region.
  • **Disassociated** - The secondary cluster has been removed from the global datastore and is now a standalone cluster in its AWS Region.
• **Global Datastore Replica lag** – Shows one value per secondary AWS Region in the global datastore. This is the lag between the secondary Region's primary node and the primary Region's primary node. For cluster mode enabled Redis, the lag indicates the maximum delay, in seconds, among the shards.

### Adding a Region to a global datastore

You can add up to one additional AWS Region to an existing global datastore. In this scenario, you are creating a read-only cluster in a separate AWS Region that receives automatic and asynchronous updates from the primary cluster.
To add an AWS Region to a global datastore

2. On the navigation pane, choose Global Datastore, and then for Global Datastore Name choose a global datastore.
3. Choose Add Region, and choose the AWS Region where the secondary cluster is to reside.
4. Under Redis settings, enter a value for Name and, optionally, for Description for the cluster.
5. Keep the following options as they are. They're prepopulated to match the primary cluster configuration, and you can't change them.
   - Engine version
   - Instance type
   - Node type
   - Number of shards
   - Parameter group

   **Note**
   ElastiCache autogenerates a new parameter group from values of the provided parameter group and applies the new parameter group to the cluster. Use this new parameter group to modify parameters on a global datastore. Each autogenerated parameter group is associated with one and only one cluster and, therefore, only one global datastore.

   - Encryption at rest

   **Note**
   You can supply a different encryption key by choosing Customer Managed AWS KMS key and choosing the key.

   - Encryption in transit
   - Redis AUTH

6. (Optional) Update the remaining secondary cluster settings. These are prepopulated with the same values as the primary cluster, but you can update them to meet specific requirements for that cluster:
   - Port
   - Number of replicas
   - Subnet group
   - Preferred Availability Zone(s)
   - Security groups
   - Customer Managed AWS KMS key
   - Redis AUTH Token
   - Enable automatic backups
   - Backup retention period
   - Backup window
   - Maintenance window
   - Topic for SNS notification

7. Choose Add.
Modifying a global datastore

You can modify properties of regional clusters. Only one modify operation can be in progress on a global datastore, with the exception of promoting a secondary cluster to primary. For more information, see Promoting the secondary cluster to primary (p. 240).

To modify a global datastore

2. On the navigation pane, choose Global Datastore, and then for Global Datastore Name, choose a global datastore.
3. Choose Modify and choose among the following options:
   - **Modify description** – Update the description of the global datastore
   - **Modify engine version** – Only Redis engine version 5.0.6 or later is available.
   - **Modify node type** – Scale regional clusters both vertically (scaling up and down) and horizontally (scaling in and out). Options include the R5 and M5 node families. For more information on node types, see Supported node types (p. 99).
   - **Modify Automatic Failover** – Enable or disable Automatic Failover. When you enable failover and primary nodes in regional clusters shut down unexpectedly, ElastiCache fails over to one of the regional replicas. For more information, see Auto failover.

   For Redis clusters with cluster-mode enabled:
   - **Add shards** – Enter the number of shards to add and optionally specify one or more Availability Zones.
   - **Delete shards** – Choose shards to be deleted in each AWS Region.
   - **Rebalance shards** – Rebalance the slot distribution to ensure uniform distribution across existing shards in the cluster.

To modify a global datastore's parameters, modify the parameter group of any member cluster for the global datastore. ElastiCache applies this change to all clusters within that global datastore automatically. To modify the parameter group of that cluster, use the Redis console or the ModifyCacheCluster API operation. For more information, see Modifying a parameter group (p. 435). When you modify the parameter group of any cluster contained within a global datastore, it is applied to all the clusters within that global datastore.

To reset an entire parameter group or specific parameters, use the ResetCacheParameterGroup API operation.

Promoting the secondary cluster to primary

If the primary cluster or AWS Region becomes unavailable or is experiencing performance issues, you can promote a secondary cluster to primary. Promotion is allowed anytime, even if other modifications are in progress. You can also issue multiple promotions in parallel and the global datastore resolves to one primary eventually. If you promote multiple secondary clusters simultaneously, ElastiCache for Redis doesn't guarantee which one ultimately resolves to primary.

To promote a secondary cluster to primary

2. On the navigation pane, choose Global Datastore under Redis.
3. Choose the global datastore name to view the details.
4. Choose the Secondary cluster.
5. Choose Promote to primary.

You're then prompted to confirm your decision with the following warning: Promoting a region to primary will make the cluster in this region as read/writeable. Are you sure you want to promote the secondary cluster to primary?

The current primary cluster in primary region will become secondary and will stop accepting writes after this operation completes. Please ensure you update your application stack to direct traffic to the new primary region.

6. Choose Confirm if you want to continue the promotion or Cancel if you don't.

If you choose to confirm, your global datastore moves to a Modifying state and is unavailable until the promotion is complete.

**Removing a Region from a global datastore**

You can remove an AWS Region from a global datastore by using the following procedure.

**To remove an AWS Region from a global datastore**

2. On the navigation pane, choose Global Datastore under Redis.
3. Choose a global datastore.
4. Choose the Region you want to remove.
5. Choose Remove region.

**Note**
This option is only available for secondary clusters.

You're then be prompted to confirm your decision with the following warning: Removing the region will remove your only available cross region replica for the primary cluster. Your primary cluster will no longer be set up for disaster recovery and improved read latency in remote region. Are you sure you want to remove the selected region from the global datastore?

6. Choose Confirm if you want to continue the promotion or Cancel if you don't.

If you choose confirm, the AWS Region is removed and the secondary cluster no longer receives replication updates.

**Deleting a global datastore**

To delete a global datastore, first remove all secondary clusters. For more information, see Removing a Region from a global datastore (p. 241). Doing this leaves the global datastore in primary-only status.

**To delete a global datastore**

2. On the navigation pane, choose Global Datastore under Redis.
3. Under Global Datastore Name choose the global datastore you want to delete and then choose Delete.
You’re then be prompted to confirm your decision with the following warning: Are you sure you want to delete this Global Datastore?

4. Choose **Delete**.

The global datastore transitions to **Deleting** status.

**Using global datastores (CLI)**

You can use the AWS Command Line Interface (AWS CLI) to control multiple AWS services from the command line and automate them through scripts. You can use the AWS CLI for ad hoc (one-time) operations.

**Downloading and configuring the AWS CLI**

The AWS CLI runs on Windows, macOS, or Linux. Use the following procedure to download and configure it.

**To download, install, and configure the CLI**

1. Download the AWS CLI on the [AWS command line interface webpage](https://aws.amazon.com/cli/).
2. Follow the instructions for Installing the AWS CLI and Configuring the AWS CLI in the [AWS Command Line Interface User Guide](https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-install.html).

**Using the AWS CLI with global datastores**

Use the following CLI operations to work with global datastores:

- `create-global-replication-group`

```bash
aws elasticache create-global-replication-group \
   --global-replication-group-id-suffix my global datastore \ 
   --primary-replication-group-id sample-repl-group \ 
   --global-replication-group-description an optional description of the global datastore
```

Amazon ElastiCache automatically applies a prefix to the global datastore ID when it is created. Each AWS Region has its own prefix. For instance, a global datastore ID created in the US West (N. California) Region begins with "virxk" along with the suffix name that you provide. The suffix, combined with the autogenerated prefix, guarantees uniqueness of the global datastore name across multiple Regions.

The following table lists each AWS Region and its global datastore ID prefix.

<table>
<thead>
<tr>
<th>Region Name/Region</th>
<th>Prefix</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio) Region</td>
<td>fpkhr</td>
</tr>
<tr>
<td>us-east-2</td>

</table>

- **create-replication-group** – Use this operation to create secondary clusters for a global datastore by supplying the name of the global datastore to the `--global-replication-group-id` parameter.

```bash
aws elasticache create-replication-group
   --replication-group-id secondary replication group name \
   --replication-group-description "Replication group description" \
   --global-replication-group-id global datastore name
```

When calling this operation and passing in a `--global-replication-group-id` value, ElastiCache for Redis will infer the values from the primary replication group of the global replication group for the following parameters. Do not pass in values for these parameters:

"PrimaryClusterId",
"AutomaticFailoverEnabled",
"NumNodeGroups",
"CacheParameterGroupName",
"CacheNodeType",
"Engine",
"EngineVersion",
"CacheSecurityGroupNames",
"EnableTransitEncryption",
"AtRestEncryptionEnabled",
"SnapshotArns",
"SnapshotName"

- **describe-global-replication-groups**

```bash
aws elasticache describe-global-replication-groups \
   --global-replication-group-id my global datastore \
   --show-member-info an optional parameter that returns a list of the primary and secondary clusters that make up the global datastore
```

- **modify-global-replication-group**

```bash
aws elasticache modify-global-replication-group
```
Using global datastores (CLI)

```
--global-replication-group-id my global datastore
--automatic-failover-enabled
--cache-node-type node type
--cache-parameter-group-name parameter group name
--engine-version engine version
--apply-immediately
--global-replication-group-description description
```

- **delete-global-replication-group**

  ```
  aws elasticache delete-global-replication-group
  --global-replication-group-id my global datastore
  --retain-primary-replication-group defaults to true
  ```

- **disassociate-global-replication-group**

  ```
  aws elasticache disassociate-global-replication-group
  --global-replication-group-id my global datastore
  --replication-group-id my secondary cluster
  --replication-group-region the AWS Region in which the secondary cluster resides
  ```

- **failover-global-replication-group**

  ```
  aws elasticache failover-replication-group
  --global-replication-group-id my global datastore
  --primary-region The AWS Region of the primary cluster
  --primary-replication-group-id The name of the global datastore, including the suffix.
  ```

- **increase-node-groups-in-global-replication-group**

  ```
  aws elasticache increase-node-groups-in-global-replication-group
  --apply-immediately yes
  --global-replication-group-id global-replication-group-name
  --node-group-count 3
  ```

- **decrease-node-groups-in-global-replication-group**

  ```
  aws elasticache decrease-node-groups-in-global-replication-group
  --apply-immediately yes
  --global-replication-group-id global-replication-group-name
  --node-group-count 3
  ```

- **rebalance-shards-in-global-replication-group**

  ```
  aws elasticache rebalance-shards-in-global-replication-group
  --apply-immediately yes
  --global-replication-group-id global-replication-group-name
  ```

Use help to list all available commands ElastiCache for Redis.

```
aws elasticache help
```

You can also use help to describe a specific command and learn more about its usage:

```
aws elasticache create-global-replication-group help
```
High availability using replication groups

Single-node Amazon ElastiCache Redis clusters are in-memory entities with limited data protection services (AOF). If your cluster fails for any reason, you lose all the cluster's data. However, if you're running the Redis engine, you can group 2 to 6 nodes into a cluster with replicas where 1 to 5 read-only nodes contain replicate data of the group's single read/write primary node. In this scenario, if one node fails for any reason, you do not lose all your data since it is replicated in one or more other nodes. Due to replication latency, some data may be lost if it is the primary read/write node that fails.

As seen in the following graphic, the replication structure is contained within a shard (called node group in the API/CLI) which is contained within a Redis cluster. Redis (cluster mode disabled) clusters always have one shard. Redis (cluster mode enabled) clusters can have up to 500 shards with the cluster's data partitioned across the shards. You can create a cluster with higher number of shards and lower number of replicas totaling up to 90 nodes per cluster. This cluster configuration can range from 90 shards and 0 replicas to 15 shards and 5 replicas, which is the maximum number of replicas allowed.

The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526).

For versions below 5.0.6, the limit is 250 per cluster.

To request a limit increase, see AWS Service Limits and choose the limit type Nodes per cluster per instance type.

Redis (cluster mode disabled) cluster has one shard and 0 to 5 replica nodes

If the cluster with replicas has Multi-AZ enabled and the primary node fails, the primary fails over to a read replica. Because the data is updated on the replica nodes asynchronously, there may be some data loss due to latency in updating the replica nodes. For more information, see Mitigating Failures when Running Redis (p. 623).

• Promoting a read replica to primary, for Redis (cluster mode disabled) replication groups (p. 309)
Understanding Redis replication

Redis implements replication in two ways:

- With a single shard that contains all of the cluster's data in each node—Redis (cluster mode disabled)
- With data partitioned across up to 500 shards—Redis (cluster mode enabled)

Each shard in a replication group has a single read/write primary node and up to 5 read-only replica nodes. You can create a cluster with higher number of shards and lower number of replicas totaling up to 90 nodes per cluster. This cluster configuration can range from 90 shards and 0 replicas to 15 shards and 5 replicas, which is the maximum number of replicas allowed.

The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526).

For versions below 5.0.6, the limit is 250 per cluster.

To request a limit increase, see AWS Service Limits and choose the limit type Nodes per cluster per instance type.

Topics
- Redis (Cluster Mode Disabled) (p. 248)
- Redis (cluster mode enabled) (p. 249)

Redis (Cluster Mode Disabled)

A Redis (cluster mode disabled) cluster has a single shard, inside of which is a collection of Redis nodes; one primary read/write node and up to five secondary, read-only replica nodes. Each read replica maintains a copy of the data from the cluster's primary node. Asynchronous replication mechanisms are used to keep the read replicas synchronized with the primary. Applications can read from any node in the cluster. Applications can write only to the primary node. Read replicas improve read throughput and guard against data loss in cases of a node failure.

Redis (cluster mode disabled) cluster with a single shard and replica nodes

You can use Redis (cluster mode disabled) clusters with replica nodes to scale your Redis solution for ElastiCache to handle applications that are read-intensive or to support large numbers of clients that simultaneously read from the same cluster.

All of the nodes in a Redis (cluster mode disabled) cluster must reside in the same region.

When you add a read replica to a cluster, all of the data from the primary is copied to the new node. From that point on, whenever data is written to the primary, the changes are asynchronously propagated to all the read replicas.
To improve fault tolerance and reduce write downtime, enable Multi-AZ with Automatic Failover for your Redis (cluster mode disabled) cluster with replicas. For more information, see Minimizing downtime in ElastiCache for Redis with Multi-AZ (p. 253).

You can change the roles of the nodes within the Redis (cluster mode disabled) cluster, with the primary and one of the replicas exchanging roles. You might decide to do this for performance tuning reasons. For example, with a web application that has heavy write activity, you can choose the node that has the lowest network latency. For more information, see Promoting a read replica to primary, for Redis (cluster mode disabled) replication groups (p. 309).

Redis (cluster mode enabled)

A Redis (cluster mode enabled) cluster is comprised of from 1 to 500 shards (API/CLI: node groups). Each shard has a primary node and up to five read-only replica nodes. The configuration can range from 90 shards and 0 replicas to 15 shards and 5 replicas, which is the maximum number or replicas allowed.

The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526).

For versions below 5.0.6, the limit is 250 per cluster.

To request a limit increase, see AWS Service Limits and choose the limit type Nodes per cluster per instance type.

Each read replica in a shard maintains a copy of the data from the shard's primary. Asynchronous replication mechanisms are used to keep the read replicas synchronized with the primary. Applications can read from any node in the cluster. Applications can write only to the primary nodes. Read replicas enhance read scalability and guard against data loss. Data is partitioned across the shards in a Redis (cluster mode enabled) cluster.

Applications use the Redis (cluster mode enabled) cluster's configuration endpoint to connect with the nodes in the cluster. For more information, see Finding connection endpoints (p. 175).

Redis (cluster mode enabled) cluster with multiple shards and replica nodes

All of the nodes in a Redis (cluster mode enabled) cluster must reside in the same region. To improve fault tolerance, you can provision both primaries and read replicas in multiple Availability Zones within that region.

Currently, in Redis (cluster mode enabled), there are some limitations.

- You cannot manually promote any of the replica nodes to primary.
- You can only change the structure of a cluster, the node type, and the number of nodes by restoring from a backup. For more information, see Restoring from a backup with optional cluster
resizing (p. 334). The number of shards in a Redis (cluster mode enabled) cluster can be changed dynamically, while the cluster continues to serve read and write requests. For more information, see Online resharding and shard rebalancing for Redis (cluster mode enabled) (p. 377).

Replication: Redis (Cluster Mode Disabled) vs. Redis (Cluster Mode Enabled)

Beginning with Redis version 3.2, you have the ability to create one of two distinct types of Redis clusters (API/CLI: replication groups). A Redis (cluster mode disabled) cluster always has a single shard (API/CLI: node group) with up to 5 read replica nodes. A Redis (cluster mode enabled) cluster has up to 500 shards with 1 to 5 read replica nodes in each.

Redis (cluster mode disabled) and Redis (cluster mode enabled) clusters

The following table summarizes important differences between Redis (cluster mode disabled) and Redis (cluster mode enabled) clusters.

### Which should I choose?

When choosing between Redis (cluster mode disabled) or Redis (cluster mode enabled), consider the following factors:

- **Scaling v. partitioning** – Business needs change. You need to either provision for peak demand or scale as demand changes. Redis (cluster mode disabled) supports scaling. You can scale read capacity by adding or deleting replica nodes, or you can scale capacity by scaling up to a larger node type. Both of these operations take time. For more information, see Scaling Redis (Cluster Mode Disabled) clusters with replica nodes (p. 360).

Redis (cluster mode enabled) supports partitioning your data across up to 500 node groups. You can dynamically change the number of shards as your business needs change. One advantage of partitioning is that you spread your load over a greater number of endpoints, which reduces access bottlenecks during peak demand. Additionally, you can accommodate a larger data set since the data can be spread across multiple servers. For information on scaling your partitions, see Scaling clusters in Redis (Cluster Mode Enabled) (p. 375).

- **Node size v. number of nodes** – Because a Redis (cluster mode disabled) cluster has only one shard, the node type must be large enough to accommodate all the cluster's data plus necessary overhead. On the other hand, because you can partition your data across several shards when using a Redis (cluster mode enabled) cluster, the node types can be smaller, though you need more of them. For more information, see Choosing your node size (p. 127).

- **Reads v. writes** – If the primary load on your cluster is applications reading data, you can scale a Redis (cluster mode disabled) cluster by adding and deleting read replicas. However, there is a maximum of
5 read replicas. If the load on your cluster is write-heavy, you can benefit from the additional write endpoints of a Redis (cluster mode enabled) cluster with multiple shards.

Whichever type of cluster you choose to implement, be sure to choose a node type that is adequate for your current and future needs.
Minimizing downtime in ElastiCache for Redis with Multi-AZ

There are a number of instances where ElastiCache for Redis may need to replace a primary node; these include certain types of planned maintenance and the unlikely event of a primary node or Availability Zone failure.

This replacement results in some downtime for the cluster, but if Multi-AZ is enabled, the downtime is minimized. The role of primary node will automatically fail over to one of the read replicas. There is no need to create and provision a new primary node, because ElastiCache will handle this transparently. This failover and replica promotion ensure that you can resume writing to the new primary as soon as promotion is complete.

ElastiCache also propagates the Domain Name Service (DNS) name of the promoted replica. It does so because then if your application is writing to the primary endpoint, no endpoint change is required in your application. If you are reading from individual endpoints, make sure that you change the read endpoint of the replica promoted to primary to the new replica’s endpoint.

In case of planned node replacements initiated due to maintenance updates or self-service updates, be aware of the following:

- For ElastiCache for Redis Cluster, the planned node replacements complete while the cluster serves incoming write requests.
- For Redis Cluster mode disabled clusters with Multi-AZ enabled that run on the 5.0.5 or later engine, the planned node replacements complete while the cluster serves incoming write requests.
- For Redis Cluster mode disabled clusters with Multi-AZ enabled that run on the 5.0.4 or earlier engine, you might notice a brief write interruption associated with DNS updates. This interruption might take up to a few seconds. This process is much faster than recreating and provisioning a new primary, which is what occurs if you don’t enable Multi-AZ.

You can enable Multi-AZ using the ElastiCache Management Console, the AWS CLI, or the ElastiCache API.

Enabling ElastiCache Multi-AZ on your Redis cluster (in the API and CLI, replication group) improves your fault tolerance. This is true particularly in cases where your cluster’s read/write primary cluster becomes unreachable or fails for any reason. Multi-AZ is only supported on Redis clusters that have more than one node in each shard.

Topics
- Enabling Multi-AZ (p. 253)
- Failure scenarios with Multi-AZ responses (p. 257)
- Testing automatic failover (p. 260)
- Limitations on Redis Multi-AZ (p. 263)

Enabling Multi-AZ

You can enable Multi-AZ when you create or modify a cluster (API or CLI, replication group) using the ElastiCache console, AWS CLI, or the ElastiCache API.

You can enable Multi-AZ only on Redis (cluster mode disabled) clusters that have at least one available read replica. Clusters without read replicas do not provide high availability or fault tolerance. For information about creating a cluster with replication, see Creating a Redis replication group (p. 266).
For information about adding a read replica to a cluster with replication, see Adding a read replica, for Redis (Cluster Mode Disabled) replication groups (p. 306).

Topics

- Enabling Multi-AZ (Console) (p. 254)
- Enabling Multi-AZ (AWS CLI) (p. 254)
- Enabling Multi-AZ (ElastiCache API) (p. 255)

Enabling Multi-AZ (Console)

You can enable Multi-AZ using the ElastiCache console when you create a new Redis cluster or by modifying an existing Redis cluster with replication.

Multi-AZ is enabled by default on Redis (cluster mode enabled) clusters.

**Important**

ElastiCache will automatically enable Multi-AZ only if the cluster contains at least one replica in a different Availability Zone from the primary in all shards.

Enabling Multi-AZ when creating a cluster using the ElastiCache console

For more information on this process, see Creating a Redis (cluster mode disabled) cluster (Console) (p. 47). Be sure to have one or more replicas and enable Multi-AZ.

Enabling Multi-AZ on an existing cluster (Console)

For more information on this process, see Modifying a Cluster Using the AWS Management Console (p. 149).

Enabling Multi-AZ (AWS CLI)

The following code example uses the AWS CLI to enable Multi-AZ for the replication group `redis12`.

**Important**

The replication group `redis12` must already exist and have at least one available read replica.

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group \
  --replication-group-id redis12 \
  --automatic-failover-enabled \
  --multi-az-enabled \
  --apply-immediately
```

For Windows:

```bash
aws elasticache modify-replication-group ^ \
  --replication-group-id redis12 ^ \
  --automatic-failover-enabled ^ \
  --multi-az-enabled ^ \
  --apply-immediately
```

The JSON output from this command should look something like the following.

```json
{
  "ReplicationGroup": {
    "Status": "modifying",
    "Description": "One shard, two nodes",
  }
}
Minimizing downtime with Multi-AZ

For more information, see these topics in the AWS CLI Command Reference:

- `create-cache-cluster`
- `create-replication-group`
- `modify-replication-group` in the AWS CLI Command Reference.

### Enabling Multi-AZ (ElastiCache API)

The following code example uses the ElastiCache API to enable Multi-AZ for the replication group `redis12`.

**Note**

To use this example, the replication group `redis12` must already exist and have at least one available read replica.

https://elasticache.us-west-2.amazonaws.com/
For more information, see these topics in the ElastiCache API Reference:

- CreateCacheCluster
- CreateReplicationGroup
- ModifyReplicationGroup
Minimizing downtime with Multi-AZ

Failure scenarios with Multi-AZ responses

Before the introduction of Multi-AZ, ElastiCache detected and replaced a cluster's failed nodes by recreating and reprovisioning the failed node. If you enable Multi-AZ, a failed primary node fails over to the replica with the least replication lag. The selected replica is automatically promoted to primary, which is much faster than creating and reprovisioning a new primary node. This process usually takes just a few seconds until you can write to the cluster again.

When Multi-AZ is enabled, ElastiCache continually monitors the state of the primary node. If the primary node fails, one of the following actions is performed depending on the type of failure.

Topics

- Failure scenarios when only the primary node fails (p. 257)
- Failure scenarios when the primary node and some read replicas fail (p. 258)
- Failure scenarios when the entire cluster fails (p. 258)

Failure scenarios when only the primary node fails

If only the primary node fails, the read replica with the least replication lag is promoted to primary. A replacement read replica is then created and provisioned in the same Availability Zone as the failed primary.

When only the primary node fails, ElastiCache Multi-AZ does the following:

1. The failed primary node is taken offline.
2. The read replica with the least replication lag is promoted to primary.

   Writes can resume as soon as the promotion process is complete, typically just a few seconds. If your application is writing to the primary endpoint, you don't need to change the endpoint for writes or reads. ElastiCache propagates the DNS name of the promoted replica.

3. A replacement read replica is launched and provisioned.

   The replacement read replica is launched in the Availability Zone that the failed primary node was in so that the distribution of nodes is maintained.

4. The replicas sync with the new primary node.

After the new replica is available, be aware of these effects:

- **Primary endpoint** – You don't need to make any changes to your application, because the DNS name of the new primary node is propagated to the primary endpoint.
- **Read endpoint** – The reader endpoint is automatically updated to point to the new replica nodes.

For information about finding the endpoints of a cluster, see the following topics:

- Finding a Redis (Cluster Mode Disabled) Cluster's Endpoints (Console) (p. 176)
- Finding the Endpoints for Replication Groups (AWS CLI) (p. 181)
- Finding Endpoints for Replication Groups (ElastiCache API) (p. 183)
Failure scenarios when the primary node and some read replicas fail

If the primary and at least one read replica fails, the available replica with the least replication lag is promoted to primary cluster. New read replicas are also created and provisioned in the same Availability Zones as the failed nodes and replica that was promoted to primary.

When the primary node and some read replicas fail, ElastiCache Multi-AZ does the following:

1. The failed primary node and failed read replicas are taken offline.
2. The available replica with the least replication lag is promoted to primary node.

   Writes can resume as soon as the promotion process is complete, typically just a few seconds. If your application is writing to the primary endpoint, there is no need to change the endpoint for writes. ElastiCache propagates the DNS name of the promoted replica.
3. Replacement replicas are created and provisioned.

   The replacement replicas are created in the Availability Zones of the failed nodes so that the distribution of nodes is maintained.
4. All clusters sync with the new primary node.

Make the following changes to your application after the new nodes are available:

- **Primary endpoint** – Don’t make any changes to your application. The DNS name of the new primary node is propagated to the primary endpoint.
- **Read endpoint** – The read endpoint is automatically updated to point to the new replica nodes.

For information about finding the endpoints of a replication group, see the following topics:

- Finding a Redis (Cluster Mode Disabled) Cluster's Endpoints (Console) (p. 176)
- Finding the Endpoints for Replication Groups (AWS CLI) (p. 181)
- Finding Endpoints for Replication Groups (ElastiCache API) (p. 183)

Failure scenarios when the entire cluster fails

If everything fails, all the nodes are recreated and provisioned in the same Availability Zones as the original nodes.

In this scenario, all the data in the cluster is lost due to the failure of every node in the cluster. This occurrence is rare.

When the entire cluster fails, ElastiCache Multi-AZ does the following:

1. The failed primary node and read replicas are taken offline.
2. A replacement primary node is created and provisioned.
3. Replacement replicas are created and provisioned.

   The replacements are created in the Availability Zones of the failed nodes so that the distribution of nodes is maintained.

   Because the entire cluster failed, data is lost and all the new nodes start cold.

Because each of the replacement nodes has the same endpoint as the node it's replacing, you don't need to make any endpoint changes in your application.
For information about finding the endpoints of a replication group, see the following topics:

- Finding a Redis (Cluster Mode Disabled) Cluster's Endpoints (Console) (p. 176)
- Finding the Endpoints for Replication Groups (AWS CLI) (p. 181)
- Finding Endpoints for Replication Groups (ElastiCache API) (p. 183)

We recommend that you create the primary node and read replicas in different Availability Zones to raise your fault tolerance level.
Testing automatic failover

After you enable automatic failover, you can test it using the ElastiCache console, the AWS CLI, and the ElastiCache API.

When testing, note the following:

- You can use this operation to test automatic failover on up to five shards (called node groups in the ElastiCache API and AWS CLI) in any rolling 24-hour period.
- If you call this operation on shards in different clusters (called replication groups in the API and CLI), you can make the calls concurrently.
- In some cases, you might call this operation multiple times on different shards in the same Redis (cluster mode enabled) replication group. In such cases, the first node replacement must complete before a subsequent call can be made.
- To determine whether the node replacement is complete, check events using the Amazon ElastiCache console, the AWS CLI, or the ElastiCache API. Look for the following events related to automatic failover, listed here in order of likely occurrence:
  1. Replication group message: Test Failover API called for node group <node-group-id>
  2. Cache cluster message: Failover from primary node <primary-node-id> to replica node <node-id> completed
  3. Replication group message: Failover from primary node <primary-node-id> to replica node <node-id> completed
  4. Cache cluster message: Recovering cache nodes <node-id>
  5. Cache cluster message: Finished recovery for cache nodes <node-id>

For more information, see the following:
- Viewing ElastiCache events (p. 611) in the ElastiCache User Guide
- DescribeEvents in the ElastiCache API Reference
- describe-events in the AWS CLI Command Reference.

This API is designed for testing the behavior of your application in case of ElastiCache failover. It is not designed to be an operational tool for initiating a failover to address an issue with the cluster. Moreover, in certain conditions such as large-scale operational events, AWS may block this API.

Topics

- Testing automatic failover using the AWS Management Console (p. 260)
- Testing automatic failover using the AWS CLI (p. 261)
- Testing automatic failover using the ElastiCache API (p. 263)

Testing automatic failover using the AWS Management Console

Use the following procedure to test automatic failover with the console.

To test automatic failover

2. In the navigation pane, choose Redis.
3. From the list of Redis clusters, choose the box to the left of the cluster you want to test. This cluster must have at least one read replica node.
4. In the Details area, confirm that this cluster is Multi-AZ enabled. If the cluster isn't Multi-AZ enabled, either choose a different cluster or modify this cluster to enable Multi-AZ. For more information, see Using the AWS Management Console (p. 149).

![Cluster Details](image)

5. For Redis (cluster mode disabled), choose the cluster's name.

   For Redis (cluster mode enabled), do the following:
   a. Choose the cluster's name.
   b. On the Shards page, for the shard (called node group in the API and CLI) on which you want to test failover, choose the shard's name.

6. On the Nodes page, choose Failover Primary.

7. Choose Continue to fail over the primary, or Cancel to cancel the operation and not fail over the primary node.

   During the failover process, the console continues to show the node's status as available. To track the progress of your failover test, choose Events from the console navigation pane. On the Events tab, watch for events that indicate your failover has started (Test Failover API called) and completed (Recovery completed).

**Testing automatic failover using the AWS CLI**

You can test automatic failover on any Multi-AZ enabled cluster using the AWS CLI operation test-failover.

**Parameters**

- `--replication-group-id` – Required. The replication group (on the console, cluster) that is to be tested.
- `--node-group-id` – Required. The name of the node group you want to test automatic failover on. You can test a maximum of five node groups in a rolling 24-hour period.

The following example uses the AWS CLI to test automatic failover on the node group `redis00-0003` in the Redis (cluster mode enabled) cluster `redis00`.

**Example Test automatic failover**

For Linux, macOS, or Unix:

```
aws elasticache test-failover \
```
--replication-group-id redis00 
--node-group-id redis00-0003

For Windows:

```bash
aws elasticache test-failover ^
   --replication-group-id redis00 ^
   --node-group-id redis00-0003
```

Output from the preceding command looks something like the following.

```json
{
   "ReplicationGroup": {
      "Status": "available",
      "Description": "1 shard, 3 nodes (1 + 2 replicas)",
      "NodeGroups": [

      "SnapshotRetentionLimit": 1
   }
}
```
To track the progress of your failover, use the AWS CLI `describe-events` operation.

For more information, see the following:

### Testing automatic failover using the ElastiCache API

You can test automatic failover on any cluster enabled with Multi-AZ using the ElastiCache API operation `TestFailover`.

**Parameters**

- **ReplicationGroupId** – Required. The replication group (on the console, cluster) to be tested.
- **NodeGroupId** – Required. The name of the node group that you want to test automatic failover on. You can test a maximum of five node groups in a rolling 24-hour period.

The following example tests automatic failover on the node group `redis00-0003` in the replication group (on the console, cluster) `redis00`.

**Example Testing automatic failover**

```plaintext
https://elasticache.us-west-2.amazonaws.com/
?Action=TestFailover
&ReplicationGroupId=redis00
&NodeGroupId=redis00-0003
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20140401T192317Z
&X-Amz-Credential=<credential>
```

To track the progress of your failover, use the ElastiCache `DescribeEvents` API operation.

For more information, see the following:

- [TestFailover](https://elasticache.amazonaws.com/) in the ElastiCache API Reference
- [DescribeEvents](https://elasticache.amazonaws.com/) in the ElastiCache API Reference

### Limitations on Redis Multi-AZ

Be aware of the following limitations for Redis Multi-AZ:
• Multi-AZ is supported on Redis version 2.8.6 and later.
• Redis Multi-AZ isn't supported on T1 node types.
• Redis replication is asynchronous. Therefore, when a primary node fails over to a replica, a small amount of data might be lost due to replication lag.

When choosing the replica to promote to primary, ElastiCache for Redis chooses the replica with the least replication lag. In other words, it chooses the replica that is most current. Doing so helps minimize the amount of lost data. The replica with the least replication lag can be in the same or different Availability Zone from the failed primary node.

• When you manually promote read replicas to primary on Redis (cluster mode disabled), you can do so only when Multi-AZ and automatic failover are disabled. To promote a read replica to primary, take the following steps:
  1. Disable Multi-AZ on the cluster.
  2. Disable automatic failover on the cluster. You can do this using the Redis console by clearing the Auto failover check box for the replication group. You can do this using the AWS CLI by setting the AutomaticFailoverEnabled property to false when calling the ModifyReplicationGroup operation.
  3. Promote the read replica to primary.
  4. Re-enable Multi-AZ.
• ElastiCache for Redis Multi-AZ and append-only file (AOF) are mutually exclusive. If you enable one, you can't enable the other.
• A node's failure can be caused by the rare event of an entire Availability Zone failing. In this case, the replica replacing the failed primary is created only when the Availability Zone is back up. For example, consider a replication group with the primary in AZ-a and replicas in AZ-b and AZ-c. If the primary fails, the replica with the least replication lag is promoted to primary cluster. Then, ElastiCache creates a new replica in AZ-a (where the failed primary was located) only when AZ-a is back up and available.
• A customer-initiated reboot of a primary doesn't trigger automatic failover. Other reboots and failures do trigger automatic failover.
• When the primary is rebooted, it's cleared of data when it comes back online. When the read replicas see the cleared primary cluster, they clear their copy of the data, which causes data loss.
• After a read replica has been promoted, the other replicas sync with the new primary. After the initial sync, the replicas' content is deleted and they sync the data from the new primary. This sync process causes a brief interruption, during which the replicas are not accessible. The sync process also causes a temporary load increase on the primary while syncing with the replicas. This behavior is native to Redis and isn't unique to ElastiCache Multi-AZ. For details about this Redis behavior, see Replication on the Redis website.

Important
For Redis version 2.8.22 and later, you can't create external replicas. For Redis versions before 2.8.22, we recommend that you don't connect an external Redis replica to an ElastiCache for Redis cluster that is Multi-AZ enabled. This unsupported configuration can create issues that prevent ElastiCache from properly performing failover and recovery. To connect an external Redis replica to an ElastiCache cluster, make sure that Multi-AZ isn't enabled before you make the connection.
How synchronization and backup are implemented

All supported versions of Redis support backup and synchronization between the primary and replica nodes. However, the way that backup and synchronization is implemented varies depending on the Redis version.

Redis Version 2.8.22 and Later

Redis replication, in versions 2.8.22 and later, choose between two methods. For more information, see Redis Versions Before 2.8.22 (p. 265) and Backup and restore for ElastiCache for Redis (p. 310).

During the forkless process, if the write loads are heavy, writes to the cluster are delayed to ensure that you don't accumulate too many changes and thus prevent a successful snapshot.

Redis Versions Before 2.8.22

Redis backup and synchronization in versions before 2.8.22 is a three-step process.

1. Fork, and in the background process, serialize the cluster data to disk. This creates a point-in-time snapshot.
2. In the foreground, accumulate a change log in the client output buffer.
   
   **Important**  
   If the change log exceeds the client output buffer size, the backup or synchronization fails. For more information, see Ensuring that you have enough memory to create a Redis snapshot (p. 221).
3. Finally, transmit the cache data and then the change log to the replica node.
Creating a Redis replication group

You have the following options for creating a cluster with replica nodes. One applies when you already have an available Redis (cluster mode disabled) cluster not associated with any cluster that has replicas to use as the primary node. The other applies when you need to create a primary node with the cluster and read replicas. Currently, a Redis (cluster mode enabled) cluster must be created from scratch.

**Option 1:** Creating a Replication Group Using an Available Redis (Cluster Mode Disabled) Cluster (p. 267)

Use this option to leverage an existing single-node Redis (cluster mode disabled) cluster. You specify this existing node as the primary node in the new cluster, and then individually add 1 to 5 read replicas to the cluster. If the existing cluster is active, read replicas synchronize with it as they are created. See Creating a Replication Group Using an Available Redis (Cluster Mode Disabled) Cluster (p. 267).

**Important**

You cannot create a Redis (cluster mode enabled) cluster using an existing cluster. To create a Redis (cluster mode enabled) cluster (API/CLI: replication group) using the ElastiCache console, see Creating a Redis (cluster mode enabled) cluster (Console) (p. 133).

**Option 2:** Creating a Redis replication group from scratch (p. 272)

Use this option if you don't already have an available Redis (cluster mode disabled) cluster to use as the cluster's primary node, or if you want to create a Redis (cluster mode enabled) cluster. See Creating a Redis replication group from scratch (p. 272).
Creating a Replication Group Using an Available Redis (Cluster Mode Disabled) Cluster

An available cluster is an existing single-node Redis cluster. Currently, Redis (cluster mode enabled) does not support creating a cluster with replicas using an available single-node cluster. If you want to create a Redis (cluster mode enabled) cluster, see Creating a Redis (Cluster Mode Enabled) cluster (Console) (p. 280).

The following procedure can only be used if you have a Redis (cluster mode disabled) single-node cluster. This cluster's node becomes the primary node in the new cluster. If you do not have a Redis (cluster mode disabled) cluster that you can use as the new cluster's primary, see Creating a Redis replication group from scratch (p. 272).

Creating a Replication Group Using an Available Redis Cluster (Console)

See the topic Using the AWS Management Console (p. 152).

Creating a replication group using an available Redis cache cluster (AWS CLI)

There are two steps to creating a replication group with read replicas when using an available Redis Cache Cluster for the primary when using the AWS CLI.

When using the AWS CLI you create a replication group specifying the available standalone node as the cluster's primary node, --primary-cluster-id and the number of nodes you want in the cluster using the CLI command, create-replication-group. Include the following parameters.

--replication-group-id

The name of the replication group you are creating. The value of this parameter is used as the basis for the names of the added nodes with a sequential 3-digit number added to the end of the --replication-group-id. For example, sample-repl-group-001.

Redis (cluster mode disabled) replication group naming constraints are as follows:
- Must contain 1–40 alphanumeric characters or hyphens.
- Must begin with a letter.
- Can't contain two consecutive hyphens.
- Can't end with a hyphen.

--replication-group-description

Description of the replication group.

--num-node-groups

The number of nodes you want in this cluster. This value includes the primary node. This parameter has a maximum value of six.

--primary-cluster-id

The name of the available Redis (cluster mode disabled) cluster's node that you want to be the primary node in this replication group.

The following command creates the replication group sample-repl-group using the available Redis (cluster mode disabled) cluster redis01 as the replication group's primary node. It creates 2 new nodes which are read replicas. The settings of redis01 (that is, parameter group, security group, node type, engine version, and so on.) will be applied to all nodes in the replication group.

For Linux, macOS, or Unix:

API Version 2015-02-02
267
Creating a replication group

aws elasticache create-replication-group \
  --replication-group-id sample-repl-group \
  --replication-group-description "demo cluster with replicas" \
  --num-cache-clusters 3 \
  --primary-cluster-id redis01

For Windows:

aws elasticache create-replication-group ^
  --replication-group-id sample-repl-group ^
  --replication-group-description "demo cluster with replicas" ^
  --num-cache-clusters 3 ^
  --primary-cluster-id redis01

For additional information and parameters you might want to use, see the AWS CLI topic create-replication-group.

Next, add read replicas to the replication group

After the replication group is created, add one to five read replicas to it using the create-cache-cluster command, being sure to include the following parameters.

--cache-cluster-id

The name of the cluster you are adding to the replication group.

Cluster naming constraints are as follows:
- Must contain 1–40 alphanumeric characters or hyphens.
- Must begin with a letter.
- Can't contain two consecutive hyphens.
- Can't end with a hyphen.

--replication-group-id

The name of the replication group to which you are adding this cache cluster.

Repeat this command for each read replica you want to add to the replication group, changing only the value of the --cache-cluster-id parameter.

Note

Remember, a replication group cannot have more than five read replicas. Attempting to add a read replica to a replication group that already has five read replicas causes the operation to fail.

The following code adds the read replica my-replica01 to the replication group sample-repl-group. The settings of the primary cluster–parameter group, security group, node type, and so on.--will be applied to nodes as they are added to the replication group.

For Linux, macOS, or Unix:

aws elasticache create-cache-cluster \
  --cache-cluster-id my-replica01 \
  --replication-group-id sample-repl-group

For Windows:

aws elasticache create-cache-cluster ^
Output from this command will look something like this.

```json
{
  "ReplicationGroup": {
    "Status": "creating",
    "Description": "demo cluster with replicas",
    "ClusterEnabled": false,
    "ReplicationGroupId": "sample-repl-group",
    "SnapshotRetentionLimit": 1,
    "AutomaticFailover": "disabled",
    "SnapshotWindow": "00:00-01:00",
    "SnapshottingClusterId": "redis01",
    "MemberClusters": [
      "sample-repl-group-001",
      "sample-repl-group-002",
      "redis01"
    ],
    "CacheNodeType": "cache.m4.large",
    "DataTiering": "disabled"
  },
  "PendingModifiedValues": {}
}
```

For additional information, see the AWS CLI topics:

- create-replication-group
- modify-replication-group

## Adding replicas to a standalone Redis (Cluster Mode Disabled) cluster (ElastiCache API)

When using the ElastiCache API, you create a replication group specifying the available standalone node as the cluster's primary node, `PrimaryClusterId` and the number of nodes you want in the cluster using the CLI command, `CreateReplicationGroup`. Include the following parameters.

### ReplicationGroupId

The name of the replication group you are creating. The value of this parameter is used as the basis for the names of the added nodes with a sequential 3-digit number added to the end of the `ReplicationGroupId`. For example, `sample-repl-group-001`.

Redis (cluster mode disabled) replication group naming constraints are as follows:

- Must contain 1–40 alphanumeric characters or hyphens.
- Must begin with a letter.
- Can't contain two consecutive hyphens.
- Can't end with a hyphen.

### ReplicationGroupDescription

Description of the cluster with replicas.

### NumCacheClusters

The number of nodes you want in this cluster. This value includes the primary node. This parameter has a maximum value of six.
PrimaryClusterId

The name of the available Redis (cluster mode disabled) cluster that you want to be the primary node in this cluster.

The following command creates the cluster with replicas sample-repl-group using the available Redis (cluster mode disabled) cluster redis01 as the replication group's primary node. It creates 2 new nodes which are read replicas. The settings of redis01 (that is, parameter group, security group, node type, engine version, and so on.) will be applied to all nodes in the replication group.

https://elasticache.us-west-2.amazonaws.com/
?Action=CreateReplicationGroup
&Engine=redis
&EngineVersion=3.2.4
&ReplicationGroupDescription=Demo%20cluster%20with%20replicas
&ReplicationGroupId=sample-repl-group
&PrimaryClusterId=redis01
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>

For additional information, see the ElastiCache APL topics:

- CreateReplicationGroup
- ModifyReplicationGroup

Next, add read replicas to the replication group

After the replication group is created, add one to five read replicas to it using the CreateCacheCluster operation, being sure to include the following parameters.

CacheClusterId

The name of the cluster you are adding to the replication group.

Cluster naming constraints are as follows:

- Must contain 1–40 alphanumeric characters or hyphens.
- Must begin with a letter.
- Can't contain two consecutive hyphens.
- Can't end with a hyphen.

ReplicationGroupId

The name of the replication group to which you are adding this cache cluster.

Repeat this operation for each read replica you want to add to the replication group, changing only the value of the CacheClusterId parameter.

The following code adds the read replica myReplica01 to the replication group myReplGroup The settings of the primary cluster–parameter group, security group, node type, and so on.–will be applied to nodes as they are added to the replication group.

https://elasticache.us-west-2.amazonaws.com/
?Action=CreateCacheCluster
Creating a replication group

```
&CacheClusterId=myReplica01
&ReplicationGroupId=myReplGroup
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2015-02-02
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
&X-Amz-Credential=[your-access-key-id]/20150202/us-west-2/elasticache/aws4_request
&X-Amz-Date=20150202T170651Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=[signature-value]
```

For additional information and parameters you might want to use, see the ElastiCache API topic [CreateCacheCluster](#).
Creating a Redis replication group from scratch

Following, you can find how to create a Redis replication group without using an existing Redis cluster as the primary. You can create a Redis (cluster mode disabled) or Redis (cluster mode enabled) replication group from scratch using the ElastiCache console, the AWS CLI, or the ElastiCache API.

Before you continue, decide whether you want to create a Redis (cluster mode disabled) or a Redis (cluster mode enabled) replication group. For guidance in deciding, see Replication: Redis (Cluster Mode Disabled) vs. Redis (Cluster Mode Enabled) (p. 250).

Topics
- Creating a Redis (Cluster Mode Disabled) replication group from scratch (p. 273)
- Creating a replication group in Redis (Cluster Mode Enabled) from scratch (p. 280)
Creating a Redis (Cluster Mode Disabled) replication group from scratch

You can create a Redis (cluster mode disabled) replication group from scratch using the ElastiCache console, the AWS CLI, or the ElastiCache API. A Redis (cluster mode disabled) replication group always has one node group, a primary cluster, and up to five read replicas. Redis (cluster mode disabled) replication groups don't support partitioning your data.

Note

The node/shard limit can be increased to a maximum of 500 per cluster. To request a limit increase, see AWS Service Limits and include the instance type in the request.

To create a Redis (cluster mode disabled) replication group from scratch, take one of the following approaches:

Creating a Redis (Cluster Mode Disabled) replication group from scratch (AWS CLI)

The following procedure creates a Redis (cluster mode disabled) replication group using the AWS CLI.

When you create a Redis (cluster mode disabled) replication group from scratch, you create the replication group and all its nodes with a single call to the AWS CLI create-replication-group command. Include the following parameters.

--replication-group-id

The name of the replication group you are creating.

Redis (cluster mode disabled) replication group naming constraints are as follows:

• Must contain 1–40 alphanumeric characters or hyphens.
• Must begin with a letter.
• Can't contain two consecutive hyphens.
• Can't end with a hyphen.

--replication-group-description

Description of the replication group.

--num-cache-clusters

The number of nodes you want created with this replication group, primary and read replicas combined.

If you enable Multi-AZ (--automatic-failover-enabled), the value of --num-cache-clusters must be at least 2.

--cache-node-type

The node type for each node in the replication group.

ElastiCache supports the following node types. Generally speaking, the current generation types provide more memory and computational power at lower cost when compared to their equivalent previous generation counterparts.

For more information on performance details for each node type, see Amazon EC2 Instance Types.

• General purpose:
  • Current generation:

M6g node types (available only for Redis engine version 5.0.6 onward).

  cache.m6g.large, cache.m6g.xlarge, cache.m6g.2xlarge, cache.m6g.4xlarge, cache.m6g.8xlarge, cache.m6g.12xlarge, cache.m6g.16xlarge
Creating a replication group

Note
For region availability, see Supported node types by AWS Region (p. 101).

M5 node types: cache.m5.large, cache.m5.xlarge, cache.m5.2xlarge, cache.m5.4xlarge, cache.m5.12xlarge, cache.m5.24xlarge

M4 node types: cache.m4.large, cache.m4.xlarge, cache.m4.2xlarge, cache.m4.4xlarge, cache.m4.10xlarge

T4g node types (available only for Redis engine version 5.0.6 onward).

T3 node types: cache.t3.micro, cache.t3.small, cache.t3.medium

T2 node types: cache.t2.micro, cache.t2.small, cache.t2.medium

• Previous generation: (not recommended. Existing clusters are still supported but creation of new clusters is not supported for these types.)

T1 node types: cache.t1.micro

M1 node types: cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge

M3 node types: cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge

• Compute optimized:

• Previous generation: (not recommended)

C1 node types: cache.c1.xlarge

• Memory optimized with data tiering:

• Current generation:

R6gd node types (available only for Redis engine version 6.2 onward). For more information, see Data tiering (p. 121).

R6g node types: cache.r6g.large, cache.r6g.xlarge, cache.r6g.2xlarge, cache.r6g.4xlarge, cache.r6g.8xlarge, cache.r6g.12xlarge, cache.r6g.16xlarge

• Memory optimized:

• Current generation:

(R6g node types are available only for Redis engine version 5.0.6 onward.)

R5 node types: cache.r5.large, cache.r5.xlarge, cache.r5.2xlarge, cache.r5.4xlarge, cache.r5.12xlarge, cache.r5.24xlarge

R4 node types: cache.r4.large, cache.r4.xlarge, cache.r4.2xlarge, cache.r4.4xlarge, cache.r4.8xlarge, cache.r4.16xlarge

• Previous generation: (not recommended)

M2 node types: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge
**R3 node types:** cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge

---data-tiering-enabled

Set this parameter if you are using an r6gd node type. If you don't want data tiering, set --no-data-tiering-enabled. For more information, see Data tiering (p. 121).

---cache-parameter-group

Specify a parameter group that corresponds to your engine version. If you are running Redis 3.2.4 or later, specify the default.redis3.2 parameter group or a parameter group derived from default.redis3.2 to create a Redis (cluster mode disabled) replication group. For more information, see Redis-specific parameters (p. 441).

---engine

redis

---engine-version

To have the richest set of features, choose the latest engine version.

The names of the nodes will be derived from the replication group name by postpending -00# to the replication group name. For example, using the replication group name myReplGroup, the name for the primary will be myReplGroup-001 and the read replicas myReplGroup-002 through myReplGroup-006.

If you want to enable in-transit or at-rest encryption on this replication group, add either or both of the --transit-encryption-enabled or --at-rest-encryption-enabled parameters and meet the following conditions.

- Your replication group must be running Redis version 3.2.6 or 4.0.10.
- The replication group must be created in an Amazon VPC.
- You must also include the parameter --cache-subnet-group.
- You must also include the parameter --auth-token with the customer specified string value for your AUTH token (password) needed to perform operations on this replication group.

The following operation creates a Redis (cluster mode disabled) replication group sample-repl-group with three nodes, a primary and two replicas.

For Linux, macOS, or Unix:

```bash
aws elasticsearch create-replication-group \
  --replication-group-id sample-repl-group \
  --replication-group-description "Demo cluster with replicas" \
  --num-cache-clusters 3 \
  --cache-node-type cache.m4.large \
  --cache-parameter-group default.redis3.2 \
  --engine redis \
  --engine-version 3.2.4
```

For Windows:

```bash
aws elasticsearch create-replication-group ^
  --replication-group-id sample-repl-group ^
  --replication-group-description "Demo cluster with replicas" ^
  --num-cache-clusters 3 ^
```
Creating a replication group

Output from the this command is something like this.

```json
{
  "ReplicationGroup": {
    "Status": "creating",
    "Description": "Demo cluster with replicas",
    "ClusterEnabled": false,
    "ReplicationGroupId": "sample-repl-group",
    "SnapshotRetentionLimit": 0,
    "AutomaticFailover": "disabled",
    "SnapshotWindow": "01:30-02:30",
    "MemberClusters": [
      "sample-repl-group-001",
      "sample-repl-group-002",
      "sample-repl-group-003"
    ],
    "CacheNodeType": "cache.m4.large",
    "DataTiering": "disabled"
    "PendingModifiedValues": {}
  }
}
```

For additional information and parameters you might want to use, see the AWS CLI topic create-replication-group.

Creating a Redis (cluster mode disabled) replication group from scratch (ElastiCache API)

The following procedure creates a Redis (cluster mode disabled) replication group using the ElastiCache API.

When you create a Redis (cluster mode disabled) replication group from scratch, you create the replication group and all its nodes with a single call to the ElastiCache API CreateReplicationGroup operation. Include the following parameters.

ReplicationGroupId

The name of the replication group you are creating.

Redis (cluster mode enabled) replication group naming constraints are as follows:
- Must contain 1–40 alphanumeric characters or hyphens.
- Must begin with a letter.
- Can't contain two consecutive hyphens.
- Can't end with a hyphen.

ReplicationGroupDescription

Your description of the replication group.

NumCacheClusters

The total number of nodes you want created with this replication group, primary and read replicas combined.

If you enable Multi-AZ (AutomaticFailoverEnabled=true), the value of NumCacheClusters must be at least 2.
CacheNodeType

The node type for each node in the replication group.

ElastiCache supports the following node types. Generally speaking, the current generation types provide more memory and computational power at lower cost when compared to their equivalent previous generation counterparts.

For more information on performance details for each node type, see Amazon EC2 Instance Types.

- General purpose:
  - Current generation:
    - **M6g node types** (available only for Redis engine version 5.0.6 onward).
      
      cache.m6g.large, cache.m6g.xlarge, cache.m6g.2xlarge, cache.m6g.4xlarge, cache.m6g.8xlarge, cache.m6g.12xlarge, cache.m6g.16xlarge
    
    **Note**
    
    For region availability, see Supported node types by AWS Region (p. 101).

      - **M5 node types**: cache.m5.large, cache.m5.xlarge, cache.m5.2xlarge, cache.m5.4xlarge, cache.m5.12xlarge, cache.m5.24xlarge
      - **M4 node types**: cache.m4.large, cache.m4.xlarge, cache.m4.2xlarge, cache.m4.4xlarge, cache.m4.10xlarge

    - **T4g node types** (available only for Redis engine version 5.0.6 onward).
      
      cache.t4g.micro, cache.t4g.small, cache.t4g.medium

    - **T3 node types**: cache.t3.micro, cache.t3.small, cache.t3.medium

    - **T2 node types**: cache.t2.micro, cache.t2.small, cache.t2.medium
  
  - Previous generation: (not recommended. Existing clusters are still supported but creation of new clusters is not supported for these types.)

    - **T1 node types**: cache.t1.micro
    
    - **M1 node types**: cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
    
    - **M3 node types**: cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge
  
  - Compute optimized:
  
    - Previous generation: (not recommended)

    - **C1 node types**: cache.c1.xlarge
  
  - Memory optimized with data tiering:
  
    - Current generation:

      - **R6gd node types** (available only for Redis engine version 6.2 onward). For more information, see Data tiering (p. 121).
      
      cache.r6gd.xlarge, cache.r6gd.2xlarge, cache.r6gd.4xlarge, cache.r6gd.8xlarge, cache.r6gd.12xlarge, cache.r6gd.16xlarge
  
  - Memory optimized:
  
    - Current generation:

      - (**R6g node types** are available only for Redis engine version 5.0.6 onward.)
R6g node types: cache.r6g.large, cache.r6g.xlarge, cache.r6g.2xlarge, cache.r6g.4xlarge, cache.r6g.8xlarge, cache.r6g.12xlarge, cache.r6g.16xlarge, cache.r6g.24xlarge

Note
For region availability, see Supported node types by AWS Region (p. 101).

R5 node types: cache.r5.large, cache.r5.xlarge, cache.r5.2xlarge, cache.r5.4xlarge, cache.r5.12xlarge, cache.r5.24xlarge

R4 node types: cache.r4.large, cache.r4.xlarge, cache.r4.2xlarge, cache.r4.4xlarge, cache.r4.8xlarge, cache.r4.16xlarge

• Previous generation: (not recommended)

M2 node types: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

R3 node types: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge

--data-tiering-enabled

Set this parameter if you are using an r6gd node type. If you don't want data tiering, set --no-data-tiering-enabled. For more information, see Data tiering (p. 121).

CacheParameterGroup

Specify a parameter group that corresponds to your engine version. If you are running Redis 3.2.4 or later, specify the default.redis3.2 parameter group or a parameter group derived from default.redis3.2 to create a Redis (cluster mode disabled) replication group. For more information, see Redis-specific parameters (p. 441).

Engine

redis

EngineVersion

3.2.4

The names of the nodes will be derived from the replication group name by postpending -00# to the replication group name. For example, using the replication group name myReplGroup, the name for the primary will be myReplGroup-001 and the read replicas myReplGroup-002 through myReplGroup-006.

If you want to enable in-transit or at-rest encryption on this replication group, add either or both of the TransitEncryptionEnabled=true or AtRestEncryptionEnabled=true parameters and meet the following conditions.

• Your replication group must be running Redis version 3.2.6 or 4.0.10.
• The replication group must be created in an Amazon VPC.
• You must also include the parameter CacheSubnetGroup.
• You must also include the parameter AuthToken with the customer specified string value for your AUTH token (password) needed to perform operations on this replication group.

The following operation creates the Redis (cluster mode disabled) replication group myReplGroup with three nodes, a primary and two replicas.

https://elasticache.us-west-2.amazonaws.com/?Action=CreateReplicationGroup

API Version 2015-02-02
278
Creating a replication group

For additional information and parameters you might want to use, see the ElastiCache API topic CreateReplicationGroup.
Creating a replication group in Redis (Cluster Mode Enabled) from scratch

You can create a Redis (cluster mode enabled) cluster (API/CLI: replication group) using the ElastiCache console, the AWS CLI, or the ElastiCache API. A Redis (cluster mode enabled) replication group has from 1 to 500 shards (API/CLI: node groups), a primary node in each shard, and up to 5 read replicas in each shard. You can create a cluster with higher number of shards and lower number of replicas totaling up to 90 nodes per cluster. This cluster configuration can range from 90 shards and 0 replicas to 15 shards and 5 replicas, which is the maximum number of replicas allowed.

The node or shard limit can be increased to a maximum of 500 per cluster if the Redis engine version is 5.0.6 or higher. For example, you can choose to configure a 500 node cluster that ranges between 83 shards (one primary and 5 replicas per shard) and 500 shards (single primary and no replicas). Make sure there are enough available IP addresses to accommodate the increase. Common pitfalls include the subnets in the subnet group have too small a CIDR range or the subnets are shared and heavily used by other clusters. For more information, see Creating a subnet group (p. 526).

For versions below 5.0.6, the limit is 250 per cluster.

To request a limit increase, see AWS Service Limits and choose the limit type Nodes per cluster per instance type.

Creating a Cluster in Redis (Cluster Mode Enabled)

- Creating a Redis (Cluster Mode Enabled) cluster (Console) (p. 280)
- Creating a Redis (Cluster Mode Enabled) replication group from scratch (AWS CLI) (p. 280)
- Creating a replication group in Redis (Cluster Mode Enabled) from scratch (ElastiCache API) (p. 285)

Creating a Redis (Cluster Mode Enabled) cluster (Console)

To create a Redis (cluster mode enabled) cluster, see Creating a Redis (cluster mode enabled) cluster (Console) (p. 133). Be sure to enable cluster mode, Cluster Mode enabled (Scale Out), and specify at least two shards and one replica node in each.

Creating a Redis (Cluster Mode Enabled) replication group from scratch (AWS CLI)

The following procedure creates a Redis (cluster mode enabled) replication group using the AWS CLI.

When you create a Redis (cluster mode enabled) replication group from scratch, you create the replication group and all its nodes with a single call to the AWS CLI create-replication-group command. Include the following parameters.

---replication-group-id

The name of the replication group you are creating.

Redis (cluster mode enabled) replication group naming constraints are as follows:

- Must contain 1–40 alphanumeric characters or hyphens.
- Must begin with a letter.
- Can't contain two consecutive hyphens.
- Can't end with a hyphen.

---replication-group-description

Description of the replication group.

---cache-node-type

The node type for each node in the replication group.
ElastiCache supports the following node types. Generally speaking, the current generation types provide more memory and computational power at lower cost when compared to their equivalent previous generation counterparts.

For more information on performance details for each node type, see Amazon EC2 Instance Types.

- **General purpose:**

  - **Current generation:**

    **M6g node types** (available only for Redis engine version 5.0.6 onward).

    - cache.m6g.large, cache.m6g.xlarge, cache.m6g.2xlarge, cache.m6g.4xlarge, cache.m6g.8xlarge, cache.m6g.12xlarge, cache.m6g.16xlarge

    **Note**

    For region availability, see Supported node types by AWS Region (p. 101).

    **M5 node types:** cache.m5.large, cache.m5.xlarge, cache.m5.2xlarge, cache.m5.4xlarge, cache.m5.12xlarge, cache.m5.24xlarge

    **M4 node types:** cache.m4.large, cache.m4.xlarge, cache.m4.2xlarge, cache.m4.4xlarge, cache.m4.10xlarge

    **T4g node types** (available only for Redis engine version 5.0.6 onward).

    - cache.t4g.micro, cache.t4g.small, cache.t4g.medium

    **T3 node types:** cache.t3.micro, cache.t3.small, cache.t3.medium

    **T2 node types:** cache.t2.micro, cache.t2.small, cache.t2.medium

  - **Previous generation: (not recommended. Existing clusters are still supported but creation of new clusters is not supported for these types.**

    **T1 node types:** cache.t1.micro

    **M1 node types:** cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge

    **M3 node types:** cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge

- **Compute optimized:**

  - **Previous generation: (not recommended)**

    **C1 node types:** cache.c1.xlarge

- **Memory optimized with data tiering:**

  - **Current generation:**

    **R6gd node types** (available only for Redis engine version 6.2 onward). For more information, see Data tiering (p. 121).

    - cache.r6gd.xlarge, cache.r6gd.2xlarge, cache.r6gd.4xlarge, cache.r6gd.8xlarge, cache.r6gd.12xlarge, cache.r6gd.16xlarge

  - **Memory optimized:**

    - **Current generation:**

      *(R6g node types are available only for Redis engine version 5.0.6 onward.)*
Creating a replication group

**R6g node types**: cache.r6g.large, cache.r6g.xlarge, cache.r6g.2xlarge, cache.r6g.4xlarge, cache.r6g.8xlarge, cache.r6g.12xlarge, cache.r6g.16xlarge, cache.r6g.24xlarge

**Note**
For region availability, see [Supported node types by AWS Region](p. 101).

**R5 node types**: cache.r5.large, cache.r5.xlarge, cache.r5.2xlarge, cache.r5.4xlarge, cache.r5.12xlarge, cache.r5.24xlarge

**R4 node types**: cache.r4.large, cache.r4.xlarge, cache.r4.2xlarge, cache.r4.4xlarge, cache.r4.8xlarge, cache.r4.16xlarge

- Previous generation: (not recommended)

**M2 node types**: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

**R3 node types**: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge

---

**--data-tiering-enabled**

Set this parameter if you are using an r6gd node type. If you don't want data tiering, set `--no-data-tiering-enabled`. For more information, see [Data tiering](p. 121).

---

**--cache-parameter-group**

Specify the `default.redis3.2.cluster.on` parameter group or a parameter group derived from `default.redis3.2.cluster.on` to create a Redis (cluster mode enabled) replication group. For more information, see [Redis 3.2.4 parameter changes](p. 451).

---

**--engine**

redis

---

**--engine-version**

3.2.4

---

**--num-node-groups**

The number of node groups in this replication group. Valid values are 1 to 500.

**Note**
The node/shard limit can be increased to a maximum of 500 per cluster. To request a limit increase, see [AWS Service Limits](https://aws.amazon.com/service-quotas/) and select limit type "Nodes per cluster per instance type".

---

**--replicas-per-node-group**

The number of replica nodes in each node group. Valid values are 0 to 5.

If you want to enable in-transit or at-rest encryption on this replication group, add either or both of the `--transit-encryption-enabled` or `--at-rest-encryption-enabled` parameters and meet the following conditions.

- Your replication group must be running Redis version 3.2.6 or 4.0.10.
- The replication group must be created in an Amazon VPC.
- You must also include the parameter `--cache-subnet-group`.
- You must also include the parameter `--auth-token` with the customer specified string value for your AUTH token (password) needed to perform operations on this replication group.
The following operation creates the Redis (cluster mode enabled) replication group `sample-repl-group` with three node groups/shards (`--num-node-groups`), each with three nodes, a primary and two read replicas (`--replicas-per-node-group`).

For Linux, macOS, or Unix:

```bash
aws elasticache create-replication-group \
  --replication-group-id sample-repl-group \
  --replication-group-description "Demo cluster with replicas" \
  --num-node-groups 3 \
  --replicas-per-node-group 2 \
  --cache-node-type cache.m4.large \
  --cache-parameter-group default.redis3.2.cluster.on \
  --engine redis \
  --engine-version 3.2.4 \
  --security-group-ids SECURITY_GROUP_ID \
  --cache-subnet-group-name SUBNET_GROUP_NAME>
```

For Windows:

```bash
aws elasticache create-replication-group ^
  --replication-group-id sample-repl-group ^
  --replication-group-description "Demo cluster with replicas" ^
  --num-node-groups 3 ^
  --replicas-per-node-group 2 ^
  --cache-node-type cache.m4.large ^
  --cache-parameter-group default.redis3.2.cluster.on ^
  --engine redis ^
  --engine-version 3.2.4 ^
  --security-group-ids SECURITY_GROUP_ID ^
  --cache-subnet-group-name SUBNET_GROUP_NAME>
```

The preceding command generates the following output.

```json
{
  "ReplicationGroup": {
    "Status": "creating",
    "Description": "Demo cluster with replicas",
    "ReplicationGroupId": "sample-repl-group",
    "SnapshotRetentionLimit": 0,
    "AutomaticFailover": "enabled",
    "SnapshotWindow": "05:30-06:30",
    "MemberClusters": [
      "sample-repl-group-0001-001",
      "sample-repl-group-0001-002",
      "sample-repl-group-0001-003",
      "sample-repl-group-0002-001",
      "sample-repl-group-0002-002",
      "sample-repl-group-0002-003",
      "sample-repl-group-0003-001",
      "sample-repl-group-0003-002",
      "sample-repl-group-0003-003"
    ],
    "PendingModifiedValues": {}
  }
}
```

When you create a Redis (cluster mode enabled) replication group from scratch, you are able to configure each shard in the cluster using the `--node-group-configuration` parameter as shown in the
The following example which configures two node groups (Console: shards). The first shard has two nodes, a primary and one read replica. The second shard has three nodes, a primary and two read replicas.

```plaintext
--node-group-configuration

The configuration for each node group. The `--node-group-configuration` parameter consists of the following fields.

- **PrimaryAvailabilityZone** – The Availability Zone where the primary node of this node group is located. If this parameter is omitted, ElastiCache chooses the Availability Zone for the primary node.
  
  **Example**: `us-west-2a`.

- **ReplicaAvailabilityZones** – A comma separated list of Availability Zones where the read replicas are located. The number of Availability Zones in this list must match the value of `ReplicaCount`. If this parameter is omitted, ElastiCache chooses the Availability Zones for the replica nodes.
  
  **Example**: "us-west-2a,us-west-2b,us-west-2c"

- **ReplicaCount** – The number of replica nodes in this node group.

- **Slots** – A string that specifies the keyspace for the node group. The string is in the format `startKey-endKey`. If this parameter is omitted, ElastiCache allocates keys equally among the node groups.
  
  **Example**: "0-4999"
```

The following operation creates the Redis (cluster mode enabled) replication group `new-group` with two node groups/shards (`--num-node-groups`). Unlike the preceding example, each node group is configured differently from the other node group (`--node-group-configuration`).

For Linux, macOS, or Unix:

```bash
aws elasticache create-replication-group \
  --replication-group-id new-group \
  --replication-group-description "Sharded replication group" \
  --engine redis \
  --engine-version 3.2.4 \
  --cache-parameter-group default.redis3.2.cluster.on \
  --snapshot-retention-limit 8 \
  --cache-node-type cache.m4.medium \
  --num-node-groups 2 \
  --node-group-configuration "ReplicaCount=1,Slots=0-8999,PrimaryAvailabilityZone='us-east-1c',ReplicaAvailabilityZones='us-east-1b'" \ 
  "ReplicaCount=2,Slots=9000-16383,PrimaryAvailabilityZone='us-east-1a',ReplicaAvailabilityZones='us-east-1a','us-east-1c'"
```

For Windows:

```bash
aws elasticache create-replication-group ^ \
  --replication-group-id new-group ^ \
  --replication-group-description "Sharded replication group" ^ \
  --engine redis ^ \
  --engine-version 3.2.4 ^ \
  --cache-parameter-group default.redis3.2.cluster.on ^ \
  --snapshot-retention-limit 8 ^ \
  --cache-node-type cache.m4.medium ^
```

API Version 2015-02-02
284
Creating a replication group

The preceding operation generates the following output.

```json
{
  "ReplicationGroup": {
    "Status": "creating",
    "Description": "Sharded replication group",
    "ReplicationGroupId": "rc-rg",
    "SnapshotRetentionLimit": 8,
    "AutomaticFailover": "enabled",
    "SnapshotWindow": "10:00-11:00",
    "MemberClusters": [
      "rc-rg-0001-001",
      "rc-rg-0001-002",
      "rc-rg-0002-001",
      "rc-rg-0002-002",
      "rc-rg-0002-003"
    ],
    "PendingModifiedValues": {}
  }
}
```

For additional information and parameters you might want to use, see the AWS CLI topic `create-replication-group`.

Creating a replication group in Redis (Cluster Mode Enabled) from scratch (ElastiCache API)

The following procedure creates a Redis (cluster mode enabled) replication group using the ElastiCache API.

When you create a Redis (cluster mode enabled) replication group from scratch, you create the replication group and all its nodes with a single call to the ElastiCache API `CreateReplicationGroup` operation. Include the following parameters.

**ReplicationGroupId**

The name of the replication group you are creating.

Redis (cluster mode enabled) replication group naming constraints are as follows:

- Must contain 1–40 alphanumeric characters or hyphens.
- Must begin with a letter.
- Can't contain two consecutive hyphens.
- Can't end with a hyphen.

**ReplicationGroupDescription**

Description of the replication group.

**NumNodeGroups**

The number of node groups you want created with this replication group. Valid values are 1 to 500.

**ReplicasPerNodeGroup**

The number of replica nodes in each node group. Valid values are 1 to 5.
Creating a replication group

NodeGroupConfiguration

The configuration for each node group. The NodeGroupConfiguration parameter consists of the following fields.

- **PrimaryAvailabilityZone** – The Availability Zone where the primary node of this node group is located. If this parameter is omitted, ElastiCache chooses the Availability Zone for the primary node.

  **Example:** `us-west-2a`.

- **ReplicaAvailabilityZones** – A list of Availability Zones where the read replicas are located. The number of Availability Zones in this list must match the value of ReplicaCount. If this parameter is omitted, ElastiCache chooses the Availability Zones for the replica nodes.

- **ReplicaCount** – The number of replica nodes in this node group.

- **Slots** – A string that specifies the keyspace for the node group. The string is in the format `startKey-endKey`. If this parameter is omitted, ElastiCache allocates keys equally among the node groups.

  **Example:** `'0-4999'`

CacheNodeType

The node type for each node in the replication group.

ElastiCache supports the following node types. Generally speaking, the current generation types provide more memory and computational power at lower cost when compared to their equivalent previous generation counterparts.

For more information on performance details for each node type, see [Amazon EC2 Instance Types](https://aws.amazon.com/ec2/instance-types/).

- **General purpose:**
  - Current generation:
    - **M6g node types** (available only for Redis engine version 5.0.6 onward).
      
      cache.m6g.large, cache.m6g.xlarge, cache.m6g.2xlarge, cache.m6g.4xlarge, cache.m6g.8xlarge, cache.m6g.12xlarge, cache.m6g.16xlarge
      
      **Note**
      
      For region availability, see [Supported node types by AWS Region](https://aws.amazon.com/ec2/instance-types/) (p. 101).

    - **M5 node types:** `cache.m5.large, cache.m5.xlarge, cache.m5.2xlarge, cache.m5.4xlarge, cache.m5.12xlarge, cache.m5.24xlarge`

    - **M4 node types:** `cache.m4.large, cache.m4.xlarge, cache.m4.2xlarge, cache.m4.4xlarge, cache.m4.10xlarge`

    - **T4g node types** (available only for Redis engine version 5.0.6 onward).
      
      cache.t4g.micro, cache.t4g.small, cache.t4g.medium

    - **T3 node types:** `cache.t3.micro, cache.t3.small, cache.t3.medium`

    - **T2 node types:** `cache.t2.micro, cache.t2.small, cache.t2.medium`

  - Previous generation: (not recommended. Existing clusters are still supported but creation of new clusters is not supported for these types.)

- **Previous generation:** (not recommended. Existing clusters are still supported but creation of new clusters is not supported for these types.)

  - **T1 node types:** `cache.t1.large`
M1 node types: cache.m1.small, cache.m1.medium, cache.m1.large, cache.m1.xlarge
M3 node types: cache.m3.medium, cache.m3.large, cache.m3.xlarge, cache.m3.2xlarge

- Compute optimized:
  - Previous generation: (not recommended)

C1 node types: cache.c1.xlarge

- Memory optimized with data tiering:
  - Current generation:

R6gd node types (available only for Redis engine version 6.2 onward). For more information, see Data tiering (p. 121).

- Memory optimized:
  - Current generation:

(R6g node types are available only for Redis engine version 5.0.6 onward.)

R6g node types: cache.r6g.large, cache.r6g.xlarge, cache.r6g.2xlarge, cache.r6g.4xlarge, cache.r6g.8xlarge, cache.r6g.12xlarge, cache.r6g.16xlarge, cache.r6g.24xlarge

Note
For region availability, see Supported node types by AWS Region (p. 101).

R5 node types: cache.r5.large, cache.r5.xlarge, cache.r5.2xlarge, cache.r5.4xlarge, cache.r5.12xlarge, cache.r5.24xlarge

R4 node types: cache.r4.large, cache.r4.xlarge, cache.r4.2xlarge, cache.r4.4xlarge, cache.r4.8xlarge, cache.r4.16xlarge

- Previous generation: (not recommended)

M2 node types: cache.m2.xlarge, cache.m2.2xlarge, cache.m2.4xlarge

R3 node types: cache.r3.large, cache.r3.xlarge, cache.r3.2xlarge, cache.r3.4xlarge, cache.r3.8xlarge

--data-tiering-enabled

Set this parameter if you are using an r6gd node type. If you don't want data tiering, set --no-data-tiering-enabled. For more information, see Data tiering (p. 121).

CacheParameterGroup

Specify the default.redis3.2.cluster.on parameter group or a parameter group derived from default.redis3.2.cluster.on to create a Redis (cluster mode enabled) replication group. For more information, see Redis 3.2.4 parameter changes (p. 451).

Engine

redis

EngineVersion

3.2.4
If you want to enable in-transit or at-rest encryption on this replication group, add either or both of the
TransitEncryptionEnabled=true or AtRestEncryptionEnabled=true parameters and meet the
following conditions.

- Your replication group must be running Redis version 3.2.6 or 4.0.10.
- The replication group must be created in an Amazon VPC.
- You must also include the parameter CacheSubnetGroup.
- You must also include the parameter AuthToken with the customer specified string value for your
  AUTH token (password) needed to perform operations on this replication group.

Line breaks are added for ease of reading.

- Viewing a replication group's details (AWS CLI) (p. 289)
- Viewing a replication group's details (ElastiCache API) (p. 291)

Viewing details for a Redis (Cluster Mode Disabled) with replicas

You can view the details of a Redis (cluster mode disabled) cluster with replicas (API/CLI: replication
group) using the ElastiCache console, the AWS CLI for ElastiCache, or the ElastiCache API.
Viewing a Redis (Cluster Mode Disabled) Cluster's Details

- Viewing Details for a Redis (Cluster Mode Disabled) Replication Group (Console) (p. 289)
- Viewing details for a Redis (Cluster Mode Disabled) replication group (AWS CLI) (p. 289)
- Viewing Details for a Redis (Cluster Mode Disabled) Replication Group (ElastiCache API) (p. 289)

Viewing Details for a Redis (Cluster Mode Disabled) Replication Group (Console)

To view the details of a Redis (cluster mode disabled) cluster with replicas using the ElastiCache console, see the topic Viewing details of a Redis (Cluster Mode Disabled) cluster (Console) (p. 139).

Viewing details for a Redis (Cluster Mode Disabled) replication group (AWS CLI)

For an AWS CLI example that displays a Redis (cluster mode disabled) replication group's details, see Viewing a replication group's details (AWS CLI) (p. 289).

Viewing Details for a Redis (Cluster Mode Disabled) Replication Group (ElastiCache API)

For an ElastiCache API example that displays a Redis (cluster mode disabled) replication group's details, see Viewing a replication group's details (ElastiCache API) (p. 291).

Viewing a replication group's details: Redis (Cluster Mode Enabled)

Viewing details for a Redis (Cluster Mode Enabled) cluster (Console)

To view the details of a Redis (cluster mode enabled) cluster using the ElastiCache console, see Viewing details for a Redis (Cluster Mode Enabled) cluster (Console) (p. 140).

Viewing details for a Redis (Cluster Mode Enabled) cluster (AWS CLI)

For an ElastiCache CLI example that displays a Redis (cluster mode enabled) replication group's details, see Viewing a replication group's details (AWS CLI) (p. 289).

Viewing details for a Redis (Cluster Mode Enabled) Cluster (ElastiCache API)

For an ElastiCache API example that displays a Redis (cluster mode enabled) replication group's details, see Viewing a replication group's details (ElastiCache API) (p. 291).

Viewing a replication group's details (AWS CLI)

You can view the details for a replication group using the AWS CLI `describe-replication-groups` command. Use the following optional parameters to refine the listing. Omitting the parameters returns the details for up to 100 replication groups.

Optional Parameters

- `--replication-group-id` – Use this parameter to list the details of a specific replication group. If the specified replication group has more than one node group, results are returned grouped by node group.
- `--max-items` – Use this parameter to limit the number of replication groups listed. The value of `--max-items` cannot be less than 20 or greater than 100.
Example

The following code lists the details for up to 100 replication groups.

```bash
aws elasticache describe-replication-groups
```

The following code lists the details for `sample-repl-group`.

```bash
aws elasticache describe-replication-groups --replication-group-id sample-repl-group
```

The following code lists the details for `sample-repl-group`.

```bash
aws elasticache describe-replication-groups --replication-group-id sample-repl-group
```

The following code list the details for up to 25 replication groups.

```bash
aws elasticache describe-replication-groups --max-items 25
```

Output from this operation should look something like this (JSON format).

```
{
  "ReplicationGroups": [
    {
      "Status": "available",
      "Description": "test",
      "NodeGroups": [
        {
          "Status": "available",
          "NodeGroupMembers": [
            {
              "CurrentRole": "primary",
              "PreferredAvailabilityZone": "us-west-2a",
              "CacheNodeIds": ["0001"],
              "ReadEndpoint": {
                "Port": 6379,
                "Address": "rg-name-001.1abc4d.0001.usw2.cache.amazonaws.com"
              },
              "CacheClusterId": "rg-name-001"
            },
            {
              "CurrentRole": "replica",
              "PreferredAvailabilityZone": "us-west-2b",
              "CacheNodeIds": ["0001"],
              "ReadEndpoint": {
                "Port": 6379,
                "Address": "rg-name-002.1abc4d.0001.usw2.cache.amazonaws.com"
              },
              "CacheClusterId": "rg-name-002"
            },
            {
              "CurrentRole": "replica",
              "PreferredAvailabilityZone": "us-west-2c",
              "CacheNodeIds": ["0001"],
              "ReadEndpoint": {
                "Port": 6379,
                "Address": "rg-name-003.1abc4d.0001.usw2.cache.amazonaws.com"
              },
              "CacheClusterId": "rg-name-003"
            }
          ]
        }
      ]
    }
  ]
}
```

For more information, see the AWS CLI for ElastiCache topic describe-replication-groups.

**Viewing a replication group's details (ElastiCache API)**

You can view the details for a replication using the AWS CLI DescribeReplicationGroups operation. Use the following optional parameters to refine the listing. Omitting the parameters returns the details for up to 100 replication groups.

**Optional Parameters**

- **ReplicationGroupId** – Use this parameter to list the details of a specific replication group. If the specified replication group has more than one node group, results are returned grouped by node group.
- **MaxRecords** – Use this parameter to limit the number of replication groups listed. The value of MaxRecords cannot be less than 20 or greater than 100. The default is 100.

**Example**

The following code list the details for up to 100 replication groups.

```plaintext
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeReplicationGroups
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>
```

The following code lists the details for myReplGroup.

```plaintext
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeReplicationGroups
&ReplicationGroupId=myReplGroup
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
```
&X-Amz-Credential=<credential>

The following code list the details for up to 25 clusters.

https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeReplicationGroups
&MaxRecords=25
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>

For more information, see the ElastiCache API reference topic DescribeReplicationGroups.
Finding replication group endpoints

An application can connect to any node in a replication group, provided that it has the DNS endpoint and port number for that node. Depending upon whether you are running a Redis (cluster mode disabled) or a Redis (cluster mode enabled) replication group, you will be interested in different endpoints.

Redis (Cluster Mode Disabled)

Redis (cluster mode disabled) clusters with replicas have three types of endpoints; the primary endpoint, the reader endpoint and the node endpoints. The primary endpoint is a DNS name that always resolves to the primary node in the cluster. The primary endpoint is immune to changes to your cluster, such as promoting a read replica to the primary role. For write activity, we recommend that your applications connect to the primary endpoint, not the primary node.

A reader endpoint will evenly split incoming connections to the endpoint between all read replicas in an ElastiCache for Redis cluster. Additional factors such as when the application creates the connections or how the application (re)-uses the connections will determine the traffic distribution. Reader endpoints keep up with cluster changes in real-time as replicas are added or removed. You can place your ElastiCache for Redis cluster's multiple read replicas in different AWS Availability Zones (AZ) to ensure high availability of reader endpoints.

Note
A reader endpoint is not a load balancer. It is a DNS record that will resolve to an IP address of one of the replica nodes in a round robin fashion.

For read activity, applications can also connect to any node in the cluster. Unlike the primary endpoint, node endpoints resolve to specific endpoints. If you make a change in your cluster, such as adding or deleting a replica, you must update the node endpoints in your application.

Redis (Cluster Mode Enabled)

Redis (cluster mode enabled) clusters with replicas, because they have multiple shards (API/CLI: node groups), which mean they also have multiple primary nodes, have a different endpoint structure than Redis (cluster mode disabled) clusters. Redis (cluster mode enabled) has a configuration endpoint which "knows" all the primary and node endpoints in the cluster. Your application connects to the configuration endpoint. Whenever your application writes to or reads from the cluster's configuration endpoint, Redis, behind the scenes, determines which shard the key belongs to and which endpoint in that shard to use. It is all quite transparent to your application.

You can find the endpoints for a cluster using the ElastiCache console, the AWS CLI, or the ElastiCache API.

Finding Replication Group Endpoints

To find the endpoints for your replication group, see one of the following topics:

- Finding a Redis (Cluster Mode Disabled) Cluster's Endpoints (Console) (p. 176)
- Finding Endpoints for a Redis (Cluster Mode Enabled) Cluster (Console) (p. 178)
- Finding the Endpoints for Replication Groups (AWS CLI) (p. 181)
- Finding Endpoints for Replication Groups (ElastiCache API) (p. 183)
Modifying a replication group

Important Constraints

- Currently, ElastiCache supports limited modifications of a Redis (cluster mode enabled) replication group, for example changing the engine version, using the API operation `ModifyReplicationGroup (CLI: modify-replication-group)`. You can modify the number of shards (node groups) in a Redis (cluster mode enabled) cluster with the API operation `ModifyReplicationGroupShardConfiguration (CLI: modify-replication-group-shard-configuration)`. For more information, see Scaling clusters in Redis (Cluster Mode Enabled) (p. 375).

Other modifications to a Redis (cluster mode enabled) cluster require that you create a cluster with the new cluster incorporating the changes.

- You can upgrade Redis (cluster mode disabled) and Redis (cluster mode enabled) clusters and replication groups to newer engine versions. However, you can't downgrade to earlier engine versions except by deleting the existing cluster or replication group and creating it again. For more information, see Upgrading engine versions (p. 198).

You can modify a Redis (cluster mode disabled) cluster's settings using the ElastiCache console, the AWS CLI, or the ElastiCache API. Currently, ElastiCache supports a limited number of modifications on a Redis (cluster mode enabled) replication group. Other modifications require you create a backup of the current replication group then using that backup to seed a new Redis (cluster mode enabled) replication group.

Topics

- Using the AWS Management Console (p. 294)
- Using the AWS CLI (p. 294)
- Using the ElastiCache API (p. 295)

Using the AWS Management Console

To modify a Redis (cluster mode disabled) cluster, see Modifying an ElastiCache cluster (p. 149).

Using the AWS CLI

The following AWS CLI command enables Multi-AZ on an existing Redis replication group. You can use the same command to make other modifications to a replication group.

For Linux, macOS, or Unix:

```
aws elasticache modify-replication-group \
  --replication-group-id myReplGroup \
  --multi-az-enabled = true
```

For Windows:

```
aws elasticache modify-replication-group ^
  --replication-group-id myReplGroup ^
  --multi-az-enabled
```

For more information on the AWS CLI `modify-replication-group` command, see `modify-replication-group`.

API Version 2015-02-02

294
Using the ElastiCache API

The following ElastiCache API operation enables Multi-AZ on an existing Redis replication group. You can use the same operation to make other modifications to a replication group.

```plaintext
https://elasticache.us-west-2.amazonaws.com/
  ?Action=ModifyReplicationGroup
  &AutomaticFailoverEnabled=true
  &Multi-AZEnabled=true
  &ReplicationGroupId=myRepGroup
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20141201T220302Z
  &Version=2014-12-01
  &X-Amz-Algorithm=AWS;4-HMAC-SHA256
  &X-Amz-Date=20141201T220302Z
  &X-Amz-SignedHeaders=Host
  &X-Amz-Expires=20141201T220302Z
  &X-Amz-Credential=<credential>
  &X-Amz-Signature=<signature>
```

For more information on the ElastiCache API ModifyReplicationGroup operation, see `ModifyReplicationGroup`. 
Deleting a replication group

If you no longer need one of your clusters with replicas (called replication groups in the API/CLI), you can delete it. When you delete a replication group, ElastiCache deletes all of the nodes in that group.

After you have begun this operation, it cannot be interrupted or canceled.

Warning
When you delete an ElastiCache for Redis cluster, your manual snapshots are retained. You will also have an option to create a final snapshot before the cluster is deleted. Automatic cache snapshots are not retained.

Deleting a Replication Group (Console)

To delete a cluster that has replicas, see Deleting a cluster (p. 165).

Deleting a Replication Group (AWS CLI)

Use the command delete-replication-group to delete a replication group.

```bash
aws elasticache delete-replication-group --replication-group-id my-repgroup
```

A prompt asks you to confirm your decision. Enter y (yes) to start the operation immediately. After the process starts, it is irreversible.

```bash
REPLICATIONGROUP  my-repgroup  My replication group  deleting
```

Deleting a replication group (ElastiCache API)

Call DeleteReplicationGroup with the ReplicationGroup parameter.

Example

```bash
https://elasticache.us-west-2.amazonaws.com/
?Action=DeleteReplicationGroup
&ReplicationGroupId=my-repgroup
&Version=2014-12-01
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20141201T220302Z
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Date=20141201T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Signature=550f354f59b4f0c29f8cb2e6380be5577e4bf839e1aae0090f04fbb2b653690f
```

Note
If you set the RetainPrimaryCluster parameter to true, all of the read replicas will be deleted, but the primary cluster will be retained.
Changing the number of replicas

You can dynamically increase or decrease the number of read replicas in your Redis replication group using the AWS Management Console, the AWS CLI, or the ElastiCache API. If your replication group is a Redis (cluster mode enabled) replication group, you can choose which shards (node groups) to increase or decrease the number of replicas.

To dynamically change the number of replicas in your Redis replication group, choose the operation from the following table that fits your situation.

<table>
<thead>
<tr>
<th>To Do This</th>
<th>For Redis (cluster mode enabled)</th>
<th>For Redis (cluster mode disabled)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add replicas</td>
<td>Increasing the number of replicas in a shard (p. 298)</td>
<td>Increasing the number of replicas in a shard (p. 298)</td>
</tr>
<tr>
<td></td>
<td>Adding a read replica, for Redis (Cluster Mode Disabled) replication groups (p. 306)</td>
<td></td>
</tr>
<tr>
<td>Delete replicas</td>
<td>Decreasing the number of replicas in a shard (p. 302)</td>
<td>Decreasing the number of replicas in a shard (p. 302)</td>
</tr>
<tr>
<td></td>
<td>Deleting a read replica, for Redis (Cluster Mode Disabled) replication groups (p. 308)</td>
<td></td>
</tr>
</tbody>
</table>
Increasing the number of replicas in a shard

You can increase the number of replicas in a Redis (cluster mode enabled) shard or Redis (cluster mode disabled) replication group up to a maximum of five. You can do so using the AWS Management Console, the AWS CLI, or the ElastiCache API.

**Topics**
- Using the AWS Management Console (p. 298)
- Using the AWS CLI (p. 298)
- Using the ElastiCache API (p. 300)

Using the AWS Management Console

The following procedure uses the console to increase the number of replicas in a Redis (cluster mode enabled) replication group.

**To increase the number of replicas in Redis shards**

2. In the navigation pane, choose **Redis**, and then choose the name of the replication group that you want to add replicas to.
3. Choose the box for each shard that you want to add replicas to.
4. Choose **Add replicas**.
5. Complete the **Add Replicas to Shards** page:
   - For **New number of replicas/shard**, enter the number of replicas that you want all of your selected shards to have. This value must be greater than or equal to **Current Number of Replicas per shard** and less than or equal to five. We recommend at least two replicas as a working minimum.
   - For **Availability Zones**, choose either **No preference** to have ElastiCache chose an Availability Zone for each new replica, or **Specify Availability Zones** to choose an Availability Zone for each new replica.
     - If you choose **Specify Availability Zones**, for each new replica specify an Availability Zone using the list.
6. Choose **Add** to add the replicas or **Cancel** to cancel the operation.

Using the AWS CLI

To increase the number of replicas in a Redis shard, use the `increase-replica-count` command with the following parameters:

- `--replication-group-id` – Required. Identifies which replication group you want to increase the number of replicas in.
- `--apply-immediately` or `--no-apply-immediately` – Required. Specifies whether to increase the replica count immediately (`--apply-immediately`) or at the next maintenance window (`--no-apply-immediately`). Currently, `--no-apply-immediately` is not supported.
- `--new-replica-count` – Optional. Specifies the number of replica nodes you want when finished, up to a maximum of five. Use this parameter for Redis (cluster mode disabled) replication groups where there is only one node group or Redis (cluster mode enabled) group, or where you want all node groups to have the same number of replicas. If this value is not larger than the current number of replicas in the node group, the call fails with an exception.
• **--replica-configuration** – Optional. Allows you to set the number of replicas and Availability Zones for each node group independently. Use this parameter for Redis (cluster mode enabled) groups where you want to configure each node group independently.

--replica-configuration has three optional members:

• **NodeGroupId** – The four-digit ID for the node group that you are configuring. For Redis (cluster mode disabled) replication groups, the shard ID is always 0001. To find a Redis (cluster mode enabled) node group's (shard's) ID, see Finding a shard's ID (p. 184).

• **NewReplicaCount** – The number of replicas that you want in this node group at the end of this operation. The value must be more than the current number of replicas, up to a maximum of five. If this value is not larger than the current number of replicas in the node group, the call fails with an exception.

• **PreferredAvailabilityZones** – A list of PreferredAvailabilityZone strings that specify which Availability Zones the replication group's nodes are to be in. The number of PreferredAvailabilityZone values must equal the value of NewReplicaCount plus 1 to account for the primary node. If this member of --replica-configuration is omitted, ElastiCache for Redis chooses the Availability Zone for each of the new replicas.

**Important**
You must include either the **--new-replica-count** or **--replica-configuration** parameter, but not both, in your call.

**Example**

The following example increases the number of replicas in the replication group sample-repl-group to three. When the example is finished, there are three replicas in each node group. This number applies whether this is a Redis (cluster mode disabled) group with a single node group or a Redis (cluster mode enabled) group with multiple node groups.

For Linux, macOS, or Unix:

```bash
aws elasticache increase-replica-count \
  --replication-group-id sample-repl-group \
  --new-replica-count 3 \n  --apply-immediately
```

For Windows:

```bash
aws elasticache increase-replica-count ^
  --replication-group-id sample-repl-group ^
  --new-replica-count 3 ^
  --apply-immediately
```

The following example increases the number of replicas in the replication group sample-repl-group to the value specified for the two specified node groups. Given that there are multiple node groups, this is a Redis (cluster mode enabled) replication group. When specifying the optional PreferredAvailabilityZones, the number of Availability Zones listed must equal the value of NewReplicaCount plus 1 more. This approach accounts for the primary node for the group identified by NodeGroupId.

For Linux, macOS, or Unix:

```bash
aws elasticache increase-replica-count \
  --replication-group-id sample-repl-group \
  --replica-configuration \
```

API Version 2015-02-02
299
### Changing the number of replicas

NodeGroupId=0001, NewReplicaCount=2, PreferredAvailabilityZones=us-east-1a, us-east-1c, us-east-1b

NodeGroupId=0003, NewReplicaCount=3, PreferredAvailabilityZones=us-east-1a, us-east-1b, us-east-1c

--apply-immediately

For Windows:

```bash
aws elasticache increase-replica-count ^
    --replication-group-id sample-repl-group ^
    --replica-configuration ^
        NodeGroupId=0001, NewReplicaCount=2, PreferredAvailabilityZones=us-east-1a, us-east-1c, us-east-1b ^
        NodeGroupId=0003, NewReplicaCount=3, PreferredAvailabilityZones=us-east-1a, us-east-1b, us-east-1c ^
    --apply-immediately
```

For more information about increasing the number of replicas using the CLI, see `increase-replica-count` in the Amazon ElastiCache Command Line Reference.

### Using the ElastiCache API

To increase the number of replicas in a Redis shard, use the `IncreaseReplicaCount` action with the following parameters:

- **ReplicationGroupId** – Required. Identifies which replication group you want to increase the number of replicas in.
- **ApplyImmediately** – Required. Specifies whether to increase the replica count immediately (ApplyImmediately=True) or at the next maintenance window (ApplyImmediately=False). Currently, ApplyImmediately=False is not supported.
- **NewReplicaCount** – Optional. Specifies the number of replica nodes you want when finished, up to a maximum of five. Use this parameter for Redis (cluster mode disabled) replication groups where there is only one node group, or Redis (cluster mode enabled) groups where you want all node groups to have the same number of replicas. If this value is not larger than the current number of replicas in the node group, the call fails with an exception.
- **ReplicaConfiguration** – Optional. Allows you to set the number of replicas and Availability Zones for each node group independently. Use this parameter for Redis (cluster mode enabled) groups where you want to configure each node group independently.

ReplicaConfiguration has three optional members:

- **NodeGroupId** – The four-digit ID for the node group you are configuring. For Redis (cluster mode disabled) replication groups, the node group (shard) ID is always 0001. To find a Redis (cluster mode enabled) node group's (shard's) ID, see *Finding a shard's ID* (p. 184).
- **NewReplicaCount** – The number of replicas that you want in this node group at the end of this operation. The value must be more than the current number of replicas and a maximum of five. If this value is not larger than the current number of replicas in the node group, the call fails with an exception.
- **PreferredAvailabilityZones** – A list of PreferredAvailabilityZone strings that specify which Availability Zones the replication group's nodes are to be in. The number of PreferredAvailabilityZone values must equal the value of NewReplicaCount plus 1 to account for the primary node. If this member of ReplicaConfiguration is omitted, ElastiCache for Redis chooses the Availability Zone for each of the new replicas.

**Important**

You must include either the NewReplicaCount or ReplicaConfiguration parameter, but not both, in your call.

---

API Version 2015-02-02

300
Example

The following example increases the number of replicas in the replication group `sample-repl-group` to three. When the example is finished, there are three replicas in each node group. This number applies whether this is a Redis (cluster mode disabled) group with a single node group or a Redis (cluster mode enabled) group with multiple node groups.

```xml
https://elasticache.us-west-2.amazonaws.com/
?Action=IncreaseReplicaCount
&ApplyImmediately=True
&NewReplicaCount=3
&ReplicationGroupId=sample-repl-group
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>
```

The following example increases the number of replicas in the replication group `sample-repl-group` to the value specified for the two specified node groups. Given that there are multiple node groups, this is a Redis (cluster mode enabled) replication group. When specifying the optional `PreferredAvailabilityZones`, the number of Availability Zones listed must equal the value of `NewReplicaCount` plus 1 more. This approach accounts for the primary node, for the group identified by `NodeGroupId`.

```xml
https://elasticache.us-west-2.amazonaws.com/
?Action=IncreaseReplicaCount
&ApplyImmediately=True
&ReplicaConfiguration.ConfigureShard.1.NodeGroupId=0001
&ReplicaConfiguration.ConfigureShard.1.NewReplicaCount=2
&ReplicaConfiguration.ConfigureShard.1.PreferredAvailabilityZones.PreferredAvailabilityZone.1=us-east-1a
&ReplicaConfiguration.ConfigureShard.1.PreferredAvailabilityZones.PreferredAvailabilityZone.2=us-east-1c
&ReplicaConfiguration.ConfigureShard.1.PreferredAvailabilityZones.PreferredAvailabilityZone.3=us-east-1b
&ReplicaConfiguration.ConfigureShard.2.NodeGroupId=0003
&ReplicaConfiguration.ConfigureShard.2.NewReplicaCount=3
&ReplicaConfiguration.ConfigureShard.2.PreferredAvailabilityZones.PreferredAvailabilityZone.1=us-east-1a
&ReplicaConfiguration.ConfigureShard.2.PreferredAvailabilityZones.PreferredAvailabilityZone.2=us-east-1b
&ReplicaConfiguration.ConfigureShard.2.PreferredAvailabilityZones.PreferredAvailabilityZone.3=us-east-1c
&ReplicaConfiguration.ConfigureShard.2.PreferredAvailabilityZones.PreferredAvailabilityZone.4=us-east-1c
&ReplicationGroupId=sample-repl-group
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>
```

For more information about increasing the number of replicas using the API, see `IncreaseReplicaCount` in the Amazon ElastiCache API Reference.
Decreasing the number of replicas in a shard

You can decrease the number of replicas in a shard for Redis (cluster mode enabled), or in a replication group for Redis (cluster mode disabled):

- For Redis (cluster mode disabled), you can decrease the number of replicas to one if Multi-AZ is enabled, and to zero if it isn’t enabled.
- For Redis (cluster mode enabled), you can decrease the number of replicas to zero. However, you can’t fail over to a replica if your primary node fails.

You can use the AWS Management Console, the AWS CLI or the ElastiCache API to decrease the number of replicas in a node group (shard) or replication group.

Topics

- Using the AWS Management Console (p. 302)
- Using the AWS CLI (p. 302)
- Using the ElastiCache API (p. 304)

Using the AWS Management Console

The following procedure uses the console to decrease the number of replicas in a Redis (cluster mode enabled) replication group.

To decrease the number of replicas in a Redis shard

2. In the navigation pane, choose Redis, then choose the name of the replication group from which you want to delete replicas.
3. Choose the box for each shard you want to remove a replica node from.
4. Choose Delete replicas.
5. Complete the Delete Replicas from Shards page:
   a. For New number of replicas/shard, enter the number of replicas that you want the selected shards to have. This number must be greater than or equal to 1. We recommend at least two replicas per shard as a working minimum.
   b. Choose Delete to delete the replicas or Cancel to cancel the operation.

Important

- If you don’t specify the replica nodes to be deleted, ElastiCache for Redis automatically selects replica nodes for deletion. While doing so, ElastiCache for Redis attempts to retain the Multi-AZ architecture for your replication group followed by retaining replicas with minimum replication lag with the primary.
- You can’t delete the primary or primary nodes in a replication group. If you specify a primary node for deletion, the operation fails with an error event indicating that the primary node was selected for deletion.

Using the AWS CLI

To decrease the number of replicas in a Redis shard, use the decrease-replica-count command with the following parameters:
Changing the number of replicas

- `--replication-group-id` – Required. Identifies which replication group you want to decrease the number of replicas in.
- `--apply-immediately` or `--no-apply-immediately` – Required. Specifies whether to decrease the replica count immediately (`--apply-immediately`) or at the next maintenance window (`--no-apply-immediately`). Currently, `--no-apply-immediately` is not supported.
- `--new-replica-count` – Optional. Specifies the number of replica nodes that you want. The value of `--new-replica-count` must be a valid value less than the current number of replicas in the node groups. For minimum permitted values, see Decreasing the number of replicas in a shard (p. 302). If the value of `--new-replica-count` doesn't meet this requirement, the call fails.
- `--replicas-to-remove` – Optional. Contains a list of node IDs specifying the replica nodes to remove.
- `--replica-configuration` – Optional. Allows you to set the number of replicas and Availability Zones for each node group independently. Use this parameter for Redis (cluster mode enabled) groups where you want to configure each node group independently.

`--replica-configuration` has three optional members:
- `NodeGroupId` – The four-digit ID for the node group that you are configuring. For Redis (cluster mode disabled) replication groups, the shard ID is always 0001. To find a Redis (cluster mode enabled) node group's (shard's) ID, see Finding a shard's ID (p. 184).
- `NewReplicaCount` – An optional parameter that specifies the number of replica nodes you want. The value of `NewReplicaCount` must be a valid value less than the current number of replicas in the node groups. For minimum permitted values, see Decreasing the number of replicas in a shard (p. 302). If the value of `NewReplicaCount` doesn't meet this requirement, the call fails.
- `PreferredAvailabilityZones` – A list of `PreferredAvailabilityZone` strings that specify which Availability Zones the replication group's nodes are in. The number of `PreferredAvailabilityZone` values must equal the value of `NewReplicaCount` plus 1 to account for the primary node. If this member of `--replica-configuration` is omitted, ElastiCache for Redis chooses the Availability Zone for each of the new replicas.

**Important**
You must include one and only one of the `--new-replica-count`, `--replicas-to-remove`, or `--replica-configuration` parameters.

**Example**
The following example uses `--new-replica-count` to decrease the number of replicas in the replication group `sample-repl-group` to one. When the example is finished, there is one replica in each node group. This number applies whether this is a Redis (cluster mode disabled) group with a single node group or a Redis (cluster mode enabled) group with multiple node groups.

For Linux, macOS, or Unix:
```
aws elasticache decrease-replica-count
  --replication-group-id sample-repl-group \
  --new-replica-count 1 \
  --apply-immediately
```

For Windows:
```
aws elasticache decrease-replica-count ^
  --replication-group-id sample-repl-group ^
  --new-replica-count 1 ^
  --apply-immediately
```

The following example decreases the number of replicas in the replication group `sample-repl-group` by removing two specified replicas (0001 and 0003) from the node group.
For Linux, macOS, or Unix:

```
aws elasticache decrease-replica-count \
   --replication-group-id sample-repl-group \
   --replicas-to-remove 0001,0003 \
   --apply-immediately
```

For Windows:

```
aws elasticache decrease-replica-count ^
   --replication-group-id sample-repl-group ^
   --replicas-to-remove 0001,0003 ^
   --apply-immediately
```

The following example uses `--replica-configuration` to decrease the number of replicas in the replication group `sample-repl-group` to the value specified for the two specified node groups. Given that there are multiple node groups, this is a Redis (cluster mode enabled) replication group. When specifying the optional `PreferredAvailabilityZones`, the number of Availability Zones listed must equal the value of `NewReplicaCount` plus 1 more. This approach accounts for the primary node for the group identified by `NodeGroupId`.

For Linux, macOS, or Unix:

```
aws elasticache decrease-replica-count \
   --replication-group-id sample-repl-group \
   --replica-configuration \
       NodeGroupId=0001,NewReplicaCount=1,PreferredAvailabilityZones=us-east-1a,us-east-1c \
       NodeGroupId=0003,NewReplicaCount=2,PreferredAvailabilityZones=us-east-1a,us-east-1b,us-east-1c \
   --apply-immediately
```

For Windows:

```
aws elasticache decrease-replica-count ^
   --replication-group-id sample-repl-group ^
   --replica-configuration ^
       NodeGroupId=0001,NewReplicaCount=2,PreferredAvailabilityZones=us-east-1a,us-east-1c ^
       NodeGroupId=0003,NewReplicaCount=3,PreferredAvailabilityZones=us-east-1a,us-east-1b,us-east-1c ^
   --apply-immediately
```

For more information about decreasing the number of replicas using the CLI, see `decrease-replica-count` in the Amazon ElastiCache Command Line Reference.

**Using the ElastiCache API**

To decrease the number of replicas in a Redis shard, use the `DecreaseReplicaCount` action with the following parameters:

- `ReplicationGroupId` – Required. Identifies which replication group you want to decrease the number of replicas in.
- `ApplyImmediately` – Required. Specifies whether to decrease the replica count immediately (`ApplyImmediately=True`) or at the next maintenance window (`ApplyImmediately=False`). Currently, `ApplyImmediately=False` is not supported.
Changing the number of replicas

- **NewReplicaCount** – Optional. Specifies the number of replica nodes you want. The value of NewReplicaCount must be a valid value less than the current number of replicas in the node groups. For minimum permitted values, see Decreasing the number of replicas in a shard (p. 302). If the value of --new-replica-count doesn't meet this requirement, the call fails.
- **ReplicasToRemove** – Optional. Contains a list of node IDs specifying the replica nodes to remove.
- **ReplicaConfiguration** – Optional. Contains a list of node groups that allows you to set the number of replicas and Availability Zones for each node group independently. Use this parameter for Redis (cluster mode enabled) groups where you want to configure each node group independently.

**ReplicaConfiguration** has three optional members:
- **NodeGroupId** – The four-digit ID for the node group you are configuring. For Redis (cluster mode disabled) replication groups, the node group ID is always 0001. To find a Redis (cluster mode enabled) node group's (shard's) ID, see Finding a shard's ID (p. 184).
- **NewReplicaCount** – The number of replicas that you want in this node group at the end of this operation. The value must be less than the current number of replicas down to a minimum of 1 if Multi-AZ is enabled or 0 if Multi-AZ with Automatic Failover isn't enabled. If this value is not less than the current number of replicas in the node group, the call fails with an exception.
- **PreferredAvailabilityZones** – A list of PreferredAvailabilityZone strings that specify which Availability Zones the replication group's nodes are in. The number of PreferredAvailabilityZone values must equal the value of NewReplicaCount plus 1 to account for the primary node. If this member of ReplicaConfiguration is omitted, ElastiCache for Redis chooses the Availability Zone for each of the new replicas.

**Important**
You must include one and only one of the NewReplicaCount, ReplicasToRemove, or ReplicaConfiguration parameters.

**Example**
The following example uses NewReplicaCount to decrease the number of replicas in the replication group `sample-repl-group` to one. When the example is finished, there is one replica in each node group. This number applies whether this is a Redis (cluster mode disabled) group with a single node group or a Redis (cluster mode enabled) group with multiple node groups.

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=DecreaseReplicaCount
  &ApplyImmediately=True
  &NewReplicaCount=1
  &ReplicationGroupId=sample-repl-group
  &Version=2015-02-02
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20150202T192317Z
  &X-Amz-Credential=<credential>
```

The following example decreases the number of replicas in the replication group `sample-repl-group` by removing two specified replicas (0001 and 0003) from the node group.

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=DecreaseReplicaCount
  &ApplyImmediately=True
  &ReplicasToRemove.ReplicaToRemove.1=0001
  &ReplicasToRemove.ReplicaToRemove.2=0003
  &ReplicationGroupId=sample-repl-group
  &Version=2015-02-02
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
```
The following example uses ReplicaConfiguration to decrease the number of replicas in the replication group sample-repl-group to the value specified for the two specified node groups. Given that there are multiple node groups, this is a Redis (cluster mode enabled) replication group. When specifying the optional PreferredAvailabilityZones, the number of Availability Zones listed must equal the value of NewReplicaCount plus 1 more. This approach accounts for the primary node for the group identified by NodeGroupId.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DecreaseReplicaCount
&ApplyImmediately=True
&ReplicaConfiguration.ConfigureShard.1.NodeGroupId=0001
&ReplicaConfiguration.ConfigureShard.1.NewReplicaCount=1
&ReplicaConfiguration.ConfigureShard.1.PreferredAvailabilityZones.PreferredAvailabilityZone.1=us-east-1a
&ReplicaConfiguration.ConfigureShard.1.PreferredAvailabilityZones.PreferredAvailabilityZone.2=us-east-1c
 &ReplicaConfiguration.ConfigureShard.2.NodeGroupId=0003
 &ReplicaConfiguration.ConfigureShard.2.NewReplicaCount=2
 &ReplicaConfiguration.ConfigureShard.2.PreferredAvailabilityZones.PreferredAvailabilityZone.1=us-east-1a
 &ReplicaConfiguration.ConfigureShard.2.PreferredAvailabilityZones.PreferredAvailabilityZone.2=us-east-1b
 &ReplicaConfiguration.ConfigureShard.2.PreferredAvailabilityZones.PreferredAvailabilityZone.4=us-east-1c
 &ReplicationGroupId=sample-repl-group
 &Version=2015-02-02
 &SignatureVersion=4
 &SignatureMethod=HmacSHA256
 &Timestamp=20150202T192317Z
 &X-Amz-Credential=<credential>
```

For more information about decreasing the number of replicas using the API, see DecreaseReplicaCount in the Amazon ElastiCache API Reference.

### Adding a read replica, for Redis (Cluster Mode Disabled) replication groups

Information in the following topic applies to Redis (cluster mode disabled) replication groups only.

As your read traffic increases, you might want to spread those reads across more nodes and reduce the read pressure on any one node. In this topic, you can find how to add a read replica to a Redis (cluster mode disabled) cluster.

A Redis (cluster mode disabled) replication group can have a maximum of five read replicas. If you attempt to add a read replica to a replication group that already has five read replicas, the operation fails.

For information about adding replicas to a Redis (cluster mode enabled) replication group, see the following:

- Scaling clusters in Redis (Cluster Mode Enabled) (p. 375)
- Increasing the number of replicas in a shard (p. 298)
You can add a read replica to a Redis (cluster mode disabled) cluster using the ElastiCache Console, the AWS CLI, or the ElastiCache API.

**Related topics**

- Adding nodes to a cluster (p. 152)
- Adding a read replica to a replication group (AWS CLI) (p. 307)
- Adding a read replica to a replication group using the API (p. 307)

**Adding a read replica to a replication group (AWS CLI)**

To add a read replica to a Redis (cluster mode disabled) replication group, use the AWS CLI `create-cache-cluster` command, with the parameter `--replication-group-id` to specify which replication group to add the cluster (node) to.

The following example creates the cluster `my-read-replica` and adds it to the replication group `my-replication-group`. The node types, parameter groups, security groups, maintenance window, and other settings for the read replica are the same as for the other nodes in `my-replication-group`.

For Linux, macOS, or Unix:

```bash
aws elasticache create-cache-cluster --cache-cluster-id my-read-replica --replication-group-id my-replication-group
```

For Windows:

```bash
aws elasticache create-cache-cluster --cache-cluster-id my-read-replica --replication-group-id my-replication-group
```

For more information on adding a read replica using the CLI, see `create-cache-cluster` in the Amazon ElastiCache Command Line Reference.

**Adding a read replica to a replication group using the API**

To add a read replica to a Redis (cluster mode disabled) replication group, use the ElastiCache `CreateCacheCluster` operation, with the parameter `ReplicationGroupId` to specify which replication group to add the cluster (node) to.

The following example creates the cluster `myReadReplica` and adds it to the replication group `myReplicationGroup`. The node types, parameter groups, security groups, maintenance window, and other settings for the read replica are the same as for the other nodes `myReplicationGroup`.

```xml
&CacheClusterId=myReadReplica
&ReplicationGroupId=myReplicationGroup
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>
```

For more information on adding a read replica using the API, see `CreateCacheCluster` in the Amazon ElastiCache API Reference.
Deleting a read replica, for Redis (Cluster Mode Disabled) replication groups

Information in the following topic applies to Redis (cluster mode disabled) replication groups only.

As read traffic on your Redis replication group changes, you might want to add or remove read replicas. Removing a node from a Redis (cluster mode disabled) replication group is the same as just deleting a cluster, though there are restrictions:

- You cannot remove the primary from a replication group. If you want to delete the primary, do the following:
  1. Promote a read replica to primary. For more information on promoting a read replica to primary, see Promoting a read replica to primary, for Redis (cluster mode disabled) replication groups (p. 309).
  2. Delete the old primary. For a restriction on this method, see the next point.
- If Multi-AZ is enabled on a replication group, you can't remove the last read replica from the replication group. In this case, do the following:
  1. Modify the replication group by disabling Multi-AZ. For more information, see Modifying a replication group (p. 294).
  2. Delete the read replica.

You can remove a read replica from a Redis (cluster mode disabled) replication group using the ElastiCache console, the AWS CLI for ElastiCache, or the ElastiCache API.

For directions on deleting a cluster from a Redis replication group, see the following:

- Using the AWS Management Console (p. 165)
- Using the AWS CLI (p. 165)
- Using the ElastiCache API (p. 166)
- Scaling clusters in Redis (Cluster Mode Enabled) (p. 375)
- Decreasing the number of replicas in a shard (p. 302)
Promoting a read replica to primary, for Redis (cluster mode disabled) replication groups

Information in the following topic applies to only Redis (cluster mode disabled) replication groups.

You can promote a Redis (cluster mode disabled) read replica to primary using the AWS Management Console, the AWS CLI, or the ElastiCache API. You can't promote a read replica to primary while Multi-AZ with Automatic Failover is enabled on the Redis (cluster mode disabled) replication group. To promote a Redis (cluster mode disabled) replica to primary on a Multi-AZ enabled replication group, do the following:

1. Modify the replication group to disable Multi-AZ (doing this doesn’t require that all your clusters be in the same Availability Zone). For more information, see Modifying a replication group (p. 294).
2. Promote the read replica to primary.
3. Modify the replication group to re-enable Multi-AZ.

Multi-AZ is not available on replication groups running Redis 2.6.13 or earlier.

Using the AWS Management Console

The following procedure uses the console to promote a replica node to primary.

To promote a read replica to primary (console)

2. If the replica you want to promote is a member of a Redis (cluster mode disabled) replication group where Multi-AZ is enabled, modify the replication group to disable Multi-AZ before you proceed. For more information, see Modifying a replication group (p. 294).
3. Choose Redis, then from the list of clusters, choose the replication group that you want to modify. This replication group must be running the "Redis" engine, not the "Clustered Redis" engine, and must have two or more nodes.
4. From the list of nodes, choose the replica node you want to promote to primary, then for Actions, choose Promote.
5. In the Promote Read Replica dialog box, do the following:
   a. For Apply Immediately, choose Yes to promote the read replica immediately, or No to promote it at the cluster's next maintenance window.
   b. Choose Promote to promote the read replica or Cancel to cancel the operation.
6. If the cluster was Multi-AZ enabled before you began the promotion process, wait until the replication group's status is available, then modify the cluster to re-enable Multi-AZ. For more information, see Modifying a replication group (p. 294).

Using the AWS CLI

You can't promote a read replica to primary if the replication group is Multi-AZ enabled. In some cases, the replica that you want to promote might be a member of a replication group where Multi-AZ is enabled. In these cases, you must modify the replication group to disable Multi-AZ before you proceed. Doing this doesn’t require that all your clusters be in the same Availability Zone. For more information on modifying a replication group, see Modifying a replication group (p. 294).

The following AWS CLI command modifies the replication group sample-repl-group, making the read replica my-replica-1 the primary in the replication group.
Backup and restore

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group \\    --replication-group-id sample-repl-group \\    --primary-cluster-id my-replica-1
```

For Windows:

```bash
aws elasticache modify-replication-group ^    --replication-group-id sample-repl-group ^    --primary-cluster-id my-replica-1
```

For more information on modifying a replication group, see modify-replication-group in the Amazon ElastiCache Command Line Reference.

Using the ElastiCache API

You can't promote a read replica to primary if the replication group is Multi-AZ enabled. In some cases, the replica that you want to promote might be a member of a replication group where Multi-AZ is enabled. In these cases, you must modify the replication group to disable Multi-AZ before you proceed. Doing this doesn't require that all your clusters be in the same Availability Zone. For more information on modifying a replication group, see Modifying a replication group (p. 294).

The following ElastiCache API action modifies the replication group myReplGroup, making the read replica myReplica-1 the primary in the replication group.

```text
https://elasticache.us-west-2.amazonaws.com/
   ?Action=ModifyReplicationGroup
   &ReplicationGroupId=myReplGroup
   &PrimaryClusterId=myReplica-1
   &Version=2014-12-01
   &SignatureVersion=4
   &SignatureMethod=HmacSHA256
   &Timestamp=20141201T220302Z
   &X-Amz-Algorithm=&AWS;4-HMAC-SHA256
   &X-Amz-Date=20141201T220302Z
   &X-Amz-SignedHeaders=Host
   &X-Amz-Expires=20141201T220302Z
   &X-Amz-Credential=<credential>
   &X-Amz-Signature=<signature>
```

For more information on modifying a replication group, see ModifyReplicationGroup in the Amazon ElastiCache API Reference.

Backup and restore for ElastiCache for Redis

Amazon ElastiCache clusters running Redis can back up their data. You can use the backup to restore a cluster or seed a new cluster. The backup consists of the cluster's metadata, along with all of the data in the cluster. All backups are written to Amazon Simple Storage Service (Amazon S3), which provides durable storage. At any time, you can restore your data by creating a new Redis cluster and populating it with data from a backup. With ElastiCache, you can manage backups using the AWS Management Console, the AWS Command Line Interface (AWS CLI), and the ElastiCache API.

Beginning with Redis version 2.8.22, the backup method is selected based upon available memory. If there is sufficient available memory, a child process is spawned that writes all changes to the cache's
reserved memory while the cache is being backed up. Depending on the number of writes to the cache during the backup process, this child process can consume all reserved memory, causing the backup to fail.

If there is insufficient memory available, a forkless, cooperative background process is employed. The forkless method can affect both latency and throughput. For more information, see How synchronization and backup are implemented (p. 265).

For more information about the performance impact of the backup process, see Performance impact of backups (p. 312).

Following, you can find an overview of working with backup and restore.

**Important**
Though it's rare, sometimes the backup process fails to create a backup, including final backups. Insufficient reserved memory is often the cause of backup failures. Therefore, make sure that you have sufficient reserved memory before attempting a backup. If you have insufficient memory, you can either evict some keys or increase the value of reserved-memory-percent. For more information, see the following:

- Ensuring that you have enough memory to create a Redis snapshot (p. 221)
- Managing Reserved Memory (p. 223)

If you plan to delete cluster and it's important to preserve the data, you can take an extra precaution. To do this, create a manual backup first, verify that its status is available, and then delete the cluster. Doing this makes sure that if the backup fails, you still have the cluster data available. You can retry making a backup, following the best practices outlined preceding.

**Topics**
- Backup constraints (p. 311)
- Backup costs (p. 312)
- Performance impact of backups (p. 312)
- Backups when running Redis 2.8.22 and later (p. 312)
- Backups when running Redis versions before 2.8.22 (p. 312)
- Improving backup performance (p. 312)
- Scheduling automatic backups (p. 314)
- Making manual backups (p. 315)
- Creating a final backup (p. 321)
- Describing backups (p. 324)
- Copying a backup (p. 326)
- Exporting a backup (p. 328)
- Restoring from a backup with optional cluster resizing (p. 334)
- Seeding a new cluster with an externally created backup (p. 337)

**Backup constraints**

Consider the following constraints when planning or making backups:

- At this time, backup and restore are supported only for clusters running on Redis.
- For Redis (cluster mode disabled) clusters, backup and restore aren't supported on cache.t1.micro nodes. All other cache node types are supported.
- For Redis (cluster mode enabled) clusters, backup and restore are supported for all node types.
Costs

- During any contiguous 24-hour period, you can create no more than 20 manual backups per node in the cluster.
- Redis (cluster mode enabled) only supports taking backups on the cluster level (for the API or CLI, the replication group level). Redis (cluster mode enabled) doesn't support taking backups at the shard level (for the API or CLI, the node group level).
- During the backup process, you can't run any other API or CLI operations on the cluster.
- If using clusters with data tiering, you cannot export a backup to Amazon S3.
- You can restore a backup of a cluster using the r6gd node type only to clusters using the r6gd node type.

Backup costs

Using ElastiCache, you can store one backup for each active Redis cluster free of charge. Storage space for additional backups is charged at a rate of $0.085/GB per month for all AWS Regions. There are no data transfer fees for creating a backup, or for restoring data from a backup to a Redis cluster.

Performance impact of backups

The backup process depends upon which Redis version you're running. Beginning with Redis 2.8.22, the process is forkless.

Backups when running Redis 2.8.22 and later

In versions 2.8.22 and later, Redis backups choose between two methods. If there isn't enough memory to support a forked backup, ElastiCache use a forkless method that uses cooperative background processing. If there is enough memory to support a forked save process, the same process is used as in earlier Redis versions.

If the write load is high during a forkless backup, writes to the cache are delayed. This delay makes sure that you don't accumulate too many changes and thus prevent a successful backup.

Backups when running Redis versions before 2.8.22

Backups are created using Redis' native BGSAVE operation. The Redis process on the cache node spawns a child process to write all the data from the cache to a Redis .rdb file. It can take up to 10 seconds to spawn the child process. During this time, the parent process is unable to accept incoming application requests. After the child process is running independently, the parent process resumes normal operations. The child process exits when the backup operation is complete.

While the backup is being written, additional cache node memory is used for new writes. If this additional memory usage exceeds the node's available memory, processing can become slow due to excessive paging, or fail.

Improving backup performance

The following are guidelines for improving backup performance.

- Set the reserved-memory-percent parameter – To mitigate excessive paging, we recommend that you set the reserved-memory-percent parameter. This parameter prevents Redis from consuming all of the node's available memory, and can help reduce the amount of paging. You might also see performance improvements by simply using a larger node. For more information about the reserved-memory and reserved-memory-percent parameters, see Managing Reserved Memory (p. 223).
• Create backups from a read replica – If you are running Redis in a node group with more than one node, you can take a backup from the primary node or one of the read replicas. Because of the system resources required during BGSAVE, we recommend that you create backups from one of the read replicas. While the backup is being created from the replica, the primary node remains unaffected by BGSAVE resource requirements. The primary node can continue serving requests without slowing down.

To do this, see Creating a manual backup (Console) (p. 315) and in the Cluster Name field in the Create Backup window, choose a replica instead of the default primary node.

If you delete a replication group and request a final backup, ElastiCache always takes the backup from the primary node. This ensures that you capture the very latest Redis data, before the replication group is deleted.
Scheduling automatic backups

For any Redis cluster, you can enable automatic backups. When automatic backups are enabled, ElastiCache creates a backup of the cluster on a daily basis. There is no impact on the cluster and the change is immediate. Automatic backups can help guard against data loss. In the event of a failure, you can create a new cluster, restoring your data from the most recent backup. The result is a warm-started cluster, preloaded with your data and ready for use. For more information, see Restoring from a backup with optional cluster resizing (p. 334).

When you schedule automatic backups, you should plan the following settings:

- **Backup window** – A period during each day when ElastiCache begins creating a backup. The minimum length for the backup window is 60 minutes. You can set the backup window for any time when it’s most convenient for you, or for a time of day that avoids doing backups during particularly high-utilization periods.

  If you don’t specify a backup window, ElastiCache assigns one automatically.

- **Backup retention limit** – The number of days the backup is retained in Amazon S3. For example, if you set the retention limit to 5, then a backup taken today is retained for 5 days. When the retention limit expires, the backup is automatically deleted.

  The maximum backup retention limit is 35 days. If the backup retention limit is set to 0, automatic backups are disabled for the cluster.

You can enable or disable automatic backups on an existing Redis cluster or replication group by modifying it using the ElastiCache console, the AWS CLI, or the ElastiCache API.

You can enable or disable automatic backups when creating a Redis cluster or replication group using the ElastiCache console, the AWS CLI, or the ElastiCache API. You can enable automatic backups when you create a Redis cluster by checking the **Enable Automatic Backups** box in the **Advanced Redis Settings** section. For more information, see step 2 of Creating a Redis (cluster mode disabled) cluster (Console) (p. 130). You can enable automatic backups when you create a Redis replication group if you are not using an existing cluster as the primary cluster. For more information, see Creating a Redis replication group from scratch (p. 272).
Making manual backups

In addition to automatic backups, you can create a manual backup at any time. Unlike automatic backups, which are automatically deleted after a specified retention period, manual backups do not have a retention period after which they are automatically deleted. You must manually delete any manual backup. Even if you delete a cluster or node, any manual backups from that cluster or node are retained. If you no longer want to keep a manual backup, you must explicitly delete it yourself.

Manual backups are useful for testing and archiving. For example, suppose that you've developed a set of baseline data for testing purposes. You can create a manual backup of the data and restore it whenever you want. After you test an application that modifies the data, you can reset the data by creating a new cluster and restoring from your baseline backup. When the cluster is ready, you can test your applications against the baseline data again—and repeat this process as often as needed.

In addition to directly creating a manual backup, you can create a manual backup in one of the following ways:

- Copying a backup (p. 326) It does not matter whether the source backup was created automatically or manually.
- Creating a final backup (p. 321) Create a backup immediately before deleting a cluster or node.

Other topics of import

- Backup constraints (p. 311)
- Backup costs (p. 312)
- Performance impact of backups (p. 312)

You can create a manual backup of a node using the AWS Management Console, the AWS CLI, or the ElastiCache API.

Creating a manual backup (Console)

To create a backup of a cluster (console)

2. From the navigation pane, choose Redis.
   
   The Redis clusters screen appears.
3. Choose the box to the left of the name of the Redis cluster you want to back up.
4. Choose Backup.
5. In the Create Backup dialog, type in a name for your backup in the Backup Name box. We recommend that the name indicate which cluster was backed up and the date and time the backup was made.

   Cluster naming constraints are as follows:
   
   - Must contain 1–40 alphanumeric characters or hyphens.
   - Must begin with a letter.
   - Can't contain two consecutive hyphens.
   - Can't end with a hyphen.
6. Choose Create Backup.
The status of the cluster changes to **snapshotting**. When the status returns to **available** the backup is complete.

**Creating a manual backup (AWS CLI)**

To create a manual backup of a cluster using the AWS CLI, use the `create-snapshot` AWS CLI operation with the following parameters:

- **--cache-cluster-id**
  - If the cluster you're backing up has no replica nodes, `--cache-cluster-id` is the name of the cluster you are backing up, for example `mycluster`.
  - If the cluster you're backing up has one or more replica nodes, `--cache-cluster-id` is the name of the node in the cluster that you want to use for the backup. For example, the name might be `mycluster-002`.
  
  Use this parameter only when backing up a Redis (cluster mode disabled) cluster.

- **--replication-group-id** – Name of the Redis (cluster mode enabled) cluster (CLI/API: a replication group) to use as the source for the backup. Use this parameter when backing up a Redis (cluster mode enabled) cluster.

- **--snapshot-name** – Name of the snapshot to be created.
  
  Cluster naming constraints are as follows:
  - Must contain 1–40 alphanumeric characters or hyphens.
  - Must begin with a letter.
  - Can't contain two consecutive hyphens.
  - Can't end with a hyphen.

**Example 1: Backing up a Redis (Cluster Mode Disabled) cluster that has no replica nodes**

The following AWS CLI operation creates the backup `bkup-20150515` from the Redis (cluster mode disabled) cluster `myNonClusteredRedis` that has no read replicas.

For Linux, macOS, or Unix:

```bash
aws elasticache create-snapshot
  --cache-cluster-id myNonClusteredRedis
  --snapshot-name bkup-20150515
```

For Windows:

```bash
aws elasticache create-snapshot ^
  --cache-cluster-id myNonClusteredRedis ^
  --snapshot-name bkup-20150515
```

**Example 2: Backing up a Redis (Cluster Mode Disabled) cluster with replica nodes**

The following AWS CLI operation creates the backup `bkup-20150515` from the Redis (cluster mode disabled) cluster `myNonClusteredRedis`. This backup has one or more read replicas.

For Linux, macOS, or Unix:

```bash
aws elasticache create-snapshot
  --replication-group-id myNonClusteredRedis
  --snapshot-name bkup-20150515
```
aws elasticache create-snapshot \
   --cache-cluster-id myNonClusteredRedis-001 \
   --snapshot-name bkup-20150515

For Windows:

aws elasticache create-snapshot ^
   --cache-cluster-id myNonClusteredRedis-001 ^
   --snapshot-name bkup-20150515

Example Output: Backing Up a Redis (Cluster Mode Disabled) Cluster with Replica Nodes

Output from the operation looks something like the following.

{
   "Snapshot": {
      "Engine": "redis",
      "CacheParameterGroupName": "default.redis3.2",
      "VpcId": "vpc-91280df6",
      "CacheClusterId": "myNonClusteredRedis-001",
      "SnapshotRetentionLimit": 0,
      "NumCacheNodes": 1,
      "SnapshotName": "bkup-20150515",
      "CacheClusterCreateTime": "2017-01-12T18:59:48.048Z",
      "AutoMinorVersionUpgrade": true,
      "PreferredAvailabilityZone": "us-east-1c",
      "SnapshotStatus": "creating",
      "SnapshotSource": "manual",
      "SnapshotWindow": "08:30-09:30",
      "EngineVersion": "3.2.4",
      "NodeSnapshots": [
         {
            "CacheSize": "",
            "CacheNodeId": "0001",
            "CacheNodeCreateTime": "2017-01-12T18:59:48.048Z"
         }
      ],
      "CacheSubnetGroupName": "default",
      "Port": 6379,
      "PreferredMaintenanceWindow": "wed:07:30-wed:08:30",
      "CacheNodeType": "cache.m3.2xlarge",
      "DataTiering": "disabled"
   }
}

Example 3: Backing up a cluster for Redis (Cluster Mode Enabled)

The following AWS CLI operation creates the backup bkup-20150515 from the Redis (cluster mode enabled) cluster myClusteredRedis. Note the use of --replication-group-id instead of --cache-cluster-id to identify the source.

For Linux, macOS, or Unix:

aws elasticache create-snapshot \
   --replication-group-id myClusteredRedis \
   --snapshot-name bkup-20150515

For Windows:

aws elasticache create-snapshot ^
   --replication-group-id myClusteredRedis ^
Example Output: Backing Up a Redis (Cluster Mode Enabled) Cluster

Output from this operation looks something like the following.

```json
{
  "Snapshot": {
    "Engine": "redis",
    "CacheParameterGroupName": "default.redis3.2.cluster.on",
    "VpcId": "vpc-91280df6",
    "NodeSnapshots": [
      {
        "CacheSize": "",
        "NodeGroupId": "0001"
      },
      {
        "CacheSize": "",
        "NodeGroupId": "0002"
      }
    ],
    "NumNodeGroups": 2,
    "SnapshotName": "bkup-20150515",
    "ReplicationGroupId": "myClusteredRedis",
    "AutoMinorVersionUpgrade": true,
    "SnapshotRetentionLimit": 1,
    "AutomaticFailover": "enabled",
    "SnapshotStatus": "creating",
    "SnapshotSource": "manual",
    "SnapshotWindow": "10:00-11:00",
    "EngineVersion": "3.2.4",
    "CacheSubnetGroupName": "default",
    "ReplicationGroupDescription": "2 shards 2 nodes each",
    "Port": 6379,
    "PreferredMaintenanceWindow": "sat:03:30-sat:04:30",
    "CacheNodeType": "cache.r3.large",
    "DataTiering": "disabled"
  }
}
```

Creating a manual backup (ElastiCache API)

To create a manual backup of a cluster using the ElastiCache API, use the `CreateSnapshot` ElastiCache API operation with the following parameters:

- **CacheClusterId**
  - If the cluster you're backing up has no replica nodes, `CacheClusterId` is the name of the cluster you are backing up, for example `mycluster`.
  - If the cluster you're backing up has one or more replica nodes, `CacheClusterId` is the name of the node in the cluster that you want to use for the backup, for example `mycluster-002`.

  Only use this parameter when backing up a Redis (cluster mode disabled) cluster.

- **ReplicationGroupId** – Name of the Redis (cluster mode enabled) cluster (CLI/API: a replication group) to use as the source for the backup. Use this parameter when backing up a Redis (cluster mode enabled) cluster.
• SnapshotName – Name of the snapshot to be created.

Cluster naming constraints are as follows:
• Must contain 1–40 alphanumeric characters or hyphens.
• Must begin with a letter.
• Can't contain two consecutive hyphens.
• Can't end with a hyphen.

API Code Examples

Creating a final backup

You can create a final backup using the ElastiCache console, the AWS CLI, or the ElastiCache API.

Creating a final backup (Console)

You can create a final backup when you delete either a Redis cluster (for the API or CLI, a replication group) using the ElastiCache console.

To create a final backup when deleting a Redis cluster, on the delete dialog box (step 5), choose Yes and give the backup a name.

Related topics

• Using the AWS Management Console (p. 165)
• Deleting a Replication Group (Console) (p. 296)

Creating a final backup (AWS CLI)

You can create a final backup when deleting a Redis cluster (for the API or CLI, a replication group) using the AWS CLI.

Topics

• When deleting a Redis cluster with no read replicas (p. 321)
• When deleting a Redis cluster with read replicas (p. 321)

When deleting a Redis cluster with no read replicas

To create a final backup, use the `delete-cache-cluster` AWS CLI operation with the following parameters.

- `--cache-cluster-id` – Name of the cluster being deleted.
- `--final-snapshot-identifier` – Name of the backup.

The following code creates the final backup `bkup-20150515-final` when deleting the cluster `myRedisCluster`.

For Linux, macOS, or Unix:

```
aws elasticache delete-cache-cluster \ 
  --cache-cluster-id myRedisCluster \ 
  --final-snapshot-identifier bkup-20150515-final
```

For Windows:

```
aws elasticache delete-cache-cluster ^ 
  --cache-cluster-id myRedisCluster ^ 
  --final-snapshot-identifier bkup-20150515-final
```

For more information, see `delete-cache-cluster` in the AWS CLI Command Reference.

When deleting a Redis cluster with read replicas

To create a final backup when deleting a replication group, use the `delete-replication-group` AWS CLI operation, with the following parameters:
Creating a final backup

- **--replication-group-id** – Name of the replication group being deleted.
- **--final-snapshot-identifier** – Name of the final backup.

The following code takes the final backup bkup-20150515-final when deleting the replication group myReplGroup.

For Linux, macOS, or Unix:

```
aws elasticache delete-replication-group \
  --replication-group-id myReplGroup \
  --final-snapshot-identifier bkup-20150515-final
```

For Windows:

```
aws elasticache delete-replication-group ^
  --replication-group-id myReplGroup ^
  --final-snapshot-identifier bkup-20150515-final
```

For more information, see delete-replication-group in the AWS CLI Command Reference.

Creating a final backup (ElastiCache API)

You can create a final backup when deleting a Redis cluster or replication group using the ElastiCache API.

**Topics**
- When deleting a Redis cluster (p. 322)
- When deleting a Redis replication group (p. 322)

When deleting a Redis cluster

To create a final backup, use the DeleteCacheCluster ElastiCache API operation with the following parameters.

- **CacheClusterId** – Name of the cluster being deleted.
- **FinalSnapshotIdentifier** – Name of the backup.

The following ElastiCache API operation creates the backup bkup-20150515-final when deleting the cluster myRedisCluster.

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=DeleteCacheCluster
  &CacheClusterId=myRedisCluster
  &FinalSnapshotIdentifier=bkup-20150515-final
  &Version=2015-02-02
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20150202T192317Z
  &X-Amz-Credential=<credential>
```

For more information, see DeleteCacheCluster in the Amazon ElastiCache API Reference.

When deleting a Redis replication group

To create a final backup when deleting a replication group, use the DeleteReplicationGroup ElastiCache API operation, with the following parameters:
Creating a final backup

- **ReplicationGroupId** – Name of the replication group being deleted.
- **FinalSnapshotIdentifier** – Name of the final backup.

The following ElastiCache API operation creates the backup `bkup-20150515-final` when deleting the replication group `myReplGroup`.

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=DeleteReplicationGroup
  &FinalSnapshotIdentifier=bkup-20150515-final
  &ReplicationGroupId=myReplGroup
  &Version=2015-02-02
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20150202T192317Z
  &X-Amz-Credential=<credential>
```

For more information, see [DeleteReplicationGroup](https://elasticache.us-west-2.amazonaws.com/) in the *Amazon ElastiCache API Reference*.

323
Describing backups

The following procedures show you how to display a list of your backups. If you desire, you can also view
the details of a particular backup.

Describing backups (Console)

To display backups using the AWS Management Console

1. Sign in to the AWS Management Console and open the ElastiCache console at https://
console.aws.amazon.com/elasticache/.
2. From the navigation pane, choose Backups.
3. Use the Filter list to display manual, automatic, or all backups.
4. To see the details of a particular backup, choose the box to the left of the backup's name.

Describing backups (AWS CLI)

To display a list of backups and optionally details about a specific backup, use the describe-
snapshots CLI operation.

Examples

The following operation uses the parameter --max-records to list up to 20 backups associated with
your account. Omitting the parameter --max-records lists up to 50 backups.

aws elasticache describe-snapshots --max-records 20

The following operation uses the parameter --cache-cluster-id to list only the backups associated
with the cluster my-cluster.

aws elasticache describe-snapshots --cache-cluster-id my-cluster

The following operation uses the parameter --snapshot-name to display the details of the backup my-
backup.

aws elasticache describe-snapshots --snapshot-name my-backup

For more information, see describe-snapshots in the AWS CLI Command Reference.

Describing backups (ElastiCache API)

To display a list of backups, use the DescribeSnapshots operation.

Examples

The following operation uses the parameter MaxRecords to list up to 20 backups associated with your
account. Omitting the parameter MaxRecords lists up to 50 backups.

https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeSnapshots
&MaxRecords=20
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Timestamp=20141201T220302Z

API Version 2015-02-02

324
Describing backups

The following operation uses the parameter `CacheClusterId` to list all backups associated with the cluster `MyCluster`.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeSnapshots
&CacheClusterId=MyCluster
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Timestamp=20141201T220302Z
&Version=2014-12-01
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
&X-Amz-Date=20141201T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Expires=20141201T220302Z
&X-Amz-Credential=<credential>
&X-Amz-Signature=<signature>
```

The following operation uses the parameter `SnapshotName` to display the details for the backup `MyBackup`.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeSnapshots
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SnapshotName=MyBackup
&Timestamp=20141201T220302Z
&Version=2014-12-01
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
&X-Amz-Date=20141201T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Expires=20141201T220302Z
&X-Amz-Credential=<credential>
&X-Amz-Signature=<signature>
```

For more information, see `DescribeSnapshots`. 
Copying a backup

You can make a copy of any backup, whether it was created automatically or manually. You can also export your backup so you can access it from outside ElastiCache. For guidance on exporting your backup, see Exporting a backup (p. 328).

The following procedures show you how to copy a backup.

Copying a backup (Console)

To copy a backup (console)

2. To see a list of your backups, from the left navigation pane choose Backups.
3. From the list of backups, choose the box to the left of the name of the backup you want to copy.
4. Choose Copy.
5. In the Create Copy of the Backup? dialog box, do the following:
   a. In the New backup name box, type a name for your new backup.
   b. Leave the optional Target S3 Bucket box blank. This field should only be used to export your backup and requires special S3 permissions. For information on exporting a backup, see Exporting a backup (p. 328).
   c. Choose Copy.

Copying a backup (AWS CLI)

To copy a backup, use the copy-snapshot operation.

Parameters

- --source-snapshot-name – Name of the backup to be copied.
- --target-snapshot-name – Name of the backup's copy.
- --target-bucket – Reserved for exporting a backup. Do not use this parameter when making a copy of a backup. For more information, see Exporting a backup (p. 328).

The following example makes a copy of an automatic backup.

For Linux, macOS, or Unix:

```bash
aws elasticache copy-snapshot
  --source-snapshot-name automatic.my-redis-primary-2014-03-27-03-15
  --target-snapshot-name my-backup-copy
```

For Windows:

```bash
aws elasticache copy-snapshot
  --source-snapshot-name automatic.my-redis-primary-2014-03-27-03-15
  --target-snapshot-name my-backup-copy
```

For more information, see copy-snapshot in the AWS CLI.
Copying a backup (ElastiCache API)

To copy a backup, use the CopySnapshot operation with the following parameters:

**Parameters**

- **SourceSnapshotName** – Name of the backup to be copied.
- **TargetSnapshotName** – Name of the backup's copy.
- **TargetBucket** – Reserved for exporting a backup. Do not use this parameter when making a copy of a backup. For more information, see Exporting a backup (p. 328).

The following example makes a copy of an automatic backup.

**Example**

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=CopySnapshot
  &SourceSnapshotName=automatic.my-redis-primary-2014-03-27-03-15
  &TargetSnapshotName=my-backup-copy
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20141201T220302Z
  &Version=2014-12-01
  &X-Amz-Algorithm=AWS4-HMAC-SHA256
  &X-Amz-Date=20141201T220302Z
  &X-Amz-SignedHeaders=Host
  &X-Amz-Expires=20141201T220302Z
  &X-Amz-Credential=<credential>
  &X-Amz-Signature=<signature>
```

For more information, see CopySnapshot in the Amazon ElastiCache API Reference.
Exporting a backup

Amazon ElastiCache supports exporting your ElastiCache backup to an Amazon Simple Storage Service (Amazon S3) bucket, which gives you access to it from outside ElastiCache. You can export a backup using the ElastiCache console, the AWS CLI, or the ElastiCache API.

Exporting a backup can be helpful if you need to launch a cluster in another AWS Region. You can export your data in one AWS Region, copy the .rdb file to the new AWS Region, and then use that .rdb file to seed the new cluster instead of waiting for the new cluster to populate through use. For information about seeding a new cluster, see Seeding a new cluster with an externally created backup (p. 337). Another reason you might want to export your cluster’s data is to use the .rdb file for offline processing.

Important

- The ElastiCache backup and the Amazon S3 bucket that you want to copy it to must be in the same AWS Region.

  Though backups copied to an Amazon S3 bucket are encrypted, we strongly recommend that you do not grant others access to the Amazon S3 bucket where you want to store your backups.

- Exporting a backup to Amazon S3 is not supported for clusters using data tiering. For more information, see Data tiering (p. 121).

Before you can export a backup to an Amazon S3 bucket, you must have an Amazon S3 bucket in the same AWS Region as the backup. Grant ElastiCache access to the bucket. The first two steps show you how to do this.

Warning

The following scenarios expose your data in ways that you might not want:

- **When another person has access to the Amazon S3 bucket that you exported your backup to.**

  To control access to your backups, only allow access to the Amazon S3 bucket to those whom you want to access your data. For information about managing access to an Amazon S3 bucket, see Managing access in the Amazon S3 Developer Guide.

- **When another person has permissions to use the CopySnapshot API operation.**

  Users or groups that have permissions to use the CopySnapshot API operation can create their own Amazon S3 buckets and copy backups to them. To control access to your backups, use an AWS Identity and Access Management (IAM) policy to control who has the ability to use the CopySnapshot API. For more information about using IAM to control the use of ElastiCache API operations, see Identity and access management in Amazon ElastiCache (p. 539) in the ElastiCache User Guide.

Topics

- Step 1: Create an Amazon S3 bucket (p. 328)
- Step 2: Grant ElastiCache access to your Amazon S3 bucket (p. 329)
- Step 3: Export an ElastiCache backup (p. 330)

Step 1: Create an Amazon S3 bucket

The following procedure uses the Amazon S3 console to create an Amazon S3 bucket where you export and store your ElastiCache backup.
To create an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose Create Bucket.
3. In Create a Bucket - Select a Bucket Name and Region, do the following:
   a. In Bucket Name, type a name for your Amazon S3 bucket.
      The name of your Amazon S3 bucket must be DNS-compliant. Otherwise, ElastiCache can't access your backup file. The rules for DNS compliance are:
         • Names must be at least 3 and no more than 63 characters long.
         • Names must be a series of one or more labels separated by a period (.) where each label:
            • Starts with a lowercase letter or a number.
            • Ends with a lowercase letter or a number.
            • Contains only lowercase letters, numbers, and dashes.
         • Names can't be formatted as an IP address (for example, 192.0.2.0).
   b. From the Region list, choose an AWS Region for your Amazon S3 bucket. This AWS Region must be the same AWS Region as the ElastiCache backup you want to export.
   c. Choose Create.

For more information about creating an Amazon S3 bucket, see Creating a bucket in the Amazon Simple Storage Service User Guide.

Step 2: Grant ElastiCache access to your Amazon S3 bucket

For ElastiCache to be able to copy a snapshot to an Amazon S3 bucket, you must update your bucket policy to grant ElastiCache access to the bucket.

Warning
Even though backups copied to an Amazon S3 bucket are encrypted, your data can be accessed by anyone with access to your Amazon S3 bucket. Therefore, we strongly recommend that you set up IAM policies to prevent unauthorized access to this Amazon S3 bucket. For more information, see Managing access in the Amazon S3 User Guide.

To create the proper permissions on an Amazon S3 bucket, take the steps described following.

To grant ElastiCache access to an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the Amazon S3 bucket that you want to copy the backup to. This should be the S3 bucket that you created in Step 1: Create an Amazon S3 bucket (p. 328).
3. Choose the Permissions tab and under Permissions, choose Access control list (ACL) and then choose Edit.
4. Add grantee Canonical Id 540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353 with the following options:
   • Objects: List, Write
   • Bucket ACL: Read, Write

   Note
   For GovCloud Regions, the Canonical Id is 40fa568277ad703bd160f66ae4f83fc9dfdfd06c2f1b5060ca22442ac3ef8be6.
5. Choose Save.

**Step 3: Export an ElastiCache backup**

Now you've created your S3 bucket and granted ElastiCache permissions to access it. Next, you can use the ElastiCache console, the AWS CLI, or the ElastiCache API to export your snapshot to it. The following assumes that you have the following additional S3 specific IAM permissions.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketLocation",
        "s3:ListAllMyBuckets",
        "s3:PutObject",
        "s3:GetObject",
        "s3:DeleteObject",
        "s3:ListBucket"
      ],
      "Resource": "arn:aws:s3:::*"
    }
  ]
}
```

**Exporting an ElastiCache backup (Console)**

The following process uses the ElastiCache console to export a backup to an Amazon S3 bucket so that you can access it from outside ElastiCache. The Amazon S3 bucket must be in the same AWS Region as the ElastiCache backup.

**To export an ElastiCache backup to an Amazon S3 bucket**

2. To see a list of your backups, from the left navigation pane choose **Backups**.
3. From the list of backups, choose the box to the left of the name of the backup you want to export.
4. Choose **Copy**.
5. In **Create a Copy of the Backup?**, do the following:

   a. In **New backup name** box, type a name for your new backup.

   The name must be between 1 and 1,000 characters and able to be UTF-8 encoded.

   ElastiCache adds an instance identifier and **.rdb** to the value that you enter here. For example, if you enter **my-exported-backup**, ElastiCache creates **my-exported-backup-0001.rdb**.

   b. From the **Target S3 Location** list, choose the name of the Amazon S3 bucket that you want to copy your backup to (the bucket that you created in **Step 1: Create an Amazon S3 bucket** (p. 328)).

   The **Target S3 Location** must be an Amazon S3 bucket in the backup's AWS Region with the following permissions for the export process to succeed.

   - Object access – **Read** and **Write**.
   - Permissions access – **Read**.

   For more information, see **Step 2: Grant ElastiCache access to your Amazon S3 bucket** (p. 329).
c. Choose Copy.

Note
If your S3 bucket does not have the permissions needed for ElastiCache to export a backup to it, you receive one of the following error messages. Return to Step 2: Grant ElastiCache access to your Amazon S3 bucket (p. 329) to add the permissions specified and retry exporting your backup.

- ElastiCache has not been granted READ permissions %s on the S3 Bucket.
  Solution: Add Read permissions on the bucket.
- ElastiCache has not been granted WRITE permissions %s on the S3 Bucket.
  Solution: Add Write permissions on the bucket.
- ElastiCache has not been granted READ_ACP permissions %s on the S3 Bucket.
  Solution: Add Read for Permissions access on the bucket.

If you want to copy your backup to another AWS Region, use Amazon S3 to copy it. For more information, see Copying an object in the Amazon Simple Storage Service User Guide.

Exporting an ElastiCache backup (AWS CLI)

Export the backup to an Amazon S3 bucket using the `copy-snapshot` CLI operation with the following parameters:

Parameters

- `--source-snapshot-name` – Name of the backup to be copied.
- `--target-snapshot-name` – Name of the backup's copy.

The name must be between 1 and 1,000 characters and able to be UTF-8 encoded.

ElastiCache adds an instance identifier and `.rdb` to the value you enter here. For example, if you enter `my-exported-backup`, ElastiCache creates `my-exported-backup-0001.rdb`.

- `--target-bucket` – Name of the Amazon S3 bucket where you want to export the backup. A copy of the backup is made in the specified bucket.

The `--target-bucket` must be an Amazon S3 bucket in the backup's AWS Region with the following permissions for the export process to succeed.

- Object access – Read and Write.
- Permissions access – Read.

For more information, see Step 2: Grant ElastiCache access to your Amazon S3 bucket (p. 329).

The following operation copies a backup to `my-s3-bucket`.

For Linux, macOS, or Unix:

```
aws elasticache copy-snapshot \
  --source-snapshot-name automatic.my-redis-primary-2016-06-27-03-15 \
  --target-snapshot-name my-exported-backup \
  --target-bucket my-s3-bucket
```

For Windows:

```
aws elasticache copy-snapshot \n  --source-snapshot-name automatic.my-redis-primary-2016-06-27-03-15 \n  --target-snapshot-name my-exported-backup \n  --target-bucket my-s3-bucket
```
Exporting a backup

```
aws elasticache copy-snapshot ^
   --source-snapshot-name automatic.my-redis-primary-2016-06-27-03-15 ^
   --target-snapshot-name my-exported-backup ^
   --target-bucket my-s3-bucket
```

**Note**

If your S3 bucket does not have the permissions needed for ElastiCache to export a backup to it, you receive one of the following error messages. Return to Step 2: Grant ElastiCache access to your Amazon S3 bucket (p. 329) to add the permissions specified and retry exporting your backup.

- ElastiCache has not been granted READ permissions %s on the S3 Bucket.
  
  **Solution:** Add Read permissions on the bucket.

- ElastiCache has not been granted WRITE permissions %s on the S3 Bucket.
  
  **Solution:** Add Write permissions on the bucket.

- ElastiCache has not been granted READ_ACP permissions %s on the S3 Bucket.
  
  **Solution:** Add Read for Permissions access on the bucket.

For more information, see copy-snapshot in the AWS CLI Command Reference.

If you want to copy your backup to another AWS Region, use Amazon S3 copy. For more information, see Copying an object in the Amazon Simple Storage Service User Guide.

### Exporting an ElastiCache backup (ElastiCache API)

Export the backup to an Amazon S3 bucket using the CopySnapshot API operation with these parameters.

**Parameters**

- **SourceSnapshotName** – Name of the backup to be copied.
- **TargetSnapshotName** – Name of the backup's copy.

  The name must be between 1 and 1,000 characters and able to be UTF-8 encoded.

  ElastiCache adds an instance identifier and .rdb to the value that you enter here. For example, if you enter my-exported-backup, you get my-exported-backup-0001.rdb.

- **TargetBucket** – Name of the Amazon S3 bucket where you want to export the backup. A copy of the backup is made in the specified bucket.

  The TargetBucket must be an Amazon S3 bucket in the backup's AWS Region with the following permissions for the export process to succeed.

  - **Object access** – Read and Write.
  - **Permissions access** – Read.

  For more information, see Step 2: Grant ElastiCache access to your Amazon S3 bucket (p. 329).

The following example makes a copy of an automatic backup to the Amazon S3 bucket my-s3-bucket.

**Example**

```
https://elasticache.us-west-2.amazonaws.com/
?Action=CopySnapshot
```
Exporting a backup

```bash
&SourceSnapshotName=automatic.my-redis-primary-2016-06-27-03-15
&TargetBucket=my-s3-bucket
&TargetSnapshotName=my-backup-copy
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20141201T220302Z
&Version=2016-01-01
&X-Amz-Algorithm=AWS;4-HMAC-SHA256
&X-Amz-Date=20141201T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Expires=20141201T220302Z
&X-Amz-Credential=<credential>
&X-Amz-Signature=<signature>
```

Note
If your S3 bucket does not have the permissions needed for ElastiCache to export a backup to it, you receive one of the following error messages. Return to Step 2: Grant ElastiCache access to your Amazon S3 bucket (p. 329) to add the permissions specified and retry exporting your backup.

- ElastiCache has not been granted READ permissions %s on the S3 Bucket.
  
  **Solution:** Add Read permissions on the bucket.

- ElastiCache has not been granted WRITE permissions %s on the S3 Bucket.
  
  **Solution:** Add Write permissions on the bucket.

- ElastiCache has not been granted READ_ACP permissions %s on the S3 Bucket.
  
  **Solution:** Add Read for Permissions access on the bucket.

For more information, see CopySnapshot in the Amazon ElastiCache API Reference.

If you want to copy your backup to another AWS Region, use Amazon S3 copy to copy the exported backup to the Amazon S3 bucket in another AWS Region. For more information, see Copying an object in the Amazon Simple Storage Service User Guide.
Restoring from a backup with optional cluster resizing

You can only restore backups running r6gd node types into clusters running r6gd node types.

The Amazon ElastiCache for Redis restore process supports the following:

- Upgrading from a Redis (cluster mode disabled) cluster to a Redis (cluster mode enabled) cluster running Redis version 3.2.4.
- Migrating from one or more .rdb backup files you created from your self-managed Redis clusters to a single ElastiCache for Redis (cluster mode enabled) cluster.

The .rdb files must be put in S3 to perform the restore.

- Specifying a number of shards (API/CLI: node groups) in the new cluster that is different from the number of shards in the cluster that was used to create the backup file.
- Specifying a different node type for the new cluster—larger or smaller. If scaling to a smaller node type, be sure that the new node type has sufficient memory for your data and Redis overhead. For more information, see Choosing your node size (p. 127).
- Configuring the slots of the new Redis (cluster mode enabled) cluster differently than in the cluster that was used to create the backup file.

Important

- You cannot restore from a backup created using a Redis (cluster mode enabled) cluster to a Redis (cluster mode disabled) cluster.
- Redis (cluster mode enabled) clusters do not support multiple databases. Therefore, when restoring to a Redis (cluster mode enabled) your restore fails if the .rdb file references more than one database.
- You cannot restore a backup from a cluster that uses data tiering (for example, r6gd node type) into a cluster that does not use data tiering (for example, r6g node type).

Whether you make any changes when restoring a cluster from a backup is governed by choices that you make. You make these choices in the Restore Cluster dialog box when using the ElastiCache console to restore. You make these choices by setting parameter values when using the AWS CLI or ElastiCache API to restore.

During the restore operation, ElastiCache creates the new cluster, and then populates it with data from the backup file. When this process is complete, the Redis cluster is warmed up and ready to accept requests.

Important

Before you proceed, be sure you have created a backup of the cluster you want to restore from. For more information, see Making manual backups (p. 315).

If you want to restore from an externally created backup, see Seeding a new cluster with an externally created backup (p. 337).

The following procedures show you how to restore a backup to a new cluster using the ElastiCache console, the AWS CLI, or the ElastiCache API.

Restoring from a backup (Console)

You can restore a Redis backup in two ways. You can restore to a single-node Redis (cluster mode disabled) cluster. Or you can restore to a Redis cluster with read replicas (a replication group), either Redis (cluster mode disabled) or Redis (cluster mode enabled).
To restore a backup to a new cluster (console)

2. From the navigation pane, choose Backups.
3. In the list of backups, choose the box to the left of the backup name you want to restore from.
4. Choose Restore.
5. Complete the Restore Cluster dialog box. Be sure to complete all the "Required" fields and any of the others you want to change from the defaults.

Redis (Cluster Mode Disabled)

1. **Cluster ID** – Required. The name of the new cluster.
2. **Engine version compatibility** – The ElastiCache for Redis engine version you want to run.
3. **Cluster mode enabled (scale out)** – Choose this to convert your Redis (cluster mode disabled) cluster to a Redis (cluster mode enabled). The engine version becomes 3.2.4.

   If you choose Cluster mode enabled (scale out):
   a. Choose the number of shards you want in the new cluster (API/CLI: node groups).
   b. Choose the number of read replicas you want in each shard.
   c. Distribute your keys among the slots as you desire.
4. **Node Type** – Specify the node type you want for the new cluster.
5. **Availability zone(s)** – Specify how you want the cluster's Availability Zones selected.
6. **Port** – Change this only if you want the new cluster to use a different port.
7. **Choose a VPC** – Choose the VPC in which to create this cluster.
8. **Parameter Group** – Choose a parameter group that reserves sufficient memory for Redis overhead for the node type you selected.

Redis (Cluster Mode Enabled)

1. **Cluster ID** – Required. The name of the new cluster.
2. **Cluster mode enabled (scale out)** – Choose this for a Redis (cluster mode enabled) cluster. Clear it for a Redis (cluster mode disabled) cluster.
3. **Node Type** – Specify the node type you want for the new cluster.
4. **Number of Shards** – Choose the number of shards you want in the new cluster (API/CLI: node groups).
5. **Replicas per Shard** – Choose the number of read replica nodes you want in each shard.
6. **Slots and keyspaces** – Choose how you want keys distributed among the shards. If you choose to specify the key distributions complete the table specifying the key ranges for each shard.
7. **Availability zone(s)** – Specify how you want the cluster's Availability Zones selected.
8. **Port** – Change this only if you want the new cluster to use a different port.
9. **Choose a VPC** – Choose the VPC in which to create this cluster.
10. **Parameter Group** – Choose a parameter group that reserves sufficient memory for Redis overhead for the node type you selected.

6. When the settings are as you want them, choose Create.
Restoring from a backup (AWS CLI)

You can restore a Redis (cluster mode disabled) backup in two ways. You can restore to a single-node Redis (cluster mode disabled) cluster using the AWS CLI operation `create-cache-cluster`. Or you can restore to a Redis cluster with read replicas (a replication group). To do the latter, you can use either Redis (cluster mode disabled) or Redis (cluster mode enabled) with the AWS CLI operation `create-replication-group`. In this case, you seed the restore with a Redis .rdb file.

When using either the `create-cache-cluster` or `create-replication-group` operation, be sure to include the parameter `--snapshot-name` or `--snapshot-arns` to seed the new cluster or replication group with the data from the backup.

For more information, see the following:

- [create-cache-cluster](AWS CLI Command Reference) in the *AWS CLI Command Reference*.

- [create-replication-group](AWS CLI Command Reference) in the *AWS CLI Command Reference*.

Restoring from a backup (ElastiCache API)

You can restore a Redis backup to either a single-node Redis (cluster mode disabled) cluster using the ElastiCache API operation `CreateCacheCluster` or to a Redis cluster with read replicas (replication group)—either Redis (cluster mode disabled) or Redis (cluster mode enabled) using the ElastiCache API operation `CreateReplicationGroup` and seeding it with a Redis .rdb file.

When using either the `CreateCacheCluster` or `CreateReplicationGroup` operation, be sure to include the parameter `SnapshotName` or `SnapshotArns` to seed the new cluster or replication group with the data from the backup.

For more information, see the following:

- [CreateCacheCluster](ElastiCache API Reference) in the *ElastiCache API Reference*.

- [CreateReplicationGroup](ElastiCache API Reference) in the *ElastiCache API Reference*. 

API Version 2015-02-02

336
Seeding a new cluster with an externally created backup

When you create a new Redis cluster, you can seed it with data from a Redis .rdb backup file. Seeding the cluster is useful if you currently manage a Redis instance outside of ElastiCache and want to populate your new ElastiCache for Redis cluster with your existing Redis data.

To seed a new Redis cluster from a Redis backup created within Amazon ElastiCache, see Restoring from a backup with optional cluster resizing (p. 334).

When you use a Redis .rdb file to seed a new Redis cluster, you can do the following:

- Upgrade from a nonpartitioned cluster to a Redis (cluster mode enabled) cluster running Redis version 3.2.4.
- Specify a number of shards (called node groups in the API and CLI) in the new cluster. This number can be different from the number of shards in the cluster that was used to create the backup file.
- Specify a different node type for the new cluster—larger or smaller than that used in the cluster that made the backup. If you scale to a smaller node type, be sure that the new node type has sufficient memory for your data and Redis overhead. For more information, see Ensuring that you have enough memory to create a Redis snapshot (p. 221).
- Distribute your keys in the slots of the new Redis (cluster mode enabled) cluster differently than in the cluster that was used to create the backup file.

**Note**

You can't seed a Redis (cluster mode disabled) cluster from an .rdb file created from a Redis (cluster mode enabled) cluster.

**Important**

- You must ensure that your Redis backup data doesn't exceed the resources of the node. For example, you can't upload an .rdb file with 5 GB of Redis data to a cache.m3.medium node that has 2.9 GB of memory.

  If the backup is too large, the resulting cluster has a status of `restore-failed`. If this happens, you must delete the cluster and start over.

  For a complete listing of node types and specifications, see Redis node-type specific parameters (p. 465) and Amazon ElastiCache product features and details.

- You can encrypt a Redis .rdb file with Amazon S3 server-side encryption (SSE-S3) only. For more information, see Protecting data using server-side encryption.

Following, you can find topics that walk you through migrating your Redis cluster from outside ElastiCache for Redis to ElastiCache for Redis.

**Migrating to ElastiCache for Redis**

- **Step 1:** Create a Redis backup (p. 338)
- **Step 2:** Create an Amazon S3 bucket and folder (p. 338)
- **Step 3:** Upload your backup to Amazon S3 (p. 339)
- **Step 4:** Grant ElastiCache read access to the .rdb file (p. 339)
- Tagging backups (p. 343)
- Deleting a backup (p. 344)
- Append only files (AOF) in ElastiCache for Redis (p. 345)
Step 1: Create a Redis backup

To create the Redis backup to seed your ElastiCache for Redis instance

1. Connect to your existing Redis instance.
2. Run either the Redis `BGSAVE` or `SAVE` operation to create a backup. Note where your `.rdb` file is located.

   `BGSAVE` is asynchronous and does not block other clients while processing. For more information, see `BGSAVE` at the Redis website.

   `SAVE` is synchronous and blocks other processes until finished. For more information, see `SAVE` at the Redis website.

For additional information on creating a backup, see Redis persistence at the Redis website.

Step 2: Create an Amazon S3 bucket and folder

When you have created the backup file, you need to upload it to a folder within an Amazon S3 bucket. To do that, you must first have an Amazon S3 bucket and folder within that bucket. If you already have an Amazon S3 bucket and folder with the appropriate permissions, you can skip to Step 3: Upload your backup to Amazon S3 (p. 339).

To create an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Follow the instructions for creating an Amazon S3 bucket in Creating a bucket in the Amazon Simple Storage Service User Guide.

   The name of your Amazon S3 bucket must be DNS-compliant. Otherwise, ElastiCache can't access your backup file. The rules for DNS compliance are:

   • Names must be at least 3 and no more than 63 characters long.
   • Names must be a series of one or more labels separated by a period (.) where each label:
     • Starts with a lowercase letter or a number.
     • Ends with a lowercase letter or a number.
     • Contains only lowercase letters, numbers, and dashes.
   • Names can't be formatted as an IP address (for example, 192.0.2.0).

   You must create your Amazon S3 bucket in the same AWS Region as your new ElastiCache for Redis cluster. This approach makes sure that the highest data transfer speed when ElastiCache reads your `.rdb` file from Amazon S3.

   **Note**
   To keep your data as secure as possible, make the permissions on your Amazon S3 bucket as restrictive as you can. At the same time, the permissions still need to allow the bucket and its contents to be used to seed your new Redis cluster.

To add a folder to an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the bucket to upload your `.rdb` file to.
3. Choose Create folder.
4. Enter a name for your new folder.
5. Choose Save.

Make note of both the bucket name and the folder name.

**Step 3: Upload your backup to Amazon S3**

Now, upload the .rdb file that you created in Step 1: Create a Redis backup (p. 338). You upload it to the Amazon S3 bucket and folder that you created in Step 2: Create an Amazon S3 bucket and folder (p. 338). For more information on this task, see Add an object to a bucket. Between steps 2 and 3, choose the name of the folder you created.

**To upload your .rdb file to an Amazon S3 folder**

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose the name of the Amazon S3 bucket you created in Step 2.
3. Choose the name of the folder you created in Step 2.
5. Choose Add files.
6. Browse to find the file or files you want to upload, then choose the file or files. To choose multiple files, hold down the Ctrl key while choosing each file name.
7. Choose Open.
8. Confirm the correct file or files are listed in the Upload dialog box, and then choose Upload.

Note the path to your .rdb file. For example, if your bucket name is myBucket and the path is myFolder/redis.rdb, enter myBucket/myFolder/redis.rdb. You need this path to seed the new cluster with the data in this backup.

For additional information, see Bucket restrictions and limitations in the Amazon Simple Storage Service User Guide.

**Step 4: Grant ElastiCache read access to the .rdb file**

Now, grant ElastiCache read access to your .rdb backup file. You grant ElastiCache access to your backup file in a different way depending if your bucket is in a default AWS Region or an opt-in AWS Region.

AWS Regions introduced before March 20, 2019, are enabled by default. You can begin working in these AWS Regions immediately. Regions introduced after March 20, 2019, such as Asia Pacific (Hong Kong) and Middle East (Bahrain), are disabled by default. You must enable, or opt in, to these Regions before you can use them, as described in Managing AWS regions in AWS General Reference.

Choose your approach depending on your AWS Region:

- For a default Region, use the procedure in Grant ElastiCache read access to the .rdb file in a default Region (p. 339).
- For an opt-in Region, use the procedure in Grant ElastiCache read access to the .rdb file in an opt-in Region (p. 340).

**Grant ElastiCache read access to the .rdb file in a default Region**

AWS Regions introduced before March 20, 2019, are enabled by default. You can begin working in these AWS Regions immediately. Regions introduced after March 20, 2019, such as Asia Pacific (Hong Kong)
and Middle East (Bahrain), are disabled by default. You must enable, or opt in, to these Regions before you can use them, as described in Managing AWS regions in AWS General Reference.

To grant ElastiCache read access to the backup file in an AWS Region enabled by default

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.  
2. Choose the name of the S3 bucket that contains your .rdb file.  
3. Choose the name of the folder that contains your .rdb file.  
4. Choose the name of your .rdb backup file. The name of the selected file appears above the tabs at the top of the page.  
5. Choose Permissions.  
6. If `aws-scs-s3-readonly` or one of the canonical IDs in the following list is not listed as a user, do the following:  
   a. Under Access for other AWS accounts, choose Add grantee.  
   b. In the box, add the AWS Region's canonical ID as shown following:  
      • AWS GovCloud (US-West) Region:
        ```
        40fa568277ad703bd160f66ae4f83fc9dfdf06c2f1b5060ca22442ac3ef8be6
        ```
      Important  
      The backup must be located in an S3 bucket in AWS GovCloud (US) for you to download it to a Redis cluster in AWS GovCloud (US).  
      • AWS Regions enabled by default:  
        ```
        540804c33a284a299d2547575ce1010f2312ef3da9b3a053c8bc45bf233e4353
        ```  
   c. Set the permissions on the bucket by choosing Yes for the following:  
      • List/write object  
      • Read/write object ACL permissions  
   d. Choose Save.  
7. Choose Overview, and then choose Download.

Grant ElastiCache read access to the .rdb file in an opt-in Region

AWS Regions introduced before March 20, 2019, are enabled by default. You can begin working in these AWS Regions immediately. Regions introduced after March 20, 2019, such as Asia Pacific (Hong Kong) and Middle East (Bahrain), are disabled by default. You must enable, or opt in, to these Regions before you can use them, as described in Managing AWS regions in AWS General Reference.

Now, grant ElastiCache read access to your .rdb backup file.

To grant ElastiCache read access to the backup file

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.  
2. Choose the name of the S3 bucket that contains your .rdb file.  
3. Choose the name of the folder that contains your .rdb file.  
4. Choose the name of your .rdb backup file. The name of the selected file appears above the tabs at the top of the page.
5. Choose the **Permissions** tab.
6. Under **Permissions**, choose **Bucket policy** and then choose **Edit**.
7. Update the policy to grant ElastiCache required permissions to perform operations:
   - Add `[ "Service" : "region-full-name.elasticache-snapshot.amazonaws.com" ]` to **Principal**.
   - Add the following permissions required for exporting a snapshot to the Amazon S3 bucket:
     - "s3:GetObject"
     - "s3:ListBucket"
     - "s3:GetBucketAcl"

   The following is an example of what the updated policy might look like.

   ```json
   {
     "Version": "2012-10-17",
     "Id": "Policy15397346",
     "Statement": [
       {
         "Sid": "Stmt15399483",
         "Effect": "Allow",
         "Principal": {
           "Service": "ap-east-1.elasticache-snapshot.amazonaws.com"
         },
         "Action": [
           "s3:GetObject",
           "s3:ListBucket",
           "s3:GetBucketAcl"
         ],
         "Resource": [
           "arn:aws:s3:::example-bucket",
           "arn:aws:s3:::example-bucket/backup1.rdb",
           "arn:aws:s3:::example-bucket/backup2.rdb"
         ]
       }
     ]
   }
   ```

8. Choose **Save changes**.

### Step 5: Seed the ElastiCache cluster with the .rdb file data

Now you are ready to create an ElastiCache cluster and seed it with the data from the .rdb file. To create the cluster, follow the directions at Creating a cluster (p. 130) or Creating a Redis replication group from scratch (p. 272). Be sure to choose Redis as your cluster engine.

The method you use to tell ElastiCache where to find the Redis backup you uploaded to Amazon S3 depends on the method you use to create the cluster:

**Seed the ElastiCache for Redis cluster or replication group with the .rdb file data**

- **Using the ElastiCache console**

   After you choose the Redis engine, expand the **Advanced Redis settings** section and locate **Import data to cluster**. In the **Seed RDB file S3 location** box, type in the Amazon S3 path for the files(s). If you have multiple .rdb files, type in the path for each file in a comma separated list. The Amazon S3 path looks something like `myBucket/myFolder/myBackupFilename.rdb`.

- **Using the AWS CLI**
If you use the `create-cache-cluster` or the `create-replication-group` operation, use the parameter `--snapshot-arns` to specify a fully qualified ARN for each .rdb file. For example, `arn:aws:s3:::myBucket/myFolder/myBackupFilename.rdb`. The ARN must resolve to the backup files you stored in Amazon S3.

- **Using the ElastiCache API**

If you use the `CreateCacheCluster` or the `CreateReplicationGroup` ElastiCache API operation, use the parameter `SnapshotArns` to specify a fully qualified ARN for each .rdb file. For example, `arn:aws:s3:::myBucket/myFolder/myBackupFilename.rdb`. The ARN must resolve to the backup files you stored in Amazon S3.

**Important**

When seeding a Redis (cluster mode enabled) cluster, you must configure each node group (shard) in the new cluster or replication group. Use the parameter `--node-group-configuration` (API: `NodeGroupConfiguration`) to do this. For more information, see the following:

- CLI: `create-replication-group` in the AWS CLI Reference
- API: `CreateReplicationGroup` in the ElastiCache API Reference

During the process of creating your cluster, the data in your Redis backup is written to the cluster. You can monitor the progress by viewing the ElastiCache event messages. To do this, see the ElastiCache console and choose **Cache Events**. You can also use the AWS ElastiCache command line interface or ElastiCache API to obtain event messages. For more information, see **Viewing ElastiCache events** (p. 611).
Tagging backups

You can assign your own metadata to each backup in the form of tags. Tags enable you to categorize your backups in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type—you can quickly identify a specific resource based on the tags that you've assigned to it. For more information, see Resources you can tag (p. 204).

Cost allocation tags are a means of tracking your costs across multiple AWS services by grouping your expenses on invoices by tag values. To learn more about cost allocation tags, see Use cost allocation tags.

Using the ElastiCache console, the AWS CLI, or ElastiCache API you can add, list, modify, remove, or copy cost allocation tags on your backups. For more information, see Monitoring costs with cost allocation tags (p. 210).
Deleting a backup

An automatic backup is automatically deleted when its retention limit expires. If you delete a cluster, all of its automatic backups are also deleted. If you delete a replication group, all of the automatic backups from the clusters in that group are also deleted.

ElastiCache provides a deletion API operation that lets you delete a backup at any time, regardless of whether the backup was created automatically or manually. Because manual backups don't have a retention limit, manual deletion is the only way to remove them.

You can delete a backup using the ElastiCache console, the AWS CLI, or the ElastiCache API.

Deleting a backup (Console)

The following procedure deletes a backup using the ElastiCache console.

To delete a backup

2. In the navigation pane, choose Backups.
   
   The Backups screen appears with a list of your backups.
3. Choose the box to the left of the name of the backup you want to delete.
4. Choose Delete.
5. If you want to delete this backup, choose Delete on the Delete Backup confirmation screen. The status changes to deleting.

Deleting a backup (AWS CLI)

Use the delete-snapshot AWS CLI operation with the following parameter to delete a backup.

- --snapshot-name – Name of the backup to be deleted.

The following code deletes the backup myBackup.

```
aws elasticache delete-snapshot --snapshot-name myBackup
```

For more information, see delete-snapshot in the AWS CLI Command Reference.

Deleting a backup (ElastiCache API)

Use the DeleteSnapshot API operation with the following parameter to delete a backup.

- SnapshotName – Name of the backup to be deleted.

The following code deletes the backup myBackup.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DeleteSnapshot
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&SnapshotId=myBackup
&Timestamp=20150202T192317Z
&Version=2015-02-02
&X-Amz-Credential=<credential>
```
Append only files (AOF) in ElastiCache for Redis

By default, the data in a Redis node on ElastiCache resides only in memory and isn't persistent. If a node is rebooted, or if the underlying physical server experiences a hardware failure, the data in the cache is lost.

If you require data durability, you can enable the Redis append-only file feature (AOF). When this feature is enabled, the node writes all of the commands that change cache data to an append-only file. When a node is rebooted and the cache engine starts, the AOF is "replayed." The result is a warm Redis cache with all of the data intact.

AOF is disabled by default. To enable AOF for a cluster running Redis, you must create a parameter group with the appendonly parameter set to yes. You then assign that parameter group to your cluster. You can also modify the appendfsync parameter to control how often Redis writes to the AOF file.

Important
Append-only files (AOF) aren't supported for cache.t1.micro and cache.t2.* nodes. For nodes of these types, the appendonly parameter value is ignored.
For Multi-AZ replication groups, AOF isn't enabled.
AOF isn't supported on Redis versions 2.8.22 and later.

Warning
AOF can't protect against all failure scenarios. For example, if a node fails due to a hardware fault in an underlying physical server, ElastiCache provisions a new node on a different server. In this case, the AOF file is no longer available and can't be used to recover the data. Thus, Redis restarts with a cold cache.
For greater reliability and faster recovery, we recommend that you create one or more read replicas in different Availability Zones for your cluster. Enable Multi-AZ on your replication group instead of using AOF. AOF isn't enabled for Multi-AZ replication groups.
For more information on mitigating failures, see Mitigating Failures when Running Redis (p. 623).

For more information, see the following:
• Redis-specific parameters (p. 441)
• Minimizing downtime in ElastiCache for Redis with Multi-AZ (p. 253)
• Mitigating Failures (p. 623)

Scaling ElastiCache for Redis clusters

The amount of data your application needs to process is seldom static. It increases and decreases as your business grows or experiences normal fluctuations in demand. If you self-manage your cache, you need to provision sufficient hardware for your demand peaks, which can be expensive. By using Amazon ElastiCache you can scale to meet current demand, paying only for what you use. ElastiCache enables you to scale your cache to match demand.

The following helps you find the correct topic for the scaling actions that you want to perform.

Scaling Redis clusters

**Topics**
- Scaling clusters for Redis (Cluster Mode Disabled) (p. 347)
- Scaling clusters in Redis (Cluster Mode Enabled) (p. 375)
Scaling clusters for Redis (Cluster Mode Disabled)

Redis (cluster mode disabled) clusters can be a single-node cluster with 0 shards or multi-node clusters with 1 shard. Single-node clusters use the one node for both reads and writes. Multi-node clusters always have 1 node as the read/write primary node with 0 to 5 read-only replica nodes.

    - Scaling up single-node Redis cache clusters (AWS CLI) (p. 350)
    - Scaling up single-node Redis cache clusters (ElastiCache API) (p. 352)
  - Scaling down single-node Redis clusters (p. 355)
    - Scaling down a single-node Redis cluster (Console) (p. 355)
    - Scaling down single-node Redis cache clusters (AWS CLI) (p. 356)
    - Scaling down single-node Redis cache clusters (ElastiCache API) (p. 358)
- Scaling Redis (Cluster Mode Disabled) clusters with replica nodes (p. 360)
  - Scaling up Redis clusters with replicas (p. 361)
  - Scaling down Redis clusters with replicas (p. 367)
  - Increasing read capacity (p. 373)
  - Decreasing read capacity (p. 374)

Scaling single-node clusters for Redis (Cluster Mode Disabled)

Redis (cluster mode disabled) nodes must be large enough to contain all the cache's data plus Redis overhead. To change the data capacity of your Redis (cluster mode disabled) cluster, you must scale vertically; scaling up to a larger node type to increase data capacity, or scaling down to a smaller node type to reduce data capacity.

The ElastiCache for Redis scaling up process is designed to make a best effort to retain your existing data and requires successful Redis replication. For Redis (cluster mode disabled) Redis clusters, we recommend that sufficient memory be made available to Redis.

You cannot partition your data across multiple Redis (cluster mode disabled) clusters. However, if you only need to increase or decrease your cluster's read capacity, you can create a Redis (cluster mode disabled) cluster with replica nodes and add or remove read replicas. To create a Redis (cluster mode disabled) cluster with replica nodes using your single-node Redis cache cluster as the primary cluster, see Creating a Redis (cluster mode disabled) cluster (Console) (p. 47).

After you create the cluster with replicas, you can increase read capacity by adding read replicas. Later, if you need to, you can reduce read capacity by removing read replicas. For more information, see Increasing read capacity (p. 373) or Decreasing read capacity (p. 374).

In addition to being able to scale read capacity, Redis (cluster mode disabled) clusters with replica provide other business advantages. For more information, see High availability using replication groups (p. 246).

Important

If your parameter group uses reserved-memory to set aside memory for Redis overhead, before you begin scaling be sure that you have a custom parameter group that reserves the correct amount of memory for your new node type. Alternatively, you can modify a custom parameter group so that it uses reserved-memory-percent and use that parameter group for your new cluster.
If you're using reserved-memory-percent, doing this is not necessary. For more information, see Managing Reserved Memory (p. 223).

Topics
- Scaling up single-node clusters for Redis (Cluster Mode Disabled) (p. 349)
- Scaling down single-node Redis clusters (p. 355)
Scaling up single-node clusters for Redis (Cluster Mode Disabled)

When you scale up a single-node Redis cluster, ElastiCache performs the following process, whether you use the ElastiCache console, the AWS CLI, or the ElastiCache API.

1. A new cache cluster with the new node type is spun up in the same Availability Zone as the existing cache cluster.
2. The cache data in the existing cache cluster is copied to the new cache cluster. How long this process takes depends upon your node type and how much data is in the cache cluster.
3. Reads and writes are now served using the new cache cluster. Because the new cache cluster's endpoints are the same as they were for the old cache cluster, you do not need to update the endpoints in your application. You will notice a brief interruption (a few seconds) of reads and writes from the primary node while the DNS entry is updated.
4. ElastiCache deletes the old cache cluster. You will notice a brief interruption (a few seconds) of reads and writes from the old node because the connections to the old node will be disconnected.

**Note**
For clusters running the r6gd node type, you can only scale to node sizes within the r6gd node family.

As shown in the following table, your Redis scale-up operation is blocked if you have an engine upgrade scheduled for the next maintenance window. For more information on Maintenance Windows, see Managing maintenance (p. 230).

### Blocked Redis operations

<table>
<thead>
<tr>
<th>Pending Operations</th>
<th>Blocked Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scale up</td>
<td>Immediate engine upgrade</td>
</tr>
<tr>
<td>Engine upgrade</td>
<td>Immediate scale up</td>
</tr>
<tr>
<td>Scale up and engine upgrade</td>
<td>Immediate scale up</td>
</tr>
<tr>
<td></td>
<td>Immediate engine upgrade</td>
</tr>
</tbody>
</table>

If you have a pending operation that is blocking you, you can do one of the following.

- Schedule your Redis scale-up operation for the next maintenance window by clearing the **Apply immediately** check box (CLI use: `--no-apply-immediately`, API use: `ApplyImmediately=false`).
- Wait until your next maintenance window (or after) to perform your Redis scale up operation.
- Add the Redis engine upgrade to this cache cluster modification with the **Apply Immediately** check box chosen (CLI use: `--apply-immediately`, API use: `ApplyImmediately=true`). This unblocks your scale up operation by causing the engine upgrade to be performed immediately.

You can scale up a single-node Redis (cluster mode disabled) cluster using the ElastiCache console, the AWS CLI, or ElastiCache API.

**Important**
If your parameter group uses reserved-memory to set aside memory for Redis overhead, before you begin scaling be sure that you have a custom parameter group that reserves the correct amount of memory for your new node type. Alternatively, you can modify a custom parameter group so that it uses reserved-memory-percent and use that parameter group for your new cluster.
If you're using reserved-memory-percent, doing this is not necessary. For more information, see Managing Reserved Memory (p. 223).

Scaling up single-node clusters for Redis (Cluster Mode Disabled) (Console)

The following procedure describes how to scale up a single-node Redis cluster using the ElastiCache Management Console. During this process, your Redis cluster will continue to serve requests with minimal downtime.

To scale up a single-node Redis cluster (console)

2. From the navigation pane, choose Redis.
3. From the list of clusters, choose the cluster you want to scale up (it must be running the Redis engine, not the Clustered Redis engine).
4. Choose Modify.
5. In the Modify Cluster wizard:
   a. Choose the node type you want to scale to from the Node type list.
   b. If you're using reserved-memory to manage your memory, from the Parameter Group list, choose the custom parameter group that reserves the correct amount of memory for your new node type.
6. If you want to perform the scale up process right away, choose the Apply immediately box. If the Apply immediately box is not chosen, the scale-up process is performed during this cluster's next maintenance window.
7. Choose Modify.

If you chose Apply immediately in the previous step, the cluster's status changes to modifying. When the status changes to available, the modification is complete and you can begin using the new cluster.

Scaling up single-node Redis cache clusters (AWS CLI)

The following procedure describes how to scale up a single-node Redis cache cluster using the AWS CLI. During this process, your Redis cluster will continue to serve requests with minimal downtime.

To scale up a single-node Redis cache cluster (AWS CLI)

1. Determine the node types you can scale up to by running the AWS CLI list-allowed-node-type-modifications command with the following parameter.
   
   * --cache-cluster-id

   For Linux, macOS, or Unix:

   ```bash
   aws elasticache list-allowed-node-type-modifications
   --cache-cluster-id my-cache-cluster-id
   ```

   For Windows:

   ```bash
   aws elasticache list-allowed-node-type-modifications
   --cache-cluster-id my-cache-cluster-id
   ```
Output from the above command looks something like this (JSON format).

```
{
  "ScaleUpModifications": [
    "cache.m3.2xlarge",
    "cache.m3.large",
    "cache.m3.xlarge",
    "cache.m4.10xlarge",
    "cache.m4.2xlarge",
    "cache.m4.4xlarge",
    "cache.m4.large",
    "cache.m4.xlarge",
    "cache.r3.2xlarge",
    "cache.r3.4xlarge",
    "cache.r3.8xlarge",
    "cache.r3.large",
    "cache.r3.xlarge"
  ],
  "ScaleDownModifications": [
    "cache.t2.micro",
    "cache.t2.small",
    "cache.t2.medium",
    "cache.t1.small",
  ],
}
```

For more information, see [list-allowed-node-type-modifications](https://docs.aws.amazon.com/cli/latest/reference/elasticache/list-allowed-node-type-modifications) in the AWS CLI Reference.

2. Modify your existing cache cluster specifying the cache cluster to scale up and the new, larger node type, using the AWS CLI `modify-cache-cluster` command and the following parameters.

   • `--cache-cluster-id` – The name of the cache cluster you are scaling up.
   
   • `--cache-node-type` – The new node type you want to scale the cache cluster. This value must be one of the node types returned by the `list-allowed-node-type-modifications` command in step 1.
   
   • `--cache-parameter-group-name` – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using `reserved-memory-percent` you can omit this parameter.
   
   • `--apply-immediately` – Causes the scale-up process to be applied immediately. To postpone the scale-up process to the cluster's next maintenance window, use the `--no-apply-immediately` parameter.

For Linux, macOS, or Unix:

```
aws elasticache modify-cache-cluster \  
  --cache-cluster-id my-redis-cache-cluster  \  
  --cache-node-type cache.m3.xlarge  \  
  --cache-parameter-group-name redis32-m2-xl  \  
  --apply-immediately
```

For Windows:

```
aws elasticache modify-cache-cluster ^  
  --cache-cluster-id my-redis-cache-cluster ^  
  --cache-node-type cache.m3.xlarge ^  
  --cache-parameter-group-name redis32-m2-xl ^
```
Output from the above command looks something like this (JSON format).

```
{
  "CacheCluster": {
    "Engine": "redis",
    "CacheParameterGroup": {
      "CacheNodeIdsToReboot": [],
      "CacheParameterGroupName": "default.redis3.2",
      "ParameterApplyStatus": "in-sync"
    },
    "SnapshotRetentionLimit": 1,
    "CacheClusterId": "my-redis-cache-cluster",
    "CacheSecurityGroups": [],
    "NumCacheNodes": 1,
    "SnapshotWindow": "00:00-01:00",
    "CacheClusterCreateTime": "2017-02-21T22:34:09.645Z",
    "AutoMinorVersionUpgrade": true,
    "CacheClusterStatus": "modifying",
    "PreferredAvailabilityZone": "us-west-2a",
    home#client-download:",
    "CacheSubnetGroupName": "default",
    "EngineVersion": "3.2.4",
    "PendingModifiedValues": {
      "CacheNodeType": "cache.m3.2xlarge"
    },
    "PreferredMaintenanceWindow": "tue:11:30-tue:12:30",
    "CacheNodeType": "cache.m3.medium",
    "DataTiering": "disabled"
  }
}
```

For more information, see modify-cache-cluster in the AWS CLI Reference.

3. If you used the `--apply-immediately`, check the status of the new cache cluster using the AWS CLI describe-cache-clusters command with the following parameter. When the status changes to available, you can begin using the new, larger cache cluster.

```
aws elasticache describe-cache-clusters --cache-cluster-id my-redis-cache-cluster
```

For more information, see describe-cache-clusters in the AWS CLI Reference.

### Scaling up single-node Redis cache clusters (ElastiCache API)

The following procedure describes how to scale up a single-node Redis cache cluster using the ElastiCache API. During this process, your Redis cluster will continue to serve requests with minimal downtime.

#### To scale up a single-node Redis cache cluster (ElastiCache API)

1. Determine the node types you can scale up to by running the ElastiCache API ListAllowedNodeTypeModifications action with the following parameter.

```
aws elasticache list-allowed-node-type-modifications --cache-cluster-id my-redis-cache-cluster
```

For more information, see list-allowed-node-type-modifications in the AWS CLI Reference.
Scaling clusters for Redis (Cluster Mode Disabled)

1. List the available node types for your cache cluster by sending a request to the `ListAllowedNodeTypeModifications` action.

   ```
   https://elasticache.us-west-2.amazonaws.com/
   ?Action=ListAllowedNodeTypeModifications
   &CacheClusterId=MyRedisCacheCluster
   &Version=2015-02-02
   &SignatureVersion=4
   &SignatureMethod=HmacSHA256
   &Timestamp=20150202T192317Z
   &X-Amz-Credential=<credential>
   ```

   For more information, see `ListAllowedNodeTypeModifications` in the Amazon ElastiCache API Reference.

2. Modify your existing cache cluster specifying the cache cluster to scale up and the new, larger node type, using the `ModifyCacheCluster` ElastiCache API action and the following parameters.

   - **CacheClusterId** – The name of the cache cluster you are scaling up.
   - **CacheNodeType** – The new, larger node type you want to scale the cache cluster up to. This value must be one of the node types returned by the `ListAllowedNodeTypeModifications` action in step 1.
   - **CacheParameterGroupName** – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent, you can omit this parameter.
   - **ApplyImmediately** – Set to true to cause the scale-up process to be performed immediately. To postpone the scale-up process to the cluster's next maintenance window, use `ApplyImmediately=false`.

   ```
   https://elasticache.us-west-2.amazonaws.com/
   ?Action=ModifyCacheCluster
   &ApplyImmediately=true
   &CacheClusterId=MyRedisCacheCluster
   &CacheNodeType=cache.m3.xlarge
   &CacheParameterGroupName=redis32-m2-xl
   &Version=2015-02-02
   &SignatureVersion=4
   &SignatureMethod=HmacSHA256
   &Timestamp=20150202T192317Z
   &X-Amz-Credential=<credential>
   ```

   For more information, see `ModifyCacheCluster` in the Amazon ElastiCache API Reference.

3. If you used `ApplyImmediately=true`, check the status of the new cache cluster using the `DescribeCacheClusters` action with the following parameter. When the status changes to `available`, you can begin using the new, larger cache cluster.

   - **CacheClusterId** – The name of your single-node Redis cache cluster. Use this parameter to describe a particular cache cluster rather than all cache clusters.

   ```
   https://elasticache.us-west-2.amazonaws.com/
   ?Action=DescribeCacheClusters
   &CacheClusterId=MyRedisCacheCluster
   &Version=2015-02-02
   &SignatureVersion=4
   &SignatureMethod=HmacSHA256
   &Timestamp=20150202T192317Z
   &X-Amz-Credential=<credential>
   ```
&X-Amz-Credential=<credential>

For more information, see DescribeCacheClusters in the Amazon ElastiCache API Reference.
Scaling down single-node Redis clusters

The following sections walk you through how to scale a single-node Redis cluster down to a smaller node type. Ensuring that the new, smaller node type is large enough to accommodate all the data and Redis overhead is important to the long-term success of your new Redis cluster. For more information, see Ensuring that you have enough memory to create a Redis snapshot (p. 221).

Note
For clusters running the r6gd node type, you can only scale to node sizes within the r6gd node family.

Topics
- Scaling down a single-node Redis cluster (Console) (p. 355)
- Scaling down single-node Redis cache clusters (AWS CLI) (p. 356)
- Scaling down single-node Redis cache clusters (ElastiCache API) (p. 358)

Scaling down a single-node Redis cluster (Console)

The following procedure walks you through scaling your single-node Redis cluster down to a smaller node type using the ElastiCache console.

Important
If your parameter group uses reserved-memory to set aside memory for Redis overhead, before you begin scaling be sure that you have a custom parameter group that reserves the correct amount of memory for your new node type. Alternatively, you can modify a custom parameter group so that it uses reserved-memory-percent and use that parameter group for your new cluster.

If you're using reserved-memory-percent, doing this is not necessary. For more information, see Managing Reserved Memory (p. 223).

To scale down your single-node Redis cluster (console)

1. Ensure that the smaller node type is adequate for your data and overhead needs.
2. If your parameter group uses reserved-memory to set aside memory for Redis overhead, ensure that you have a custom parameter group to set aside the correct amount of memory for your new node type.

   Alternatively, you can modify your custom parameter group to use reserved-memory-percent. For more information, see Managing Reserved Memory (p. 223).
4. From the list of clusters, choose the cluster you want to scale down. This cluster must be running the Redis engine and not the Clustered Redis engine.
5. Choose Modify.
6. In the Modify Cluster wizard:
   a. Choose the node type you want to scale down to from the Node type list.
   b. If you're using reserved-memory to manage your memory, from the Parameter Group list, choose the custom parameter group that reserves the correct amount of memory for your new node type.
7. If you want to perform the scale-down process right away, choose the Apply immediately check box. If the Apply immediately check box is left not chosen, the scale-down process is performed during this cluster's next maintenance window.
8. Choose Modify.
9. When the cluster’s status changes from *modifying* to *available*, your cluster has scaled to the new node type. There is no need to update the endpoints in your application.

**Scaling down single-node Redis cache clusters (AWS CLI)**

The following procedure describes how to scale down a single-node Redis cache cluster using the AWS CLI.

**To scale down a single-node Redis cache cluster (AWS CLI)**

1. Determine the node types you can scale down to by running the AWS CLI `list-allowed-node-type-modifications` command with the following parameter.
   
   • `--cache-cluster-id`

   For Linux, macOS, or Unix:
   
   ```
   aws elasticache list-allowed-node-type-modifications \\
   --cache-cluster-id my-cache-cluster-id
   ```

   For Windows:
   
   ```
   aws elasticache list-allowed-node-type-modifications ^
   --cache-cluster-id my-cache-cluster-id
   ```

   Output from the above command looks something like this (JSON format).

   ```
   {
   "ScaleUpModifications": [
   "cache.m3.2xlarge",
   "cache.m3.large",
   "cache.m3.xlarge",
   "cache.m4.10xlarge",
   "cache.m4.2xlarge",
   "cache.m4.4xlarge",
   "cache.m4.large",
   "cache.m4.xlarge",
   "cache.r3.2xlarge",
   "cache.r3.4xlarge",
   "cache.r3.8xlarge",
   "cache.r3.large",
   "cache.r3.xlarge"
   ],
   "ScaleDownModifications": [
   "cache.t2.micro",
   "cache.t2.small",
   "cache.t2.medium",
   "cache.t1.small",
   ],
   }
   ```

   For more information, see `list-allowed-node-type-modifications` in the *AWS CLI Reference*.

2. Modify your existing cache cluster specifying the cache cluster to scale down and the new, smaller node type, using the AWS CLI `modify-cache-cluster` command and the following parameters.
   
   • `--cache-cluster-id` – The name of the cache cluster you are scaling down.
• --cache-node-type – The new node type you want to scale the cache cluster. This value must be one of the node types returned by the list-allowed-node-type-modifications command in step 1.

• --cache-parameter-group-name – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.

• --apply-immediately – Causes the scale-down process to be applied immediately. To postpone the scale-up process to the cluster's next maintenance window, use the --no-apply-immediately parameter.

For Linux, macOS, or Unix:

```bash
aws elasticache modify-cache-cluster \
    --cache-cluster-id my-redis-cache-cluster \
    --cache-node-type cache.m3.xlarge \
    --cache-parameter-group-name redis32-m2-xl \
    --apply-immediately
```

For Windows:

```bash
aws elasticache modify-cache-cluster ^
    --cache-cluster-id my-redis-cache-cluster ^
    --cache-node-type cache.m3.xlarge ^
    --cache-parameter-group-name redis32-m2-xl ^
    --apply-immediately
```

Output from the above command looks something like this (JSON format).

```json
{

Scaling down single-node Redis cache clusters (ElastiCache API)

The following procedure describes how to scale up or down a single-node Redis cache cluster using the ElastiCache API.

To scale down a single-node Redis cache cluster (ElastiCache API)

1. Determine the node types you can scale down to by running the ElastiCache API ListAllowedNodeTypeModifications action with the following parameter.

   • CacheClusterId – The name of the single-node Redis cache cluster you want to scale down.

   ```
   https://elasticache.us-west-2.amazonaws.com/?Action=ListAllowedNodeTypeModifications
   &CacheClusterId=MyRedisCacheCluster
   &Version=2015-02-02
   &SignatureVersion=4
   &SignatureMethod=HmacSHA256
   &Timestamp=20150202T192317Z
   &X-Amz-Credential=<credential>
   ```

   For more information, see ListAllowedNodeTypeModifications in the Amazon ElastiCache API Reference.

2. Modify your existing cache cluster specifying the cache cluster to scale up and the new, larger node type, using the ModifyCacheCluster ElastiCache API action and the following parameters.

   • CacheClusterId – The name of the cache cluster you are scaling down.
   • CacheNodeType – The new, smaller node type you want to scale the cache cluster down to. This value must be one of the node types returned by the ListAllowedNodeTypeModifications action in step 1.
   • CacheParameterGroupName – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.
   • ApplyImmediately – Set to true to cause the scale-down process to be performed immediately. To postpone the scale-up process to the cluster's next maintenance window, use ApplyImmediately=false.

   ```
   https://elasticache.us-west-2.amazonaws.com/
   ?Action=ModifyCacheCluster
   ```

   For more information, see modify-cache-cluster in the AWS CLI Reference.
&ApplyImmediately=true
&CacheClusterId=MyRedisCacheCluster
&CacheNodeType=cache.m3.xlarge
&CacheParameterGroupName redis32-m2-xl
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>

For more information, see ModifyCacheCluster in the Amazon ElastiCache API Reference.

3. If you used ApplyImmediately=true, check the status of the new cache cluster using the ElastiCache API DescribeCacheClusters action with the following parameter. When the status changes to available, you can begin using the new, smaller cache cluster.

- CacheClusterId – The name of your single-node Redis cache cluster. Use this parameter to describe a particular cache cluster rather than all cache clusters.

https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeCacheClusters
&CacheClusterId=MyRedisCacheCluster
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>

For more information, see DescribeCacheClusters in the Amazon ElastiCache API Reference.
Scaling Redis (Cluster Mode Disabled) clusters with replica nodes

A Redis cluster with replica nodes (called replication group in the API/CLI) provides high availability via replication that has Multi-AZ with automatic failover enabled. A cluster with replica nodes is a logical collection of up to six Redis clusters where one node, the Primary, is able to serve both read and write requests. All the other nodes in the cluster are read-only replicas of the Primary. Data written to the Primary is asynchronously replicated to all the read replicas in the cluster. Because Redis (cluster mode disabled) does not support partitioning your data across multiple clusters, each node in a Redis (cluster mode disabled) replication group contains the entire cache dataset. Redis (cluster mode enabled) clusters support partitioning your data across up to 500 shards.

To change the data capacity of your cluster you must scale it up to a larger node type, or down to a smaller node type.

To change the read capacity of your cluster, add more read replicas, up to a maximum of 5, or remove read replicas.

The ElastiCache scaling up process is designed to make a best effort to retain your existing data and requires successful Redis replication. For Redis clusters with replicas, we recommend that sufficient memory be made available to Redis.

- Ensuring that you have enough memory to create a Redis snapshot (p. 221)

Topics

- Scaling up Redis clusters with replicas (p. 361)
- Scaling down Redis clusters with replicas (p. 367)
- Increasing read capacity (p. 373)
- Decreasing read capacity (p. 374)
Scaling up Redis clusters with replicas

Amazon ElastiCache provides console, CLI, and API support for scaling your Redis (cluster mode disabled) replication group up.

When the scale-up process is initiated, ElastiCache does the following:

1. Launches a replication group using the new node type.
2. Copies all the data from the current primary node to the new primary node.
3. Syncs the new read replicas with the new primary node.
4. Updates the DNS entries so they point to the new nodes. Because of this you don't have to update the endpoints in your application. For Redis 5.0.5 and above, you can scale auto failover enabled clusters while the cluster continues to stay online and serve incoming requests. On version 5.0.4 and below, you may notice a brief interruption of reads and writes on previous versions from the primary node while the DNS entry is updated.
5. Deletes the old nodes (CLI/API: replication group). You will notice a brief interruption (a few seconds) of reads and writes from the old nodes because the connections to the old nodes will be disconnected.

How long this process takes is dependent upon your node type and how much data is in your cluster.

As shown in the following table, your Redis scale-up operation is blocked if you have an engine upgrade scheduled for the cluster's next maintenance window.

<table>
<thead>
<tr>
<th>Pending Operations</th>
<th>Blocked Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scale up</td>
<td>Immediate engine upgrade</td>
</tr>
<tr>
<td>Engine upgrade</td>
<td>Immediate scale up</td>
</tr>
<tr>
<td>Scale up and engine upgrade</td>
<td>Immediate scale up</td>
</tr>
<tr>
<td></td>
<td>Immediate engine upgrade</td>
</tr>
</tbody>
</table>

If you have a pending operation that is blocking you, you can do one of the following.

- Schedule your Redis scale-up operation for the next maintenance window by clearing the Apply immediately check box (CLI use: --no-apply-immediately, API use: ApplyImmediately=false).
- Wait until your next maintenance window (or after) to perform your Redis scale-up operation.
- Add the Redis engine upgrade to this cache cluster modification with the Apply Immediately check box chosen (CLI use: --apply-immediately, API use: ApplyImmediately=true). This unblocks your scale-up operation by causing the engine upgrade to be performed immediately.

The following sections describe how to scale your Redis cluster with replicas up using the ElastiCache console, the AWS CLI, and the ElastiCache API.

**Important**

If your parameter group uses reserved-memory to set aside memory for Redis overhead, before you begin scaling be sure that you have a custom parameter group that reserves the correct amount of memory for your new node type. Alternatively, you can modify a custom parameter group so that it uses reserved-memory-percent and use that parameter group for your new cluster.

If you're using reserved-memory-percent, doing this is not necessary.

For more information, see Managing Reserved Memory (p. 223).
Scaling up a Redis cluster with replicas (Console)

The amount of time it takes to scale up to a larger node type varies, depending upon the node type and the amount of data in your current cluster.

The following process scales your cluster with replicas from its current node type to a new, larger node type using the ElastiCache console. During this process, there may be a brief interruption of reads and writes for other versions from the primary node while the DNS entry is updated. You might see less than 1 second downtime for nodes running on 5.0.5 versions and above and a few seconds for older versions.

To scale up Redis cluster with replicas (console)

2. From the navigation pane, choose Redis.
3. From the list of clusters, choose the cluster you want to scale up. This cluster must be running the Redis engine and not the Clustered Redis engine.
4. Choose Modify.
5. In the Modify Cluster wizard:
   a. Choose the node type you want to scale to from the Node type list. Note that not all node types are available to scale down to.
   b. If you're using reserved-memory to manage your memory, from the Parameter Group list, choose the custom parameter group that reserves the correct amount of memory for your new node type.
6. If you want to perform the scale-up process right away, choose the Apply immediately check box. If the Apply immediately check box is left not chosen, the scale-up process is performed during this cluster's next maintenance window.
7. Choose Modify.
8. When the cluster's status changes from modifying to available, your cluster has scaled to the new node type. There is no need to update the endpoints in your application.

Scaling up a Redis replication group (AWS CLI)

The following process scales your replication group from its current node type to a new, larger node type using the AWS CLI. During this process, ElastiCache for Redis updates the DNS entries so they point to the new nodes. Because of this you don't have to update the endpoints in your application. For Redis 5.0.5 and above, you can scale auto failover enabled clusters while the cluster continues to stay online and serve incoming requests. On version 5.0.4 and below, you may notice a brief interruption of reads and writes on previous versions from the primary node while the DNS entry is updated.

The amount of time it takes to scale up to a larger node type varies, depending upon your node type and the amount of data in your current cache cluster.

To scale up a Redis Replication Group (AWS CLI)

1. Determine which node types you can scale up to by running the AWS CLI list-allowed-node-type-modifications command with the following parameter.

   - --replication-group-id - the name of the replication group. Use this parameter to describe a particular replication group rather than all replication groups.

For Linux, macOS, or Unix:

```
aws elasticache list-allowed-node-type-modifications
```
For Windows:

```
aws elasticache list-allowed-node-type-modifications 
--replication-group-id my-repl-group
```

Output from this operation looks something like this (JSON format).

```
{
  "ScaleUpModifications": [
    "cache.m3.2xlarge",
    "cache.m3.large",
    "cache.m3.xlarge",
    "cache.m4.10xlarge",
    "cache.m4.2xlarge",
    "cache.m4.4xlarge",
    "cache.m4.large",
    "cache.m4.xlarge",
    "cache.r3.2xlarge",
    "cache.r3.4xlarge",
    "cache.r3.8xlarge",
    "cache.r3.large",
    "cache.r3.xlarge"
  ]
}
```

For more information, see `list-allowed-node-type-modifications` in the AWS CLI Reference.

2. Scale your current replication group up to the new node type using the AWS CLI `modify-replication-group` command with the following parameters:

- `--replication-group-id` – the name of the replication group.
- `--cache-node-type` – the new, larger node type of the cache clusters in this replication group. This value must be one of the instance types returned by the `list-allowed-node-type-modifications` command in step 1.
- `--cache-parameter-group-name` – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.
- `--apply-immediately` – Causes the scale-up process to be applied immediately. To postpone the scale-up operation to the next maintenance window, use `--no-apply-immediately`.

For Linux, macOS, or Unix:

```
aws elasticache modify-replication-group \
  --replication-group-id my-repl-group \
  --cache-node-type cache.m3.xlarge \
  --cache-parameter-group-name redis32-m3-2xl \
  --apply-immediately
```

For Windows:

```
aws elasticache modify-replication-group ^
  --replication-group-id my-repl-group ^
  --cache-node-type cache.m3.xlarge ^
  --cache-parameter-group-name redis32-m3-2xl ^
```

API Version 2015-02-02

363
Output from this command looks something like this (JSON format).

```json
{
  "ReplicationGroup": {
    "Status": "available",
    "Description": "Some description",
    "NodeGroups": [
      {
        "Status": "available",
        "NodeGroupMembers": [
          {
            "CurrentRole": "primary",
            "PreferredAvailabilityZone": "us-west-2b",
            "CacheNodeId": "0001",
            "ReadEndpoint": {
              "Port": 6379,
              "Address": "my-repl-group-001.8fdx4s.0001.usw2.cache.amazonaws.com"
            },
            "CacheClusterId": "my-repl-group-001"
          },
          {
            "CurrentRole": "replica",
            "PreferredAvailabilityZone": "us-west-2c",
            "CacheNodeId": "0001",
            "ReadEndpoint": {
              "Port": 6379,
              "Address": "my-repl-group-002.8fdx4s.0001.usw2.cache.amazonaws.com"
            },
            "CacheClusterId": "my-repl-group-002"
          }
        ],
        "NodeGroupId": "0001",
        "PrimaryEndpoint": {
          "Port": 6379,
          "Address": "my-repl-group.8fdx4s.ng.0001.usw2.cache.amazonaws.com"
        }
      }
    ],
    "ReplicationGroupId": "my-repl-group",
    "SnapshotRetentionLimit": 1,
    "AutomaticFailover": "disabled",
    "SnapshotWindow": "12:00-13:00",
    "SnapshottingClusterId": "my-repl-group-002",
    "MemberClusters": [
      "my-repl-group-001",
      "my-repl-group-002"
    ],
    "PendingModifiedValues": {}
  }
}
```

For more information, see modify-replication-group in the AWS CLI Reference.

3. If you used the `--apply-immediately` parameter, monitor the status of the replication group using the AWS CLI describe-replication-group command with the following parameter. While the status is still in `modifying`, you might see less than 1 second downtime for nodes running on 5.0.5 versions and above and a brief interruption of reads and writes for older versions from the primary node while the DNS entry is updated.

- `--replication-group-id` – the name of the replication group. Use this parameter to describe a particular replication group rather than all replication groups.
Scaling clusters for Redis (Cluster Mode Disabled)

For Linux, macOS, or Unix:

```
aws elasticache describe-replication-groups \
--replication-group-id my-replication-group
```

For Windows:

```
aws elasticache describe-replication-groups ^
--replication-group-id my-replication-group
```

For more information, see `describe-replication-groups` in the AWS CLI Reference.

Scaling up a Redis replication group (ElastiCache API)

The following process scales your replication group from its current node type to a new, larger node type using the ElastiCache API. For Redis 5.0.5 and above, you can scale auto failover enabled clusters while the cluster continues to stay online and serve incoming requests. On version 5.0.4 and below, you may notice a brief interruption of reads and writes on previous versions from the primary node while the DNS entry is updated.

The amount of time it takes to scale up to a larger node type varies, depending upon your node type and the amount of data in your current cache cluster.

To scale up a Redis Replication Group (ElastiCache API)

1. Determine which node types you can scale up to using the ElastiCache API `ListAllowedNodeTypeModifications` action with the following parameter.

   - ReplicationGroupId – the name of the replication group. Use this parameter to describe a specific replication group rather than all replication groups.

   ```
   https://elasticache.us-west-2.amazonaws.com/
   ?Action=ListAllowedNodeTypeModifications
   &ReplicationGroupId=MyReplGroup
   &Version=2015-02-02
   &SignatureVersion=4
   &SignatureMethod=HmacSHA256
   &Timestamp=20150202T192317Z
   &X-Amz-Credential=<credential>
   ```

   For more information, see `ListAllowedNodeTypeModifications` in the Amazon ElastiCache API Reference.

2. Scale your current replication group up to the new node type using the `ModifyReplicationGroup` ElastiCache API action and with the following parameters.

   - ReplicationGroupId – the name of the replication group.
   - CacheNodeType – the new, larger node type of the cache clusters in this replication group. This value must be one of the instance types returned by the `ListAllowedNodeTypeModifications` action in step 1.
   - CacheParameterGroupName – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.
• **ApplyImmediately** – Set to true to causes the scale-up process to be applied immediately. To postpone the scale-up process to the next maintenance window, use `ApplyImmediately=false`.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=ModifyReplicationGroup
&ApplyImmediately=true
&CacheNodeType=cache.m3.2xlarge
&CacheParameterGroupName=redis32-m3-2xl
&ReplicationGroupId=myReplGroup
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20141201T220302Z
&Version=2014-12-01
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
&X-Amz-Date=20141201T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Expires=20141201T220302Z
&X-Amz-Credential=<credential>
&X-Amz-Signature=<signature>
```

For more information, see [ModifyReplicationGroup](https://elasticache.us-west-2.amazonaws.com/?Action=ModifyReplicationGroup) in the *Amazon ElastiCache API Reference*.

3. If you used `ApplyImmediately=true`, monitor the status of the replication group using the ElastiCache API `DescribeReplicationGroups` action with the following parameters. When the status changes from *modifying* to *available*, you can begin writing to your new, scaled up replication group.

• **ReplicationGroupId** – the name of the replication group. Use this parameter to describe a particular replication group rather than all replication groups.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeReplicationGroups
&ReplicationGroupId=MyReplGroup
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>
```

For more information, see [DescribeReplicationGroups](https://elasticache.us-west-2.amazonaws.com/?Action=DescribeReplicationGroups) in the *Amazon ElastiCache API Reference*.
Scaling down Redis clusters with replicas

The following sections walk you through how to scale a Redis (cluster mode disabled) cache cluster with replica nodes down to a smaller node type. Ensuring that the new, smaller node type is large enough to accommodate all the data and overhead is very important to success. For more information, see Ensuring that you have enough memory to create a Redis snapshot (p. 221).

Note
For clusters running the r6gd node type, you can only scale to node sizes within the r6gd node family.

Important
If your parameter group uses reserved-memory to set aside memory for Redis overhead, before you begin scaling be sure that you have a custom parameter group that reserves the correct amount of memory for your new node type. Alternatively, you can modify a custom parameter group so that it uses reserved-memory-percent and use that parameter group for your new cluster.

If you're using reserved-memory-percent, doing this is not necessary.
For more information, see Managing Reserved Memory (p. 223).

Scaling down a Redis cluster with replicas (Console)

The following process scales your Redis cluster with replica nodes to a smaller node type using the ElastiCache console.

To scale down a Redis cluster with replica nodes (console)

1. Ensure that the smaller node type is adequate for your data and overhead needs.
2. If your parameter group uses reserved-memory to set aside memory for Redis overhead, ensure that you have a custom parameter group that reserves the correct amount of memory for your new node type.

   Alternatively, you can modify your custom parameter group to use reserved-memory-percent. For more information, see Managing Reserved Memory (p. 223).
4. From the list of clusters, choose the cluster you want to scale down. This cluster must be running the Redis engine and not the Clustered Redis engine.
5. Choose Modify.
6. In the Modify Cluster wizard:
   a. Choose the node type you want to scale down to from the Node type list.
   b. If you're using reserved-memory to manage your memory, from the Parameter Group list, choose the custom parameter group that reserves the correct amount of memory for your new node type.
7. If you want to perform the scale-down process right away, choose the Apply immediately check box. If the Apply immediately check box is left not chosen, the scale-down process is performed during this cluster's next maintenance window.
8. Choose Modify.
9. When the cluster's status changes from modifying to available, your cluster has scaled to the new node type. There is no need to update the endpoints in your application.

Scaling down a Redis replication group (AWS CLI)

The following process scales your replication group from its current node type to a new, smaller node type using the AWS CLI. During this process, ElastiCache for Redis updates the DNS entries so they point to the new nodes. Because of this you don't have to update the endpoints in your application. For Redis
5.0.5 and above, you can scale auto failover enabled clusters while the cluster continues to stay online and serve incoming requests. On version 5.0.4 and below, you may notice a brief interruption of reads and writes on previous versions from the primary node while the DNS entry is updated.

However, reads from the read replica cache clusters continue uninterrupted.

The amount of time it takes to scale down to a smaller node type varies, depending upon your node type and the amount of data in your current cache cluster.

To scale down a Redis Replication Group (AWS CLI)

1. Determine which node types you can scale down to by running the AWS CLI list-allowed-node-type-modifications command with the following parameter.

   • `--replication-group-id` – the name of the replication group. Use this parameter to describe a particular replication group rather than all replication groups.

   For Linux, macOS, or Unix:

   ```
   aws elasticache list-allowed-node-type-modifications \
   --replication-group-id my-repl-group
   ```

   For Windows:

   ```
   aws elasticache list-allowed-node-type-modifications ^
   --replication-group-id my-repl-group
   ```

   Output from this operation looks something like this (JSON format).

   ```
   {
   "ScaleDownModifications": [
   "cache.m3.2xlarge",
   "cache.m3.large",
   "cache.m3.xlarge",
   "cache.m4.10xlarge",
   "cache.m4.2xlarge",
   "cache.m4.4xlarge",
   "cache.m4.large",
   "cache.m4.xlarge",
   "cache.r3.2xlarge",
   "cache.r3.4xlarge",
   "cache.r3.8xlarge",
   "cache.r3.large",
   "cache.r3.xlarge"
   ]
   }
   ```

   For more information, see list-allowed-node-type-modifications in the AWS CLI Reference.

2. Scale your current replication group up to the new node type using the AWS CLI modify-replication-group command with the following parameters.

   • `--replication-group-id` – the name of the replication group.
   • `--cache-node-type` – the new, smaller node type of the cache clusters in this replication group. This value must be one of the instance types returned by the list-allowed-node-type-modifications command in step 1.
   • `--cache-parameter-group-name` – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group API Version 2015-02-02

368
Scaling clusters for Redis (Cluster Mode Disabled)

that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.

- `--apply-immediately` – Causes the scale-up process to be applied immediately. To postpone the scale-up operation to the next maintenance window, use `--no-apply-immediately`.

For Linux, macOS, or Unix:

```
aws elasticache modify-replication-group \
    --replication-group-id my-repl-group \
    --cache-node-type cache.t2.small \
    --cache-parameter-group-name redis32-m3-2x1 \
    --apply-immediately
```

For Windows:

```
aws elasticache modify-replication-group ^
    --replication-group-id my-repl-group ^
    --cache-node-type cache.t2.small ^
    --cache-parameter-group-name redis32-m3-2x1 ^
    --apply-immediately
```

Output from this command looks something like this (JSON format).

```
{"ReplicationGroup": {
    "Status": "available",
    "Description": "Some description",
    "NodeGroups": [
      {
        "Status": "available",
        "NodeGroupMembers": [
          {
            "CurrentRole": "primary",
            "PreferredAvailabilityZone": "us-west-2b",
            "CacheNodeId": "0001",
            "ReadEndpoint": {
              "Port": 6379,
              "Address": "my-repl-group-001.8fdx4s.0001.usw2.cache.amazonaws.com"
            },
            "CacheClusterId": "my-repl-group-001"
          },
          {
            "CurrentRole": "replica",
            "PreferredAvailabilityZone": "us-west-2c",
            "CacheNodeId": "0001",
            "ReadEndpoint": {
              "Port": 6379,

}
```

For more information, see modify-replication-group in the AWS CLI Reference.

3. If you used the --apply-immediately parameter, monitor the status of the replication group using the AWS CLI describe-replication-group command with the following parameter. When the status changes from modifying to available, you can begin writing to your new, scaled down replication group.

```
• --replication-group-id – the name of the replication group. Use this parameter to describe a particular replication group rather than all replication groups.
```

For Linux, macOS, or Unix:

```
aws elasticache describe-replication-group \
   --replication-group-id my-replication-group
```

For Windows:

```
aws elasticache describe-replication-groups ^
   --replication-group-id my-replication-group
```

For more information, see describe-replication-groups in the AWS CLI Reference.

Scaling down a Redis replication group (ElastiCache API)

The following process scales your replication group from its current node type to a new, smaller node type using the ElastiCache API. During this process, ElastiCache for Redis updates the DNS entries so they point to the new nodes. Because of this you don't have to update the endpoints in your application. For Redis 5.0.5 and above, you can scale auto failover enabled clusters while the cluster continues to stay online and serve incoming requests. On version 5.0.4 and below, you may notice a brief interruption of reads and writes on previous versions from the primary node while the DNS entry is updated. However, reads from the read replica cache clusters continue uninterrupted.

The amount of time it takes to scale down to a smaller node type varies, depending upon your node type and the amount of data in your current cache cluster.

To scale down a Redis Replication Group (ElastiCache API)

1. Determine which node types you can scale down to using the ElastiCache API ListAllowedNodeTypeModifications action with the following parameter.

```
• ReplicationGroupId – the name of the replication group. Use this parameter to describe a specific replication group rather than all replication groups.
```
Scaling clusters for Redis (Cluster Mode Disabled)

For more information, see `ListAllowedNodeTypeModifications` in the Amazon ElastiCache API Reference.

2. Scale your current replication group up to the new node type using the `ModifyReplicationGroup` ElastiCache API action and with the following parameters.
   
   - **ReplicationGroupId** – the name of the replication group.
   - **CacheNodeType** – the new, smaller node type of the cache clusters in this replication group. This value must be one of the instance types returned by the `ListAllowedNodeTypeModifications` action in step 1.
   - **CacheParameterGroupName** – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.
   - **ApplyImmediately** – Set to true to causes the scale-up process to be applied immediately. To postpone the scale-down process to the next maintenance window, use `ApplyImmediately=false`.

   
   For more information, see `ModifyReplicationGroup` in the Amazon ElastiCache API Reference.

3. If you used `ApplyImmediately=true`, monitor the status of the replication group using the ElastiCache API `DescribeReplicationGroups` action with the following parameters. When the status changes from `modifying` to `available`, you can begin writing to your new, scaled down replication group.
   
   - **ReplicationGroupId** – the name of the replication group. Use this parameter to describe a particular replication group rather than all replication groups.

   For more information, see `DescribeReplicationGroups` in the Amazon ElastiCache API Reference.
&ReplicationGroupId=MyReplGroup
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&X-Amz-Credential=<credential>

For more information, see DescribeReplicationGroups in the Amazon ElastiCache API Reference.
Increasing read capacity

To increase read capacity, add read replicas (up to a maximum of five) to your Redis replication group.

You can scale your Redis cluster's read capacity using the ElastiCache console, the AWS CLI, or the ElastiCache API. For more information, see Adding a read replica, for Redis (Cluster Mode Disabled) replication groups (p. 306).
Decreasing read capacity

To decrease read capacity, delete one or more read replicas from your Redis cluster with replicas (called replication group in the API/CLI). If the cluster is Multi-AZ with automatic failover enabled, you cannot delete the last read replica without first disabling Multi-AZ. For more information, see Modifying a replication group (p. 294).

For more information, see Deleting a read replica, for Redis (Cluster Mode Disabled) replication groups (p. 308).
Scaling clusters in Redis (Cluster Mode Enabled)

As demand on your clusters changes, you might decide to improve performance or reduce costs by changing the number of shards in your Redis (cluster mode enabled) cluster. We recommend using online horizontal scaling to do so, because it allows your cluster to continue serving requests during the scaling process.

Conditions under which you might decide to rescale your cluster include the following:

- **Memory pressure:**
  If the nodes in your cluster are under memory pressure, you might decide to scale out so that you have more resources to better store data and serve requests.
  
  You can determine whether your nodes are under memory pressure by monitoring the following metrics: FreeableMemory, SwapUsage, and BytesUseForCache.

- **CPU or network bottleneck:**
  If latency/throughput issues are plaguing your cluster, you might need to scale out to resolve the issues.
  
  You can monitor your latency and throughput levels by monitoring the following metrics: CPUUtilization, NetworkBytesIn, NetworkBytesOut, CurrConnections, and NewConnections.

- **Your cluster is over-scaled:**
  Current demand on your cluster is such that scaling in doesn't hurt performance and reduces your costs.
  
  You can monitor your cluster's use to determine whether or not you can safely scale in using the following metrics: FreeableMemory, SwapUsage, BytesUseForCache, CPUUtilization, NetworkBytesIn, NetworkBytesOut, CurrConnections, and NewConnections.

Performance Impact of Scaling

When you scale using the offline process, your cluster is offline for a significant portion of the process and thus unable to serve requests. When you scale using the online method, because scaling is a compute-intensive operation, there is some degradation in performance, nevertheless, your cluster continues to serve requests throughout the scaling operation. How much degradation you experience depends upon your normal CPU utilization and your data.

There are two ways to scale your Redis (cluster mode enabled) cluster; horizontal and vertical scaling.

- **Horizontal scaling** allows you to change the number of node groups (shards) in the replication group by adding or removing node groups (shards). The online resharding process allows scaling in/out while the cluster continues serving incoming requests.
  
  Configure the slots in your new cluster differently than they were in the old cluster. Offline method only.

- **Vertical Scaling** - Change the node type to resize the cluster. The online vertical scaling allows scaling up/down while the cluster continues serving incoming requests.

If you are reducing the size and memory capacity of the cluster, by either scaling in or scaling down, ensure that the new configuration has sufficient memory for your data and Redis overhead.

For more information, see Choosing your node size (p. 127).

Contents
Offline resharding and shard rebalancing for Redis (cluster mode enabled)

The main advantage you get from offline shard reconfiguration is that you can do more than merely add or remove shards from your replication group. When you reshard offline, in addition to changing the number of shards in your replication group, you can do the following:

- Change the node type of your replication group.
- Specify the Availability Zone for each node in the replication group.
- Upgrade to a newer engine version.
- Specify the number of replica nodes in each shard independently.
- Specify the keyspace for each shard.

The main disadvantage of offline shard reconfiguration is that your cluster is offline beginning with the restore portion of the process and continuing until you update the endpoints in your application. The length of time that your cluster is offline varies with the amount of data in your cluster.

**To reconfigure your shards Redis (cluster mode enabled) cluster offline**

1. Create a manual backup of your existing Redis cluster. For more information, see Making manual backups (p. 315).
2. Create a new cluster by restoring from the backup. For more information, see Restoring from a backup with optional cluster resizing (p. 334).
3. Update the endpoints in your application to the new cluster's endpoints. For more information, see Finding connection endpoints (p. 175).
Online resharding and shard rebalancing for Redis (cluster mode enabled)

By using online resharding and shard rebalancing with Amazon ElastiCache for Redis version 3.2.10 or newer, you can scale your ElastiCache for Redis (cluster mode enabled) dynamically with no downtime. This approach means that your cluster can continue to serve requests even while scaling or rebalancing is in process.

You can do the following:

- **Scale out** – Increase read and write capacity by adding shards (node groups) to your Redis (cluster mode enabled) cluster (replication group).
  
  If you add one or more shards to your replication group, the number of nodes in each new shard is the same as the number of nodes in the smallest of the existing shards.

- **Scale in** – Reduce read and write capacity, and thereby costs, by removing shards from your Redis (cluster mode enabled) cluster.

- **Rebalance** – Move the keyspaces among the shards in your ElastiCache for Redis (cluster mode enabled) cluster so they are as equally distributed among the shards as possible.

You can't do the following:

- **Configure shards independently:**

  You can't specify the keyspace for shards independently. To do this, you must use the offline process.

Currently, the following limitations apply to ElastiCache for Redis online resharding and rebalancing:

- These processes require Redis engine version 3.2.10 or newer. For information on upgrading your engine version, see Upgrading engine versions (p. 198).

- There are limitations with slots or keyspaces and large items:

  If any of the keys in a shard contain a large item, that key isn't migrated to a new shard when scaling out or rebalancing. This functionality can result in unbalanced shards.

  If any of the keys in a shard contain a large item (items greater than 256 MB after serialization), that shard isn't deleted when scaling in. This functionality can result in some shards not being deleted.

  - When scaling out, the number of nodes in any new shards equals the number of nodes in the smallest existing shard.
  
  - When scaling out, any tags that are common to all existing shards are copied to the new shards.

For more information, see Best practices: Online cluster resizing (p. 229).

You can horizontally scale or rebalance your ElastiCache for Redis (cluster mode enabled) clusters using the AWS Management Console, the AWS CLI, and the ElastiCache API.

Adding shards with online resharding

You can add shards to your Redis (cluster mode enabled) cluster using the AWS Management Console, AWS CLI, or ElastiCache API. When you add shards to a Redis (cluster mode enabled) cluster, any tags on the existing shards are copied over to the new shards.
Adding shards (Console)

You can use the AWS Management Console to add one or more shards to your Redis (cluster mode enabled) cluster. The following procedure describes the process.

To add shards to your Redis (cluster mode enabled) cluster

2. From the navigation pane, choose Redis.
3. Locate and choose the name, not the box to the left of the cluster's name, of the Redis (cluster mode enabled) cluster that you want to add shards to.
   
   **Tip**
   
   Redis (cluster mode enabled) show Clustered Redis in the Mode column

4. Choose Add shard.
   
   a. For Number of shards to be added, choose the number of shards you want added to this cluster.
   
   b. For Availability zone(s), choose either No preference or Specify availability zones.
   
   c. If you chose Specify availability zones, for each node in each shard, select the node's Availability Zone from the list of Availability Zones.
   
   d. Choose Add.

Adding shards (AWS CLI)

The following process describes how to reconfigure the shards in your Redis (cluster mode enabled) cluster by adding shards using the AWS CLI.

Use the following parameters with modify-replication-group-shard-configuration.

Parameters

- **--apply-immediately** – Required. Specifies the shard reconfiguration operation is to be started immediately.
- **--replication-group-id** – Required. Specifies which replication group (cluster) the shard reconfiguration operation is to be performed on.
- **--node-group-count** – Required. Specifies the number of shards (node groups) to exist when the operation is completed. When adding shards, the value of --node-group-count must be greater than the current number of shards.

Optionally, you can specify the Availability Zone for each node in the replication group using --resharding-configuration.

- **--resharding-configuration** – Optional. A list of preferred Availability Zones for each node in each shard in the replication group. Use this parameter only if the value of --node-group-count is greater than the current number of shards. If this parameter is omitted when adding shards, Amazon ElastiCache selects the Availability Zones for the new nodes.

The following example reconfigures the keyspaces over four shards in the Redis (cluster mode enabled) cluster my-cluster. The example also specifies the Availability Zone for each node in each shard. The operation begins immediately.

**Example - Adding Shards**

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group-shard-configuration \
```
Scaling clusters in Redis (Cluster Mode Enabled)

--replication-group-id my-cluster \
--node-group-count 4 \
--resharding-configuration \ 
  "PreferredAvailabilityZones=us-east-2a,us-east-2c" \ 
  "PreferredAvailabilityZones=us-east-2b,us-east-2a" \ 
  "PreferredAvailabilityZones=us-east-2c,us-east-2d" \ 
  "PreferredAvailabilityZones=us-east-2d,us-east-2c" \
--apply-immediately

For Windows:

aws elasticache modify-replication-group-shard-configuration ^
  --replication-group-id my-cluster ^
  --node-group-count 4 ^
  --resharding-configuration ^
    "PreferredAvailabilityZones=us-east-2a,us-east-2c" ^
    "PreferredAvailabilityZones=us-east-2b,us-east-2a" ^
    "PreferredAvailabilityZones=us-east-2c,us-east-2d" ^
    "PreferredAvailabilityZones=us-east-2d,us-east-2c" ^
  --apply-immediately

For more information, see modify-replication-group-shard-configuration in the AWS CLI documentation.

Adding shards (ElastiCache API)

You can use the ElastiCache API to reconfigure the shards in your Redis (cluster mode enabled) cluster online by using the ModifyReplicationGroupShardConfiguration operation.

Use the following parameters with ModifyReplicationGroupShardConfiguration.

Parameters

- **ApplyImmediately=true** – Required. Specifies the shard reconfiguration operation is to be started immediately.
- **ReplicationGroupId** – Required. Specifies which replication group (cluster) the shard reconfiguration operation is to be performed on.
- **NodeGroupCount** – Required. Specifies the number of shards (node groups) to exist when the operation is completed. When adding shards, the value of **NodeGroupCount** must be greater than the current number of shards.

Optionally, you can specify the Availability Zone for each node in the replication group using ReshardingConfiguration.

- **ReshardingConfiguration** – Optional. A list of preferred Availability Zones for each node in each shard in the replication group. Use this parameter only if the value of **NodeGroupCount** is greater than the current number of shards. If this parameter is omitted when adding shards, Amazon ElastiCache selects the Availability Zones for the new nodes.

The following process describes how to reconfigure the shards in your Redis (cluster mode enabled) cluster by adding shards using the ElastiCache API.

**Example - Adding Shards**

The following example adds node groups to the Redis (cluster mode enabled) cluster `my-cluster`, so there are a total of four node groups when the operation completes. The example also specifies the Availability Zone for each node in each shard. The operation begins immediately.

https://elasticache.us-east-2.amazonaws.com/  
?Action=ModifyReplicationGroupShardConfiguration
Removing shards with online resharding

You can remove shards from your Redis (cluster mode enabled) cluster using the AWS Management Console, AWS CLI, or ElastiCache API.

Topics
- Removing shards (Console) (p. 380)
- Removing shards (AWS CLI) (p. 381)
- Removing shards (ElastiCache API) (p. 382)

Removing shards (Console)

The following process describes how to reconfigure the shards in your Redis (cluster mode enabled) cluster by removing shards using the AWS Management Console.

Before removing node groups (shards) from your replication group, ElastiCache makes sure that all your data will fit in the remaining shards. If the data will fit, the specified shards are deleted from the replication group as requested. If the data won’t fit in the remaining node groups, the process is terminated and the replication group is left with the same node group configuration as before the request was made.

You can use the AWS Management Console to remove one or more shards from your Redis (cluster mode enabled) cluster. You cannot remove all the shards in a replication group. Instead, you must delete the replication group. For more information, see Deleting a replication group (p. 296). The following procedure describes the process for deleting one or more shards.

For more information, see ModifyReplicationGroupShardConfiguration in the ElastiCache API Reference.
To remove shards from your Redis (cluster mode enabled) cluster

2. From the navigation pane, choose Redis.
3. Locate and choose the name, not the box to the left of the cluster's name, of the Redis (cluster mode enabled) cluster you want to remove shards from.
   
   **Tip**
   Redis (cluster mode enabled) clusters have a value of 1 or greater in the **Shards** column.
4. From the list of shards, choose the box to the left of the name of each shard that you want to delete.
5. Choose **Delete shard**.

Removing shards (AWS CLI)

The following process describes how to reconfigure the shards in your Redis (cluster mode enabled) cluster by removing shards using the AWS CLI.

**Important**
Before removing node groups (shards) from your replication group, ElastiCache makes sure that all your data will fit in the remaining shards. If the data will fit, the specified shards (**--node-groups-to-remove**) are deleted from the replication group as requested and their keyspaces mapped into the remaining shards. If the data will not fit in the remaining node groups, the process is terminated and the replication group is left with the same node group configuration as before the request was made.

You can use the AWS CLI to remove one or more shards from your Redis (cluster mode enabled) cluster. You cannot remove all the shards in a replication group. Instead, you must delete the replication group. For more information, see Deleting a replication group (p. 296).

Use the following parameters with **modify-replication-group-shard-configuration**.

**Parameters**

- **--apply-immediately** – Required. Specifies the shard reconfiguration operation is to be started immediately.
- **--replication-group-id** – Required. Specifies which replication group (cluster) the shard reconfiguration operation is to be performed on.
- **--node-group-count** – Required. Specifies the number of shards (node groups) to exist when the operation is completed. When removing shards, the value of **--node-group-count** must be less than the current number of shards.
- **--node-groups-to-remove** – Required when **--node-group-count** is less than the current number of node groups (shards). A list of shard (node group) IDs to remove from the replication group.

The following procedure describes the process for deleting one or more shards.

**Example - Removing Shards**

The following example removes two node groups from the Redis (cluster mode enabled) cluster my-cluster, so there are a total of two node groups when the operation completes. The keyspaces from the removed shards are distributed evenly over the remaining shards.

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group-shard-configuration \
```
For Windows:

```bash
aws elasticache modify-replication-group-shard-configuration
--replication-group-id my-cluster
--node-group-count 2
--node-groups-to-remove "0002" "0003"
--apply-immediately
```

Removing shards (ElastiCache API)

You can use the ElastiCache API to reconfigure the shards in your Redis (cluster mode enabled) cluster online by using the `ModifyReplicationGroupShardConfiguration` operation.

The following process describes how to reconfigure the shards in your Redis (cluster mode enabled) cluster by removing shards using the ElastiCache API.

**Important**

Before removing node groups (shards) from your replication group, ElastiCache makes sure that all your data will fit in the remaining shards. If the data will fit, the specified shards (`NodeGroupsToRemove`) are deleted from the replication group as requested and their keyspaces mapped into the remaining shards. If the data will not fit in the remaining node groups, the process is terminated and the replication group is left with the same node group configuration as before the request was made.

You can use the ElastiCache API to remove one or more shards from your Redis (cluster mode enabled) cluster. You cannot remove all the shards in a replication group. Instead, you must delete the replication group. For more information, see Deleting a replication group (p. 296).

Use the following parameters with `ModifyReplicationGroupShardConfiguration`.

**Parameters**

- `ApplyImmediately=true` – Required. Specifies the shard reconfiguration operation is to be started immediately.
- `ReplicationGroupId` – Required. Specifies which replication group (cluster) the shard reconfiguration operation is to be performed on.
- `NodeGroupCount` – Required. Specifies the number of shards (node groups) to exist when the operation is completed. When removing shards, the value of `NodeGroupCount` must be less than the current number of shards.
- `NodeGroupsToRemove` – Required when `--node-group-count` is less than the current number of node groups (shards). A list of shard (node group) IDs to remove from the replication group.

The following procedure describes the process for deleting one or more shards.

**Example - Removing Shards**

The following example removes two node groups from the Redis (cluster mode enabled) cluster `my-cluster`, so there are a total of two node groups when the operation completes. The keyspaces from the removed shards are distributed evenly over the remaining shards.
Online shard rebalancing

You can rebalance shards in your Redis (cluster mode enabled) cluster using the AWS Management Console, AWS CLI, or ElastiCache API.

Topics
- Online Shard Rebalancing (Console) (p. 383)
- Online shard rebalancing (AWS CLI) (p. 383)
- Online shard rebalancing (ElastiCache API) (p. 384)

Online Shard Rebalancing (Console)

The following process describes how to reconfigure the shards in your Redis (cluster mode enabled) cluster by rebalancing shards using the AWS Management Console.

**To rebalance the keyspaces among the shards on your Redis (cluster mode enabled) cluster**

2. From the navigation pane, choose Redis.
3. Choose the name, not the box to the left of the name, of the Redis (cluster mode enabled) cluster that you want to rebalance.
   
   Tip
   Redis (cluster mode enabled) clusters have a value of 1 or greater in the Shards column.
5. When prompted, choose Rebalance. You might see a message similar to this one:
   
   Slots in the replication group are uniformly distributed. Nothing to do. (Service: AmazonElastiCache; Status Code: 400; Error Code: InvalidReplicationGroupState; Request ID: 2246cebd-9721-11e7-8d5b-e1b0f086c8cf). If you do, choose Cancel.

Online shard rebalancing (AWS CLI)

Use the following parameters with modify-replication-group-shard-configuration.

**Parameters**

- -apply-immediately – Required. Specifies the shard reconfiguration operation is to be started immediately.
- --replication-group-id – Required. Specifies which replication group (cluster) the shard reconfiguration operation is to be performed on.
- --node-group-count – Required. To rebalance the keyspaces across all shards in the cluster, this value must be the same as the current number of shards.
The following process describes how to reconfigure the shards in your Redis (cluster mode enabled) cluster by rebalancing shards using the AWS CLI.

**Example - Rebalancing the Shards in a Cluster**

The following example rebalances the slots in the Redis (cluster mode enabled) cluster `my-cluster` so that the slots are distributed as equally as possible. The value of `--node-group-count` (4) is the number of shards currently in the cluster.

For Linux, macOS, or Unix:

```bash
aws elasti cache modify-replication-group-shard-configuration \
  --replication-group-id my-cluster \
  --node-group-count 4 \n  --apply-immediately
```

For Windows:

```bash
aws elasti cache modify-replication-group-shard-configuration ^
  --replication-group-id my-cluster ^
  --node-group-count 4 ^
  --apply-immediately
```

**Online shard rebalancing (ElastiCache API)**

You can use the ElastiCache API to reconfigure the shards in your Redis (cluster mode enabled) cluster online by using the `ModifyReplicationGroupShardConfiguration` operation.

Use the following parameters with `ModifyReplicationGroupShardConfiguration`.

**Parameters**

- `ApplyImmediately=true` – Required. Specifies the shard reconfiguration operation is to be started immediately.
- `ReplicationGroupId` – Required. Specifies which replication group (cluster) the shard reconfiguration operation is to be performed on.
- `NodeGroupCount` – Required. To rebalance the keyspaces across all shards in the cluster, this value must be the same as the current number of shards.

The following process describes how to reconfigure the shards in your Redis (cluster mode enabled) cluster by rebalancing the shards using the ElastiCache API.

**Example - Rebalancing a Cluster**

The following example rebalances the slots in the Redis (cluster mode enabled) cluster `my-cluster` so that the slots are distributed as equally as possible. The value of `NodeGroupCount` (4) is the number of shards currently in the cluster.

```bash
https://elasticache.us-east-2.amazonaws.com/
    ?Action=ModifyReplicationGroupShardConfiguration
    &ApplyImmediately=true
    &NodeGroupCount=4
    &ReplicationGroupId=my-cluster
    &Version=2015-02-02
    &SignatureVersion=4
    &SignatureMethod=HmacSHA256
    &Timestamp=20171002T192317Z
    &X-Amz-Credential=<credential>
```
Online vertical scaling by modifying node type

By using online vertical scaling with Amazon ElastiCache for Redis version 3.2.10 or newer, you can scale your Redis clusters dynamically with minimal downtime. This allows your Redis cluster to serve requests even while scaling.

**Note**
Scaling is not supported between a data tiering cluster (for example, a cluster using an r6gd node type) and a cluster that does not use data tiering (for example, a cluster using an r6g node type). For more information, see Data tiering (p. 121).

You can do the following:

- **Scale up** – Increase read and write capacity by adjusting the node type of your Redis cluster to use a larger node type.
  
  ElastiCache dynamically resizes your cluster while remaining online and serving requests.

- **Scale down** – Reduce read and write capacity by adjusting the node type down to use a smaller node. Again, ElastiCache dynamically resizes your cluster while remaining online and serving requests. In this case, you reduce costs by downsizing the node.

**Note**
The scale up and scale down processes rely on creating clusters with newly selected node types and synchronizing the new nodes with the previous ones. To ensure a smooth scale up/down flow, do the following:

- Ensure you have sufficient ENI (Elastic Network Interface) capacity. If scaling down, ensure the smaller node has sufficient memory to absorb expected traffic.
  
  For best practices on memory management, see Managing Reserved Memory (p. 223).

- While the vertical scaling process is designed to remain fully online, it does rely on synchronizing data between the old node and the new node. We recommend that you initiate scale up/down during hours when you expect data traffic to be at its minimum.

- Test your application behavior during scaling in a staging environment, if possible.

Contents

- Online scaling up (p. 385)
  - Scaling up Redis cache clusters (Console) (p. 386)
  - Scaling up Redis cache clusters (AWS CLI) (p. 350)
  - Scaling up Redis cache clusters (ElastiCache API) (p. 388)

- Online scaling down (p. 390)
  - Scaling down Redis cache clusters (Console) (p. 390)
  - Scaling down Redis cache clusters (AWS CLI) (p. 390)

**Online scaling up**

**Topics**

- Scaling up Redis cache clusters (Console) (p. 386)
- Scaling up Redis cache clusters (AWS CLI) (p. 350)
- Scaling up Redis cache clusters (ElastiCache API) (p. 388)
Scaling up Redis cache clusters (Console)

The following procedure describes how to scale up a Redis cluster using the ElastiCache Management Console. During this process, your Redis cluster will continue to serve requests with minimal downtime.

To scale up a Redis cluster (console)

2. From the navigation pane, choose Redis.
3. From the list of clusters, choose the cluster.
4. Choose Modify.
5. In the Modify Cluster wizard:
   - Choose the node type you want to scale to from the Node type list. To scale up, select a node type larger than your existing node.
6. If you want to perform the scale-up process right away, choose the Apply immediately box. If the Apply immediately box is not chosen, the scale-up process is performed during this cluster's next maintenance window.
7. Choose Modify.

If you chose Apply immediately in the previous step, the cluster's status changes to modifying. When the status changes to available, the modification is complete and you can begin using the new cluster.

Scaling up Redis cache clusters (AWS CLI)

The following procedure describes how to scale up a Redis cache cluster using the AWS CLI. During this process, your Redis cluster will continue to serve requests with minimal downtime.

To scale up a Redis cache cluster (AWS CLI)

1. Determine the node types you can scale up to by running the AWS CLI list-allowed-node-type-modifications command with the following parameter.

   For Linux, macOS, or Unix:

   ```bash
   aws elasticache list-allowed-node-type-modifications
   --replication-group-id my-replication-group-id
   ```

   For Windows:

   ```bash
   aws elasticache list-allowed-node-type-modifications
   --replication-group-id my-replication-group-id
   ```

   Output from the above command looks something like this (JSON format).

   ```json
   {
     "ScaleUpModifications": [
       "cache.m3.2xlarge",
       "cache.m3.large",
       "cache.m3.xlarge",
       "cache.m4.10xlarge",
       "cache.m4.2xlarge",
       "cache.m4.4xlarge",
       "cache.m4.large",
       ...
     ]
   }
   ```

API Version 2015-02-02
386
For more information, see `list-allowed-node-type-modifications` in the AWS CLI Reference.

2. Modify your replication group to scale up to the new, larger node type, using the AWS CLI `modify-replication-group` command and the following parameters.

- `--replication-group-id` – The name of the replication group you are scaling up to.
- `--cache-node-type` – The new node type you want to scale the cache cluster. This value must be one of the node types returned by the `list-allowed-node-type-modifications` command in step 1.
- `--cache-parameter-group-name` – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.
- `--apply-immediately` – Causes the scale-up process to be applied immediately. To postpone the scale-up process to the cluster's next maintenance window, use the `--no-apply-immediately` parameter.

For Linux, macOS, or Unix:

```
aws elasticache modify-replication-group  
  --replication-group-id my-redis-cluster 
  --cache-node-type cache.m3.xlarge 
  --apply-immediately
```

For Windows:

```
aws elasticache modify-replication-group ^
  --replication-group-id my-redis-cluster ^
  --cache-node-type cache.m3.xlarge ^
  --apply-immediately
```

Output from the above command looks something like this (JSON format).

```json
{
  "ReplicationGroup": {
    "Status": "modifying",
    "Description": "my-redis-cluster",
    "NodeGroups": [
      {
        "Status": "modifying",
        "Slots": "0-16383",
        "NodeGroupId": "0001",
```
Scaling clusters in Redis (Cluster Mode Enabled)

```
"NodeGroupMembers": [
    {
        "PreferredAvailabilityZone": "us-east-1f",
        "CacheNodeId": "0001",
        "CacheClusterId": "my-redis-cluster-0001-001"
    },
    {
        "PreferredAvailabilityZone": "us-east-1d",
        "CacheNodeId": "0001",
        "CacheClusterId": "my-redis-cluster-0001-002"
    }
],
"ConfigurationEndpoint": {
    "Port": 6379,
    "Address": "my-redis-cluster.r7gdfi.clustercfg.use1.cache.amazonaws.com"
},

"ReplicationGroupId": "my-redis-cluster",
"SnapshotRetentionLimit": 1,
"AutomaticFailover": "enabled",
"SnapshotWindow": "07:30-08:30",
"MemberClusters": [
    "my-redis-cluster-0001-001",
    "my-redis-cluster-0001-002"
],
"CacheNodeType": "cache.m3.xlarge",
"DataTiering": "disabled"
"PendingModifiedValues": {}
}
```

For more information, see modify-replication-group in the AWS CLI Reference.

3. If you used the --apply-immediately, check the status of the cache cluster using the AWS CLI describe-cache-clusters command with the following parameter. When the status changes to available, you can begin using the new, larger cache cluster node.

Scaling up Redis cache clusters (ElastiCache API)

The following process scales your cache cluster from its current node type to a new, larger node type using the ElastiCache API. During this process, ElastiCache for Redis updates the DNS entries so they point to the new nodes. Because of this you don’t have to update the endpoints in your application. For Redis 5.0.5 and above, you can scale auto failover enabled clusters while the cluster continues to stay online and serve incoming requests. On version 5.0.4 and below, you may notice a brief interruption of reads and writes on previous versions from the primary node while the DNS entry is updated.

The amount of time it takes to scale up to a larger node type varies, depending upon your node type and the amount of data in your current cache cluster.

To scale up a Redis Cache Cluster (ElastiCache API)

1. Determine which node types you can scale up to using the ElastiCache API ListAllowedNodeTypeModifications action with the following parameter.

    - ReplicationGroupId – the name of the replication group. Use this parameter to describe a specific replication group rather than all replication groups.

https://elasticache.us-west-2.amazonaws.com/
?Action=ListAllowedNodeTypeModifications

API Version 2015-02-02
388
Scaling clusters in Redis (Cluster Mode Enabled)

2. Scale your current replication group up to the new node type using the ModifyReplicationGroup Elasticache API action and with the following parameters.

- ReplicationGroupId – the name of the replication group.
- CacheNodeType – the new, larger node type of the cache clusters in this replication group. This value must be one of the instance types returned by the ListAllowedNodeTypeModifications action in step 1.
- CacheParameterGroupName – [Optional] Use this parameter if you are using reserved-memory to manage your cluster’s reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.
- ApplyImmediately – Set to true to causes the scale-up process to be applied immediately. To postpone the scale-up process to the next maintenance window, use ApplyImmediately=false.

For more information, see ModifyReplicationGroup in the Amazon ElastiCache API Reference.

3. If you used ApplyImmediately=true, monitor the status of the replication group using the DescribReplicationGroups action with the following parameters. When the status changes from modifying to available, you can begin writing to your new, scaled up replication group.

- ReplicationGroupId – the name of the replication group. Use this parameter to describe a particular replication group rather than all replication groups.

For more information, see DescribeReplicationGroups in the Amazon ElastiCache API Reference.
Online scaling down

Topics

• Scaling down Redis cache clusters (Console) (p. 390)
• Scaling down Redis cache clusters (AWS CLI) (p. 390)
• Scaling down Redis cache clusters (ElastiCache API) (p. 392)

Scaling down Redis cache clusters (Console)

The following procedure describes how to scale down a Redis cluster using the ElastiCache Management Console. During this process, your Redis cluster will continue to serve requests with minimal downtime.

To scale Down a Redis cluster (console)

2. From the navigation pane, choose Redis.
3. From the list of clusters, choose your preferred cluster.
4. Choose Modify.
5. In the Modify Cluster wizard:
   • Choose the node type you want to scale to from the Node type list. To scale down, select a node type smaller than your existing node. Note that not all node types are available to scale down to.
6. If you want to perform the scale down process right away, choose the Apply immediately box. If the Apply immediately box is not chosen, the scale-down process is performed during this cluster's next maintenance window.
7. Choose Modify.
   If you chose Apply immediately in the previous step, the cluster's status changes to modifying.
   When the status changes to available, the modification is complete and you can begin using the new cluster.

Scaling down Redis cache clusters (AWS CLI)

The following procedure describes how to scale down a Redis cache cluster using the AWS CLI. During this process, your Redis cluster will continue to serve requests with minimal downtime.

To scale down a Redis cache cluster (AWS CLI)

1. Determine the node types you can scale down to by running the AWS CLI list-allowed-node-type-modifications command with the following parameter.

   For Linux, macOS, or Unix:
   
   ```bash
   aws elasticache list-allowed-node-type-modifications \ 
   --replication-group-id my-replication-group-id
   ```

   For Windows:

   ```bat
   aws elasticache list-allowed-node-type-modifications \ 
   --replication-group-id my-replication-group-id
   ```

   For more information, see DescribeReplicationGroups in the Amazon ElastiCache API Reference.
aws elasticache list-allowed-node-type-modifications ^
   --replication-group-id my-replication-group-id

Output from the above command looks something like this (JSON format).

```json
{
   "ScaleUpModifications": [
      "cache.m3.2xlarge",
      "cache.m3.large",
      "cache.m3.xlarge",
      "cache.m4.10xlarge",
      "cache.m4.2xlarge",
      "cache.m4.4xlarge",
      "cache.m4.large",
      "cache.m4.xlarge",
      "cache.r3.2xlarge",
      "cache.r3.4xlarge",
      "cache.r3.8xlarge",
      "cache.r3.large",
      "cache.r3.xlarge"
   ],
   "ScaleDownModifications": [
      "cache.t2.micro",
      "cache.t2.small",
      "cache.t2.medium",
      "cache.t1.small"
   ]
}
```

For more information, see list-allowed-node-type-modifications in the AWS CLI Reference.

2. Modify your replication group to scale down to the new, smaller node type, using the AWS CLI modify-replication-group command and the following parameters.

- `--replication-group-id` – The name of the replication group you are scaling down to.
- `--cache-node-type` – The new node type you want to scale the cache cluster. This value must be one of the node types returned by the list-allowed-node-type-modifications command in step 1.
- `--cache-parameter-group-name` – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.
- `--apply-immediately` – Causes the scale-up process to be applied immediately. To postpone the scale-down process to the cluster's next maintenance window, use the `--no-apply-immediately` parameter.

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group  \
   --replication-group-id my-redis-cluster  \
   --cache-node-type cache.t2.micro  \
   --apply-immediately
```

For Windows:

```bash
aws elasticache modify-replication-group ^
```
Output from the above command looks something like this (JSON format).

```json
{
   "ReplicationGroup": {
      "Status": "modifying",
      "Description": "my-redis-cluster",
      "NodeGroups": [{
         "Status": "modifying",
         "Slots": "0-16383",
         "NodeGroupId": "0001",
         "NodeGroupMembers": [
            {
               "PreferredAvailabilityZone": "us-east-1f",
               "CacheNodeId": "0001",
               "CacheClusterId": "my-redis-cluster-0001-001"
            },
            {
               "PreferredAvailabilityZone": "us-east-1d",
               "CacheNodeId": "0001",
               "CacheClusterId": "my-redis-cluster-0001-002"
            }
         ]
      }
   ],
   "ConfigurationEndpoint": {
      "Port": 6379,
      "Address": "my-redis-cluster.r7gdfi.clustercfg.use1.cache.amazonaws.com"
   },
   "ClusterEnabled": true,
   "ReplicationGroupId": "my-redis-cluster",
   "SnapshotRetentionLimit": 1,
   "AutomaticFailover": "enabled",
   "SnapshotWindow": "07:30-08:30",
   "MemberClusters": [
      "my-redis-cluster-0001-001",
      "my-redis-cluster-0001-002"
   ],
   "CacheNodeType": "cache.t2.micro",
   "DataTiering": "disabled"
   "PendingModifiedValues": {}
}
```

For more information, see modify-replication-group in the AWS CLI Reference.

3. If you used the `--apply-immediately`, check the status of the cache cluster using the AWS CLI `describe-cache-clusters` command with the following parameter. When the status changes to `available`, you can begin using the new, smaller cache cluster node.

Scaling down Redis cache clusters (ElastiCache API)

The following process scales your replication group from its current node type to a new, smaller node type using the ElastiCache API. During this process, your Redis cluster will continue to serve requests with minimal downtime.
The amount of time it takes to scale down to a smaller node type varies, depending upon your node type and the amount of data in your current cache cluster.

**Scaling down (ElastiCache API)**

1. Determine which node types you can scale down to using the ElastiCache API ListAllowedNodeTypeModifications action with the following parameter.
   - ReplicationGroupId – the name of the replication group. Use this parameter to describe a specific replication group rather than all replication groups.

   ```
   https://elasticache.us-west-2.amazonaws.com/
   ?Action=ListAllowedNodeTypeModifications
   &ReplicationGroupId=MyReplGroup
   &Version=2015-02-02
   &SignatureVersion=4
   &SignatureMethod=HmacSHA256
   &Timestamp=20150202T192317Z
   &X-Amz-Credential=<credential>
   
   For more information, see ListAllowedNodeTypeModifications in the Amazon ElastiCache API Reference.
   ```

2. Scale your current replication group down to the new node type using the ModifyReplicationGroup ElastiCache API action and with the following parameters.
   - ReplicationGroupId – the name of the replication group.
   - CacheNodeType – the new, smaller node type of the cache clusters in this replication group. This value must be one of the instance types returned by the ListAllowedNodeTypeModifications action in step 1.
   - CacheParameterGroupName – [Optional] Use this parameter if you are using reserved-memory to manage your cluster's reserved memory. Specify a custom cache parameter group that reserves the correct amount of memory for your new node type. If you are using reserved-memory-percent you can omit this parameter.
   - ApplyImmediately – Set to true to causes the scale-down process to be applied immediately. To postpone the scale-down process to the next maintenance window, use ApplyImmediately=false.

   ```
   https://elasticache.us-west-2.amazonaws.com/
   ?Action=ModifyReplicationGroup
   &ApplyImmediately=true
   &CacheNodeType=cache.t2.micro
   &CacheParameterGroupName=redis32-m3-2xl
   &ReplicationGroupId=myReplGroup
   &SignatureVersion=4
   &SignatureMethod=HmacSHA256
   &Timestamp=20141201T220302Z
   &Version=2014-12-01
   &X-Amz-Algorithm=&AWS;4-HMAC-SHA256
   &X-Amz-Date=20141201T220302Z
   &X-Amz-SignedHeaders=Host
   &X-Amz-Expires=20141201T220302Z
   &X-Amz-Credential=<credential>
   &X-Amz-Signature=<signature>
   
   For more information, see ModifyReplicationGroup in the Amazon ElastiCache API Reference.
   ```
Auto Scaling ElastiCache for Redis clusters

Prerequisites

ElastiCache for Redis Auto Scaling is limited to the following:

- Redis (cluster mode enabled) clusters running Redis engine version 6.0 onwards
- Instance type families - R5, R6g, M5, M6g
- Instance sizes - Large, XLarge, 2XLarge
- Auto Scaling in ElastiCache for Redis is not supported for clusters running in Global datastores, Outposts or Local Zones.
- AWS Auto Scaling for ElastiCache for Redis is not available in the following regions: China (Beijing), China (Ningxia), AWS GovCloud (US-West) and AWS GovCloud (US-East).

Managing Capacity Automatically with ElastiCache for Redis Auto Scaling

ElastiCache for Redis auto scaling is the ability to increase or decrease the desired shards or replicas in your ElastiCache for Redis service automatically. ElastiCache for Redis leverages the Application Auto Scaling service to provide this functionality. For more information, see Application Auto Scaling. To use automatic scaling, you define and apply a scaling policy that uses CloudWatch metrics and target values that you assign. ElastiCache for Redis auto scaling uses the policy to increase or decrease the number of instances in response to actual workloads.

You can use the AWS Management Console to apply a scaling policy based on a predefined metric. A predefined metric is defined in an enumeration so that you can specify it by name in code or use it in the AWS Management Console. Custom metrics are not available for selection using the AWS Management Console. Alternatively, you can use either the AWS CLI or the Application Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

ElastiCache for Redis supports scaling for the following dimensions:

- **Shards** – Automatically add/remove shards in the cluster similar to manual online resharding. In this case, ElastiCache for Redis auto scaling triggers scaling on your behalf.
- **Replicas** – Automatically add/remove replicas in the cluster similar to manual Increase/Decrease replica operations. ElastiCache for Redis auto scaling adds/removes replicas uniformly across all shards in the cluster.

ElastiCache for Redis supports the following types of automatic scaling policies:

- **Target tracking scaling policies (p. 400)** – Increase or decrease the number of shards/replicas that your service runs based on a target value for a specific metric. This is similar to the way that your thermostat maintains the temperature of your home. You select a temperature and the thermostat does the rest.
- **Scheduled scaling for Application ElastiCache for Redis auto scaling** – Increase or decrease the number of shards/replicas that your service runs based on the date and time.
The following steps summarize the ElastiCache for Redis auto scaling process as shown in the previous diagram:

1. You create an ElastiCache for Redis auto scaling policy for your ElastiCache for Redis Replication Group.

2. ElastiCache for Redis auto scaling creates a pair of CloudWatch alarms on your behalf. Each pair represents your upper and lower boundaries for metrics. These CloudWatch alarms are triggered when the cluster's actual utilization deviates from your target utilization for a sustained period of time. You can view the alarms in the console.

3. If the configured metric value exceeds your target utilization (or falls below the target) for a specific length of time, CloudWatch triggers an alarm that invokes ElastiCache for Redis auto scaling to evaluate your scaling policy.

4. ElastiCache for Redis auto scaling issues a Modify request to adjust your cluster capacity.

5. ElastiCache for Redis processes the Modify request, dynamically increasing (or decreasing) the cluster Shards/Replicas capacity so that it approaches your target utilization.

To understand how ElastiCache for Redis Auto Scaling works, suppose that you have a cluster named UsersCluster. By monitoring the CloudWatch metrics for UsersCluster, you determine the Max shards that the cluster requires when traffic is at its peak and Min Shards when traffic is at its lowest point. You also decide a target value for CPU utilization for the UsersCluster cluster. ElastiCache for Redis auto scaling uses its target tracking algorithm to ensure that the provisioned shards of UsersCluster is adjusted as required so that utilization remains at or near to the target value.
Note
Scaling may take noticeable time and will require extra cluster resources for shards to rebalance.
ElastiCache for Redis Auto Scaling modifies resource settings only when the actual workload stays elevated (or depressed) for a sustained period of several minutes. The ElastiCache for Redis auto scaling target-tracking algorithm seeks to keep the target utilization at or near your chosen value over the long term.

Auto Scaling policies

A scaling policy has the following components:

- A target metric – The CloudWatch metric that ElastiCache for Redis Auto Scaling uses to determine when and how much to scale.
- Minimum and maximum capacity – The minimum and maximum number of shards or replicas to use for scaling.
  
  Important
  While creating Auto scaling policy, if current capacity is higher than max capacity configured, we scaleIn to the MaxCapacity during policy creation. Similarly if current capacity is lower than min capacity configured, we scaleOut to the MinCapacity.
- A cooldown period – The amount of time, in seconds, after a scale-in or scale-out activity completes before another scale-out activity can start.
- A service-linked role – An AWS Identity and Access Management (IAM) role that is linked to a specific AWS service. A service-linked role includes all of the permissions that the service requires to call other AWS services on your behalf. ElastiCache for Redis Auto Scaling automatically generates this role, AWSServiceRoleForApplicationAutoScaling_ElastiCacheRG, for you.
- Enable or disable scale-in activities - Ability to enable or disable scale-in activities for a policy.

Topics

- Target metric for Auto Scaling (p. 396)
- Minimum and maximum capacity (p. 396)
- Cool down period (p. 397)
- Enable or disable scale-in activities (p. 397)

Target metric for Auto Scaling

In this type of policy, a predefined or custom metric and a target value for the metric is specified in a target-tracking scaling policy configuration. ElastiCache for Redis Auto Scaling creates and manages CloudWatch alarms that trigger the scaling policy and calculates the scaling adjustment based on the metric and target value. The scaling policy adds or removes shards/replicas as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target-tracking scaling policy also adjusts to fluctuations in the metric due to a changing workload. Such a policy also minimizes rapid fluctuations in the number of available shards/replicas for your cluster.

For example, consider a scaling policy that uses the predefined average ElastiCachePrimaryEngineCPUUtilization metric. Such a policy can keep CPU utilization at, or close to, a specified percentage of utilization, such as 70 percent.

Note
For each cluster, you can create only one Auto Scaling policy for each target metric.

Minimum and maximum capacity

Shards
You can specify the maximum number of shards that can be scaled to by ElastiCache for Redis auto scaling. This value must be less than or equal to 250 with a minimum of 1. You can also specify the minimum number of shards to be managed by ElastiCache for Redis auto scaling. This value must be at least 1, and equal to or less than the value specified for the maximum shards 250.

Repli cas

You can specify the maximum number of replicas to be managed by ElastiCache for Redis auto scaling. This value must be less than or equal to 5. You can also specify the minimum number of replicas to be managed by ElastiCache for Redis auto scaling. This value must be at least 1, and equal to or less than the value specified for the maximum replicas 5.

To determine the minimum and maximum number of shards/replicas that you need for typical traffic, test your Auto Scaling configuration with the expected rate of traffic to your model.

Note
ElastiCache for Redis auto scaling policies increase cluster capacity until it reaches your defined maximum size or until service limits apply. To request a limit increase, see AWS Service Limits and choose the limit type **Nodes per cluster per instance type**.

Important
Scaling-in occurs when there is no traffic. If a variant's traffic becomes zero, ElastiCache for Redis automatically scales in to the minimum number of instances specified.

Cool down period

You can tune the responsiveness of a target-tracking scaling policy by adding cooldown periods that affect scaling your cluster. A cooldown period blocks subsequent scale-in or scale-out requests until the period expires. This slows the deletions of shards/replicas in your ElastiCache for Redis cluster for scale-in requests, and the creation of shards/replicas for scale-out requests. You can specify the following cooldown periods:

- A scale-in activity reduces the number of shards/replicas in your ElastiCache for Redis cluster. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.
- A scale-out activity increases the number of shards/replicas in your ElastiCache for Redis cluster. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

When a scale-in or a scale-out cooldown period is not specified, the default for scale-out is 600 seconds and for scale-in 900 seconds.

Enable or disable scale-in activities

You can enable or disable scale-in activities for a policy. Enabling scale-in activities allows the scaling policy to delete shards/replicas. When scale-in activities are enabled, the scale-in cooldown period in the scaling policy applies to scale-in activities. Disabling scale-in activities prevents the scaling policy from deleting shards/replicas.

Note
Scale-out activities are always enabled so that the scaling policy can create ElastiCache for Redis shards/replicas as needed.

I AM Permissions Required for ElastiCache for Redis Auto Scaling

ElastiCache for Redis Auto Scaling is made possible by a combination of the ElastiCache for Redis, CloudWatch, and Application Auto Scaling APIs. Clusters are created and updated with ElastiCache...
for Redis, alarms are created with CloudWatch, and scaling policies are created with Application Auto Scaling. In addition to the standard IAM permissions for creating and updating clusters, the IAM user that accesses ElastiCache for Redis Auto Scaling settings must have the appropriate permissions for the services that support dynamic scaling. IAM users must have permissions to use the actions shown in the following example policy:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "application-autoscaling:*",
        "elasticache:DescribeReplicationGroups",
        "elasticache:ModifyReplicationGroupShardConfiguration",
        "elasticache:IncreaseReplicaCount",
        "elasticache:DecreaseReplicaCount",
        "elasticache:DescribeCacheClusters",
        "elasticache:DescribeCacheParameters",
        "cloudwatch:DescribeAlarmHistory",
        "cloudwatch:DescribeAlarms",
        "cloudwatch:DescribeAlarmsForMetric",
        "cloudwatch:GetMetricStatistics",
        "cloudwatch:ListMetrics",
        "cloudwatch:GetMetricAlarm",
        "cloudwatch:DisableAlarmActions",
        "cloudwatch:EnableAlarmActions",
        "iam:CreateServiceLinkedRole",
        "sns:CreateTopic",
        "sns:Subscribe",
        "sns:Get*",
        "sns:Get**",
        "sns:List**"
      ],
      "Resource": "arn:aws:iam::123456789012:role/autoscaling-roles-for-cluster"
    }
  ]
}
```

### Service-linked role

The ElastiCache for Redis auto scaling service also needs permission to describe your clusters and CloudWatch alarms, and permissions to modify your ElastiCache for Redis target capacity on your behalf. If you enable Auto Scaling for your ElastiCache for Redis cluster, it creates a service-linked role named AWSServiceRoleForApplicationAutoScaling_ElastiCacheRG. This service-linked role grants ElastiCache for Redis auto scaling permission to describe the alarms for your policies, to monitor the current capacity of the fleet, and to modify the capacity of the fleet. The service-linked role is the default role for ElastiCache for Redis auto scaling. For more information, see Service-linked roles for ElastiCache for Redis auto scaling in the Application Auto Scaling User Guide.

### Auto Scaling Best Practices

Before registering to Auto Scaling, we recommend the following:

1. **Use just one tracking metric** – Identify if your cluster has CPU- or memory-intensive workloads and use a corresponding predefined metric to define Scaling Policy. We recommend you avoid multiple policies per dimension on the cluster. ElastiCache for Redis Auto scaling will scale out the scalable target if any of the target tracking policies are ready for scale out, but will scale in only if all of the target tracking policies (with the scale-in portion enabled) are ready to scale in. If multiple policies
instruct the scalable target to scale out or in at the same time, it scales based on the policy that provides the largest capacity for both scale in and scale out.

2. **Use just one dimension** – Identify if your cluster has a write- or read-heavy workload and use corresponding dimension (shards/replicas) to define scaling policy. Having policies on multiple dimensions for the same cluster can have repercussions on scaling actions. For example, if you create scaling policies on engine CPU for both shards and replicas, and if a scale-out action is triggered on a shard dimension which adds new shards along with their replicas, this increase in new replicas can impact scaling policy of replica dimension that can trigger scale-in of replicas and vise versa. \( \text{Avg} \) metric is used across cluster nodes for the Predefined Metrics.

3. **Customized Metrics for Target Tracking** – Be cautious when using customized metrics for Target Tracking as Auto scaling is best suited to scale-out/in proportional to change in metrics chosen for the policy. If such metrics that don't change proportionally to the scaling actions are used for policy creation, it might lead to continuous scale-out or scale-in actions which might affect availability or cost.

4. **Scheduled Scaling** – If you identify that your workload is deterministic (reaches high/low at a specific time), we recommend using Scheduled Scaling and configure your target capacity according to the need. Target Tracking is best suitable for non-deterministic workloads and for the cluster to operate at the required target metric by scaling out when you need more resources and scaling in when you need less.

5. **Disable Scale-In** – Auto scaling on Target Tracking is best suited for clusters with gradual increase/decrease of workloads as spikes/dip in metrics can trigger consecutive scale-out/in oscillations. In order to avoid such oscillations, you can start with scale-in disabled and later you can always manually scale-in to your need.

6. **Test your application** – We recommend you test your application with your estimated Min/Max workloads to determine absolute Min,Max shards/replicas required for the cluster while creating Scaling policies to avoid availability issues. Auto scaling can scale out to the Max and scale-in to the Min threshold configured for the target.

7. **Defining Target Value** – You can analyze corresponding CloudWatch metrics for cluster utilization over a four-week period to determine the target value threshold. If you are still not sure of of what value to choose, we recommend starting with a minimum supported predefined metric value.

8. **AutoScaling on Target Tracking** is best suited for clusters with uniform distribution of workloads across shards/replicas dimension. Having non-uniform distribution can lead to:
   - Scaling when not required due to workload spike/dip on a few hot shards/replicas.
   - Not scaling when required due to overall avg close to target even though having hot shards/replicas.

After registering to AutoScaling, note the following:

- There are limitations on Auto scaling Supported Configurations, so we recommend you not change configuration of a replication group that is registered for Auto scaling. The following are examples:
  - Manually modifying instance type to unsupported types.
  - Associating the replication group to a Global datastore.
  - Changing \text{ReservedMemoryPercent} parameter.
  - Manually increasing/decreasing shards/replicas beyond the Min/Max capacity configured during policy creation.

**Using Auto Scaling with shards**

The following provides details on target tracking and scheduled policies and how to apply them using the AWS Management Console AWS CLI and APIs.
Target tracking scaling policies

With target tracking scaling policies, you select a metric and set a target value. ElastiCache for Redis Auto Scaling creates and manages the CloudWatch alarms that trigger the scaling policy and calculates the scaling adjustment based on the metric and the target value. The scaling policy adds or removes shards as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target tracking scaling policy also adjusts to the fluctuations in the metric due to a fluctuating load pattern and minimizes rapid fluctuations in the capacity of the fleet.

For example, consider a scaling policy that uses the predefined average ElastiCachePrimaryEngineCPUUtilization metric with configured target value. Such a policy can keep CPU utilization at, or close to the specified target value.

Auto Scaling criteria for shards

Your Auto Scaling policy defines the following predefined metrics for your cluster:

- **ElastiCachePrimaryEngineCPUUtilization**: The average value of the EngineCPUUtilization metric in CloudWatch across all primary nodes in the ElastiCache for Redis cluster. You can find the aggregated metric value in CloudWatch under ElastiCache for Redis ReplicationGroupId, Role for required ReplicationGroupId and Role Primary.
- **ElastiCacheDatabaseMemoryUsageCountedForEvictPercentage**: The average value of the DatabaseMemoryUsageCountedForEvictPercentage metric in CloudWatch across all nodes in the ElastiCache for Redis cluster. You can find the aggregated metric value for the ReplicationGroup in CloudWatch under ElastiCache for Redis Redis Replication Group Metrics.

When the service detects that your ElastiCachePrimaryEngineCPUUtilization metric is equal to or greater than the Target setting, it will increase your shards capacity automatically. ElastiCache for Redis scales out your cluster shards by a count equal to the larger of two numbers: Percent variation from Target and 20 percent of current shards. For scale-in, ElastiCache for Redis won't auto scale-in unless the overall metric value is below 75 percent of your defined Target.

For a scale out example, if you have 50 shards and

- if your Target breaches by 30 percent, ElastiCache for Redis scales out by 30 percent, which results in 65 shards per cluster.
- if your Target breaches by 10 percent, ElastiCache for Redis scales out by default Minimum of 20 percent, which results in 60 shards per cluster.

For a scale-in example, if you have selected a Target value of 60 percent, ElastiCache for Redis won't auto scale-in until the metric is less than or equal to 45 percent (25 percent below the Target 60 percent).

Auto Scaling considerations

Keep the following considerations in mind:

- A target tracking scaling policy assumes that it should perform scale out when the specified metric is above the target value. You cannot use a target tracking scaling policy to scale out when the specified metric is below the target value. ElastiCache for Redis scales out shards by a minimum of 20 percent deviation of target of existing shards in the cluster.
- A target tracking scaling policy does not perform scaling when the specified metric has insufficient data. It does not perform scale-in because it does not interpret insufficient data as low utilization.
- You may see gaps between the target value and the actual metric data points. This is because ElastiCache for Redis Auto Scaling always acts conservatively by rounding up or down when it determines how much capacity to add or remove. This prevents it from adding insufficient capacity or removing too much capacity.
To ensure application availability, the service scales out proportionally to the metric as fast as it can, but scales in more conservatively.

You can have multiple target tracking scaling policies for an ElastiCache for Redis cluster, provided that each of them uses a different metric. The intention of ElastiCache for Redis Auto Scaling is to always prioritize availability, so its behavior differs depending on whether the target tracking policies are ready for scale out or scale in. It will scale out the service if any of the target tracking policies are ready for scale out, but will scale in only if all of the target tracking policies (with the scale-in portion enabled) are ready to scale in.

Do not edit or delete the CloudWatch alarms that ElastiCache for Redis Auto Scaling manages for a target tracking scaling policy. ElastiCache for Redis Auto Scaling deletes the alarms automatically when you delete the scaling policy.

ElastiCache for Redis Auto Scaling doesn't prevent you from manually modifying cluster shards. These manual adjustments don't affect any existing CloudWatch alarms that are attached to the scaling policy but can impact metrics that may trigger these CloudWatch alarms.

These CloudWatch alarms managed by Auto Scaling are defined over the AVG metric across all the shards in the cluster. So, having hot shards can result in either scenario of:

- scaling when not required due to load on a few hot shards triggering a CloudWatch alarm
- not scaling when required due to aggregated AVG across all shards affecting alarm not to breach.

ElastiCache for Redis default limits on Nodes per cluster still applies. So, when opting for Auto Scaling and if you expect maximum nodes to be more than default limit, request a limit increase at AWS Service Limits and choose the limit type **Nodes per cluster per instance type**.

Ensure that you have enough ENIs (Elastic Network Interfaces) available in your VPC, which are required during scale-out. For more information, see [Elastic network interfaces](#).

If there is not enough capacity available from EC2, ElastiCache for Redis Auto Scaling would not scale and be delayed till the capacity is available.

ElastiCache for Redis Auto Scaling during scale-in will not remove shards with slots having an item size larger than 256 MB post-serialization.

During scale-in it will not remove shards if insufficient memory available on resultant shard configuration.

### Adding a scaling policy

You can add a scaling policy using the AWS Management Console.

**To add an Auto Scaling policy to an ElastiCache for Redis cluster**

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. In the navigation pane, choose **Redis**.
3. Choose the cluster that you want to add a policy to.
4. Choose the Manage Auto Scaling policies from the Actions dropdown.
5. Choose the Auto Scaling policies tab.
6. In the Add Scaling policy dialog box, choose **Dynamic scaling**.
7. For **Policy name** enter a policy name.
8. For **Scalable Dimension** choose **shards**.
9. For the target metric, choose one of the following:
   - **Primary CPU Utilization** to create a policy based on the average CPU utilization.
   - **Memory** to create a policy based on the average database memory.
10. For the target value, choose one of the following:
• If you chose **Primary CPU Utilization**, type the percentage of CPU utilization that you want to maintain on Elasticache shards. This value must be greater than or equal to 35 and less than or equal to 70.

• If you chose **Memory** to create a policy based on the average database memory, type the percentage of Redis memory that you want to maintain on ElastiCache for Redis shards. This value must be greater than or equal to 35 and less than or equal to 70.

Cluster shards are added or removed to keep the metric close to the specified value.

11. (Optional) Scale-in or scale-out cooldown periods are not supported from the console. Use the AWS CLI to modify the cooldown values.

12. For **Minimum capacity**, type the minimum number of shards that the ElastiCache for Redis Auto Scaling policy is required to maintain.

13. For **Maximum capacity**, type the maximum number of shards that the ElastiCache for Redis Auto Scaling policy is required to maintain. This value must be less than or equal to 250.

14. Choose **Add policy**.

### Registering a Scalable Target

Before you can use Auto Scaling with an ElastiCache for Redis cluster, you register your cluster with ElastiCache for Redis auto scaling. You do so to define the scaling dimension and limits to be applied to that cluster. ElastiCache for Redis auto scaling dynamically scales the ElastiCache for Redis cluster along the `elasticache:replication-group:NodeGroups` scalable dimension, which represents the number of cluster shards.

#### Using the AWS CLI

To register your ElastiCache for Redis cluster, use the `register-scalable-target` command with the following parameters:

• `--service-namespace` – Set this value to `elasticache`

• `--resource-id` – The resource identifier for the ElastiCache for Redis cluster. For this parameter, the resource type is `ReplicationGroup` and the unique identifier is the name of the ElastiCache for Redis cluster, for example `replication-group/myscalablecluster`.

• `--scalable-dimension` – Set this value to `elasticache:replication-group:NodeGroups`.

• `--max-capacity` – The maximum number of shards to be managed by ElastiCache for Redis auto scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of shards in your cluster, see Minimum and maximum capacity (p. 396).

• `--min-capacity` – The minimum number of shards to be managed by ElastiCache for Redis auto scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of shards in your cluster, see Minimum and maximum capacity (p. 396).

#### Example

In the following example, you register an ElastiCache for Redis cluster named `myscalablecluster`. The registration indicates that the cluster should be dynamically scaled to have from one to ten shards.

For Linux, macOS, or Unix:

```bash
aws application-autoscaling register-scalable-target
  --service-namespace elasticache
  --resource-id replication-group/myscalablecluster
  --scalable-dimension elasticache:replication-group:NodeGroups
```
Using Auto Scaling with shards

```
--min-capacity 1 \
--max-capacity 10 \
```

For Windows:

```
aws application-autoscaling register-scalable-target ^
   --service-namespace elasticache ^
   --resource-id replication-group/myscalablecluster ^
   --scalable-dimension elasticache:replication-group:NodeGroups ^
   --min-capacity 1 ^
   --max-capacity 10 ^
```

Using the API

To register your ElastiCache cluster, use the `register-scalable-target` command with the following parameters:

- **ServiceNamespace** – Set this value to `elasticache`.
- **ResourceId** – The resource identifier for the ElastiCache cluster. For this parameter, the resource type is `ReplicationGroup` and the unique identifier is the name of the ElastiCache for Redis cluster, for example `replication-group/myscalablecluster`.
- **ScalableDimension** – Set this value to `elasticache:replication-group:NodeGroups`.
- **MinCapacity** – The minimum number of shards to be managed by ElastiCache for Redis auto scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of replicas in your cluster, see Minimum and maximum capacity (p. 396).
- **MaxCapacity** – The maximum number of shards to be managed by ElastiCache for Redis auto scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of replicas in your cluster, see Minimum and maximum capacity (p. 396).

**Example**

In the following example, you register an ElastiCache for Redis cluster named `myscalablecluster` with the Application Auto Scaling API. This registration indicates that the cluster should be dynamically scaled to have from one to 5 replicas.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
   "ServiceNamespace": "elasticache",
   "ResourceId": "replication-group/myscalablecluster",
   "ScalableDimension": "elasticache:replication-group:NodeGroups",
   "MinCapacity": 1,
   "MaxCapacity": 5
}
```

**Defining a scaling policy**

A target-tracking scaling policy configuration is represented by a JSON block that the metrics and target values are defined in. You can save a scaling policy configuration as a JSON block in a text file. You use
that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

The following options are available for defining a target-tracking scaling policy configuration:

**Topics**
- Using a predefined metric (p. 404)
- Using a custom metric (p. 404)
- Using cooldown periods (p. 405)
- Disabling scale-in activity (p. 405)
- Applying a scaling policy (p. 406)

**Using a predefined metric**

By using predefined metrics, you can quickly define a target-tracking scaling policy for an ElastiCache for Redis cluster that works with target tracking in ElastiCache for Redis Auto Scaling.

Currently, ElastiCache for Redis supports the following predefined metrics in ElastiCache for Redis NodeGroup Auto Scaling:

- ElastiCachePrimaryEngineCPUUtilization – The average value of the EngineCPUUtilization metric in CloudWatch across all primary nodes in the ElastiCache for Redis cluster.
- ElastiCacheDatabaseMemoryUsageCountedForEvictPercentage – The average value of the DatabaseMemory metric in CloudWatch across all primary nodes in the ElastiCache for Redis cluster.

For more information about the EngineCPUUtilization and DatabaseMemory metrics, see Monitoring use with CloudWatch Metrics (p. 588). To use a predefined metric in your scaling policy, you create a target tracking configuration for your scaling policy. This configuration must include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.

**Example**

The following example describes a typical policy configuration for target-tracking scaling for an ElastiCache for Redis cluster. In this configuration, the ElastiCachePrimaryEngineCPUUtilization predefined metric is used to adjust the ElastiCache for Redis cluster based on an average CPU utilization of 40 percent across all primary nodes in the cluster.

```json
{
   "TargetValue": 40.0,
   "PredefinedMetricSpecification":
   {
      "PredefinedMetricType": "ElastiCachePrimaryEngineCPUUtilization"
   }
}
```

**Using a custom metric**

By using custom metrics, you can define a target-tracking scaling policy that meets your custom requirements. You can define a custom metric based on any ElastiCache metric that changes in proportion to scaling. Not all ElastiCache metrics work for target tracking. The metric must be a valid utilization metric and describe how busy an instance is. The value of the metric must increase or decrease in proportion to the number of Shards in the cluster. This proportional increase or decrease is necessary to use the metric data to proportionally scale out or in the number of shards.
Example

The following example describes a target-tracking configuration for a scaling policy. In this configuration, a custom metric adjusts an ElastiCache for Redis cluster based on an average CPU utilization of 50 percent across all shards in a cluster named `my-db-cluster`.

```json
{
   "TargetValue": 50,
   "CustomizedMetricSpecification": {
      "MetricName": "EngineCPUUtilization",
      "Namespace": "AWS/ElastiCache",
      "Dimensions": [
         {
            "Name": "RelocationGroup","Value": "my-db-cluster"
         },
         {
            "Name": "Role","Value": "PRIMARY"
         }
      ],
      "Statistic": "Average",
      "Unit": "Percent"
   }
}
```

Using cooldown periods

You can specify a value, in seconds, for `ScaleOutCooldown` to add a cooldown period for scaling out your cluster. Similarly, you can add a value, in seconds, for `ScaleInCooldown` to add a cooldown period for scaling in your cluster. For more information, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.

The following example describes a target-tracking configuration for a scaling policy. In this configuration, the `ElastiCachePrimaryEngineCPUUtilization` predefined metric is used to adjust an ElastiCache for Redis cluster based on an average CPU utilization of 40 percent across all primary nodes in that cluster. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```json
{
   "TargetValue": 40.0,
   "PredefinedMetricSpecification": {
      "PredefinedMetricType": "ElastiCachePrimaryEngineCPUUtilization"
   },
   "ScaleInCooldown": 600,
   "ScaleOutCooldown": 300
}
```

Disabling scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your ElastiCache for Redis cluster by disabling scale-in activity. Disabling scale-in activity prevents the scaling policy from deleting shards, while still allowing the scaling policy to create them as needed.

You can specify a Boolean value for `DisableScaleIn` to enable or disable scale in activity for your cluster. For more information, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.

The following example describes a target-tracking configuration for a scaling policy. In this configuration, the `ElastiCachePrimaryEngineCPUUtilization` predefined metric adjusts an ElastiCache for Redis...
cluster based on an average CPU utilization of 40 percent across all primary nodes in that cluster. The configuration disables scale-in activity for the scaling policy.

```
{
  "TargetValue": 40.0,
  "PredefinedMetricSpecification":
  {
    "PredefinedMetricType": "ElastiCachePrimaryEngineCPUUtilization"
  },
  "DisableScaleIn": true
}
```

### Applying a scaling policy

After registering your cluster with ElastiCache for Redis auto scaling and defining a scaling policy, you apply the scaling policy to the registered cluster. To apply a scaling policy to an ElastiCache for Redis cluster, you can use the AWS CLI or the Application Auto Scaling API.

#### Applying a scaling policy using the AWS CLI

To apply a scaling policy to your ElastiCache for Redis cluster, use the `put-scaling-policy` command with the following parameters:

- **--policy-name** – The name of the scaling policy.
- **--policy-type** – Set this value to `TargetTrackingScaling`.
- **--resource-id** – The resource identifier for the ElastiCache for Redis. For this parameter, the resource type is `ReplicationGroup` and the unique identifier is the name of the ElastiCache for Redis cluster, for example `replication-group/myscalablecluster`.
- **--service-namespace** – Set this value to `elasticache`.
- **--scalable-dimension** – Set this value to `elasticache:replication-group:NodeGroups`.

In the following example, you apply a target-tracking scaling policy named `myscalablepolicy` to an ElastiCache for Redis cluster named `myscalablecluster` with ElastiCache for Redis auto scaling. To do so, you use a policy configuration saved in a file named `config.json`.

For Linux, macOS, or Unix:

```
aws application-autoscaling put-scaling-policy
  --policy-name myscalablepolicy
  --policy-type TargetTrackingScaling
  --resource-id replication-group/myscalablecluster
  --service-namespace elasticache
  --scalable-dimension elasticache:replication-group:NodeGroups
  --target-tracking-scaling-policy-configuration file://config.json
```

For Windows:

```
aws application-autoscaling put-scaling-policy
  --policy-name myscalablepolicy
  --policy-type TargetTrackingScaling
  --resource-id replication-group/myscalablecluster
  --service-namespace elasticache
  --scalable-dimension elasticache:replication-group:NodeGroups
```

API Version 2015-02-02

406
Applying a scaling policy using the API

To apply a scaling policy to your ElastiCache for Redis cluster, use the `PutScalingPolicy` AWS CLI command with the following parameters:

- `--policy-name` – The name of the scaling policy.
- `--resource-id` – The resource identifier for the ElastiCache for Redis. For this parameter, the resource type is `ReplicationGroup` and the unique identifier is the name of the ElastiCache for Redis cluster, for example `replication-group/myscalablecluster`.
- `--service-namespace` – Set this value to `elasticache`.
- `--scalable-dimension` – Set this value to `elasticache:replication-group:NodeGroups`.

In the following example, you apply a target-tracking scaling policy named `myscalablepolicy` to an ElastiCache for Redis cluster named `myscalablecluster` with ElastiCache for Redis auto scaling. You use a policy configuration based on the `ElastiCachePrimaryEngineCPUUtilization` predefined metric.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.PutScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "elasticache",
    "ResourceId": "replication-group/myscalablecluster",
    "ScalableDimension": "elasticache:replication-group:NodeGroups",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration": {
        "TargetValue": 40.0,
        "PredefinedMetricSpecification": {
            "PredefinedMetricType": "ElastiCachePrimaryEngineCPUUtilization"
        }
    }
}
```

Editing a scaling policy

You can edit a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Editing a scaling policy using the AWS Management Console

To edit an Auto Scaling policy for an ElastiCache for Redis cluster

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at [https://console.aws.amazon.com/elasticache/](https://console.aws.amazon.com/elasticache/).
2. In the navigation pane, choose **Redis**.
3. Choose the cluster whose Auto Scaling policy you want to edit.
4. Choose **Actions** and then choose **Manage Auto Scaling policies**.
5. Choose the **Auto Scaling policies** tab.
6. In the **Auto Scaling policies** section, choose the Auto Scaling policy, and then choose **Edit** from the **Actions** menu.
7. Make the requisite changes to the policy.
8. Choose **Update policy**.

### Editing a scaling policy using the AWS CLI and API

You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- When using the AWS CLI, specify the name of the policy you want to edit in the **--policy-name** parameter. Specify new values for the parameters you want to change.
- When using the Application Auto Scaling API, specify the name of the policy you want to edit in the **PolicyName** parameter. Specify new values for the parameters you want to change.

For more information, see [Applying a scaling policy](#p.406).

### Deleting a scaling policy

You can delete a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

#### Deleting a scaling policy using the AWS Management Console

**To delete an Auto Scaling policy for an ElastiCache for Redis cluster**

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at [https://console.aws.amazon.com/elasticache/](https://console.aws.amazon.com/elasticache/).
2. In the navigation pane, choose **Redis**.
3. Choose the cluster whose Auto Scaling policy you want to edit.
4. Choose the **Auto Scaling policies** tab.
5. In the **Auto Scaling policies** section, choose the Auto Scaling policy, and then choose **Delete** from the **Actions** menu.

#### Deleting a scaling policy using the AWS CLI

To delete a scaling policy to your ElastiCache for Redis cluster, use the `delete-scaling-policy` AWS CLI command with the following parameters:

- **--policy-name** – The name of the scaling policy.
- **--resource-id** – The resource identifier for the ElastiCache for Redis. For this parameter, the resource type is `ReplicationGroup` and the unique identifier is the name of the ElastiCache for Redis cluster, for example `replication-group/myscalablecluster`.
- **--service-namespace** – Set this value to `elasticache`.
- **--scalable-dimension** – Set this value to `elasticache:replication-group:NodeGroups`.  

API Version 2015-02-02

408
In the following example, you delete a target-tracking scaling policy named `myscalablepolicy` from an ElastiCache for Redis cluster named `myscalablecluster`.

For Linux, macOS, or Unix:

```bash
aws application-autoscaling delete-scaling-policy
   --policy-name myscalablepolicy
   --resource-id replication-group/myscalablecluster
   --service-namespace elasticache
   --scalable-dimension elasticache:replication-group:NodeGroups
```

For Windows:

```bash
aws application-autoscaling delete-scaling-policy
   --policy-name myscalablepolicy
   --resource-id replication-group/myscalablecluster
   --service-namespace elasticache
   --scalable-dimension elasticache:replication-group:NodeGroups
```

### Deleting a scaling policy using the API

To delete a scaling policy to your ElastiCache for Redis cluster, use the `DeleteScalingPolicy` AWS CLI command with the following parameters:

- **--policy-name** – The name of the scaling policy.
- **--resource-id** – The resource identifier for the ElastiCache for Redis. For this parameter, the resource type is `ReplicationGroup` and the unique identifier is the name of the ElastiCache for Redis cluster, for example `replication-group/myscalablecluster`.
- **--service-namespace** – Set this value to `elasticache`.
- **--scalable-dimension** – Set this value to `elasticache:replication-group:NodeGroups`.

In the following example, you delete a target-tracking scaling policy named `myscalablepolicy` from an ElastiCache for Redis cluster named `myscalablecluster`.

POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

```json
{
   "PolicyName": "myscalablepolicy",
   "ServiceNamespace": "elasticache",
   "ResourceId": "replication-group/myscalablecluster",
   "ScalableDimension": "elasticache:replication-group:NodeGroups"
}
```

### Use AWS CloudFormation for Auto Scaling policies

This snippet shows how to create a target tracking policy and apply it to an `AWS::ElastiCache::ReplicationGroup` resource using the `AWS::ApplicationAutoScaling::ScalableTarget` resource. It uses the `Fn::Join` and `Ref` intrinsic functions to construct the `ResourceId` property with the logical name of the `AWS::ElastiCache::ReplicationGroup` resource that is specified in the same template.
ScalingTarget:
    Type: 'AWS::ApplicationAutoScaling::ScalableTarget'
    Properties:
        MaxCapacity: 3
        MinCapacity: 1
        ResourceId: !Sub replication-group/${logicalName}
        ScalableDimension: 'elasticache:replication-group:NodeGroups'
        ServiceNamespace: elasticache
        RoleARN: !Sub "arn:aws:iam::${AWS::AccountId}:role/aws-service-role/elasticache.application-autoscaling.amazonaws.com/AWSServiceRoleForApplicationAutoScaling_ElastiCacheRG"

ScalingPolicy:
    Type: "AWS::ApplicationAutoScaling::ScalingPolicy"
    Properties:
        ScalingTargetId: !Ref ScalingTarget
        ServiceNamespace: elasticache
        PolicyName: testpolicy
        PolicyType: TargetTrackingScaling
        ScalableDimension: 'elasticache:replication-group:NodeGroups'
        TargetTrackingScalingPolicyConfiguration:
            PredefinedMetricSpecification:
                PredefinedMetricType: ElastiCachePrimaryEngineCPUUtilization
            TargetValue: 20

Scheduled scaling

Scaling based on a schedule enables you to scale your application in response to predictable changes in demand. To use scheduled scaling, you create scheduled actions, which tell ElastiCache for Redis to perform scaling activities at specific times. When you create a scheduled action, you specify an existing ElastiCache for Redis cluster, when the scaling activity should occur, minimum capacity, and maximum capacity. You can create scheduled actions that scale one time only or that scale on a recurring schedule.

You can only create a scheduled action for ElastiCache for Redis clusters that already exist. You can't create a scheduled action at the same time that you create a cluster.

For more information on terminology for scheduled action creation, management, and deletion, see Commonly used commands for scheduled action creation, management, and deletion

To create on a recurring schedule:

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. In the navigation pane, choose Redis.
3. Choose the cluster that you want to add a policy for.
4. Choose the Manage Auto Scaling policy from the Actions dropdown.
5. Choose the Auto Scaling policies tab.
6. In the Auto scaling policies section, the Add Scaling policy dialog box appears. Choose Scheduled scaling.
7. For Policy Name, enter the policy name.
8. For Scalable Dimension, choose Shards.
9. For Target Shards, choose the value.
10. For Recurrence, choose Recurring.
11. For Frequency, choose the respective value.
12. For Start Date and Start time, choose the time from when the policy will go into effect.
13. Choose Add Policy.
To create a one-time scheduled action:

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. In the navigation pane, choose Redis.
3. Choose the cluster that you want to add a policy for.
4. Choose the Manage Auto Scaling policies from the Actions dropdown.
5. Choose the Auto Scaling policies tab.
6. In the Auto scaling policies section, the Add Scaling policy dialog box appears. Choose Scheduled scaling.
7. For Policy Name, enter the policy name.
8. For Scalable Dimension, choose Shards.
9. For Target Shards, choose the value.
10. For Recurrence, choose One Time.
11. For Start Date and Start time, choose the time from when the policy will go into effect.
12. For End Date choose the date until when the policy would be in effect.
13. Choose Add Policy.

To delete a scheduled action

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. In the navigation pane, choose Redis.
3. Choose the cluster that you want to add a policy for.
4. Choose the Manage Auto Scaling policies from the Actions dropdown.
5. Choose the Auto Scaling policies tab.
6. In the Auto scaling policies section, choose the auto scaling policy, and then choose Delete from the Actions dialog.

To manage scheduled scaling using the AWS CLI

Use the following application-autoscaling APIs:

- put-scheduled-action
- describe-scheduled-actions
- delete-scheduled-action

Use AWS CloudFormation to create a scheduled action

This snippet shows how to create a target tracking policy and apply it to an AWS::ElastiCache::ReplicationGroup resource using the AWS::ApplicationAutoScaling::ScalableTarget resource. It uses the Fn::Join and Ref intrinsic functions to construct the ResourceId property with the logical name of the AWS::ElastiCache::ReplicationGroup resource that is specified in the same template.

```
ScalingTarget:
  Type: 'AWS::ApplicationAutoScaling::ScalableTarget'
  Properties:
    MaxCapacity: 3
    MinCapacity: 1
```
Using Auto Scaling with replicas

The following provides details on target tracking and scheduled policies and how to apply them using the AWS Management Console AWS CLI and APIs.

Target tracking scaling policies

With target tracking scaling policies, you select a metric and set a target value. ElastiCache for Redis AutoScaling creates and manages the CloudWatch alarms that trigger the scaling policy and calculates the scaling adjustment based on the metric and the target value. The scaling policy adds or removes replicas uniformly across all shards as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target tracking scaling policy also adjusts to the fluctuations in the metric due to a fluctuating load pattern and minimizes rapid fluctuations in the capacity of the fleet.

Auto Scaling criteria for replicas

Your Auto Scaling policy defines the following predefined metric for your cluster:

ElastiCacheReplicaEngineCPUUtilization: The AVG EngineCPU utilization threshold aggregated across all replicas that ElastiCache for Redis uses to trigger an auto-scaling operation. You can set the utilization target between 35 percent and 70 percent.

When the service detects that your `ElastiCacheReplicaEngineCPUUtilization` metric is equal to or greater than the Target setting, it will increase replicas across your shards automatically. ElastiCache for Redis scales out your cluster replicas by a count equal to the larger of two numbers: Percent variation from Target and one replica. For scale-in, ElastiCache for Redis won't auto scale-in unless the overall metric value is below 75 percent of your defined Target.

For a scale-out example, if you have 5 shards and 1 replica each:

If your Target breaches by 30 percent, ElastiCache for Redis scales out by 1 replica (max(0.3, default 1)) across all shards. which results in 5 shards with 2 replicas each,

For a scale-in example, if you have selected Target value of 60 percent, ElastiCache for Redis won't auto scale-in unless the metric is less than or equal to 45 percent (25 percent below the Target 60 percent).

Auto Scaling considerations

Keep the following considerations in mind:

- A target tracking scaling policy assumes that it should perform scale out when the specified metric is above the target value. You cannot use a target tracking scaling policy to scale out when the specified metric is below the target value. ElastiCache for Redis scales out replicas by maximum of (% deviation rounded off from Target, default 1) of existing replicas across all shards in the cluster.
A target tracking scaling policy does not perform scaling when the specified metric has insufficient data. It does not perform scale in because it does not interpret insufficient data as low utilization.

You may see gaps between the target value and the actual metric data points. This is because ElastiCache for Redis Auto Scaling always acts conservatively by rounding up or down when it determines how much capacity to add or remove. This prevents it from adding insufficient capacity or removing too much capacity.

To ensure application availability, the service scales out proportionally to the metric as fast as it can, but scales in more gradually with max scale in of 1 replica across the shards in the cluster.

You can have multiple target tracking scaling policies for an ElastiCache for Redis cluster, provided that each of them uses a different metric. The intention of ElastiCache for Redis Auto Scaling is to always prioritize availability, so its behavior differs depending on whether the target tracking policies are ready for scale out or scale in. It will scale out the service if any of the target tracking policies are ready for scale out, but will scale in only if all of the target tracking policies (with the scale-in portion enabled) are ready to scale in.

Do not edit or delete the CloudWatch alarms that ElastiCache for Redis Auto Scaling manages for a target tracking scaling policy. ElastiCache for Redis Auto Scaling deletes the alarms automatically when you delete the scaling policy or deleting the cluster.

ElastiCache for Redis Auto Scaling doesn't prevent you from manually modifying replicas across shards. These manual adjustments don't affect any existing CloudWatch alarms that are attached to the scaling policy but can impact metrics that may trigger these CloudWatch alarms.

These CloudWatch alarms managed by Auto Scaling are defined over the AVG metric across all the shards in the cluster. So, having hot shards can result in either scenario of:
- scaling when not required due to load on a few hot shards triggering a CloudWatch alarm
- not scaling when required due to aggregated AVG across all shards affecting alarm not to breach.

ElastiCache for Redis default limits on Nodes per cluster still applies. So, when opting for Auto Scaling and if you expect maximum nodes to be more than default limit, request a limit increase at AWS Service Limits and choose the limit type **Nodes per cluster per instance type**.

Ensure that you have enough ENIs (Elastic Network Interfaces) available in your VPC, which are required during scale-out. For more information, see Elastic network interfaces.

If there is not enough capacity available from EC2, ElastiCache for Redis Auto Scaling would not scale out until the capacity is available or if you manually modify the cluster to the instance types that have enough capacity.

ElastiCache for Redis Auto Scaling doesn't support scaling of replicas with a cluster having **ReservedMemoryPercent** less than 25 percent. For more information, see Managing Reserved Memory.

### Adding a scaling policy

You can add a scaling policy using the AWS Management Console.

**Adding a scaling policy using the AWS Management Console**

To add an auto scaling policy to an ElastiCache for Redis

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at [https://console.aws.amazon.com/elasticache/](https://console.aws.amazon.com/elasticache/).
2. In the navigation pane, choose **Redis**.
3. Choose the ElastiCache for Redis cluster that you want to add a policy for.
4. Select the **Manage Auto Scaling policies** from **Actions** dropdown.
5. Choose the **Auto Scaling policies** tab.
6. In the **Auto scaling policies** section, the **Add Scaling policy** dialog box appears. Choose **Dynamic scaling**.

---

API Version 2015-02-02

413
7. For **Policy Name**, enter the policy name.
8. For **Scalable Dimension**, select **Replicas** from dialog box.
9. For the target value, type the Avg percentage of CPU utilization that you want to maintain on Elasticache Replicas. This value must be >=35 and <=70. Cluster replicas are added or removed to keep the metric close to the specified value.
10. (Optional) scale-in or scale-out cooldown periods are not supported from the Console. Use the AWS CLI to modify the cool down values.
11. For **Minimum capacity**, type the minimum number of replicas that the ElastiCache for Redis Auto Scaling policy is required to maintain.
12. For **Maximum capacity**, type the maximum number of replicas the ElastiCache for Redis Auto Scaling policy is required to maintain. This value must be >=5.
13. Choose **Add policy**.

**Registering a Scalable Target**

You can apply a scaling policy based on either a predefined or custom metric. To do so, you can use the AWS CLI or the Application Auto Scaling API. The first step is to register your ElastiCache for Redis replication group with ElastiCache for Redis auto scaling.

Before you can use ElastiCache for Redis auto scaling with an ElastiCache for Redis cluster, you register your cluster with ElastiCache for Redis auto scaling. You do so to define the scaling dimension and limits to be applied to that cluster. ElastiCache for Redis auto scaling dynamically scales the ElastiCache for Redis cluster along the `elasticache:replication-group:Replicas` scalable dimension, which represents the number of cluster replicas per shard.

**Using the CLI**

To register your Elasticache cluster, use the `register-scalable-target` command with the following parameters:

- `--service-namespace` – Set this value to elasticache.
- `--resource-id` – The resource identifier for the Elasticache cluster. For this parameter, the resource type is ReplicationGroup and the unique identifier is the name of the ElastiCache for Redis cluster, for example `replication-group/myscalablecluster`.
- `--scalable-dimension` – Set this value to `elasticache:replication-group:Replicas`.
- `--min-capacity` – The minimum number of replicas to be managed by ElastiCache for Redis auto scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of replicas in your cluster, see Minimum and maximum capacity (p. 396).
- `--max-capacity` – The maximum number of replicas to be managed by ElastiCache for Redis auto scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of replicas in your cluster, see Minimum and maximum capacity (p. 396).

**Example**

In the following example, you register an ElastiCache for Redis cluster named `myscalablecluster`. The registration indicates that the cluster should be dynamically scaled to have from one to 5 replicas.

For Linux, macOS, or Unix:

```
aws application-autoscaling register-scalable-target \
  --service-namespace elasticache \
  --resource-id replication-group/myscalablecluster \
  --scalable-dimension elasticache:replication-group:Replicas
```
Using Auto Scaling with replicas

```
--min-capacity 1 \
--max-capacity 5 \
```

For Windows:

```
aws application-autoscaling register-scalable-target ^
  --service-namespace elasticache ^
  --resource-id replication-group/myscalablecluster ^
  --scalable-dimension elasticache:replication-group:Replicas ^
  --min-capacity 1 ^
  --max-capacity 5 ^
```

Using the API

To register your Elasticache cluster, use the `register-scalable-target` command with the following parameters:

- **ServiceNamespace** – Set this value to `elasticache`.
- **ResourceId** – The resource identifier for the Elasticache cluster. For this parameter, the resource type is `ReplicationGroup` and the unique identifier is the name of the ElastiCache for Redis cluster, for example `replication-group/myscalablecluster`.
- **ScalableDimension** – Set this value to `elasticache:replication-group:Replicas`.
- **MinCapacity** – The minimum number of replicas to be managed by ElastiCache for Redis auto scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of replicas in your cluster, see Minimum and maximum capacity (p. 396).
- **MaxCapacity** – The maximum number of replicas to be managed by ElastiCache for Redis auto scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of replicas in your cluster, see Minimum and maximum capacity (p. 396).

**Example**

In the following example, you register an ElastiCache for Redis cluster named `myscalablecluster` with the Application Auto Scaling API. This registration indicates that the cluster should be dynamically scaled to have from one to 5 replicas.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
  "ServiceNamespace": "elasticache",
  "ResourceId": "replication-group/myscalablecluster",
  "ScalableDimension": "elasticache:replication-group:Replicas",
  "MinCapacity": 1,
  "MaxCapacity": 5
}
```

**Defining a scaling policy**

A target-tracking scaling policy configuration is represented by a JSON block that the metrics and target values are defined in. You can save a scaling policy configuration as a JSON block in a text file. You use
that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

The following options are available for defining a target-tracking scaling policy configuration:

**Topics**
- Using a predefined metric (p. 416)
- Using a custom metric (p. 416)
- Using cooldown periods (p. 417)
- Disabling scale-in activity (p. 417)
- Applying a scaling policy to an ElastiCache for Redis cluster (p. 417)

**Using a predefined metric**

By using predefined metrics, you can quickly define a target-tracking scaling policy for an ElastiCache for Redis cluster that works with target tracking in ElastiCache for Redis Auto Scaling. Currently, ElastiCache for Redis supports the following predefined metric in Elasticache Replicas Auto Scaling:

ElastiCacheReplicaEngineCPUUtilization – The average value of the EngineCPUUtilization metric in CloudWatch across all replicas in the ElastiCache for Redis cluster. The average value of the EngineCPUUtilization metric in CloudWatch across all replicas in the ElastiCache for Redis cluster. You can find the aggregated metric value in CloudWatch under ElastiCache for Redis ReplicationGroupId, Role for required ReplicationGroupId and Role Replica.

To use a predefined metric in your scaling policy, you create a target tracking configuration for your scaling policy. This configuration must include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.

**Using a custom metric**

By using custom metrics, you can define a target-tracking scaling policy that meets your custom requirements. You can define a custom metric based on any ElastiCache for Redis metric that changes in proportion to scaling. Not all ElastiCache for Redis metrics work for target tracking. The metric must be a valid utilization metric and describe how busy an instance is. The value of the metric must increase or decrease in proportion to the number of replicas in the cluster. This proportional increase or decrease is necessary to use the metric data to proportionally increase or decrease the number of replicas.

**Example**

The following example describes a target-tracking configuration for a scaling policy. In this configuration, a custom metric adjusts an ElastiCache for Redis cluster based on an average CPU utilization of 50 percent across all replicas in a cluster named my-db-cluster.

```json
{"TargetValue": 50,
 "CustomizedMetricSpecification":
  {
  "MetricName": "EngineCPUUtilization",
  "Namespace": "AWS/ElastiCache",
  "Dimensions": [
   {"Name": "RelocationGroup","Value": "my-db-cluster"},
   {"Name": "Role","Value": "REPLICA"}
  ],
  "Statistic": "Average",
  "Unit": "Percent"
  }
}
```
Using cooldown periods

You can specify a value, in seconds, for ScaleOutCooldown to add a cooldown period for scaling out your cluster. Similarly, you can add a value, in seconds, for ScaleInCooldown to add a cooldown period for scaling in your cluster. For more information about ScaleInCooldown and ScaleOutCooldown, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference. The following example describes a target-tracking configuration for a scaling policy. In this configuration, the ElastiCacheReplicaEngineCPUUtilization predefined metric is used to adjust an ElastiCache for Redis cluster based on an average CPU utilization of 40 percent across all replicas in that cluster. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```json
{  "TargetValue": 40.0,  "PredefinedMetricSpecification":    {"PredefinedMetricType": "ElastiCacheReplicaEngineCPUUtilization" },  "ScaleInCooldown": 600,  "ScaleOutCooldown": 300}
```

Disabling scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your ElastiCache for Redis cluster by disabling scale-in activity. Disabling scale-in activity prevents the scaling policy from deleting replicas, while still allowing the scaling policy to add them as needed.

You can specify a Boolean value for DisableScaleIn to enable or disable scale in activity for your cluster. For more information about DisableScaleIn, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

**Example**

The following example describes a target-tracking configuration for a scaling policy. In this configuration, the ElastiCacheReplicaEngineCPUUtilization predefined metric adjusts an ElastiCache for Redis cluster based on an average CPU utilization of 40 percent across all replicas in that cluster. The configuration disables scale-in activity for the scaling policy.

```json
{  "TargetValue": 40.0,  "PredefinedMetricSpecification":    {"PredefinedMetricType": "ElastiCacheReplicaEngineCPUUtilization" },  "DisableScaleIn": true}
```

Applying a scaling policy to an ElastiCache for Redis cluster

After registering your cluster with ElastiCache for Redis auto scaling and defining a scaling policy, you apply the scaling policy to the registered cluster. To apply a scaling policy to an ElastiCache for Redis cluster, you can use the AWS CLI or the Application Auto Scaling API.

**Using the AWS CLI**

To apply a scaling policy to your ElastiCache for Redis cluster, use the `put-scaling-policy` command with the following parameters:

- `--policy-name` – The name of the scaling policy.
- `--policy-type` – Set this value to TargetTrackingScaling.
Using Auto Scaling with replicas

• --resource-id – The resource identifier for the ElastiCache for Redis cluster. For this parameter, the resource type is ReplicationGroup and the unique identifier is the name of the ElastiCache for Redis cluster, for example replication-group/myscalablecluster.
• --service-namespace – Set this value to elasticsearch.
• --scalable-dimension – Set this value to elasticache:replication-group:Replicas.
• --target-tracking-scaling-policy-configuration – The target-tracking scaling policy configuration to use for the ElastiCache for Redis cluster.

Example

In the following example, you apply a target-tracking scaling policy named myscalablepolicy to an ElastiCache for Redis cluster named myscalablecluster with ElastiCache for Redis auto scaling. To do so, you use a policy configuration saved in a file named config.json.

For Linux, macOS, or Unix:

```
aws application-autoscaling put-scaling-policy 
  --policy-name myscalablepolicy 
  --resource-id replication-group/myscalablecluster 
  --service-namespace elasticsearch 
  --scalable-dimension elasticache:replication-group:Replicas 
  --target-tracking-scaling-policy-configuration file://config.json
```

```json
{  "TargetValue": 40.0,  "PredefinedMetricSpecification":  {"PredefinedMetricType": "ElastiCacheReplicaEngineCPUUtilization" },  "DisableScaleIn": true}
```

For Windows:

```
aws application-autoscaling put-scaling-policy ^
  --policy-name myscalablepolicy ^
  --resource-id replication-group/myscalablecluster ^
  --service-namespace elasticsearch ^
  --scalable-dimension elasticache:replication-group:Replicas ^
  --target-tracking-scaling-policy-configuration file://config.json
```

Using the API

To apply a scaling policy to your ElastiCache for Redis cluster with the Application Auto Scaling API, use the PutScalingPolicy Application Auto Scaling API operation with the following parameters:

• PolicyName – The name of the scaling policy.
• PolicyType – Set this value to TargetTrackingScaling.
• ResourceID – The resource identifier for the ElastiCache for Redis cluster. For this parameter, the resource type is ReplicationGroup and the unique identifier is the name of the ElastiCache for Redis cluster, for example replication-group/myscalablecluster.
• ServiceNamespace – Set this value to elasticsearch.
• ScalableDimension – Set this value to elasticache:replication-group:Replicas.
• TargetTrackingScalingPolicyConfiguration – The target-tracking scaling policy configuration to use for the ElastiCache for Redis cluster.

Example

In the following example, you apply a target-tracking scaling policy named scalablepolicy to an ElastiCache for Redis cluster named myscalablecluster with ElastiCache for Redis auto scaling. You use a policy configuration based on the ElastiCacheReplicaEngineCPUUtilization predefined metric.

```json
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.PutScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "elasticache",
    "ResourceId": "replication-group/myscalablecluster",
    "ScalableDimension": "elasticache:replication-group:Replicas",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration": {
        "TargetValue": 40.0,
        "PredefinedMetricSpecification": {
            "PredefinedMetricType": "ElastiCacheReplicaEngineCPUUtilization"
        }
    }
}
```

Editing a scaling policy

You can edit a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Editing a scaling policy using the AWS Management Console

You can only edit policies with type Predefined metrics by using the AWS Management Console.

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. In the navigation pane, choose Redis.
3. Choose the cluster whose auto scaling policy you want to edit.
4. Choose the Auto Scaling policies tab.
5. In the Auto scaling policies section, choose the auto scaling policy, and then choose Edit from the Actions dialog box.
6. Make changes to the policy.
7. Choose Update policy.

Editing a scaling policy using the AWS CLI or the Application Auto Scaling API
You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- When using the Application Auto Scaling API, specify the name of the policy you want to edit in the `PolicyName` parameter. Specify new values for the parameters you want to change.

For more information, see Applying a scaling policy to an ElastiCache for Redis cluster (p. 417).

**Deleting a scaling policy**

You can delete a scaling policy using the AWS Management Console, the AWS CLI or the Application Auto Scaling API.

**Deleting a scaling policy using the AWS Management Console**

You can only edit policies with type Predefined metrics by using the AWS Management Console.

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. In the navigation pane, choose Redis.
3. Choose the cluster whose auto scaling policy you want to delete.
4. Choose the **Auto Scaling policies** tab.
5. In the **Auto scaling policies** section, choose the auto scaling policy, and then choose **Delete** from the **Actions** dialog box.

**Deleting a scaling policy using the AWS CLI or the Application Auto Scaling API**

You can use the AWS CLI or the Application Auto Scaling API to delete a scaling policy from an Elasticache cluster.

**CLI**

To delete a scaling policy from your ElastiCache for Redis cluster, use the `delete-scaling-policy` command with the following parameters:

- `--policy-name` – The name of the scaling policy.
- `--resource-id` – The resource identifier for the ElastiCache for Redis cluster. For this parameter, the resource type is ReplicationGroup and the unique identifier is the name of the Elasticache cluster, for example `replication-group/myscalablecluster`.
- `--service-namespace` – Set this value to `elasticache`.
- `--scalable-dimension` – Set this value to `elasticache:replication-group:Replicas`.

**Example**

In the following example, you delete a target-tracking scaling policy named `myscalablepolicy` from an ELC; cluster named `myscalablecluster`.

For Linux, macOS, or Unix:

```
aws application-autoscaling delete-scaling-policy \
  --policy-name myscalablepolicy \
  --resource-id replication-group/myscalablecluster \
  --service-namespace elasticache \
  --scalable-dimension elasticache:replication-group:Replicas
```
For Windows:

```
aws application-autoscaling delete-scaling-policy ^
   --policy-name myscalablepolicy ^
   --resource-id replication-group/myscalablecluster ^
   --service-namespace elasticache ^
   --scalable-dimension elasticache:replication-group:Replicas ^
```

API

To delete a scaling policy from your ElastiCache for Redis cluster, use the `DeleteScalingPolicy` Application Auto Scaling API operation with the following parameters:

- **PolicyName** – The name of the scaling policy.
- **ResourceId** – The resource identifier for the ElastiCache for Redis cluster. For this parameter, the resource type is ReplicationGroup and the unique identifier is the name of the Elasticache cluster, for example `replication-group/myscalablecluster`.
- **ServiceNamespace** – Set this value to elasticache.
- **ScalableDimension** – Set this value to `elasticache:replication-group:Replicas`.

In the following example, you delete a target-tracking scaling policy named `myscalablepolicy` from an ElastiCache for Redis cluster named `myscalablecluster` with the Application Auto Scaling API.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
   "PolicyName": "myscalablepolicy",
   "ServiceNamespace": "elasticache",
   "ResourceId": "replication-group/myscalablecluster",
   "ScalableDimension": "elasticache:replication-group:Replicas"
}
```

Use AWS CloudFormation for Auto Scaling policies

This snippet shows how to create a scheduled action and apply it to an `AWS::ElastiCache::ReplicationGroup` resource using the `AWS::ApplicationAutoScaling::ScalableTarget` resource. It uses the `Fn::Join` and `Ref` intrinsic functions to construct the `ResourceId` property with the logical name of the `AWS::ElastiCache::ReplicationGroup` resource that is specified in the same template.

```
ScalingTarget:
  Type: 'AWS::ApplicationAutoScaling::ScalableTarget'
  Properties:
    MaxCapacity: 0
    MinCapacity: 0
    ResourceId: !Sub replication-group/${logicalName}
    ScalableDimension: 'elasticache:replication-group:Replicas'
    ServiceNamespace: elasticache
```

API Version 2015-02-02

421
Scheduled scaling

Scaling based on a schedule enables you to scale your application in response to predictable changes in demand. To use scheduled scaling, you create scheduled actions, which tell ElastiCache for Redis to perform scaling activities at specific times. When you create a scheduled action, you specify an existing ElastiCache for Redis cluster, when the scaling activity should occur, minimum capacity, and maximum capacity. You can create scheduled actions that scale one time only or that scale on a recurring schedule.

You can only create a scheduled action for ElastiCache for Redis clusters that already exist. You can't create a scheduled action at the same time that you create a cluster.

For more information on terminology for scheduled action creation, management, and deletion, see Commonly used commands for scheduled action creation, management, and deletion

To create a one-time scheduled action:

Similar to Shard dimension. See Scheduled scaling (p. 410).

To delete a scheduled action

Similar to Shard dimension. See Scheduled scaling (p. 410).

To manage scheduled scaling using the AWS CLI

Use the following application-autoscaling APIs:

- put-scheduled-action
- describe-scheduled-actions
- delete-scheduled-action

Use AWS CloudFormation to create Auto Scaling policies

This snippet shows how to create a scheduled action and apply it to an AWS::ElastiCache::ReplicationGroup resource using the AWS::ApplicationAutoScaling::ScalableTarget resource. It uses the Fn::Join and Ref intrinsic functions to construct the ResourceId property with the logical name of the AWS::ElastiCache::ReplicationGroup resource that is specified in the same template.

```
ScalingTarget:
  Type: 'AWS::ApplicationAutoScaling::ScalableTarget'
```

RoleARN: !Sub "arn:aws:iam::${AWS::AccountId}:role/aws-service-role/elasticache.application-autoscaling.amazonaws.com/AWSServiceRoleForApplicationAutoScaling_ElastiCacheRG"

ScalingPolicy:
  Type: "AWS::ApplicationAutoScaling::ScalingPolicy"
  Properties:
    ScalingTargetId: !Ref ScalingTarget
    ServiceNamespace: elasticache
    PolicyName: testpolicy
    PolicyType: TargetTrackingScaling
    ScalableDimension: 'elasticache:replication-group:Replicas'
    TargetTrackingScalingPolicyConfiguration:
      PredefinedMetricSpecification:
        PredefinedMetricType: ElastiCacheReplicaEngineCPUUtilization
        TargetValue: 20
Configuring engine parameters using parameter groups

Amazon ElastiCache uses parameters to control the runtime properties of your nodes and clusters. Generally, newer engine versions include additional parameters to support the newer functionality. For tables of parameters, see Redis-specific parameters (p. 441).

As you would expect, some parameter values, such as \texttt{maxmemory}, are determined by the engine and node type. For a table of these parameter values by node type, see Redis node-type specific parameters (p. 465).

Topics

- Parameter management (p. 424)
- Cache parameter group tiers (p. 425)
- Creating a parameter group (p. 425)
- Listing parameter groups by name (p. 429)
- Listing a parameter group's values (p. 434)
- Modifying a parameter group (p. 435)
- Deleting a parameter group (p. 439)
- Redis-specific parameters (p. 441)
Parameter management

Parameters are grouped together into named parameter groups for easier parameter management. A parameter group represents a combination of specific values for the parameters that are passed to the engine software during startup. These values determine how the engine processes on each node behave at runtime. The parameter values on a specific parameter group apply to all nodes that are associated with the group, regardless of which cluster they belong to.

To fine-tune your cluster's performance, you can modify some parameter values or change the cluster's parameter group.

- You cannot modify or delete the default parameter groups. If you need custom parameter values, you must create a custom parameter group.
- The parameter group family and the cluster you're assigning it to must be compatible. For example, if your cluster is running Redis version 3.2.10, you can only use parameter groups, default or custom, from the Redis3.2 family.
- If you change a cluster's parameter group, the values for any conditionally modifiable parameter must be the same in both the current and new parameter groups.
- When you change a cluster's parameters, the change is applied to the cluster either immediately or, with the exceptions noted following, after the cluster nodes are rebooted. This is true whether you change the cluster's parameter group itself or a parameter value within the cluster's parameter group. To determine when a particular parameter change is applied, see the Changes Take Effect column in the tables for Redis-specific parameters (p. 441).

If you have a Redis (cluster mode disabled) cluster and make changes to the following parameters, you must reboot the nodes in the cluster:
- activerehashing
- databases

For more information, see Rebooting nodes.

**Redis (Cluster Mode Enabled) parameter changes**

If you make changes to the following parameters on a Redis (cluster mode enabled) cluster, follow the ensuing steps.
- activerehashing
- databases

2. Delete the Redis (cluster mode enabled) cluster. See Deleting a cluster (p. 165).
3. Restore the cluster using the altered parameter group and backup to seed the new cluster. See Restoring from a backup with optional cluster resizing (p. 334).

Changes to other parameters do not require this.

- You can associate parameter groups with Redis global datastores. Global datastores are a collection of one or more clusters that span AWS Regions. In this case, the parameter group is shared by all clusters that make up the global datastore. Any modifications to the parameter group of the primary cluster are replicated to all remaining clusters in the global datastore. For more information, see Replication across AWS Regions using global datastores (p. 231).

You can check if a parameter group is part of a global datastore by looking in these locations:
- On the ElastiCache console on the Parameter Groups page, the yes/no Global attribute
- The yes/no IsGlobal property of the CacheParameterGroup API operation
Cache parameter group tiers

Amazon ElastiCache has three tiers of cache parameter groups as shown following.

Global Default

The top-level root parameter group for all Amazon ElastiCache customers in the region.

The global default cache parameter group:

- Is reserved for ElastiCache and not available to the customer.

Customer Default

A copy of the Global Default cache parameter group which is created for the customer's use.

The Customer Default cache parameter group:

- Is created and owned by ElastiCache.
- Is available to the customer for use as a cache parameter group for any clusters running an engine version supported by this cache parameter group.
- Cannot be edited by the customer.

Customer Owned

A copy of the Customer Default cache parameter group. A Customer Owned cache parameter group is created whenever the customer creates a cache parameter group.

The Customer Owned cache parameter group:

- Is created and owned by the customer.
- Can be assigned to any of the customer's compatible clusters.
- Can be modified by the customer to create a custom cache parameter group.

Not all parameter values can be modified. For more information, see Redis-specific parameters (p. 441).

Creating a parameter group

You need to create a new parameter group if there is one or more parameter values that you want changed from the default values. You can create a parameter group using the ElastiCache console, the AWS CLI, or the ElastiCache API.
Creating a parameter group (Console)

The following procedure shows how to create a parameter group using the ElastiCache console.

To create a parameter group using the ElastiCache console

2. To see a list of all available parameter groups, in the left hand navigation pane choose Parameter Groups.
3. To create a parameter group, choose Create Parameter Group.
   
   The Create Parameter Group screen appears.
4. From the Family list, choose the parameter group family that will be the template for your parameter group.
   
   The parameter group family, such as redis3.2, defines the actual parameters in your parameter group and their initial values. The parameter group family must coincide with the cluster's engine and version.
5. In the Name box, type in a unique name for this parameter group.
   
   When creating a cluster or modifying a cluster's parameter group, you will choose the parameter group by its name. Therefore, we recommend that the name be informative and somehow identify the parameter group's family.
   
   Parameter group naming constraints are as follows:
   
   • Must begin with an ASCII letter.
   • Can only contain ASCII letters, digits, and hyphens.
   • Must be 1–255 characters long.
   • Can't contain two consecutive hyphens.
   • Can't end with a hyphen.
6. In the Description box, type in a description for the parameter group.
7. To create the parameter group, choose Create.
   
   To terminate the process without creating the parameter group, choose Cancel.
8. When the parameter group is created, it will have the family's default values. To change the default values you must modify the parameter group. For more information, see Modifying a parameter group (p. 435).

Creating a parameter group (AWS CLI)

To create a parameter group using the AWS CLI, use the command create-cache-parameter-group with these parameters.

• --cache-parameter-group-name — The name of the parameter group.

Parameter group naming constraints are as follows:
• Must begin with an ASCII letter.
• Can only contain ASCII letters, digits, and hyphens.
• Must be 1–255 characters long.
• Can't contain two consecutive hyphens.
• Can't end with a hyphen.
Creating a parameter group

• **--cache-parameter-group-family** — The engine and version family for the parameter group.
• **--description** — A user supplied description for the parameter group.

**Example**

The following example creates a parameter group named *myRed28* using the *redis2.8* family as the template.

For Linux, macOS, or Unix:

```
aws elasticache create-cache-parameter-group \
  --cache-parameter-group-name myRed28 \
  --cache-parameter-group-family redis2.8 \
  --description "My first parameter group"
```

For Windows:

```
aws elasticache create-cache-parameter-group ^
  --cache-parameter-group-name myRed28 ^
  --cache-parameter-group-family redis2.8 ^
  --description "My first parameter group"
```

The output from this command should look something like this.

```
{
  "CacheParameterGroup": {
    "CacheParameterGroupName": "myRed28",
    "CacheParameterGroupFamily": "redis2.8",
    "Description": "My first parameter group"
  }
}
```

When the parameter group is created, it will have the family's default values. To change the default values you must modify the parameter group. For more information, see [Modifying a parameter group](p. 435).

For more information, see [create-cache-parameter-group](annex).

**Creating a parameter group (ElastiCache API)**

To create a parameter group using the ElastiCache API, use the `CreateCacheParameterGroup` action with these parameters.

• **ParameterGroupName** — The name of the parameter group.

  Parameter group naming constraints are as follows:
  • Must begin with an ASCII letter.
  • Can only contain ASCII letters, digits, and hyphens.
  • Must be 1–255 characters long.
  • Can't contain two consecutive hyphens.
  • Can't end with a hyphen.

• **CacheParameterGroupFamily** — The engine and version family for the parameter group. For example, *redis2.8*.
• **Description** — A user supplied description for the parameter group.
Example

The following example creates a parameter group named *myRed28* using the redis2.8 family as the template.

https://elasticache.us-west-2.amazonaws.com/
?Action=CreateCacheParameterGroup
&CacheParameterGroupFamily=redis2.8
&CacheParameterGroupName=myRed28
&Description=My first parameter group
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&Version=2015-02-02
&X-Amz-Credential=<credential>

The response from this action should look something like this.

```xml
  <CreateCacheParameterGroupResult>
    <CacheParameterGroup>
      <CacheParameterGroupName>myRed28</CacheParameterGroupName>
      <CacheParameterGroupFamily>redis2.8</CacheParameterGroupFamily>
      <Description>My first parameter group</Description>
    </CacheParameterGroup>
  </CreateCacheParameterGroupResult>
  <ResponseMetadata>
    <RequestId>d8465952-af48-11e0-8d36-859edca6f4b8</RequestId>
  </ResponseMetadata>
</CreateCacheParameterGroupResponse>
```

When the parameter group is created, it will have the family's default values. To change the default values you must modify the parameter group. For more information, see *Modifying a parameter group* (p. 435).

For more information, see `CreateCacheParameterGroup`.
Listing parameter groups by name

You can list the parameter groups using the ElastiCache console, the AWS CLI, or the ElastiCache API.

Listing parameter groups by name (Console)

The following procedure shows how to view a list of the parameter groups using the ElastiCache console.

To list parameter groups using the ElastiCache console

2. To see a list of all available parameter groups, in the left hand navigation pane choose Parameter Groups.

Listing parameter groups by name (AWS CLI)

To generate a list of parameter groups using the AWS CLI, use the command describe-cache-parameter-groups. If you provide a parameter group's name, only that parameter group will be listed. If you do not provide a parameter group's name, up to --max-records parameter groups will be listed. In either case, the parameter group's name, family, and description are listed.

Example

The following sample code lists the parameter group myRed28.

For Linux, macOS, or Unix:

```bash
aws elasticache describe-cache-parameter-groups \
  --cache-parameter-group-name myRed28
```

For Windows:

```bash
aws elasticache describe-cache-parameter-groups ^
  --cache-parameter-group-name myRed28
```

The output of this command will look something like this, listing the name, family, and description for the parameter group.

```
{
  "CacheParameterGroups": [
    {
      "CacheParameterGroupName": "myRed28",
      "CacheParameterGroupFamily": "redis2.8",
      "Description": "My first parameter group"
    }
  ]
}
```

Example

The following sample code lists the parameter group myRed56 for parameter groups running on Redis engine version 5.0.6 onwards. If the parameter group is part of a Replication across AWS Regions using global datastores (p. 231), the IsGlobal property value returned in the output will be Yes.

For Linux, macOS, or Unix:
aws elasticache describe-cache-parameter-groups \
 --cache-parameter-group-name myRed56

For Windows:

aws elasticache describe-cache-parameter-groups ^
 --cache-parameter-group-name myRed56

The output of this command will look something like this, listing the name, family, isGlobal and description for the parameter group.

```
{
    "CacheParameterGroups": [
    {
        "CacheParameterGroupName": "myRed56",
        "CacheParameterGroupFamily": "redis5.0",
        "Description": "My first parameter group",
        "IsGlobal": "yes"
    }
    ]
}
```

**Example**

The following sample code lists up to 10 parameter groups.

```
aws elasticache describe-cache-parameter-groups --max-records 10
```

The JSON output of this command will look something like this, listing the name, family, description and, in the case of redis5.6 whether the parameter group is part of a global datastore (isGlobal), for each parameter group.

```
{
    "CacheParameterGroups": [
    {
        "CacheParameterGroupName": "custom-redis32",
        "CacheParameterGroupFamily": "redis3.2",
        "Description": "custom parameter group with reserved-memory > 0"
    },
    {
        "CacheParameterGroupName": "default.memcached1.4",
        "CacheParameterGroupFamily": "memcached1.4",
        "Description": "Default parameter group for memcached1.4"
    },
    {
        "CacheParameterGroupName": "default.redis2.6",
        "CacheParameterGroupFamily": "redis2.6",
        "Description": "Default parameter group for redis2.6"
    },
    {
        "CacheParameterGroupName": "default.redis2.8",
        "CacheParameterGroupFamily": "redis2.8",
        "Description": "Default parameter group for redis2.8"
    },
    {
        "CacheParameterGroupName": "default.redis3.2",
        "CacheParameterGroupFamily": "redis3.2",
        "Description": "Default parameter group for redis3.2"
    }
    ]
}
```
Listing parameter groups by name (ElastiCache API)

To generate a list of parameter groups using the ElastiCache API, use the DescribeCacheParameterGroups action. If you provide a parameter group's name, only that parameter group will be listed. If you do not provide a parameter group's name, up to MaxRecords parameter groups will be listed. In either case, the parameter group's name, family, and description are listed.

Example

The following sample code lists up to 10 parameter groups.

```xml
&MaxRecords=10
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&Version=2015-02-02
&X-Amz-Credential=<credential>
```

The response from this action will look something like this, listing the name, family, description and, in the case of redis5.6 if the parameter group belongs to a global datastore (isGlobal), for each parameter group.

```xml
<DescribeCacheParameterGroupsResult>
<CacheParameterGroups>
<CacheParameterGroup>
<CacheParameterGroupName>myRedis28</CacheParameterGroupName>
<CacheParameterGroupFamily>redis2.8</CacheParameterGroupFamily>
<Description>My custom Redis 2.8 parameter group</Description>
</CacheParameterGroup>
<CacheParameterGroup>
<CacheParameterGroupName>myMem14</CacheParameterGroupName>
<CacheParameterGroupFamily>memcached1.4</CacheParameterGroupFamily>
<Description>My custom Memcached 1.4 parameter group</Description>
</CacheParameterGroup>
<CacheParameterGroup>
<CacheParameterGroupName>myRedis56</CacheParameterGroupName>
<CacheParameterGroupFamily>redis5.0</CacheParameterGroupFamily>
<Description>My custom redis 5.6 parameter group</Description>
</CacheParameterGroup>
</CacheParameterGroups>
</DescribeCacheParameterGroupsResult>
</DescribeCacheParameterGroupsResponse>
```
Example

The following sample code lists the parameter group **myRed28**.

```plaintext
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeCacheParameterGroups
&CacheParameterGroupName=myRed28
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&Version=2015-02-02
&X-Amz-Credential=<credential>
```

The response from this action will look something like this, listing the name, family, description and whether the parameter group is part of a global datastore (isGlobal).

```xml
  <DescribeCacheParameterGroupsResult>
    <CacheParameterGroups>
      <CacheParameterGroup>
        <CacheParameterGroupName>myRed28</CacheParameterGroupName>
        <CacheParameterGroupFamily>redis2.8</CacheParameterGroupFamily>
        <Description>My custom Redis 2.8 parameter group</Description>
        <isGlobal>yes</isGlobal>
      </CacheParameterGroup>
    </CacheParameterGroups>
  </DescribeCacheParameterGroupsResult>
  <ResponseMetadata>
    <RequestId>3540cc3d-af48-11e0-97f9-279771c4477e</RequestId>
  </ResponseMetadata>
</DescribeCacheParameterGroupsResponse>
```

Example

The following sample code lists the parameter group **myRed56**.

```plaintext
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeCacheParameterGroups
&CacheParameterGroupName=myRed56
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&Version=2015-02-02
&X-Amz-Credential=<credential>
```

The response from this action will look something like this, listing the name, family, description and whether the parameter group is part of a global datastore (isGlobal).

```xml
  <DescribeCacheParameterGroupsResult>
    <CacheParameterGroups>
      <CacheParameterGroup>
        <CacheParameterGroupName>myRed56</CacheParameterGroupName>
        <CacheParameterGroupFamily>redis2.8</CacheParameterGroupFamily>
        <Description>My custom Redis 2.8 parameter group</Description>
        <isGlobal>yes</isGlobal>
      </CacheParameterGroup>
    </CacheParameterGroups>
  </DescribeCacheParameterGroupsResult>
  <ResponseMetadata>
    <RequestId>3540cc3d-af48-11e0-97f9-279771c4477e</RequestId>
  </ResponseMetadata>
</DescribeCacheParameterGroupsResponse>
```
Listing parameter groups by name

For more information, see DescribeCacheParameterGroups.
Listing a parameter group's values

You can list the parameters and their values for a parameter group using the ElastiCache console, the AWS CLI, or the ElastiCache API.

Listing a parameter group's values (Console)

The following procedure shows how to list the parameters and their values for a parameter group using the ElastiCache console.

To list a parameter group's parameters and their values using the ElastiCache console

2. To see a list of all available parameter groups, in the left hand navigation pane choose Parameter Groups.
3. Choose the parameter group for which you want to list the parameters and values by choosing the box to the left of the parameter group's name.

   The parameters and their values will be listed at the bottom of the screen. Due to the number of parameters, you may have to scroll up and down to find the parameter you're interested in.

Listing a parameter group's values (AWS CLI)

To list a parameter group's parameters and their values using the AWS CLI, use the command describe-cache-parameters.

Example

The following sample code list all the parameters and their values for the parameter group myRedis28.

For Linux, macOS, or Unix:

```
aws elasticache describe-cache-parameters \
  --cache-parameter-group-name myRedis28
```

For Windows:

```
aws elasticache describe-cache-parameters ^
  --cache-parameter-group-name myRed28
```

For more information, see describe-cache-parameters.

Listing a parameter group's values (ElastiCache API)

To list a parameter group's parameters and their values using the ElastiCache API, use the DescribeCacheParameters action.

Example

The following sample code list all the parameters for the parameter group myRed28.

```
```
Modifying a parameter group

Important
You cannot modify any default parameter group.

You can modify some parameter values in a parameter group. These parameter values are applied to clusters associated with the parameter group. For more information on when a parameter value change is applied to a parameter group, see Redis-specific parameters (p. 441).

Modifying a parameter group (Console)

The following procedure shows how to change the cluster-enabled parameter's value using the ElastiCache console. You would use the same procedure to change the value of any parameter.
Modifying a parameter group

To change a parameter's value using the ElastiCache console

2. To see a list of all available parameter groups, in the left hand navigation pane choose Parameter Groups.  
3. Choose the parameter group you want to modify by choosing the box to the left of the parameter group's name.  
   The parameter group's parameters will be listed at the bottom of the screen. You may need to page through the list to see all the parameters.  
4. To modify one or more parameters, choose Edit Parameters.  
5. Choose Save Changes.  
6. To find the name of the parameter you changed, see Redis-specific parameters (p. 441). If you have a Redis (cluster mode disabled) cluster and make changes to the following parameters, you must reboot the nodes in the cluster:  
   * activerehashing  
   * databases  
   For more information, see Rebooting nodes.  

Redis (Cluster Mode Enabled) parameter changes  
If you make changes to the following parameters on a Redis (cluster mode enabled) cluster, follow the ensuing steps.  
   * activerehashing  
   * databases  
   2. Delete the Redis (cluster mode enabled) cluster. See Deleting a cluster (p. 165).  
   3. Restore the cluster using the altered parameter group and backup to seed the new cluster. See Restoring from a backup with optional cluster resizing (p. 334).  
   Changes to other parameters do not require this.

Modifying a parameter group (AWS CLI)

To change a parameter's value using the AWS CLI, use the command modify-cache-parameter-group.

Example

To find the name and permitted values of the parameter you want to change, see Redis-specific parameters (p. 441)

The following sample code sets the value of two parameters, reserved-memory-percent and cluster-enabled on the parameter group myredis32-on-30. We set reserved-memory-percent to 30 (30 percent) and cluster-enabled to yes so that the parameter group can be used with Redis (cluster mode enabled) clusters (replication groups).

For Linux, macOS, or Unix:
aws elasticache modify-cache-parameter-group \
   --cache-parameter-group-name myredis32-on-30 \
   --parameter-name-values \
       ParameterName=reserved-memory-percent,ParameterValue=30 \
       ParameterName=cluster-enabled,ParameterValue=yes

For Windows:

aws elasticache modify-cache-parameter-group ^
   --cache-parameter-group-name myredis32-on-30 ^
   --parameter-name-values ^
       ParameterName=reserved-memory-percent,ParameterValue=30 ^
       ParameterName=cluster-enabled,ParameterValue=yes

Output from this command will look something like this.

```
{
   "CacheParameterGroupName": "my-redis32-on-30"
}
```

For more information, see `modify-cache-parameter-group`.

To find the name of the parameter you changed, see `Redis-specific parameters (p. 441)`.

If you have a Redis (cluster mode disabled) cluster and make changes to the following parameters, you must reboot the nodes in the cluster:

- activerehashing
- databases

For more information, see `Rebooting nodes`.

**Redis (Cluster Mode Enabled) parameter changes**

If you make changes to the following parameters on a Redis (cluster mode enabled) cluster, follow the ensuing steps.

- activerehashing
- databases

1. Create a manual backup of your cluster. See `Making manual backups (p. 315)`.
2. Delete the Redis (cluster mode enabled) cluster. See `Deleting a cluster (p. 165)`.
3. Restore the cluster using the altered parameter group and backup to seed the new cluster. See `Restoring from a backup with optional cluster resizing (p. 334)`.

Changes to other parameters do not require this.

### Modifying a parameter group (ElastiCache API)

To change a parameter group's parameter values using the ElastiCache API, use the `ModifyCacheParameterGroup` action.

**Example**

To find the name and permitted values of the parameter you want to change, see `Redis-specific parameters (p. 441)`.
The following sample code sets the value of two parameters, `reserved-memory-percent` and `cluster-enabled` on the parameter group `myredis32-on-30`. We set `reserved-memory-percent` to 30 (30 percent) and `cluster-enabled` to `yes` so that the parameter group can be used with Redis (cluster mode enabled) clusters (replication groups).

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=ModifyCacheParameterGroup
  &CacheParameterGroupName=myredis32-on-30
  &ParameterNameValues.member.1.ParameterName=reserved-memory-percent
  &ParameterNameValues.member.1.ParameterValue=30
  &ParameterNameValues.member.2.ParameterName=cluster-enabled
  &ParameterNameValues.member.2.ParameterValue=yes
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20150202T192317Z
  &Version=2015-02-02
  &X-Amz-Credential=<credential>
```

For more information, see [ModifyCacheParameterGroup](#).

If you have a Redis (cluster mode disabled) cluster and make changes to the following parameters, you must reboot the nodes in the cluster:

- `activerehashing`
- `databases`

For more information, see [Rebooting nodes](#).

**Redis (Cluster Mode Enabled) parameter changes**

If you make changes to the following parameters on a Redis (cluster mode enabled) cluster, follow the ensuing steps.

- `activerehashing`
- `databases`

1. Create a manual backup of your cluster. See [Making manual backups](#).
2. Delete the Redis (cluster mode enabled) cluster. See [Deleting a cluster](#).
3. Restore the cluster using the altered parameter group and backup to seed the new cluster. See [Restoring from a backup with optional cluster resizing](#).

Changes to other parameters do not require this.
Deleting a parameter group

You can delete a custom parameter group using the ElastiCache console, the AWS CLI, or the ElastiCache API.

You cannot delete a parameter group if it is associated with any clusters. Nor can you delete any of the default parameter groups.

Deleting a parameter group (Console)

The following procedure shows how to delete a parameter group using the ElastiCache console.

To delete a parameter group using the ElastiCache console

2. To see a list of all available parameter groups, in the left hand navigation pane choose Parameter Groups.
3. Choose the parameter groups you want to delete by choosing the box to the left of the parameter group's name.

   The Delete button will become active.
4. Choose Delete.

   The Delete Parameter Groups confirmation screen will appear.
5. To delete the parameter groups, on the Delete Parameter Groups confirmation screen, choose Delete.

   To keep the parameter groups, choose Cancel.

Deleting a parameter group (AWS CLI)

To delete a parameter group using the AWS CLI, use the command delete-cache-parameter-group. For the parameter group to delete, the parameter group specified by --cache-parameter-group-name cannot have any clusters associated with it, nor can it be a default parameter group.

The following sample code deletes the myMem14 parameter group.

Example

For Linux, macOS, or Unix:

```
aws elasticache delete-cache-parameter-group \
    --cache-parameter-group-name myRed28
```

For Windows:

```
aws elasticache delete-cache-parameter-group ^
    --cache-parameter-group-name myRed28
```

For more information, see delete-cache-parameter-group.
Deleting a parameter group (ElastiCache API)

To delete a parameter group using the ElastiCache API, use the `DeleteCacheParameterGroup` action. For the parameter group to delete, the parameter group specified by `CacheParameterGroupName` cannot have any clusters associated with it, nor can it be a default parameter group.

**Example**

The following sample code deletes the `myRed28` parameter group.

```bash
https://elasticache.us-west-2.amazonaws.com/
?Action=DeleteCacheParameterGroup
&CacheParameterGroupName=myRed28
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
&Version=2015-02-02
&X-Amz-Credential=<credential>

For more information, see `DeleteCacheParameterGroup`.```
Redis-specific parameters

If you do not specify a parameter group for your Redis cluster, then a default parameter group appropriate to your engine version will be used. You can't change the values of any parameters in the default parameter group. However, you can create a custom parameter group and assign it to your cluster at any time as long as the values of conditionally modifiable parameters are the same in both parameter groups. For more information, see Creating a parameter group (p. 425).

- Redis 2.8.24 (enhanced) added parameters (p. 455)
- Redis 2.8.23 (enhanced) added parameters (p. 455)
- Redis 2.8.22 (enhanced) added parameters (p. 456)
- Redis 2.8.21 added parameters (p. 457)
- Redis 2.8.19 added parameters (p. 457)
- Redis 2.8.6 added parameters (p. 457)
- Redis 2.6.13 parameters (p. 459)
- Redis node-type specific parameters (p. 465)

Note

Because the newer Redis versions provide a better and more stable user experience, Redis versions 5.0.0, 5.0.3, 5.0.4 and 5.0.5 as well as 2.6.13, 2.8.6, and 2.8.19 are deprecated when using the ElastiCache console. We recommend against using these Redis versions. If you need to use one of them, work with the AWS CLI or ElastiCache API. For more information, see the following topics:

<table>
<thead>
<tr>
<th></th>
<th>AWS CLI</th>
<th>ElastiCache API</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Cluster</td>
<td>Creating a cluster (AWS CLI) (p. 137)</td>
<td>Creating a cluster (ElastiCache API) (p. 137)</td>
</tr>
<tr>
<td></td>
<td>You can't use this action to create a replication group with cluster mode enabled.</td>
<td>You can't use this action to create a replication group with cluster mode enabled.</td>
</tr>
<tr>

<td>You can't use this action to create a replication group with cluster mode enabled.</td>
</tr>
<tr>
<td>Create Replication Group</td>
<td>Creating a Redis (Cluster Mode Disabled) replication group from scratch (AWS CLI) (p. 273)</td>
<td>Creating a Redis (cluster mode disabled) replication group from scratch (ElastiCache API) (p. 276)</td>
</tr>
</tbody>
</table>
Redis 6.x parameter changes

Parameter group family: redis6.x

Redis 6.x default parameter groups are as follows:

- default.redis6.x – Use this parameter group, or one derived from it, for Redis (cluster mode disabled) clusters and replication groups.
- default.redis6.x.cluster.on – Use this parameter group, or one derived from it, for Redis (cluster mode enabled) clusters and replication groups.

Note
In Redis engine version 6.2, when the r6gd node family was introduced for use with Data tiering (p. 121), only noeviction, volatile-lru and allkeys-lru max-memory policies are supported with r6gd node types.

For more information, see ElastiCache for Redis version 6.2 (enhanced) (p. 190) and ElastiCache for Redis version 6.0 (enhanced) (p. 190).

Parameters added in Redis 6.x are as follows.

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl-pubsub-default (added in 6.2)</td>
<td>Permitted values: resetchannels, allchannels</td>
<td>Default pubsub channel permissions for ACL users deployed to this cluster.</td>
</tr>
<tr>
<td></td>
<td>Default: allchannels</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Type: string</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Modifiable: Yes</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Changes take effect: The existing Redis users associated to the cluster will continue to have existing permissions. Either update the users or reboot the cluster to update the existing Redis users.</td>
<td></td>
</tr>
<tr>
<td>cluster-allow-reads-when-down (added in 6.0)</td>
<td>Default: no</td>
<td>When set to yes, a Redis (cluster mode enabled) replication group continues to process read commands even when a node is not able to reach a quorum of primaries.</td>
</tr>
<tr>
<td></td>
<td>Type: string</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Modifiable: Yes</td>
<td></td>
</tr>
<tr>
<td></td>
<td>When set to the default of no, the replication group rejects all commands. We recommend</td>
<td></td>
</tr>
</tbody>
</table>
### Redis-specific parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tracking-table-max-keys (added in 6.0)</td>
<td>Default: 1,000,000, Type: number, Modifiable: Yes. Changes take effect: Immediately across all nodes in the cluster</td>
<td>To assist client-side caching, Redis supports tracking which clients have accessed which keys. When the tracked key is modified, invalidation messages are sent to all clients to notify them their cached values are no longer valid. This value enables you to specify the upper bound of this table. After this parameter value is exceeded, clients are sent invalidation randomly. This value should be tuned to limit memory usage while still keeping track of enough keys. Keys are also invalidated under low memory conditions.</td>
</tr>
<tr>
<td>acllog-max-len (added in 6.0)</td>
<td>Default: 128, Type: number, Modifiable: Yes. Changes take effect: Immediately across all nodes in the cluster</td>
<td>This value corresponds to the max number of entries in the ACL log.</td>
</tr>
<tr>
<td>active-expire-effort (added in 6.0)</td>
<td>Default: 1, Type: number, Modifiable: Yes. Changes take effect: Immediately across all nodes in the cluster</td>
<td>Redis deletes keys that have exceeded their time to live by two mechanisms. In one, a key is accessed and is found to be expired. In the other, a periodic job samples keys and causes those that have exceeded their time to live to expire. This parameter defines the amount of effort that Redis uses to expire items in the periodic job. The default value of 1 tries to avoid having more than 10 percent of expired keys still in memory. It also tries to avoid consuming more than 25 percent of total memory and to add latency to the system. You can increase this value up to 10 to increase the amount of effort spent on expiring keys. The tradeoff is higher CPU and potentially higher latency. We recommend a value of 1 unless you are seeing high memory usage and can tolerate an increase in CPU utilization.</td>
</tr>
<tr>
<td>lazyfree-lazy-user-del (added in 6.0)</td>
<td>Default: no, Type: string, Modifiable: Yes. Changes take effect: Immediately across all nodes in the cluster</td>
<td>When the value is set to yes, the <code>DEL</code> command acts the same as <code>UNLINK</code>.</td>
</tr>
</tbody>
</table>
Parameters removed in Redis 6.x are as follows.

</tr>
</tbody>
</table>

Redis has renamed several parameters in engine version 5.0 in response to community feedback. For more information, see [What's New in Redis 5?](#). The following table lists the new names and how they map to previous versions.

**Parameters renamed in Redis 5.0**

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>replica-lazy-flush</td>
<td>Default: yes Type: boolean Modifiable: No Former name: slave-lazy-flush</td>
<td>Performs an asynchronous flushDB during replica sync.</td>
</tr>
<tr>
<td>client-output-buffer-limit</td>
<td>Default: For values see Redis node-type specific parameters (p. 465) Type: integer Modifiable: No Former name: client-output-buffer-limit-slave-hard-limit</td>
<td>For Redis read replicas: If a client's output buffer reaches the specified number of bytes, the client will be disconnected.</td>
</tr>
<tr>
<td>Name</td>
<td>Details</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>client-output-buffer-limit</td>
<td>Default: For values see Redis node-type specific parameters (p. 465)</td>
<td>For Redis read replicas: If a client's output buffer reaches the specified number of bytes, the client will be disconnected, but only if this condition persists for <code>client-output-buffer-limit-replica-soft-seconds</code>.</td>
</tr>
<tr>
<td>replica-allow-chaining</td>
<td>Default: no</td>
<td>Determines whether a read replica in Redis can have read replicas of its own.</td>
</tr>
<tr>
<td>min-replicas-to-write</td>
<td>Default: 0</td>
<td>The minimum number of read replicas which must be available in order for the primary node to accept writes from clients. If the number of available replicas falls below this number, then the primary node will no longer accept write requests. If either this parameter or <code>min-replicas-max-lag</code> is 0, then the primary node will always accept write requests, even if no replicas are available.</td>
</tr>
<tr>
<td>min-replicas-max-lag</td>
<td>Default: 10</td>
<td>The number of seconds within which the primary node must receive a ping request from a read replica. If this amount of time passes and the primary does not receive a ping, then the replica is no longer considered available. If the number of available replicas drops below <code>min-replicas-to-write</code>, then the primary will stop accepting writes at that point. If either this parameter or <code>min-replicas-to-write</code> is 0, then the primary node will always accept write requests, even if no replicas are available.</td>
</tr>
</tbody>
</table>
### Redis-specific parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close-on-replica-write</td>
<td>Default: yes, Type: boolean, Modifiable: Yes, Former name: close-on-slave-write, Changes Take Effect: Immediately</td>
<td>If enabled, clients who attempt to write to a read-only replica will be disconnected.</td>
</tr>
</tbody>
</table>

**Parameters removed in Redis 5.0**

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>repl-timeout</td>
<td>Default: 60, Modifiable: No</td>
<td>Parameter is not available in this version.</td>
</tr>
</tbody>
</table>

**Redis 4.0.10 parameter changes**

**Parameter group family: redis4.0**

Redis 4.0.x default parameter groups

- default.redis4.0 – Use this parameter group, or one derived from it, for Redis (cluster mode disabled) clusters and replication groups.
- default.redis4.0.cluster.on – Use this parameter group, or one derived from it, for Redis (cluster mode enabled) clusters and replication groups.

**Parameters changed in Redis 4.0.10**

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxmemory-policy</td>
<td>Permitted values: allkeys-lru, volatile-lru, allkeys-lfu, volatile-lfu, allkeys-random, volatile-random, volatile-ttl, noeviction, Default: volatile-lru, Type: string, Modifiable: Yes, Changes take place: immediately</td>
<td>maxmemory-policy was added in version 2.6.13. In version 4.0.10 two new permitted values are added: allkeys-lfu, which will evict any key using approximated LFU, and volatile-lfu, which will evict using approximated LFU among the keys with an expire set. In version 6.2, when the r6gd node family was introduced for use with data-tiering, only noeviction, volatile-lru and allkeys-lru max-memory policies are supported with r6gd node types.</td>
</tr>
</tbody>
</table>

Redis 3.2.10 parameter changes

Parameter group family: redis3.2

ElastiCache for Redis 3.2.10 there are no additional parameters supported.

Redis 3.2.6 parameter changes

Parameter group family: redis3.2

For Redis 3.2.6 there are no additional parameters supported.

Redis 3.2.4 parameter changes

Parameter group family: redis3.2
Beginning with Redis 3.2.4 there are two default parameter groups.

- **default.redis3.2** – When running Redis 3.2.4, specify this parameter group or one derived from it, if you want to create a Redis (cluster mode disabled) replication group and still use the additional features of Redis 3.2.4.

- **default.redis3.2.cluster.on** – Specify this parameter group or one derived from it, when you want to create a Redis (cluster mode enabled) replication group.

**Topics**

- **New parameters for Redis 3.2.4** (p. 452)
- **Parameters changed in Redis 3.2.4 (enhanced)** (p. 454)

### New parameters for Redis 3.2.4

**Parameter group family:** redis3.2

For Redis 3.2.4 the following additional parameters are supported.

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
</table>
| list-max-ziplist-size       | Default: -2 Type: integer Modifiable: No | Lists are encoded in a special way to save space. The number of entries allowed per internal list node can be specified as a fixed maximum size or a maximum number of elements. For a fixed maximum size, use -5 through -1, meaning:
   - -5: max size: 64 Kb - not recommended for normal workloads
   - -4: max size: 32 Kb - not recommended
   - -3: max size: 16 Kb - not recommended
   - -2: max size: 8 Kb - recommended
   - -1: max size: 4 Kb - recommended
   - Positive numbers mean store up to exactly that number of elements per list node. |
| list-compress-depth         | Default: 0 Type: integer Modifiable: Yes Changes Take Effect: Immediately | Lists may also be compressed. Compress depth is the number of quicklist ziplist nodes from each side of the list to exclude from compression. The head and tail of the list are always uncompressed for fast push and pop operations. Settings are:
   - 0: Disable all compression.
   - 1: Start compressing with the 1st node in from the head and tail.
   - [head]->node->node->...->node->[tail]
   - All nodes except [head] and [tail] compress.
   - 2: Start compressing with the 2nd node in from the head and tail.
   - [head]->[next]->node->node->...->node->[prev]->[tail] |
<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[head], [next], [prev], [tail]</td>
<td>do not compress. All other nodes compress. • Etc.</td>
<td></td>
</tr>
<tr>
<td>cluster-enabled</td>
<td>Default: no/yes *</td>
<td>Indicates whether this is a Redis (cluster mode enabled) replication group in cluster mode (yes) or a Redis (cluster mode enabled) replication group in non-cluster mode (no). Redis (cluster mode enabled) replication groups in cluster mode can partition their data across up to 500 node groups. * Redis 3.2.x has two default parameter groups. • default.redis3.2 – default value no. • default.redis3.2.cluster.on – default value yes.</td>
</tr>
<tr>
<td>cluster-require-full-coverage</td>
<td>Default: no</td>
<td>Modifiable: yes</td>
</tr>
<tr>
<td>hll-sparse-max-bytes</td>
<td>Default: 3000</td>
<td>Modifiable: Yes</td>
</tr>
</tbody>
</table>
### Redis-specific parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reserved-memory-percent</td>
<td>Default: 25</td>
<td>The percent of a node’s memory reserved for non-data use. By default, the Redis data footprint grows until it consumes all of the node’s memory. If this occurs, then node performance will likely suffer due to excessive memory paging. By reserving memory, you can set aside some of the available memory for non-Redis purposes to help reduce the amount of paging. This parameter is specific to ElastiCache, and is not part of the standard Redis distribution. For more information, see <code>reserved-memory</code> and Managing Reserved Memory (p. 223).</td>
</tr>
</tbody>
</table>

#### Parameters changed in Redis 3.2.4 (enhanced)

**Parameter group family: redis3.2**

For Redis 3.2.4 the following parameters were changed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Change</th>
</tr>
</thead>
<tbody>
<tr>
<td>activerehashing</td>
<td>Modifiable: Yes if the parameter group is not associated with any cache clusters. Otherwise, no.</td>
<td>Modifiable was No.</td>
</tr>
<tr>
<td>databases</td>
<td>Modifiable: Yes if the parameter group is not associated with any cache clusters. Otherwise, no.</td>
<td>Modifiable was No.</td>
</tr>
<tr>
<td>appendonly</td>
<td>Default: off</td>
<td>If you want to upgrade from an earlier Redis version, you must first turn <code>appendonly</code> off.</td>
</tr>
<tr>
<td>appendfsync</td>
<td>Default: off</td>
<td>If you want to upgrade from an earlier Redis version, you must first turn <code>appendfsync</code> off.</td>
</tr>
<tr>
<td>repl-timeout</td>
<td>Default: 60</td>
<td>Is now unmodifiable with a default of 60.</td>
</tr>
<tr>
<td>tcp-keepalive</td>
<td>Default: 300</td>
<td>Default was 0.</td>
</tr>
<tr>
<td>list-max-ziplist-entries</td>
<td></td>
<td>Parameter is no longer available.</td>
</tr>
<tr>
<td>list-max-ziplist-value</td>
<td></td>
<td>Parameter is no longer available.</td>
</tr>
</tbody>
</table>
Redis 2.8.24 (enhanced) added parameters

Parameter group family: redis2.8

For Redis 2.8.24 there are no additional parameters supported.

Redis 2.8.23 (enhanced) added parameters

Parameter group family: redis2.8

For Redis 2.8.23 the following additional parameter is supported.

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close-on-slave-write</td>
<td>Default: yes</td>
<td>If enabled, clients who attempt to write to a read-only replica will be disconnected.</td>
</tr>
<tr>
<td></td>
<td>Type: string (yes/no)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Modifiable: Yes</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Changes Take Effect: Immediately</td>
<td></td>
</tr>
</tbody>
</table>

How close-on-slave-write works

The `close-on-slave-write` parameter is introduced by Amazon ElastiCache to give you more control over how your cluster responds when a primary node and a read replica node swap roles due to promoting a read replica to primary.

Before read-replica promotion

If the read-replica cluster is promoted to primary for any reason other than a Multi-AZ enabled replication group failing over, the client will continue trying to write to endpoint A. Because endpoint A is now the endpoint for a read-replica, these writes will fail. This is the behavior for Redis before ElastiCache introducing `close-on-replica-write` and the behavior if you disable `close-on-replica-write`. 
With close-on-replica-write enabled, any time a client attempts to write to a read-replica, the client connection to the cluster is closed. Your application logic should detect the disconnection, check the DNS table, and reconnect to the primary endpoint, which now would be endpoint B.

### When you might disable close-on-replica-write

If disabling close-on-replica-write results in writes to the failing cluster, why disable close-on-replica-write?

As previously mentioned, with close-on-replica-write enabled, any time a client attempts to write to a read-replica the client connection to the cluster is closed. Establishing a new connection to the node takes time. Thus, disconnecting and reconnecting as a result of a write request to the replica also affects the latency of read requests that are served through the same connection. This effect remains in place until a new connection is established. If your application is especially read-heavy or very latency-sensitive, you might keep your clients connected to avoid degrading read performance.

### Redis 2.8.22 (enhanced) added parameters

**Parameter group family:** redis2.8

For Redis 2.8.22 there are no additional parameters supported.

**Important**

- Beginning with Redis version 2.8.22, repl-backlog-size applies to the primary cluster as well as to replica clusters.
- Beginning with Redis version 2.8.22, the repl-timeout parameter is not supported. If it is changed, ElastiCache will overwrite with the default (60s), as we do with appendonly.
The following parameters are no longer supported.

- `appendonly`
- `appendfsync`
- `repl-timeout`

### Redis 2.8.21 added parameters

**Parameter group family:** redis2.8

For Redis 2.8.21, there are no additional parameters supported.

### Redis 2.8.19 added parameters

**Parameter group family:** redis2.8

For Redis 2.8.19 there are no additional parameters supported.

### Redis 2.8.6 added parameters

**Parameter group family:** redis2.8

For Redis 2.8.6 the following additional parameters are supported.

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
</table>
| `min-slaves-max-lag`  | Default: 10  
|                       | Type: integer  
|                       | Modifiable: Yes  
|                       | Changes Take Effect: Immediately  
|                       | The number of seconds within which the primary node must receive a ping request from a read replica. If this amount of time passes and the primary does not receive a ping, then the replica is no longer considered available. If the number of available replicas drops below `min-slaves-to-write`, then the primary will stop accepting writes at that point.  
|                       | If either this parameter or `min-slaves-to-write` is 0, then the primary node will always accept writes requests, even if no replicas are available. |
| `min-slaves-to-write` | Default: 0  
|                       | Type: integer  
|                       | Modifiable: Yes  
|                       | Changes Take Effect: Immediately  
|                       | The minimum number of read replicas which must be available in order for the primary node to accept writes from clients. If the number of available replicas falls below this number, then the primary node will no longer accept write requests.  
<p>|                       | If either this parameter or <code>min-slaves-max-lag</code> is 0, then the primary node will always accept writes requests, even if no replicas are available. |</p>
<table>

</tbody>
</table>
### Redis 2.6.13 parameters

**Parameter group family:** redis2.6

Redis 2.6.13 was the first version of Redis supported by ElastiCache. The following table shows the Redis 2.6.13 parameters that ElastiCache supports.

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>repl-backlog-size</td>
<td>Default: 1048576</td>
<td>The size, in bytes, of the primary node backlog buffer. The backlog is used for recording updates to data at the primary node. When a read replica connects to the primary, it attempts to perform a partial sync (psync), where it applies data from the backlog to catch up with the primary node. If the psync fails, then a full sync is required. The minimum value for this parameter is 16384. <strong>Note</strong> Beginning with Redis 2.8.22, this parameter applies to the primary cluster as well as the read replicas.</td>
</tr>
<tr>
<td>repl-backlog-ttl</td>
<td>Default: 3600</td>
<td>The number of seconds that the primary node will retain the backlog buffer. Starting from the time the last replica node disconnected, the data in the backlog will remain intact until repl-backlog-ttl expires. If the replica has not connected to the primary within this time, then the primary will release the backlog buffer. When the replica eventually reconnects, it will have to perform a full sync with the primary. If this parameter is set to 0, then the backlog buffer will never be released.</td>
</tr>
</tbody>
</table>
| repl-timeout       | Default: 60                  | Represents the timeout period, in seconds, for:  
  - Bulk data transfer during synchronization, from the read replica's perspective  
  - Primary node timeout from the replica's perspective  
  - Replica timeout from the primary node's perspective |
<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>activerehashing</td>
<td>Default: yes</td>
<td>Determines whether to enable Redis' active rehashing feature. The main hash table is rehashed ten times per second; each rehash operation consumes 1 millisecond of CPU time.</td>
</tr>
<tr>
<td></td>
<td>Type: string (yes/no)</td>
<td>This value is set when you create the parameter group. When assigning a new parameter group to a cluster, this value must be the same in both the old and new parameter groups.</td>
</tr>
<tr>
<td></td>
<td>Modifiable: Yes</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Changes take place: At Creation</td>
<td></td>
</tr>
<tr>
<td>appendonly</td>
<td>Default: no</td>
<td>Enables or disables Redis' append only file feature (AOF). AOF captures any Redis commands that change data in the cache, and is used to recover from certain node failures.</td>
</tr>
<tr>
<td></td>
<td>Type: string</td>
<td>The default value is <code>no</code>, meaning AOF is turned off. Set this parameter to <code>yes</code> to enable AOF.</td>
</tr>

## Redis-specific parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
</table>
| databases             | Default: 16  
Type: integer  
Modifiable: No  
Changes take place: At Creation | The number of logical partitions the databases is split into. We recommend keeping this value low. This value is set when you create the parameter group. When assigning a new parameter group to a cluster, this value must be the same in both the old and new parameter groups.                                                                                      |
| hash-max-ziplist-entries | Default: 512  
Type: integer  
Modifiable: Yes  
Changes Take Effect: Immediately | Determines the amount of memory used for hashes. Hashes with fewer than the specified number of entries are stored using a special encoding that saves space.                                                                                                                  |
| hash-max-ziplist-value | Default: 64  
Type: integer  
Modifiable: Yes  
Changes Take Effect: Immediately | Determines the amount of memory used for hashes. Hashes with entries that are smaller than the specified number of bytes are stored using a special encoding that saves space.                                                                                                           |
| list-max-ziplist-entries | Default: 512  
Type: integer  
Modifiable: Yes  
Changes Take Effect: Immediately | Determines the amount of memory used for lists. Lists with fewer than the specified number of entries are stored using a special encoding that saves space.                                                                                                                                 |
| list-max-ziplist-value | Default: 64  
Type: integer  
Modifiable: Yes  
Changes Take Effect: Immediately | Determines the amount of memory used for lists. Lists with entries that are smaller than the specified number of bytes are stored using a special encoding that saves space.                                                                                                                                 |
| lua-time-limit         | Default: 5000  
Type: integer  
Modifiable: No | The maximum execution time for a Lua script, in milliseconds, before ElastiCache takes action to stop the script. If lua-time-limit is exceeded, all Redis commands will return an error of the form **BUSY**. Since this state can cause interference with many essential Redis operations, ElastiCache will first issue a SCRIPT KILL command. If this is unsuccessful, ElastiCache will forcibly restart Redis. |

<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
</table>
| `timeout`              | Default: 0  
Type: integer  
Modifiable: Yes  
Changes Take Effect: Immediately | The number of seconds a node waits before timing out. Values are: |

- 0 – never disconnect an idle client.
- 1–19 – invalid values.
- >=20 – the number of seconds a node waits before disconnecting an idle client.

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
</table>
| `zset-max-ziplist-entries` | Default: 128  
Type: integer  
Modifiable: Yes  
Changes Take Effect: Immediately | Determines the amount of memory used for sorted sets. Sorted sets with fewer than the specified number of elements are stored using a special encoding that saves space. |

<table>
<thead>
<tr>
<th>Name</th>
<th>Details</th>
<th>Description</th>
</tr>
</thead>
</table>
| `zset-max-ziplist-value` | Default: 64  
Type: integer  
Modifiable: Yes  
Changes Take Effect: Immediately | Determines the amount of memory used for sorted sets. Sorted sets with entries that are smaller than the specified number of bytes are stored using a special encoding that saves space. |

#### Note

If you do not specify a parameter group for your Redis 2.6.13 cluster, then a default parameter group (`default.redis2.6`) will be used. You cannot change the values of any parameters in the default parameter group; however, you can always create a custom parameter group and assign it to your cluster at any time.

### Redis node-type specific parameters

Although most parameters have a single value, some parameters have different values depending on the node type used. The following table shows the default values for the `maxmemory`, `client-output-buffer-limit-slave-hard-limit`, and `client-output-buffer-limit-slave-soft-limit` parameters for each node type. The value of `maxmemory` is the maximum number of bytes available to you for use, data and other uses, on the node. For more information, see [Available memory](p. 454).

**Note**

The `maxmemory` parameter cannot be modified.

**Note**

All current generation instance types are created in an Amazon Virtual Private Cloud VPC by default.

T1 instances do not support Multi-AZ.

T1 and T2 instances do not support Redis AOF.

Redis configuration variables `appendonly` and `appendfsync` are not supported on Redis version 2.8.22 and later.
Security in Amazon ElastiCache

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon ElastiCache, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon ElastiCache. The following topics show you how to configure Amazon ElastiCache to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon ElastiCache resources.

**Topics**

- Data protection in Amazon ElastiCache (p. 469)
- Internetwork traffic privacy (p. 502)
- Identity and access management in Amazon ElastiCache (p. 539)
- Logging and monitoring in Elasticache (p. 578)
- Compliance validation for Amazon ElastiCache (p. 618)
- Resilience in Amazon ElastiCache (p. 622)
- Infrastructure security in AWS Elasticache (p. 625)
- Self-service updates in Amazon ElastiCache (p. 626)
- Troubleshooting (p. 635)

Data protection in Amazon ElastiCache

The AWS shared responsibility model applies to data protection in AWS Elasticache (Elasticache). As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data privacy FAQ.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
• Use advanced managed security services such as Amazon Macie, which assists in discovering and securing personal data that is stored in Amazon S3.

We strongly recommend that you never put sensitive identifying information, such as your customers' account numbers, into free-form fields such as a Name field. This includes when you work with ElastiCache or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into ElastiCache or other services might get picked up for inclusion in diagnostic logs. When you provide a URL to an external server, don't include credentials information in the URL to validate your request to that server.

**Topics**
• Data security in Amazon ElastiCache (p. 470)

**Data security in Amazon ElastiCache**

To help keep your data secure, Amazon ElastiCache and Amazon EC2 provide mechanisms to guard against unauthorized access of your data on the server.

Amazon ElastiCache for Redis also provides optional encryption features for data on clusters running Redis versions 3.2.6, 4.0.10 or later:

• In-transit encryption encrypts your data whenever it is moving from one place to another, such as between nodes in your cluster or between your cluster and your application.
• At-rest encryption encrypts your on-disk data during sync and backup operations.

If you want to enable in-transit or at-rest encryption, you must meet the following conditions.

• Your cluster or replication group must be running Redis 3.2.6, 4.0.10 or later.
• Your cluster or replication group must be created in a VPC based on Amazon VPC.
• Optionally, you can also use AUTH and the AUTH token (password) needed to perform operations on this cluster or replication group.
ElastiCache for Redis in-transit encryption (TLS)

To help keep your data secure, Amazon ElastiCache and Amazon EC2 provide mechanisms to guard against unauthorized access of your data on the server. By providing in-transit encryption capability, ElastiCache gives you a tool you can use to help protect your data when it is moving from one location to another. For example, you might move data from a primary node to a read replica node within a replication group, or between your replication group and your application.

In-transit encryption is optional and can only be enabled on Redis replication groups when they are created. You enable in-transit encryption on a replication group by setting the parameter `TransitEncryptionEnabled` (CLI: `--transit-encryption-enabled`) when you create the replication group. You can do this whether you are creating the replication group using the AWS Management Console, the AWS CLI, or the ElastiCache API. If you enable in-transit encryption, you must also provide a value for `CacheSubnetGroup`.

**Important**
The parameters `TransitEncryptionEnabled` (CLI: `--transit-encryption-enabled`) are only available when using the `CreateReplicationGroup` (CLI: `create-replication-group`) operation.

**In-transit encryption overview**

Amazon ElastiCache in-transit encryption is an optional feature that allows you to increase the security of your data at its most vulnerable points—when it is in transit from one location to another. Because there is some processing needed to encrypt and decrypt the data at the endpoints, enabling in-transit encryption can have some performance impact. You should benchmark your data with and without in-transit encryption to determine the performance impact for your use cases.

ElastiCache in-transit encryption implements the following features:

- **Encrypted connections**—both the server and client connections are Secure Socket Layer (SSL) encrypted.
- **Encrypted replication**—data moving between a primary node and replica nodes is encrypted.
- **Server authentication**—clients can authenticate that they are connecting to the right server.
- **Client authentication**—using the Redis AUTH feature, the server can authenticate the clients.
In-transit encryption conditions

The following constraints on Amazon ElastiCache in-transit encryption should be kept in mind when you plan your implementation:

- In-transit encryption is supported on replication groups running Redis versions 3.2.6, 4.0.10 and later.
- In-transit encryption is supported only for replication groups running in an Amazon VPC.
- In-transit encryption is only supported for replication groups running the following node types.
  - R6g, R5, R4, R3
  - M6g, M5, M4, M3
  - T4g, T3, T2

For more information, see Supported node types (p. 99).

- In-transit encryption is enabled by explicitly setting the parameter TransitEncryptionEnabled to true.
- You can enable in-transit encryption on a replication group only when creating the replication group. You cannot toggle in-transit encryption on and off by modifying a replication group. For information on implementing in-transit encryption on an existing replication group, see Enabling in-transit encryption (p. 472).
- To connect to an in-transit encryption enabled replication group, a database must be enabled for transport layer security (TLS). To connect to a replication group that is not in-transit encryption enabled, the database cannot be TLS-enabled.

Because of the processing required to encrypt and decrypt the data at the endpoints, implementing in-transit encryption can reduce performance. Benchmark in-transit encryption compared to no encryption on your own data to determine its impact on performance for your implementation.

**Tip**

Because creating new connections can be expensive, you can reduce the performance impact of in-transit encryption by persisting your SSL connections.

Enabling in-transit encryption

You can enable in-transit encryption when you create an ElastiCache for Redis replication group using the AWS Management Console, the AWS CLI, or the ElastiCache API.

Enabling in-transit encryption on an existing cluster

You can only enable in-transit encryption when you create a Redis replication group. If you have an existing replication group on which you want to enable in-transit encryption, do the following.

To enable in-transit encryption for an existing Redis replication group

1. Create a manual backup of the replication group. For more information, see Making manual backups (p. 315).
2. Create a new replication group by restoring from the backup setting the engine version to 3.2.6, 4.0.10 and later, and the parameter TransitEncryptionEnabled to true (CLI: --transit-encryption-enabled). For more information, see Restoring from a backup with optional cluster resizing (p. 334).
3. Update the endpoints in your application to the new replication group's endpoints. For more information, see Finding connection endpoints (p. 175).
4. Delete the old replication group. For more information, see the following:
Enabling in-transit encryption using the AWS Management Console

To enable in-transit encryption when creating a replication group using the AWS Management Console, make the following selections:

- Choose Redis as your engine.
- Choose engine version 3.2.6, 4.0.10 or later.
- Choose Yes from the Encryption in-transit list.

For the step-by-step process, see the following:

- Creating a Redis (cluster mode disabled) cluster (Console) (p. 47)
- Creating a Redis (cluster mode enabled) cluster (Console) (p. 133)

Enabling in-transit encryption using the AWS CLI

To enable in-transit encryption when creating a Redis replication group using the AWS CLI, use the parameter transit-encryption-enabled.

Enabling in-transit encryption on Redis (Cluster Mode Disabled) cluster (CLI)

Use the AWS CLI operation create-replication-group and the following parameters to create a Redis replication group with replicas that has in-transit encryption enabled:

**Key parameters:**
- **--engine**—Must be redis.
- **--engine-version**—Must be 3.2.6, 4.0.10 or later.
- **--transit-encryption-enabled**—Required. If you enable in-transit encryption you must also provide a value for the --cache-subnet-group parameter.
- **--num-cache-clusters**—Must be at least 1. The maximum value for this parameter is six.

For more information, see the following:

- Creating a Redis (Cluster Mode Disabled) replication group from scratch (AWS CLI) (p. 273)
- create-replication-group

Enabling in-transit encryption on a cluster for Redis (Cluster Mode Enabled) (CLI)

Use the AWS CLI operation create-replication-group and the following parameters to create a Redis (cluster mode enabled) replication group that has in-transit encryption enabled:

**Key parameters:**
- **--engine**—Must be redis.
- **--engine-version**—Must be 3.2.6, 4.0.10 or later.
• `--transit-encryption-enabled`—Required. If you enable in-transit encryption you must also provide a value for the `--cache-subnet-group` parameter.

• Use one of the following parameter sets to specify the configuration of the replication group's node groups:
  
  • `--num-node-groups`—Specifies the number of shards (node groups) in this replication group. The maximum value of this parameter is 500.
  
  • `--replicas-per-node-group`—Specifies the number of replica nodes in each node group. The value specified here is applied to all shards in this replication group. The maximum value of this parameter is 5.

  • `--node-group-configuration`—Specifies the configuration of each shard independently.

For more information, see the following:

- Creating a Redis (Cluster Mode Enabled) replication group from scratch (AWS CLI) (p. 280)
- create-replication-group

Enabling in-transit encryption using the AWS API

To enable in-transit encryption when creating a Redis replication group using the ElastiCache API, set the parameter `TransitEncryptionEnabled` to `true` with either `CreateReplicationGroup` for a single node Redis replication group, or `CreateReplicationGroup` for a replication group with read replicas.

Enabling in-transit encryption on a cluster for Redis (Cluster Mode Disabled) (API)

Use the ElastiCache API operation `CreateReplicationGroup` and the following parameters to create a Redis (cluster mode disabled) replication group that has in-transit encryption enabled:

**Key parameters**

• **Engine**—Must be `redis`.

• **EngineVersion**—Must be 3.2.6, 4.0.10 or later.

• **TransitEncryptionEnabled**—Must set to `true`.

  When `TransitEncryptionEnabled` is set to `true`, you must also provide a value for `CacheSubnetGroup`.

• **NumCacheClusters**—Must be at least 1. The maximum value for this parameter is six.

For more information, see the following:

- Creating a Redis (cluster mode disabled) replication group from scratch (ElastiCache API) (p. 276)
- CreateReplicationGroup

Enabling in-transit encryption on a cluster for Redis (Cluster Mode Enabled) (API)

Use the ElastiCache API operation `CreateReplicationGroup` and the following parameters to create a Redis (cluster mode enabled) replication group that has in-transit encryption enabled:

**Key parameters**

• **Engine**—Must be `redis`.

• **EngineVersion**—Must be 3.2.6, 4.0.10 or later.
• **TransitEncryptionEnabled**—Must set to `true`.

When `TransitEncryptionEnabled` is set to `true`, you must also provide a value for `CacheSubnetGroup`.

• Use one of the following parameter sets to specify the configuration of the replication group's node groups:
  
  • **NumNodeGroups**—Specifies the number of shards (node groups) in this replication group. The maximum value of this parameter is 500 but can be increased to a maximum of 250 by a service limit increase request. For more information, see AWS service limits.

  • **ReplicasPerNodeGroup**—Specifies the number of replica nodes in each node group. The value specified here is applied to all shards in this replication group. The maximum value of this parameter is 5.

  • **NodeGroupConfiguration**—Specifies the configuration of each shard independently.

For more information, see the following:

• [Creating a replication group in Redis (Cluster Mode Enabled) from scratch (ElastiCache API) (p. 285)](#)

• [CreateReplicationGroup](#)

### Connecting to Amazon ElastiCache for Redis nodes enabled with in-transit encryption using redis-cli

To access data from ElastiCache for Redis nodes enabled with in-transit encryption, you use clients that work with Secure Socket Layer (SSL). You can also use redis-cli with TLS/SSL on Amazon Linux and Amazon Linux 2.

**To use redis-cli to connect to a Redis cluster enabled with in-transit encryption on Amazon Linux 2 or Amazon Linux**

1. Download and compile the redis-cli utility. This utility is included in the Redis software distribution.
2. At the command prompt of your EC2 instance, type the following commands:

   **Amazon Linux 2**
   
   ```
   sudo yum -y install openssl-devel gcc
   wget http://download.redis.io/redis-stable.tar.gz
   tar xvzf redis-stable.tar.gz
   cd redis-stable
   make distclean
   make redis-cli BUILD_TLS=yes
   sudo install -m 755 src/redis-cli /usr/local/bin/
   ```

   **Amazon Linux**
   
   ```
   sudo yum install gcc jemalloc-devel openssl-devel tcl tcl-devel clang wget
   wget http://download.redis.io/redis-stable.tar.gz
   tar xvzf redis-stable.tar.gz
   cd redis-stable
   make redis-cli CC=clang BUILD_TLS=yes
   sudo install -m 755 src/redis-cli /usr/local/bin/
   ```

   On Amazon Linux, you may also need to run the following additional steps:
3. After this, it is recommended that you run the optional `make-test` command.

4. At the command prompt of your EC2 instance, type the following command, substituting the endpoint of your cluster and port for what is shown in this example.

```
redis-cli -h Primary or Configuration Endpoint --tls -p 6379
```

For more information on finding the endpoint, see Find your Node Endpoints.

The following example connects to a cluster with encryption and authentication enabled:

```
redis-cli -h Primary or Configuration Endpoint --tls -a 'your-password' -p 6379
```

To work around this, you can use the `stunnel` command to create an SSL tunnel to the redis nodes. You then use `redis-cli` to connect to the tunnel to access data from encrypted Redis nodes.

To use `redis-cli` to connect to a Redis cluster enabled with in-transit encryption using `stunnel`

1. Use SSH to connect to your client and install `stunnel`.

```
sudo yum install stunnel
```

2. Run the following command to create and edit file `/etc/stunnel/redis-cli.conf` simultaneously to add a ElastiCache for Redis cluster endpoint to one or more connection parameters, using provided output below as template:

```
vi /etc/stunnel/redis-cli.conf
```

```
fips = no
setuid = root
setgid = root
pid = /var/run/stunnel.pid
debug = 7
delay = yes
options = NO_SSLv2
options = NO_SSLv3
[redis-cli]
client = yes
accept = 127.0.0.1:6379
connect = primary.ssltest.wif01h.use1.cache.amazonaws.com:6379
[redis-cli-replica]
client = yes
accept = 127.0.0.1:6380
connect = ssltest-02.ssltest.wif01h.use1.cache.amazonaws.com:6379
```

In this example, the config file has two connections, the `redis-cli` and the `redis-cli-replica`. The parameters are set as follows:

- **client** is set to yes to specify this stunnel instance is a client.
- **accept** is set to the client IP. In this example, the primary is set to the Redis default 127.0.0.1 on port 6379. The replica must call a different port and set to 6380. You can use ephemeral ports 1024–65535. For more information, see Ephemeral ports in the Amazon VPC User Guide.
• **connect** is set to the Redis server endpoint. For more information, see Finding connection endpoints (p. 175).

3. Start stunnel.

```
sudo stunnel /etc/stunnel/redis-cli.conf
```

Use the `netstat` command to confirm that the tunnels started.

```
sudo netstat -tulnp | grep -i stunnel
```

```
tcp        0      0 127.0.0.1:6379              0.0.0.0:*                   LISTEN
3189/stunnel

tcp        0      0 127.0.0.1:6380              0.0.0.0:*                   LISTEN
3189/stunnel
```

4. Connect to the encrypted Redis node using the local endpoint of the tunnel.

- If no AUTH password was used during ElastiCache for Redis cluster creation, this example uses the `redis-cli` to connect to the ElastiCache for Redis server using complete path for `redis-cli`, on Amazon Linux:

```
/home/ec2-user/redis-stable/src/redis-cli -h localhost -p 6379
```

- If AUTH password was used during Redis cluster creation, this example uses `redis-cli` to connect to the Redis server using complete path for `redis-cli`, on Amazon Linux:

```
/home/ec2-user/redis-stable/src/redis-cli -h localhost -p 6379 -a my-secret-password
```

OR

• Change directory to `redis-stable` and do the following:

- If no AUTH password was used during ElastiCache for Redis cluster creation, this example uses the `redis-cli` to connect to the ElastiCache for Redis server using complete path for `redis-cli`, on Amazon Linux:

```
src/redis-cli -h localhost -p 6379
```

- If AUTH password was used during Redis cluster creation, this example uses `redis-cli` to connect to the Redis server using complete path for `redis-cli`, on Amazon Linux:

```
src/redis-cli -h localhost -p 6379 -a my-secret-password
```

This example uses Telnet to connect to the Redis server.

```
telnet localhost 6379
```

Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
auth MySecretPassword
*OK
get foo
$3
5. To stop and close the SSL tunnels, `pkill` the stunnel process.

```
sudo pkill stunnel
```

Authenticating users with the Redis AUTH command

Redis authentication tokens, or passwords, enable Redis to require a password before allowing clients to run commands, thereby improving data security.

Topics

- Overview of AUTH in ElastiCache for Redis (p. 478)
- Applying authentication to an ElastiCache for Redis cluster (p. 478)
- Modifying the AUTH token on an existing ElastiCache for Redis cluster (p. 479)

Overview of AUTH in ElastiCache for Redis

When you use Redis `AUTH` with your ElastiCache for Redis cluster, there are some refinements.

In particular, be aware of these `AUTH` token, or password, constraints when using `AUTH` with ElastiCache for Redis:

- Tokens, or passwords, must be 16–128 printable characters.
- Nonalphanumeric characters are restricted to (!, &, #, $, ^, <, >, -).
- `AUTH` can only be enabled for encryption in-transit enabled ElastiCache for Redis clusters.

To set up a strong token, we recommend that you follow a strict password policy, such as requiring the following:

- Tokens, or passwords, must include at least three of the following character types:
  - Uppercase characters
  - Lowercase characters
  - Digits
  - Nonalphanumeric characters (!, &, #, $, ^, <, >, -)
- Tokens, or passwords, must not contain a dictionary word or a slightly modified dictionary word.
- Tokens, or passwords, must not be the same as or similar to a recently used token.

Applying authentication to an ElastiCache for Redis cluster

You can require that users enter a token (password) on a token-protected Redis server. To do this, include the parameter `--auth-token` (API: `AuthToken`) with the correct token when you create your replication group or cluster. Also include it in all subsequent commands to the replication group or cluster.
The following AWS CLI operation creates a replication group with encryption in transit (TLS) enabled and the **AUTH** token *This-is-a-sample-token*. Replace the subnet group *sng-test* with a subnet group that exists.

**Key parameters**

- **--engine** – Must be `redis`.
- **--engine-version** – Must be 3.2.6, 4.0.10, or later.
- **--transit-encryption-enabled** – Required for authentication and HIPAA eligibility.
- **--auth-token** – Required for HIPAA eligibility. This value must be the correct token for this token-protected Redis server.
- **--cache-subnet-group** – Required for HIPAA eligibility.

For Linux, macOS, or Unix:

```bash
aws elasticache create-replication-group
  --replication-group-id authtestgroup
  --replication-group-description authtest
  --engine redis
  --engine-version 4.0.10
  --cache-node-type cache.m4.large
  --num-node-groups 1
  --replicas-per-node-group 2
  --cache-parameter-group default.redis3.2.cluster.on
  --transit-encryption-enabled
  --auth-token This-is-a-sample-token
  --cache-subnet-group sng-test
```

For Windows:

```bash
aws elasticache create-replication-group
  --replication-group-id authtestgroup
  --replication-group-description authtest
  --engine redis
  --engine-version 4.0.10
  --cache-node-type cache.m4.large
  --num-node-groups 1
  --replicas-per-node-group 2
  --cache-parameter-group default.redis3.2.cluster.on
  --transit-encryption-enabled
  --auth-token This-is-a-sample-token
  --cache-subnet-group sng-test
```

**Modifying the AUTH token on an existing ElastiCache for Redis cluster**

To make it easier to update your authentication, you can modify the **AUTH** token used on an ElastiCache for Redis cluster. You can make this modification if the engine version is 5.0.5 or higher and if ElastiCache for Redis has encryption in transit enabled.

Modifying the auth token supports two strategies: **ROTATE** and **SET**. The **ROTATE** strategy adds an additional **AUTH** token to the server while retaining the previous token. The **SET** strategy updates the server to support just a single **AUTH** token. Make these modification calls with the **--apply-immediately** parameter to apply changes immediately.

**Rotating the AUTH token**

To update a Redis server with a new **AUTH** token, call the `ModifyReplicationGroup` API with the **--auth-token** parameter as the new auth token and the **--auth-token-update-strategy** with the
value ROTATE. After the modification is complete, the cluster will support the previous AUTH token in addition to the one specified in the auth-token parameter.

**Note**

If you do not configure the AUTH token before, then once the modification is complete, the cluster will support no AUTH token in addition to the one specified in the auth-token parameter.

If this modification is performed on a server that already supports two AUTH tokens, the oldest AUTH token will also be removed during this operation, allowing a server to support up to two most recent AUTH tokens at a given time.

At this point, you can proceed by updating the client to use the latest AUTH token. After the clients are updated, you can use the SET strategy for AUTH token rotation (explained in the following section) to exclusively start using the new token.

The following AWS CLI operation modifies a replication group to rotate the AUTH token `This-is-the-rotated-token`.

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group \
--replication-group-id authtestgroup \n--auth-token This-is-the-rotated-token \n--auth-token-update-strategy ROTATE \n--apply-immediately
```

For Windows:

```bash
aws elasticache modify-replication-group ^
--replication-group-id authtestgroup ^
--auth-token This-is-the-rotated-token ^
--auth-token-update-strategy ROTATE ^
--apply-immediately
```

**Setting the AUTH token**

To update a Redis server with two AUTH tokens to support a single AUTH token, call the `ModifyReplicationGroup` API operation. Call `ModifyReplicationGroup` with the `--auth-token` parameter as the new AUTH token and the `--auth-token-update-strategy` parameter with the value SET. The auth-token parameter must be the same value as the last AUTH token rotated. After the modification is complete, the Redis server supports only the AUTH token specified in the auth-token parameter.

The following AWS CLI operation modifies a replication group to set the AUTH token to `This-is-the-set-token`.

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group \
--replication-group-id authtestgroup \
--auth-token This-is-the-set-token \
--auth-token-update-strategy SET \
--apply-immediately
```

For Windows:

```bash
aws elasticache modify-replication-group ^
--replication-group-id authtestgroup ^
--auth-token This-is-the-set-token ^
```
Enabling authentication on an existing ElastiCache for Redis cluster

To enable authentication on an existing Redis server, call the `ModifyReplicationGroup` API operation. Call `ModifyReplicationGroup` with the `--auth-token` parameter as the new token and the `--auth-token-update-strategy` with the value `ROTATE`.

After the modification is complete, the cluster supports the `AUTH` token specified in the `auth-token` parameter in addition to supporting connecting without authentication. Enabling authentication is only supported on Redis servers with encryption in transit (TLS) enabled.

Migrating from RBAC to Redis AUTH

If you are authenticating users with Redis Role-Based Access Control (RBAC) as described in Authenticating users with role-based access control (RBAC) and want to migrate to Redis AUTH, use the following procedures. You can migrate using either console or CLI.

To migrate from RBAC to Redis AUTH using the console

2. From the list in the upper-right corner, choose the AWS Region where the cluster that you want to modify is located.
3. In the navigation pane, choose the engine running on the cluster that you want to modify.
   
   A list of the chosen engine's clusters appears.
4. In the list of clusters, for the cluster that you want to modify, choose its name.
5. For Actions, choose Modify.

   The Modify Cluster window appears.
6. For Access Control Option, choose Redis AUTH Default User.
7. Under AUTH token, accept either No change, rotate an existing token, or set a new token.
8. Choose Modify.

To migrate from RBAC to Redis AUTH using the AWS CLI

- Use one of the following commands.

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group \
  --replication-group-id test \
  --remove-user-groups \
  --auth-token password \
  --auth-token-update-strategy SET \ 
  --apply-immediately
```

For Windows:

```bash
aws elasticache modify-replication-group \
  --replication-group-id test \
  --remove-user-groups \
  --auth-token password \
  --auth-token-update-strategy SET \
```

Enabling authentication on an existing ElastiCache for Redis cluster

To enable authentication on an existing Redis server, call the `ModifyReplicationGroup` API operation. Call `ModifyReplicationGroup` with the `--auth-token` parameter as the new token and the `--auth-token-update-strategy` with the value `ROTATE`.

After the modification is complete, the cluster supports the `AUTH` token specified in the `auth-token` parameter in addition to supporting connecting without authentication. Enabling authentication is only supported on Redis servers with encryption in transit (TLS) enabled.

Migrating from RBAC to Redis AUTH

If you are authenticating users with Redis Role-Based Access Control (RBAC) as described in Authenticating users with role-based access control (RBAC) and want to migrate to Redis AUTH, use the following procedures. You can migrate using either console or CLI.

To migrate from RBAC to Redis AUTH using the console

2. From the list in the upper-right corner, choose the AWS Region where the cluster that you want to modify is located.
3. In the navigation pane, choose the engine running on the cluster that you want to modify.

   A list of the chosen engine's clusters appears.
4. In the list of clusters, for the cluster that you want to modify, choose its name.
5. For Actions, choose Modify.

   The Modify Cluster window appears.
6. For Access Control Option, choose Redis AUTH Default User.
7. Under AUTH token, accept either No change, rotate an existing token, or set a new token.
8. Choose Modify.

To migrate from RBAC to Redis AUTH using the AWS CLI

- Use one of the following commands.

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group \
  --replication-group-id test \
  --remove-user-groups \
  --auth-token password \
  --auth-token-update-strategy SET \
  --apply-immediately
```

For Windows:

```bash
aws elasticache modify-replication-group \
  --replication-group-id test \
  --remove-user-groups \
  --auth-token password \
  --auth-token-update-strategy SET \
```
For more information on working with AUTH, see AUTH token on the redis.io website.
At-Rest Encryption in ElastiCache for Redis

To help keep your data secure, Amazon ElastiCache and Amazon S3 provide different ways to restrict access to data in your cache. For more information, see Amazon VPCs and ElastiCache security (p. 502) and Identity and access management in Amazon ElastiCache (p. 539).

Elasticache for Redis at-rest encryption is an optional feature to increase data security by encrypting on-disk data. When enabled on a replication group, it encrypts the following aspects:

- Data stored on SSDs (solid-state drives) in data tiering enabled clusters is always encrypted by default. However, when the cluster is backed up, the snapshot data is not automatically encrypted. Encryption needs to be enabled on the snapshot. For more information, see Enabling At-Rest Encryption.
- Disk during sync, backup and swap operations
- Backups stored in Amazon S3

Elasticache for Redis offers default (service managed) encryption at rest, as well as ability to use your own symmetric customer managed AWS KMS keys in AWS Key Management Service (KMS).

**Note**
The default (service managed) encryption is the only option available in the GovCloud (US) Regions.

At-rest encryption can be enabled on a replication group only when it is created. Because there is some processing needed to encrypt and decrypt the data, enabling at-rest encryption can have a performance impact during these operations. You should benchmark your data with and without at-rest encryption to determine the performance impact for your use cases.

For information on encryption in transit, see ElastiCache for Redis in-transit encryption (TLS) (p. 471)

**Topics**

- At-Rest Encryption Conditions (p. 483)
- Using customer managed keys from AWS KMS (p. 484)
- Enabling At-Rest Encryption (p. 485)
- See Also (p. 489)

**At-Rest Encryption Conditions**

The following constraints on ElastiCache at-rest encryption should be kept in mind when you plan your implementation of ElastiCache encryption at-rest:

- At-rest encryption is supported on replication groups running Redis versions 3.2.6, 4.0.10 or later.
- At-rest encryption is supported only for replication groups running in an Amazon VPC.
- At-rest encryption is only supported for replication groups running the following node types.
  - R6gd, R6g, R5, R4, R3
  - M6g, M5, M4, M3
  - T4g, T3, T2

For more information, see Supported node types (p. 99)

- At-rest encryption is enabled by explicitly setting the parameter `AtRestEncryptionEnabled` to true.
- You can enable at-rest encryption on a replication group only when creating the replication group. You cannot toggle at-rest encryption on and off by modifying a replication group. For information on implementing at-rest encryption on an existing replication group, see Enabling At-Rest Encryption (p. 485).
• If a cluster is using a node type from the r6gd family, data stored on SSD is encrypted whether at-rest encryption is enabled or not.

• The option to use customer managed key for encryption at rest is not available in AWS GovCloud (us-gov-east-1 and us-gov-west-1) regions.

• If a cluster is using a node type from the r6gd family, data stored on SSD is encrypted with the chosen customer managed AWS KMS key (or service-managed encryption in AWS GovCloud Regions).

Implementing at-rest encryption can reduce performance during backup and node sync operations. Benchmark at-rest encryption compared to no encryption on your own data to determine its impact on performance for your implementation.

Using customer managed keys from AWS KMS

ElastiCache for Redis supports symmetric customer managed AWS KMS keys (KMS key) for encryption at rest. Customer-managed KMS keys are encryption keys that you create, own and manage in your AWS account. For more information, see AWS KMS keys in the AWS Key Management Service Developer Guide. The keys must be created in AWS KMS before they can be used with ElastiCache.

To learn how to create AWS KMS root keys, see Creating Keys in the AWS Key Management Service Developer Guide.

ElastiCache for Redis allows you to integrate with AWS KMS. For more information, see Using Grants in the AWS Key Management Service Developer Guide. No customer action is needed to enable Amazon ElastiCache integration with AWS KMS.

The kms:ViaService condition key limits use of an AWS KMS key (KMS key) to requests from specified AWS services. To use kms:ViaService with ElastiCache, include both ViaService names in the condition key value: elasticache.AWS_region.amazonaws.com and dax.AWS_region.amazonaws.com. For more information, see kms:ViaService.

You can use AWS CloudTrail to track the requests that Amazon ElastiCache sends to AWS Key Management Service on your behalf. All API calls to AWS Key Management Service related to customer managed keys have corresponding CloudTrail logs. You can also see the grants that ElastiCache creates by calling the ListGrants KMS API call.

Once a replication group is encrypted using customer managed key, all backups for the replication group are encrypted as follows:

• Automatic daily backups are encrypted using the customer managed key associated with the cluster.

• Final backup created when replication group is deleted, is also encrypted using the customer managed key associated with the replication group.

• Manually created backups are encrypted by default to use the KMS key associated with the replication group. You may override this by choosing another customer managed key.

• Copying a backup defaults to using a customer managed key associated with the source backup. You may override this by choosing another customer managed key.

Note

• Customer managed keys cannot be used when exporting backups to your selected Amazon S3 bucket. However, all backups exported to Amazon S3 are encrypted using Server side encryption. You may choose to copy the backup file to a new S3 object and encrypt using a customer managed KMS key, copy the file to another S3 bucket that is set up with default encryption using a KMS key or change an encryption option in the file itself.

• You can also use customer managed keys to encrypt manually-created backups for replication groups that do not use customer managed keys for encryption. With this option, the backup
Data security in Amazon ElastiCache

file stored in Amazon S3 is encrypted using a KMS key, even though the data is not encrypted on the original replication group.

Restoring from a backup allows you to choose from available encryption options, similar to encryption choices available when creating a new replication group.

- If you delete the key or disable the key and revoke grants for the key that you used to encrypt a replication group, the replication group becomes irrecoverable. In other words, it cannot be modified or recovered after a hardware failure. AWS KMS deletes root keys only after a waiting period of at least seven days. After the key is deleted, you can use a different customer managed key to create a backup for archival purposes.
- Automatic key rotation preserves the properties of your AWS KMS root keys, so the rotation has no effect on your ability to access your ElastiCache data. Encrypted Amazon ElastiCache replication groups don't support manual key rotation, which involves creating a new root key and updating any references to the old key. To learn more, see Rotating AWS KMS keys in the AWS Key Management Service Developer Guide.
- Encrypting an ElastiCache replication group using KMS key requires one grant per replication group. This grant is used throughout the lifespan of the replication group. Additionally, one grant per backup is used during backup creation. This grant is retired once the backup is created.
- For more information on AWS KMS grants and limits, see Limits in the AWS Key Management Service Developer Guide.

Enabling At-Rest Encryption

You can enable ElastiCache at-rest encryption when you create a Redis replication group by setting the parameter `AtRestEncryptionEnabled` to `true`. You can't enable at-rest encryption on existing replication groups.

You can enable at-rest encryption when you create an ElastiCache for Redis replication group. You can do so using the AWS Management Console, the AWS CLI, or the ElastiCache API.

When creating a replication group, you can pick one of the following options:

- **Default** – This option uses service managed encryption at rest.
- **Customer managed key** – This option allows you to provide the Key ID/ARN from AWS KMS for encryption at rest.

To learn how to create AWS KMS root keys, see Create Keys in the AWS Key Management Service Developer Guide

Contents

Enabling At-Rest Encryption on an Existing Redis Cluster

You can only enable at-rest encryption when you create a Redis replication group. If you have an existing replication group on which you want to enable at-rest encryption, do the following.

To enable at-rest encryption on an existing replication group

1. Create a manual backup of your existing replication group. For more information, see Making manual backups (p. 315).
2. Create a new replication group by restoring from the backup. On the new replication group, enable at-rest encryption. For more information, see Restoring from a backup with optional cluster resizing (p. 334).
3. Update the endpoints in your application to point to the new replication group.
4. Delete the old replication group. For more information, see Deleting a cluster (p. 165) or Deleting a replication group (p. 296).

Enabling At-Rest Encryption Using the AWS Management Console

To enable at-rest encryption when creating a replication group using the AWS Management Console, make the following selections:

- Choose redis as your engine.
- Choose version 3.2.6, 4.0.10 or later as your engine version.
- Choose Yes from the Encryption at-rest list.

For the step-by-step procedure, see the following:

- Creating a Redis (cluster mode disabled) cluster (Console) (p. 47)
- Creating a Redis (cluster mode enabled) cluster (Console) (p. 133)

Enabling At-Rest Encryption Using the AWS CLI

To enable at-rest encryption when creating a Redis cluster using the AWS CLI, use the --at-rest-encryption-enabled parameter when creating a replication group.

Enabling At-Rest Encryption on a Redis (Cluster Mode Disabled) Cluster (CLI)

The following operation creates the Redis (cluster mode disabled) replication group my-classic-rg with three nodes (--num-cache-clusters), a primary and two read replicas. At-rest encryption is enabled for this replication group (--at-rest-encryption-enabled).

The following parameters and their values are necessary to enable encryption on this replication group:

Key Parameters

- --engine—Must be redis.
- --engine-version—Must be 3.2.6, 4.0.10 or later.
- --at-rest-encryption-enabled—Required to enable at-rest encryption.

Example 1: Redis (Cluster Mode Disabled) Cluster with Replicas

For Linux, macOS, or Unix:
aws elasticache create-replication-group \
  --replication-group-id my-classic-rg \
  --replication-group-description "3 node replication group" \
  --cache-node-type cache.m4.large \
  --engine redis \
  --engine-version 4.0.10 \
  --at-rest-encryption-enabled \
  --num-cache-clusters 3 \
  --cache-parameter-group default.redis4.0

For Windows:

aws elasticache create-replication-group ^
  --replication-group-id my-classic-rg ^
  --replication-group-description "3 node replication group" ^
  --cache-node-type cache.m4.large ^
  --engine redis ^
  --engine-version 4.0.10 ^
  --at-rest-encryption-enabled ^
  --num-cache-clusters 3 ^
  --cache-parameter-group default.redis4.0

For additional information, see the following:

- Creating a Redis (Cluster Mode Disabled) replication group from scratch (AWS CLI) (p. 273)
- create-replication-group

Enabling At-Rest Encryption on a Cluster for Redis (Cluster Mode Enabled) (CLI)

The following operation creates the Redis (cluster mode enabled) replication group my-clustered-rg
with three node groups or shards (--num-node-groups). Each has three nodes, a primary and two read
replicas (--replicas-per-node-group). At-rest encryption is enabled for this replication group (--at-rest-
encryption-enabled).

The following parameters and their values are necessary to enable encryption on this replication group:

**Key Parameters**

- --engine—Must be redis.
- --engine-version—Must be 4.0.10 or later.
- --at-rest-encryption-enabled—Required to enable at-rest encryption.
- --cache-parameter-group—Must be default-redis4.0.cluster.on or one derived from it to
  make this a cluster mode enabled replication group.

**Example 2: A Redis (Cluster Mode Enabled) Cluster**

For Linux, macOS, or Unix:

aws elasticache create-replication-group \
  --replication-group-id my-clustered-rg \
  --replication-group-description "redis clustered cluster" \
  --cache-node-type cache.m3.large \
  --num-node-groups 3 \
  --replicas-per-node-group 2 \

API Version 2015-02-02
487
For Windows:

```
aws elasticache create-replication-group ^
   --replication-group-id my-clustered-rg ^
   --replication-group-description "redis clustered cluster" ^
   --cache-node-type cache.m3.large ^
   --num-node-groups 3 ^
   --replicas-per-node-group 2 ^
   --engine redis ^
   --engine-version 4.0.10 ^
   --at-rest-encryption-enabled ^
   --cache-parameter-group default.redis4.0.cluster.on
```

For additional information, see the following:

- Creating a Redis (Cluster Mode Enabled) replication group from scratch (AWS CLI) (p. 280)
- create-replication-group

**Enabling At-Rest Encryption Using the ElastiCache API**

To enable at-rest encryption when creating a Redis replication group using the ElastiCache API, set the parameter `AtRestEncryptionEnabled` to `true` with `CreateReplicationGroup`.

**Enabling At-Rest Encryption on a Redis (Cluster Mode Disabled) Cluster (API)**

The following operation creates the Redis (cluster mode disabled) replication group `my-classic-rg` with three nodes (`NumCacheClusters`), a primary and two read replicas. At-rest encryption is enabled for this replication group (`AtRestEncryptionEnabled=true`).

The following parameters and their values are necessary to enable encryption on this replication group:

- **Engine**—Must be `redis`.
- **EngineVersion**—Must be 3.2.6, 4.0.10 or later.
- **AtRestEncryptionEnabled**—Required to be `true` to enable at-rest encryption.

**Example 3: A Redis (Cluster Mode Disabled) Cluster with Replicas**

Line breaks are added for ease of reading.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=CreateReplicationGroup
&AtRestEncryptionEnabled=true
&CacheNodeType=cache.m3.large
&CacheParameterGroup=default.redis4.0
&Engine=redis
&EngineVersion=4.0.10
&NumCacheClusters=3
&ReplicationGroupDescription=test%20group
&ReplicationGroupId=my-classic-rg
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T192317Z
```
For additional information, see the following:

- Creating a Redis (cluster mode disabled) replication group from scratch (ElastiCache API) (p. 276)
- CreateReplicationGroup

Enabling At-Rest Encryption on a Cluster for Redis (Cluster Mode Enabled) (API)

The following operation creates the Redis (cluster mode enabled) replication group `my-clustered-rg` with three node groups/shards (`NumNodeGroups`), each with three nodes, a primary and two read replicas (`ReplicasPerNodeGroup`). At-rest encryption is enabled for this replication group (`AtRestEncryptionEnabled=true`).

The following parameters and their values are necessary to enable encryption on this replication group:

- **Engine**—Must be `redis`.
- **AtRestEncryptionEnabled**—Required to be `true` to enable at-rest encryption.
- **EngineVersion**—Must be 3.2.6, 4.0.10 or later.
- **CacheParameterGroup**—Must be `default-redis4.0.cluster.on`, or one derived from it for this to be a Redis (cluster mode enabled) cluster.

Example 4: A Redis (Cluster Mode Enabled) Cluster

Line breaks are added for ease of reading.

```plaintext
https://elasticache.us-west-2.amazonaws.com/
?Action=CreateReplicationGroup

Authenticating users with Role-Based Access Control (RBAC)

Instead of authenticating users with the Redis AUTH command as described in Authenticating users with the Redis AUTH command (p. 478), in Redis 6.0 onward you can use a feature called Role-Based Access Control (RBAC).

Unlike Redis AUTH, where all authenticated clients have full replication group access if their token is authenticated, RBAC enables you to control cluster access through user groups. These user groups are designed as a way to organize access to replication groups.

With RBAC, you create users and assign them specific permissions by using an access string, as described following. You assign the users to user groups aligned with a specific role (administrators, human resources) that are then deployed to one or more ElastiCache for Redis replication groups. By doing this, you can establish security boundaries between clients using the same Redis replication group or groups and prevent clients from accessing each other’s data.

RBAC is designed to support the introduction of Redis ACL in Redis 6. When you use RBAC with your ElastiCache for Redis cluster, there are some limitations:

• You can’t specify passwords in an access string. You set passwords with CreateUser or ModifyUser calls.
• For user rights, you pass on and off as a part of the access string. If neither is specified in the access string, the user is assigned off and doesn’t have access rights to the replication group.
• You can’t use forbidden and renamed commands. If you specify a forbidden or a renamed command, an exception will be thrown. If you want to use access control lists (ACLs) for a renamed command, specify the original name of the command, in other words the name of the command before it was renamed.
• You can’t use the reset command as a part of an access string. You specify passwords with API parameters, and ElastiCache for Redis manages passwords. Thus, you can’t use reset because it would remove all passwords for a user.
• Redis 6 introduces the ACL LIST command. This command returns a list of users along with the ACL rules applied to each user. ElastiCache for Redis supports the ACL LIST command, but does not include support for password hashes as Redis does. With ElastiCache for Redis, you can use the describe-users operation to get similar information, including the rules contained within the access string. However, describe-users doesn’t retrieve a user password.

Other read-only commands supported by ElastiCache for Redis include ACL WHOAMI, ACL USERS, and ACL CAT. ElastiCache for Redis doesn’t support any other write-based ACL commands.

• The following constraints apply:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Maximum allowed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Users per user group</td>
<td>100</td>
</tr>
<tr>
<td>Number of users</td>
<td>1000</td>
</tr>
<tr>
<td>Number of user groups</td>
<td>100</td>
</tr>
</tbody>
</table>

Using RBAC with ElastiCache for Redis is described in more detail following.

Topics

• Specifying Permissions Using an Access String (p. 491)
Specifying Permissions Using an Access String

To specify permissions to an ElastiCache for Redis replication group, you create an access string and assign it to a user, using either the AWS CLI or AWS Management Console.

Access strings are defined as a list of space-delimited rules which are applied on the user. They define which commands a user can execute and which keys a user can operate on. In order to execute a command, a user must have access to the command being executed and all keys being accessed by the command. Rules are applied from left to right cumulatively, and a simpler string may be used instead of the one provided if there are redundancies in the string provided.

For information about the syntax of the ACL rules, see ACL.

In the following example, the access string represents an active user with access to all available keys and commands.

```
on ~* +@all
```

The access string syntax is broken down as follows:

- **on** – The user is an active user.
- **~*** – Access is given to all available keys.
- **+@all** – Access is given to all available commands.

The preceding settings are the least restrictive. You can modify these settings to make them more secure.

In the following example, the access string represents a user with access restricted to read access on keys that start with "app::" keyspace

```
on -app::* -@all +@read
```

You can refine these permissions further by listing commands the user has access to:

```
+command1 – The user's access to commands is limited to command1.
+@category – The user's access is limited to a category of commands.
```

For information on assigning an access string to a user, see Creating Users and User Groups with the Console and CLI (p. 492).

If you are migrating an existing workload to ElastiCache, you can retrieve the access string by calling ACL LIST, excluding the user and any password hashes.

Applying RBAC to a Replication Group for ElastiCache for Redis

To use ElastiCache for Redis RBAC, you take the following steps:

1. Create one or more users.
2. Create a user group and add users to the group.
3. Assign the user group to a replication group that has in-transit encryption enabled.

These steps are described in detail following.

**Topics**
- Creating Users and User Groups with the Console and CLI (p. 492)
- Managing User Groups with the Console and CLI (p. 496)
- Assigning User Groups to Replication Groups (p. 499)

**Creating Users and User Groups with the Console and CLI**

The user information for RBAC users is a user ID, user name, and optionally a password and an access string. The access string provides the permission level on keys and commands. The user ID is unique to the user, and the user name is what is passed to the engine.

Make sure that the user permissions you provide make sense with the intended purpose of the user group. For example, if you create a user group called *Administrators*, any user you add to that group should have its access string set to full access to keys and commands. For users in an *e-commerce* user group, you might set their access strings to read-only access.

ElastiCache automatically configures a default user with user ID and user name "default" and adds it to all user groups. You can't modify or delete this user. This user is intended for compatibility with the default behavior of previous Redis versions and has an access string that permits it to call all commands and access all keys.

To add proper access control to a cluster, replace this default user with a new one that isn't enabled or uses a strong password. To change the default user, create a new user with the user name set to *default*. You can then swap it with the original default user.

The following procedures shows how to swap the original *default* user with another *default* user that has a modified access string.

**If you are using the older version of the ElastiCache console:**

**To modify the default user on the console**

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. Choose Redis from the navigation pane.
3. Choose User Group Management.
4. For User Group ID, choose the ID that you want to modify. Make sure that you choose the link and not the check box.
5. Choose Swap Default.
6. In the Swap Default window, for Default User choose the user that you want as the default user.
7. Choose Swap. When you do this, any existing connections to a replication group that the original default user has are terminated.

**If you are using the new version of the ElastiCache console:**

**To modify the default user on the console**

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. Choose **Redis** from the navigation pane.
3. Choose **User Group Management**.
4. For **User Group ID**, choose the ID that you want to modify. Make sure that you choose the link and not the check box.
5. Choose **Modify**.
6. In the **Modify** window, choose **Manage** and for **Default User** choose the user that you want as the default user.
7. Choose **Modify**. When you do this, any existing connections to a replication group that the original default user has are terminated.

**To modify the default user with the AWS CLI**

1. Create a new user with the user name `default` by using the following commands.

   For Linux, macOS, or Unix:
   ```bash
   aws elasticache create-user \
   --user-id "new-default-user" \ 
   --user-name "default" \ 
   --engine "REDIS" \ 
   --passwords "a-strong-password" \ 
   --access-string "off +get ~keys*"
   ```

   For Windows:
   ```bash
   aws elasticache create-user ^
   --user-id "new-default-user" ^
   --user-name "default" ^
   --engine "REDIS" ^
   --passwords "a-strong-password" ^
   --access-string "off +get ~keys*"
   ```

2. Create a user group and add the user that you created previously.

   For Linux, macOS, or Unix:
   ```bash
   aws elasticache create-user-group \
   --user-group-id "new-group-2" \ 
   --engine "REDIS" \ 
   --user-ids "new-default-user"
   ```

   For Windows:
   ```bash
   aws elasticache create-user-group ^
   --user-group-id "new-group-2" ^
   --engine "REDIS" ^
   --user-ids "new-default-user"
   ```

3. Swap the new default user with the original default user.

   For Linux, macOS, or Unix:
   ```bash
   aws elasticache modify-user-group \
   --user-group-id test-group \ 
   --user-ids-to-add "new-default-user" \ 
   --user-ids-to-remove "default"
   ```
For Windows:

```
aws elasticache modify-user-group
--user-group-id test-group
--user-ids-to-add "new-default-user"
--user-ids-to-remove "default"
```

When this modify operation is called, any existing connections to a replication group that the original default user has are terminated.

When creating a user, you can set up to two passwords. When you modify a password, any existing connections to replication groups are maintained.

In particular, be aware of these user password constraints when using RBAC for ElastiCache for Redis:

- Passwords must be 16–128 printable characters.
- The following nonalphanumeric characters are not allowed: , " / @.

**Managing Users with the Console and CLI**

Use the following procedure to manage users on the console.

**To manage users on the console**

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. On the Amazon ElastiCache dashboard, choose **User Management**. The following options are available:
   - **Create User** – When creating a user, you enter a user ID, user name, password, and access string. The access string sets the permission level for what keys and commands the user is allowed.
   - **Modify User** – Enables you to update a user's password or change its access string.
   - **Delete User** – The user account will be removed from any User Management Groups to which it belongs.

Use the following procedures to manage users with the AWS CLI.

**To modify a user by using the CLI**

- Use the `modify-user` command to update a user's password or passwords or change a user's access permissions.

When a user is modified, the user groups associated with the user are updated, along with any replication groups associated with the user group. All existing connections are maintained. The following are examples.

For Linux, macOS, or Unix:

```
aws elasticache modify-user \
--user-id user-id-1 \
--access-string "~objects:* -items:* -public:*" \
--no-password-required
```

API Version 2015-02-02

494
For Windows:

```bash
aws elasticache modify-user ^
   --user-id user-id-1 ^
   --access-string "~objects:* ~items:* ~public:*" ^
   --no-password-required
```

The preceding examples return the following response.

```json
{
   "UserId": "user-id-1",
   "UserName": "user-name-1",
   "Status": "modifying",
   "Engine": "redis",
   "AccessString": "off ~objects:* ~items:* ~public:* -@all",
   "UserGroupIds": [
      "new-group-1"
   ],
   "Authentication": {
      "Type": "no-password"
   },
   "ARN": "arn:aws:elasticache:us-east-1:493071037918:user:user-id-1"
}
```

**Note**

We don't recommend using the `nopass` option. If you do, we recommend setting the user's permissions to read-only with access to a limited set of keys.

**To delete a user by using the CLI**

- Use the `delete-user` command to delete a user. The user account is deleted and removed from any user groups to which it belongs. The following is an example.

  For Linux, macOS, or Unix:

  ```bash
  aws elasticache delete-user \
   --user-id user-id-2
  ```

  For Windows:

  ```bash
  aws elasticache delete-user ^
   --user-id user-id-2
  ```

  The preceding examples return the following response.

  ```json
  {
   "UserId": "user-id-2",
   "UserName": "user-name-2",
   "Status": "deleting",
   "Engine": "redis",
   "AccessString": "on ~keys* -@all +get",
   "UserGroupIds": [
      "new-group-1"
   ],
   "Authentication": {
      "Type": "password",
      "PasswordCount": 1
   }
  }
  ```
To see a list of users, call the `describe-users` operation.

```bash
aws elasticache describe-users
{
  "Users": [
    {
      "UserId": "user-id-1",
      "UserName": "user-id-1",
      "Status": "active",
      "Engine": "redis",
      "AccessString": "+get -keys*",
      "UserGroupIds": [],
      "Authentication": {
        "Type": "password",
        "PasswordCount": 1
      }
    }
  ]
}
```

### Managing User Groups with the Console and CLI

You can create user groups to organize and control access of users to one or more replication groups, as shown following.

Use the following procedure to manage user groups using the console.

**To manage user groups using the console**

1. Sign in to the AWS Management Console and open the Amazon ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. On the Amazon ElastiCache dashboard, choose **User Management**.

The following operations are available to create new user groups:

- **Create** – When you create a user group, you add users and then assign the user groups to replication groups. For example, you can create an `Admin` user group for users who have administrative roles on a cluster.
  
  **Important**
  
  When you create a user group, you are required to include the default user.

- **Add Users** – Add users to the user group.
- **Remove Users** – Remove users from the user group. When users are removed from a user group, any existing connections they have to a replication group are terminated.
- **Delete** – Use this to delete a user group. Note that the user group itself, not the users belonging to the group, will be deleted.

For existing user groups, you can do the following:

- **Add Users** – Add existing users to the user group.
- **Delete Users** – Removes existing users from the user group.

  **Note**
  
  Users are removed from the user group, but not deleted from the system.
Use the following procedures to manage user groups using the CLI.

**To create a new user group and add a user by using the CLI**

- Use the `create-user-group` command as shown following.

  For Linux, macOS, or Unix:

  ```
  aws elasticache create-user-group \
  --user-group-id "new-group-1" \ 
  --engine "REDIS" \ 
  --user-ids user-id-1, user-id-2
  ```

  For Windows:

  ```
  aws elasticache create-user-group ^ 
  --user-group-id "new-group-1" ^ 
  --engine "REDIS" ^ 
  --user-ids user-id-1, user-id-2
  ```

  The preceding examples return the following response.

  ```
  { 
  "UserGroupId": "new-group-1", 
  "Status": "creating", 
  "Engine": "redis", 
  "UserIds": [ 
  "user-id-1", 
  "user-id-2" 
  ], 
  "ReplicationGroups": [], 
  "ARN": "arn:aws:elasticache:us-east-1:493071037918:usergroup:new-group-1"
  }
  ```

- Use the `modify-user-group` command as shown following.

  For Linux, macOS, or Unix:

  ```
  aws elasticache modify-user-group --user-group-id new-group-1 \
  --user-ids-to-add user-id-3 \ 
  --user-ids-to-remove user-2
  ```

  For Windows:

  ```
  aws elasticache modify-user-group --user-group-id new-group-1 ^ 
  --user-ids-to-add userid-3 ^ 
  --user-ids-to-removere userid-2
  ```

  The preceding examples return the following response.

  ```
  { 
  "UserGroupId": "new-group-1", 
  "Status": "modifying", 
  "Engine": "redis", 
  "UserIds": [ 
  ]
  }
Data security in Amazon ElastiCache

```
"user-id-1",
"user-id-2"
],
"PendingChanges": {
  "UserIdsToRemove": [
    "user-id-2"
  ],
  "UserIdsToAdd": [
    "user-id-3"
  ]
},
"ReplicationGroups": [],
"ARN": "arn:aws:elasticache:us-east-1:493071037918:usergroup:new-group-1"
}
```

**Note**
Any open connections belonging to a user removed from a user group are ended by this command.

**To delete a user group by using the CLI**

- Use the `delete-user-group` command as shown following. The user group itself, not the users belonging to the group, is deleted.

  **For Linux, macOS, or Unix:**
  ```
  aws elasticache delete-user-group /
  --user-group-id
  ```

  **For Windows:**
  ```
  aws elasticache delete-user-group ^
  --user-group-id
  ```

  The preceding examples return the following response.

  ```
  aws elasticache delete-user-group --user-group-id "new-group-1"
  {
    "UserId": "new-group-1",
    "Status": "deleting",
    "Engine": "redis",
    "UserIds": [
      "user-id-1",
      "user-id-3"
    ],
    "ReplicationGroups": [],
    "ARN": "arn:aws:elasticache:us-east-1:493071037918:usergroup:new-group-1"
  }
  ```

  **To see a list of user groups, you can call the `describe-user-groups` operation.**

  ```
  aws elasticache describe-user-groups \\n  --user-group-id test-group
  ```

  ```
  {
    "UserGroups": [{
      "UserGroupId": "test-group",
      "Status": "deleting",
      "Engine": "redis",
      "UserIds": [
        "user-id-1",
        "user-id-2"
      ],
      "ReplicationGroups": [],
      "ARN": "arn:aws:elasticache:us-east-1:493071037918:usergroup:new-group-1"
    }
  ```
Assigning User Groups to Replication Groups

After you have created a user group and added users, the final step in implementing RBAC is assigning the user group to a replication group.

Assigning User Groups to Replication Groups Using the Console

To add a user group to a replication using the AWS Management Console, do the following:

- For cluster mode disabled, see Creating a Redis (cluster mode disabled) cluster (Console) (p. 47)
- For cluster mode enabled, see Creating a Redis (cluster mode enabled) cluster (Console) (p. 133)

Assigning User Groups to Replication Groups Using the AWS CLI

The following AWS CLI operation creates a replication group with encryption in transit (TLS) enabled and the user-group-ids parameter with the value my-user-group-id. Replace the subnet group sng-test with a subnet group that exists.

Key Parameters

- --engine – Must be redis.
- --engine-version – Must be 6.0 or later.
- --transit-encryption-enabled – Required for authentication and for associating a user group.
- --user-group-ids – This value provides user groups comprised of users with specified access permissions for the cluster.
- --cache-subnet-group – Required for associating a user group.

For Linux, macOS, or Unix:

```
aws elasticache create-replication-group \
  --replication-group-id "new-replication-group" \
  --replication-group-description "new-replication-group" \
  --engine "redis" \
  --engine-version "6.0" \
  --cache-node-type cache.m5.large \
  --transit-encryption-enabled \
  --user-group-ids "new-group-1" \
  --cache-subnet-group "cache-subnet-group"
```

For Windows:

```
aws elasticache create-replication-group ^
  --replication-group-id "new-replication-group" ^
  --replication-group-description "new-replication-group" ^
  --engine "redis" ^
  --engine-version "6.0" ^
  --cache-node-type cache.m5.large ^
  --transit-encryption-enabled ^
```
The preceding code returns the following response.

```
{
    "ReplicationGroup": {
        "ReplicationGroupId": "new-replication-group",
        "Description": "new-replication-group",
        "Status": "creating",
        "PendingModifiedValues": {},
        "MemberClusters": [
            "new-replication-group-001"
        ],
        "AutomaticFailover": "disabled",
        "SnapshotRetentionLimit": 0,
        "SnapshotWindow": "10:30-11:30",
        "ClusterEnabled": false,
        "UserGroupIds": ["new-group-1"]
    }
}
```

The following AWS CLI operation modifies a replication group with encryption in transit (TLS) enabled and the `user-group-ids` parameter with the value `my-user-group-id`.

For Linux, macOS, or Unix:

```
aws elasticache modify-replication-group \
    --replication-group-id replication-group-1 \
    --user-group-ids-to-remove "new-group-1" \
    --user-group-ids-to-add "new-group-2"
```

For Windows:

```
aws elasticache modify-replication-group ^
    --replication-group-id replication-group-1 ^
    --user-group-ids-to-remove "new-group-1" ^
    --user-group-ids-to-add "new-group-2"
```

The preceding code returns the following response (abbreviated):

```
{
    "ReplicationGroupId": "replication-group-1",
    "PendingChanges": {"UserGroups": {
        "UserGroupIdsToRemove": ["new-group-1"],
        "UserGroupIdsToAdd": ["new-group-2"]
    }
}
```
aws elasticache modify-replication-group --replication-group-id replication-group-1 --user-group-ids-to-remove "new-group-1" --user-group-ids-to-add "new-group-2"

```
{
  "ReplicationGroupId": "replication-group-1",
  "PendingChanges": {
    "UserGroups": {
      "UserGroupIdsToRemove": ["new-group-1"],
      "UserGroupIdsToAdd": ["new-group-2"]
    }
  }
}
```

Note the PendingChanges in the response. Any modifications made to a replication group are updated asynchronously. You can monitor this progress by viewing the events. For more information, see Viewing ElastiCache events (p. 611).

**Migrating from Redis AUTH to RBAC**

If you are using Redis AUTH as described in Authenticating users with the Redis AUTH command (p. 478) and want to migrate to using RBAC, use the following procedures.

Use the following procedure to migrate from Redis AUTH to RBAC using the console.

**To migrate from Redis AUTH to RBAC using the console**

2. From the list in the upper-right corner, choose the AWS Region where the cluster that you want to modify is located.
3. In the navigation pane, choose the engine running on the cluster that you want to modify.
   
   A list of the chosen engine's clusters appears.
4. In the list of clusters, for the cluster that you want to modify, choose its name.
5. For **Actions**, choose **Modify**.
   
   The Modify Cluster window appears.
6. For **Access Control Option**, choose **User Group Access Control List**.
7. For **User Group Access Control List**, choose a user group.
8. Choose **Modify**.

Use the following procedure to migrate from Redis AUTH to RBAC using the CLI.

**To migrate from Redis AUTH to RBAC using the CLI**

- Use the `modify-replication-group` command as shown following.

  For Linux, macOS, or Unix:

  ```
  aws elasticache modify-replication-group --replication-group-id test
  ```
Internetwork traffic privacy

Amazon ElastiCache uses the following techniques to secure your cache data and protect it from unauthorized access:

- Amazon VPCs and ElastiCache security (p. 502) explains the type of security group you need for your installation.
- Identity and access management in Amazon ElastiCache (p. 539) for granting and limiting actions of users, groups, and roles.

Amazon VPCs and ElastiCache security

Because data security is important, ElastiCache provides means for you to control who has access to your data. How you control access to your data is dependent upon whether or not you launched your clusters in an Amazon Virtual Private Cloud (Amazon VPC) or Amazon EC2-Classic.

Important

We have deprecated the use of Amazon EC2-Classic for launching ElastiCache clusters. All current generation nodes are launched in Amazon Virtual Private Cloud only.

The Amazon Virtual Private Cloud (Amazon VPC) service defines a virtual network that closely resembles a traditional data center. When you configure your Amazon VPC you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings. You can also add a cache cluster to the virtual network, and control access to the cache cluster by using Amazon VPC security groups.

This section explains how to manually configure an ElastiCache cluster in an Amazon VPC. This information is intended for users who want a deeper understanding of how ElastiCache and Amazon VPC work together.

Topics

- Understanding ElastiCache and Amazon VPCs (p. 504)
- Access Patterns for Accessing an ElastiCache Cluster in an Amazon VPC (p. 508)
- Migrating an EC2-Classic cluster into a VPC (p. 514)
- Creating a Virtual Private Cloud (VPC) (p. 516)
- Creating a replication group in an Amazon VPC (p. 518)
- Connecting to a cache cluster running in an Amazon VPC (p. 519)
Understanding ElastiCache and Amazon VPCs

ElastiCache is fully integrated with the Amazon Virtual Private Cloud (Amazon VPC). For ElastiCache users, this means the following:

- If your AWS account supports only the EC2-VPC platform, ElastiCache always launches your cluster in an Amazon VPC.
- If you're new to AWS, your clusters will be deployed into an Amazon VPC. A default VPC will be created for you automatically.
- If you have a default VPC and don't specify a subnet when you launch a cluster, the cluster launches into your default Amazon VPC.

For more information, see Detecting Your Supported Platforms and Whether You Have a Default VPC.

With Amazon Virtual Private Cloud, you can create a virtual network in the AWS cloud that closely resembles a traditional data center. You can configure your Amazon VPC, including selecting its IP address range, creating subnets, and configuring route tables, network gateways, and security settings.

The basic functionality of ElastiCache is the same in a virtual private cloud; ElastiCache manages software upgrades, patching, failure detection and recovery whether your clusters are deployed inside or outside an Amazon VPC.

ElastiCache cache nodes deployed outside an Amazon VPC are assigned an IP address to which the endpoint/DNS name resolves. This provides connectivity from Amazon Elastic Compute Cloud (Amazon EC2) instances. When you launch an ElastiCache cluster into an Amazon VPC private subnet, every cache node is assigned a private IP address within that subnet.

Overview of ElastiCache in an Amazon VPC

The following diagram and table describe the Amazon VPC environment, along with ElastiCache clusters and Amazon EC2 instances that are launched in the Amazon VPC.
The Amazon VPC is an isolated portion of the AWS Cloud that is assigned its own block of IP addresses.

An Internet gateway connects your Amazon VPC directly to the Internet and provides access to other AWS resources such as Amazon Simple Storage Service (Amazon S3) that are running outside your Amazon VPC.

An Amazon VPC subnet is a segment of the IP address range of an Amazon VPC where you can isolate AWS resources according to your security and operational needs.

A routing table in the Amazon VPC directs network traffic between the subnet and the Internet. The Amazon VPC has an implied router, which is symbolized in this diagram by the circle with the R.
An Amazon VPC security group controls inbound and outbound traffic for your ElastiCache clusters and Amazon EC2 instances.

You can launch an ElastiCache cluster in the subnet. The cache nodes have private IP addresses from the subnet's range of addresses.

You can also launch Amazon EC2 instances in the subnet. Each Amazon EC2 instance has a private IP address from the subnet's range of addresses. The Amazon EC2 instance can connect to any cache node in the same subnet.

For an Amazon EC2 instance in your Amazon VPC to be reachable from the Internet, you need to assign a static, public address called an Elastic IP address to the instance.

**Why use the Amazon VPC instead of EC2 classic with your ElastiCache deployment?**

Launching your instances into an Amazon VPC allows you to:

- Assign static private IP addresses to your instances that persist across starts and stops.
- Assign multiple IP addresses to your instances.
- Define network interfaces, and attach one or more network interfaces to your instances.
- Change security group membership for your instances while they're running.
- Control the outbound traffic from your instances (egress filtering) in addition to controlling the inbound traffic to them (ingress filtering).
- Add an additional layer of access control to your instances in the form of network access control lists (ACL).
- Run your instances on single-tenant hardware.

For a comparison of Amazon EC2 Classic, Default VPC, and Non-default VPC, see Differences Between EC2-Classic and EC2-VPC.

The Amazon VPC must allow non-dedicated Amazon EC2 instances. You cannot use ElastiCache in an Amazon VPC that is configured for dedicated instance tenancy.

**Prerequisites**

To create an ElastiCache cluster within an Amazon VPC, your Amazon VPC must meet the following requirements:

- The Amazon VPC must allow nondedicated Amazon EC2 instances. You cannot use ElastiCache in an Amazon VPC that is configured for dedicated instance tenancy.
- A cache subnet group must be defined for your Amazon VPC. ElastiCache uses that cache subnet group to select a subnet and IP addresses within that subnet to associate with your cache nodes.
- A cache security group must be defined for your Amazon VPC, or you can use the default provided.
- CIDR blocks for each subnet must be large enough to provide spare IP addresses for ElastiCache to use during maintenance activities.

**Routing and security**

You can configure routing in your Amazon VPC to control where traffic flows (for example, to the Internet gateway or virtual private gateway). With an Internet gateway, your Amazon VPC has direct access to other AWS resources that are not running in your Amazon VPC. If you choose to have only a virtual private gateway with a connection to your organization's local network, you can route your...
Internet-bound traffic over the VPN and use local security policies and firewall to control egress. In that case, you incur additional bandwidth charges when you access AWS resources over the Internet.

You can use Amazon VPC security groups to help secure the ElastiCache clusters and Amazon EC2 instances in your Amazon VPC. Security groups act like a firewall at the instance level, not the subnet level.

**Note**
We strongly recommend that you use DNS names to connect to your cache nodes, as the underlying IP address can change if you reboot the cache node.

### Amazon VPC documentation

Amazon VPC has its own set of documentation to describe how to create and use your Amazon VPC. The following table gives links to the Amazon VPC guides.

<table>
<thead>
<tr>
<th>Description</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>How to get started using Amazon VPC</td>
<td>Getting started with Amazon VPC</td>
</tr>
<tr>
<td>How to use Amazon VPC through the AWS Management Console</td>
<td>Amazon VPC User Guide</td>
</tr>
<tr>
<td>Complete descriptions of all the Amazon VPC commands</td>
<td>Amazon EC2 Command Line Reference (the Amazon VPC commands are found in the Amazon EC2 reference)</td>
</tr>
<tr>
<td>Complete descriptions of the Amazon VPC API operations, data types, and errors</td>
<td>Amazon EC2 API Reference (the Amazon VPC API operations are found in the Amazon EC2 reference)</td>
</tr>
<tr>
<td>Information for the network administrator who needs to configure the gateway at your end of an optional IPsec VPN connection</td>
<td>What is AWS Site-to-Site VPN?</td>
</tr>
</tbody>
</table>

For more detailed information about Amazon Virtual Private Cloud, see [Amazon Virtual Private Cloud](https://aws.amazon.com/documentation/vpc/).
Access Patterns for Accessing an ElastiCache Cluster in an Amazon VPC

Amazon ElastiCache supports the following scenarios for accessing a cluster in an Amazon VPC:

**Contents**
- Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in the Same Amazon VPC (p. 508)
- Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in Different Amazon VPCs (p. 509)
  - Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in Different Amazon VPCs in the Same Region (p. 510)
  - Using Transit Gateway (p. 511)
  - Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in Different Amazon VPCs in Different Regions (p. 511)
    - Using Transit VPC (p. 511)
- Accessing an ElastiCache Cluster from an Application Running in a Customer's Data Center (p. 512)
  - Accessing an ElastiCache Cluster from an Application Running in a Customer's Data Center Using VPN Connectivity (p. 512)
  - Accessing an ElastiCache Cluster from an Application Running in a Customer's Data Center Using Direct Connect (p. 513)

### Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in the Same Amazon VPC

The most common use case is when an application deployed on an EC2 instance needs to connect to a Cluster in the same VPC.

The following diagram illustrates this scenario

![Diagram showing VPC, EC2 instance, and ElastiCache cluster](image)

The simplest way to manage access between EC2 instances and clusters in the same VPC is to do the following:

1. Create a VPC security group for your cluster. This security group can be used to restrict access to the cluster instances. For example, you can create a custom rule for this security group that allows TCP access using the port you assigned to the cluster when you created it and an IP address you will use to access the cluster.

   The default port for Redis clusters and replication groups is 6379.
2. Create a VPC security group for your EC2 instances (web and application servers). This security group can, if needed, allow access to the EC2 instance from the Internet via the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.

3. Create custom rules in the security group for your Cluster that allow connections from the security group you created for your EC2 instances. This would allow any member of the security group to access the clusters.

**Note**
If you are planning to use Local Zones, ensure that you have enabled them. When you create a subnet group in that local zone, your VPC is extended to that Local Zone and your VPC will treat the subnet as any subnet in any other Availability Zone. All relevant gateways and route tables will be automatically adjusted.

**To create a rule in a VPC security group that allows connections from another security group**

2. In the navigation pane, choose **Security Groups**.
3. Select or create a security group that you will use for your Cluster instances. Under **Inbound Rules**, select **Edit Inbound Rules** and then select **Add Rule**. This security group will allow access to members of another security group.
4. From **Type** choose **Custom TCP Rule**.
   a. For **Port Range**, specify the port you used when you created your cluster. The default port for Redis clusters and replication groups is 6379.
   b. In the **Source** box, start typing the ID of the security group. From the list select the security group you will use for your Amazon EC2 instances.
5. Choose **Save** when you finish.

**Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in Different Amazon VPCs**

When your Cluster is in a different VPC from the EC2 instance you are using to access it, there are several ways to access the cluster. If the Cluster and EC2 instance are in different VPCs but in the same region, you can use VPC peering. If the Cluster and the EC2 instance are in different regions, you can create VPN connectivity between regions.

**Topics**
- Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in Different Amazon VPCs in the Same Region (p. 510)
• **Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in Different Amazon VPCs in Different Regions (p. 511)**

**Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in Different Amazon VPCs in the Same Region**

The following diagram illustrates accessing a cluster by an Amazon EC2 instance in a different Amazon VPC in the same region using an Amazon VPC peering connection.

![Cluster accessed by an Amazon EC2 instance in a different Amazon VPC within the same Region - VPC Peering Connection](image)

A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Instances in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own Amazon VPCs, or with an Amazon VPC in another AWS account within a single region. To learn more about Amazon VPC peering, see the VPC documentation.

**To access a cluster in a different Amazon VPC over peering**

1. Make sure that the two VPCs do not have an overlapping IP range or you will not be able to peer them.
2. Peer the two VPCs. For more information, see Creating and Accepting an Amazon VPC Peering Connection.
3. Update your routing table. For more information, see Updating Your Route Tables for a VPC Peering Connection.

Following is what the route tables look like for the example in the preceding diagram. Note that `pcx-a894f1c1` is the peering connection.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.16.0.0/16</td>
<td>local</td>
<td>10.10.0.0/16</td>
<td>local</td>
</tr>
<tr>
<td>10.10.0.0/16</td>
<td><code>pcx-a894f1c1</code></td>
<td>0.0.0.0/0</td>
<td><code>igw-bfcccc8</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>172.16.0.0/16</td>
<td><code>pcx-a894f1c1</code></td>
</tr>
</tbody>
</table>

**VPC Routing Table**
4. Modify the Security Group of your ElastiCache cluster to allow inbound connection from the Application security group in the peered VPC. For more information, see Reference Peer VPC Security Groups.

Accessing a cluster over a peering connection will incur additional data transfer costs.

**Using Transit Gateway**

A transit gateway enables you to attach VPCs and VPN connections in the same AWS Region and route traffic between them. A transit gateway works across AWS accounts, and you can use AWS Resource Access Manager to share your transit gateway with other accounts. After you share a transit gateway with another AWS account, the account owner can attach their VPCs to your transit gateway. A user from either account can delete the attachment at any time.

You can enable multicast on a transit gateway, and then create a transit gateway multicast domain that allows multicast traffic to be sent from your multicast source to multicast group members over VPC attachments that you associate with the domain.

You can also create a peering connection attachment between transit gateways in different AWS Regions. This enables you to route traffic between the transit gateways’ attachments across different Regions.

For more information, see Transit gateways.

**Accessing an ElastiCache Cluster when it and the Amazon EC2 Instance are in Different Amazon VPCs in Different Regions**

**Using Transit VPC**

An alternative to using VPC peering, another common strategy for connecting multiple, geographically disperse VPCs and remote networks is to create a transit VPC that serves as a global network transit center. A transit VPC simplifies network management and minimizes the number of connections required to connect multiple VPCs and remote networks. This design can save time and effort and also reduce costs, as it is implemented virtually without the traditional expense of establishing a physical presence in a colocation transit hub or deploying physical network gear.

**Connecting across different VPCs in different regions**

Once the Transit Amazon VPC is established, an application deployed in a “spoke” VPC in one region can connect to an ElastiCache cluster in a “spoke” VPC within another region.
To access a cluster in a different VPC within a different AWS Region

1. Deploy a Transit VPC Solution. For more information, see, AWS Transit Gateway.
2. Update the VPC routing tables in the App and Cache VPCs to route traffic through the VGW (Virtual Private Gateway) and the VPN Appliance. In case of Dynamic Routing with Border Gateway Protocol (BGP) your routes may be automatically propagated.
3. Modify the Security Group of your ElastiCache cluster to allow inbound connection from the Application instances IP range. Note that you will not be able to reference the application server Security Group in this scenario.

Accessing a cluster across regions will introduce networking latencies and additional cross-region data transfer costs.

Accessing an ElastiCache Cluster from an Application Running in a Customer's Data Center

Another possible scenario is a Hybrid architecture where clients or applications in the customer’s data center may need to access an ElastiCache Cluster in the VPC. This scenario is also supported providing there is connectivity between the customers’ VPC and the data center either through VPN or Direct Connect.

Topics

- Accessing an ElastiCache Cluster from an Application Running in a Customer's Data Center Using VPN Connectivity (p. 512)
- Accessing an ElastiCache Cluster from an Application Running in a Customer's Data Center Using Direct Connect (p. 513)

Accessing an ElastiCache Cluster from an Application Running in a Customer's Data Center Using VPN Connectivity

The following diagram illustrates accessing an ElastiCache cluster from an application running in your corporate network using VPN connections.
Connecting to ElastiCache from your data center via a VPN

To access a cluster in a VPC from on-prem application over VPN connection

1. Establish VPN Connectivity by adding a hardware Virtual Private Gateway to your VPC. For more information, see Adding a Hardware Virtual Private Gateway to Your VPC.
2. Update the VPC routing table for the subnet where your ElastiCache cluster is deployed to allow traffic from your on-premises application server. In case of Dynamic Routing with BGP your routes may be automatically propagated.
3. Modify the Security Group of your ElastiCache cluster to allow inbound connection from the on-premises application servers.

Accessing a cluster over a VPN connection will introduce networking latencies and additional data transfer costs.

Accessing an ElastiCache Cluster from an Application Running in a Customer's Data Center Using Direct Connect

The following diagram illustrates accessing an ElastiCache cluster from an application running on your corporate network using Direct Connect.
Connecting to ElastiCache from your data center via Direct Connect

To access an ElastiCache cluster from an application running in your network using Direct Connect

1. Establish Direct Connect connectivity. For more information, see, Getting Started with AWS Direct Connect.
2. Modify the Security Group of your ElastiCache cluster to allow inbound connection from the on-premises application servers.

Accessing a cluster over DX connection may introduce networking latencies and additional data transfer charges.

Migrating an EC2-Classic cluster into a VPC

Some legacy ElastiCache clusters on the EC2-Classic platform are not in an Amazon VPC. You can use the AWS Management Console to move it into an Amazon VPC using the following steps:

Migrating an EC2-Classic Redis cluster into a VPC

Note
To determine if your cluster is on the EC2-Classic platform, see Determine the cluster's platform (p. 167).

1. You first need to create a Virtual Private Cloud (VPC). Follow the steps to create a VPC at Creating a Virtual Private Cloud (VPC).
2. Once you have created the VPC, follow the steps to create a subnet group at Subnets and Subnet Groups.

3. Your VPC comes with a default security group. You can choose to use it or you can create one by following the steps at Security groups for your VPC in the Amazon VPC documentation.

4. In order to add your cluster to a VPC, you must first create a backup of it and then restore the backup into the VPC. Go to the ElastiCache for Redis console and choose your cluster. Choose Actions and then choose Backup. Enter a Backup Name and then choose Create Backup.

5. Once the backup is created, you add it to the VPC you created previously. Return to the ElastiCache for Redis console and choose Backups. Choose the backup you created and then choose Restore.

6. In Cluster name, enter a name for your cluster.

7. In Choose a Subnet group, select the subnet group you created previously and then choose Continue.

Once the restoration process is complete, your cluster will be available in the VPC.

Note
Previous generation node types might not be supported on the VPC platform. For a full list of VPC supported node types, see Supported node types by AWS Region (p. 101).
Creating a Virtual Private Cloud (VPC)

In this example, you create an Amazon VPC with a private subnet for each Availability Zone.

Creating an Amazon VPC (Console)

To create an ElastiCache cluster inside an Amazon Virtual Private Cloud

1. Sign in to the AWS Management Console, and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Create a new Amazon VPC by using the Amazon Virtual Private Cloud wizard:
   a. In the navigation list, choose VPC Dashboard.
   b. Choose Start VPC Wizard.
   c. In the Amazon VPC wizard, choose VPC with Public and Private Subnets, and then choose Next.
   d. On the VPC with Public and Private Subnets page, keep the default options, and then choose Create VPC.
   e. In the confirmation message that appears, choose Close.
3. Confirm that there are two subnets in your Amazon VPC, a public subnet and a private subnet. These subnets are created automatically.
   a. In the navigation list, choose Subnets.
   b. In the list of subnets, find the two subnets that are in your Amazon VPC:

   ![Subnets Table]

   The public subnet will have one fewer available IP address, because the wizard creates an Amazon EC2 NAT instance and an Elastic IP address (for which Amazon EC2 rates apply) for outbound communication to the Internet from your private subnet.

   **Tip**
   Make a note of your two subnet identifiers, and which is public and private. You will need this information later when you launch your cache clusters and add an Amazon EC2 instance to your Amazon VPC.

4. Create an Amazon VPC security group. You will use this group for your cache cluster and your Amazon EC2 instance.
   a. In the navigation pane of the Amazon VPC Management console, choose Security Groups.
   c. Type a name and a description for your security group in the corresponding boxes. In the VPC box, choose the identifier for your Amazon VPC.
d. When the settings are as you want them, choose Yes, Create.

5. Define a network ingress rule for your security group. This rule will allow you to connect to your Amazon EC2 instance using Secure Shell (SSH).

a. In the navigation list, choose Security Groups.

b. Find your security group in the list, and then choose it.

c. Under Security Group, choose the Inbound tab. In the Create a new rule box, choose SSH, and then choose Add Rule.

d. Set the following values for your new inbound rule to allow HTTP access:

- Type: HTTP
- Source: 0.0.0.0/0

Choose Apply Rule Changes.

Now you are ready to create a cache subnet group and launch a cache cluster in your Amazon VPC.

- Creating a subnet group (p. 526)
- Creating a Redis (cluster mode disabled) cluster (Console) (p. 47).
Creating a replication group in an Amazon VPC

Creating a replication group in an Amazon VPC (Console)

To launch a Redis (cluster mode disabled) replication group in a VPC, see Creating a Redis (Cluster Mode Disabled) replication group from scratch (p. 273)

To launch a Redis (cluster mode enabled) replication group, see Creating a Redis (Cluster Mode Enabled) cluster (Console) (p. 280)

You have now launched a Redis replication group inside an Amazon VPC. For an example of one way to connect to your new replication group running in the Amazon VPC, continue to Connecting to a cache cluster running in an Amazon VPC (p. 519).
Connecting to a cache cluster running in an Amazon VPC

This example shows how to launch an Amazon EC2 instance in your Amazon VPC. You can then log in to this instance and access the ElastiCache cluster that is running in the Amazon VPC.

Connecting to a cache cluster running in an Amazon VPC (Console)

In this example, you create an Amazon EC2 instance in your Amazon VPC. You can use this Amazon EC2 instance to connect to cache nodes running in the Amazon VPC.

Note
For information about using Amazon EC2, see the Amazon EC2 Getting Started Guide in the Amazon EC2 documentation.

To create an Amazon EC2 instance in your Amazon VPC using the Amazon EC2 console

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the console, choose Launch Instance and follow these steps:
3. On the Choose an Amazon Machine Image (AMI) page, choose the 64-bit Amazon Linux AMI, and then choose Select.
4. On the Choose an Instance Type page, choose 3. Configure Instance.
5. On the Configure Instance Details page, make the following selections:
   a. In the Network list, choose your Amazon VPC.
   b. In the Subnet list, choose your public subnet.

   When the settings are as you want them, choose 4. Add Storage.
7. On the Tag Instance page, type a name for your Amazon EC2 instance, and then choose 6. Configure Security Group.
8. On the Configure Security Group page, choose Select an existing security group. For more information on security groups, see Amazon EC2 security groups for Linux instances.
Choose the name of your Amazon VPC security group, and then choose **Review and Launch**.

9. On the **Review Instance and Launch** page, choose **Launch**.

10. In the **Select an existing key pair or create a new key pair** window, specify a key pair that you want to use with this instance.

    **Note**
    For information about managing key pairs, see the Amazon EC2 Getting Started Guide.

11. When you are ready to launch your Amazon EC2 instance, choose **Launch**.

You can now assign an Elastic IP address to the Amazon EC2 instance that you just created. You need to use this IP address to connect to the Amazon EC2 instance.

**To assign an elastic IP address (Console)**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation list, choose Elastic IPs.
3. Choose **Allocate Elastic IP address**.
4. In the **Allocate Elastic IP address** dialog box, accept the default **Network Border Group** and choose **Allocate**.
5. Choose the Elastic IP address that you just allocated from the list and choose **Associate Address**.
6. In the **Associate Address** dialog box, in the **Instance** box, choose the ID of the Amazon EC2 instance that you launched.

    In the **Private IP address** box, select the box to obtain the private IP address and then choose **Associate**.

    You can now use SSH to connect to the Amazon EC2 instance using the Elastic IP address that you created.

**To connect to your Amazon EC2 instance**

- Open a command window. At the command prompt, issue the following command, replacing `mykeypair.pem` with the name of your key pair file and `54.207.55.251` with your Elastic IP address.
Important
Do not log out of your Amazon EC2 instance yet.

You are now ready to interact with your ElastiCache cluster. Before you can do that, if you haven't already done so, you need to install the `telnet` utility.

To install `telnet` and interact with your cache cluster (AWS CLI)

1. Open a command window. At the command prompt, issue the following command. At the confirmation prompt, type `y`.

   ```bash
   sudo yum install telnet
   ```

   Output omitted...

   Total download size: 63 k
   Installed size: 109 k
   Is this ok [y/N]: y
   Downloading Packages:
   telnet-0.17-47.7.amzn1.x86_64.rpm |  63 kB 00:00
   ...
   Complete!

2. Use `telnet` to connect to your cache node endpoint over port 6379. Replace the hostname shown below with the hostname of your cache node.

   ```bash
   telnet my-cache-cluster.7wufxa.0001.use1.cache.amazonaws.com 6379
   ```

   You are now connected to the cache engine and can issue commands. In this example, you add a data item to the cache and then get it immediately afterward. Finally, you'll disconnect from the cache node.

   To store a key and a value, type the following two lines:

   ```bash
   set mykey myvalue
   ```

   The cache engine responds with the following:

   ```bash
   OK
   ```

   To retrieve the value for `mykey`, type the following:

   ```bash
   get mykey
   ```

   To disconnect from the cache engine, type the following:
3. Go to the ElastiCache console at https://console.aws.amazon.com/elasticache/ and obtain the endpoint for one of the nodes in your cache cluster. For more information, Finding connection endpoints for Redis.

4. Use `telnet` to connect to your cache node endpoint over port 6379. Replace the hostname shown below with the hostname of your cache node.

```
telnet my-cache-cluster.7wufxa.0001.use1.cache.amazonaws.com 6379
```

You are now connected to the cache engine and can issue commands. In this example, you add a data item to the cache and then get it immediately afterward. Finally, you'll disconnect from the cache node.

To store a key and a value, type the following:

```
set mykey myvalue
```

The cache engine responds with the following:

```
OK
```

To retrieve the value for `mykey`, type the following:

```
get mykey
```

The cache engine responds with the following:

```
get mykey
myvalue
```

To disconnect from the cache engine, type the following:

```
quit
```

**Important**

To avoid incurring additional charges on your AWS account, be sure to delete any AWS resources you no longer want after trying these examples.

---

**Amazon ElastiCache API and interface VPC endpoints (AWS PrivateLink)**

You can establish a private connection between your VPC and Amazon ElastiCache API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by AWS PrivateLink. AWS PrivateLink allows you to privately access Amazon ElastiCache API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection.

Instances in your VPC don't need public IP addresses to communicate with Amazon ElastiCache API endpoints. Your instances also don't need public IP addresses to use any of the available ElastiCache API
operations. Traffic between your VPC and Amazon ElastiCache doesn't leave the Amazon network. Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see Elastic network interfaces in the Amazon EC2 User Guide.

- For more information about VPC endpoints, see Interface VPC endpoints (AWS PrivateLink) in the Amazon VPC User Guide.
- For more information about ElastiCache API operations, see ElastiCache API operations.

After you create an interface VPC endpoint, if you enable private DNS hostnames for the endpoint, the default ElastiCache endpoint (https://elasticache.Region.amazonaws.com) resolves to your VPC endpoint. If you do not enable private DNS hostnames, Amazon VPC provides a DNS endpoint name that you can use in the following format:

VPC_Endpoint_ID.elasticache.Region.vpce.amazonaws.com

For more information, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide. ElastiCache supports making calls to all of its API Actions inside your VPC.

Note
Private DNS hostnames can be enabled for only one VPC endpoint in the VPC. If you want to create an additional VPC endpoint then private DNS hostname should be disabled for it.

Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon ElastiCache API endpoints, ensure that you review Interface endpoint properties and limitations in the Amazon VPC User Guide. All ElastiCache API operations relevant to managing Amazon ElastiCache resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for ElastiCache API endpoints. By default, full access to ElastiCache API operations is allowed through the endpoint. For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Creating an interface VPC endpoint for the ElastiCache API

You can create a VPC endpoint for the Amazon ElastiCache API using either the Amazon VPC console or the AWS CLI. For more information, see Creating an interface endpoint in the Amazon VPC User Guide.

After you create an interface VPC endpoint, you can enable private DNS hostnames for the endpoint. When you do, the default Amazon ElastiCache endpoint (https://elasticache.Region.amazonaws.com) resolves to your VPC endpoint. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint by using elasticache.cn-north-1.amazonaws.com.cn for Beijing and elasticache.cn-northwest-1.amazonaws.com.cn for Ningxia. For more information, see Accessing a service through an interface endpoint in the Amazon VPC User Guide.

Creating a VPC endpoint policy for the Amazon ElastiCache API

You can attach an endpoint policy to your VPC endpoint that controls access to the ElastiCache API. The policy specifies the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.
Example VPC endpoint policy for ElastiCache API actions

The following is an example of an endpoint policy for the ElastiCache API. When attached to an endpoint, this policy grants access to the listed ElastiCache API actions for all principals on all resources.

```json

{
    "Statement": [{
        "Principal": "*",
        "Effect": "Allow",
        "Action": ["elasticache:CreateCacheCluster",
                    "elasticache:ModifyCacheCluster",
                    "elasticache:CreateSnapshot"],
        "Resource": "*"
    }]

}
```

Example VPC endpoint policy that denies all access from a specified AWS account

The following VPC endpoint policy denies AWS account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```json

{
    "Statement": [{
        "Action": "*",
        "Effect": "Allow",
        "Resource": "*",
        "Principal": "*"
    },
    {
        "Action": "*",
        "Effect": "Deny",
        "Resource": "*",
        "Principal": {
            "AWS": [
                "123456789012"
            ]
        }
    }
}
```

Subnets and subnet groups

A subnet group is a collection of subnets (typically private) that you can designate for your clusters running in an Amazon Virtual Private Cloud (VPC) environment.

If you create a cluster in an Amazon VPC, you must specify a subnet group. ElastiCache uses that subnet group to choose a subnet and IP addresses within that subnet to associate with your nodes.

This section covers how to create and leverage subnets and subnet groups to manage access to your ElastiCache resources.

For more information about subnet group usage in an Amazon VPC environment, see Step 3: Authorize access to the cluster (p. 52).

Topics
- Creating a subnet group (p. 526)
- Assigning a subnet group to a cluster or replication group (p. 529)
- Modifying a subnet group (p. 530)
- Deleting a subnet group (p. 532)
Creating a subnet group

A cache subnet group is a collection of subnets that you may want to designate for your cache clusters in a VPC. When launching a cache cluster in a VPC, you need to select a cache subnet group. Then ElastiCache uses that cache subnet group to assign IP addresses within that subnet to each cache node in the cluster.

When you create a new subnet group, note the number of available IP addresses. If the subnet has very few free IP addresses, you might be constrained as to how many more nodes you can add to the cluster. To resolve this issue, you can assign one or more subnets to a subnet group so that you have a sufficient number of IP addresses in your cluster's Availability Zone. After that, you can add more nodes to your cluster.

The following procedures show you how to create a subnet group called mysubnetgroup (console), the AWS CLI, and the ElastiCache API.

Creating a subnet group (Console)

The following procedure shows how to create a subnet group (console).

To create a subnet group (Console)

2. In the navigation list, choose Subnet Groups.
3. Choose Create Subnet Group.
4. In the Create Subnet Group wizard, do the following. When all the settings are as you want them, choose Yes, Create.
   a. In the Name box, type a name for your subnet group.
   b. In the Description box, type a description for your subnet group.
   c. In the VPC ID box, choose the Amazon VPC that you created.
   d. In the Availability Zone and Subnet ID lists, choose the Availability Zone or Local Zone and ID of your private subnet, and then choose Add.
5. In the confirmation message that appears, choose **Close**.

Your new subnet group appears in the **Subnet Groups** list of the ElastiCache console. At the bottom of the window you can choose the subnet group to see details, such as all of the subnets associated with this group.

**Creating a subnet group (AWS CLI)**

At a command prompt, use the command `create-cache-subnet-group` to create a subnet group.

For Linux, macOS, or Unix:

```
aws elasticache create-cache-subnet-group \\n  --cache-subnet-group-name mysubnetgroup \\n  --cache-subnet-group-description "Testing" \\n  --subnet-ids subnet-53df9c3a
```

For Windows:

```
aws elasticache create-cache-subnet-group ^
  --cache-subnet-group-name mysubnetgroup ^
  --cache-subnet-group-description "Testing" ^
  --subnet-ids subnet-53df9c3a
```

This command should produce output similar to the following:

```
{
  "CacheSubnetGroup": {
    "VpcId": "vpc-37c3cd17",
    "CacheSubnetGroupDescription": "Testing",
    "Subnets": [  
```
For more information, see the AWS CLI topic `create-cache-subnet-group`.

**Creating a subnet group (ElastiCache API)**

Using the ElastiCache API, call `CreateCacheSubnetGroup` with the following parameters:

- `CacheSubnetGroupName=mysubnetgroup`
- `CacheSubnetGroupDescription=Testing`
- `SubnetIds.member.1=subnet-53df9c3a`

**Example**

```plaintext
https://elasticache.us-west-2.amazonaws.com/
?Action=CreateCacheSubnetGroup
&CacheSubnetGroupDescription=Testing
&CacheSubnetGroupName=mysubnetgroup
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SubnetIds.member.1=subnet-53df9c3a
&Timestamp=20141201T220302Z
&Version=2014-12-01
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
&X-Amz-Credential=<credential>
&X-Amz-Date=20141201T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Signature=<signature>
&X-Amz-SignedHeaders=Host
```

API Version 2015-02-02

528
Assigning a subnet group to a cluster or replication group

After you have created a subnet group, you can launch a cluster or replication group in an Amazon VPC. For more information, see the following.

- **Standalone Redis cluster** – To launch a single-node Redis cluster, see Creating a Redis (cluster mode disabled) cluster (Console) (p. 47). In step 7.a (Advanced Redis Settings), choose a VPC subnet group.

- **Redis (cluster mode disabled) replication group** – To launch a Redis (cluster mode disabled) replication group in a VPC, see Creating a Redis (Cluster Mode Disabled) replication group from scratch (p. 273). In step 7.b (Advanced Redis Settings), choose a VPC subnet group.

- **Redis (cluster mode enabled) replication group** – Creating a Redis (Cluster Mode Enabled) cluster (Console) (p. 280). In step 6.i (Advanced Redis Settings), choose a VPC subnet group.
Modifying a subnet group

You can modify a subnet group's description, or modify the list of subnet IDs associated with the subnet group. You cannot delete a subnet ID from a subnet group if a cluster is currently using that subnet.

The following procedures show you how to modify a subnet group.

Modifying subnet groups (Console)

To modify a subnet group

2. In the navigation pane, choose Subnet Groups.
3. In the list of subnet groups, choose the one you want to modify.
4. In the lower portion of the ElastiCache console, make any changes to the description or the list of subnet IDs for the subnet group. To save your changes, choose Save.

Modifying subnet groups (AWS CLI)

At a command prompt, use the command `modify-cache-subnet-group` to modify a subnet group.

For Linux, macOS, or Unix:

```bash
aws elasticache modify-cache-subnet-group
   --cache-subnet-group-name mysubnetgroup
   --cache-subnet-group-description "New description"
   --subnet-ids "subnet-42df9c3a" "subnet-48fc21a9"
```

For Windows:

```bash
aws elasticache modify-cache-subnet-group
   --cache-subnet-group-name mysubnetgroup
   --cache-subnet-group-description "New description"
   --subnet-ids "subnet-42df9c3a" "subnet-48fc21a9"
```

This command should produce output similar to the following:

```json
{
   "CacheSubnetGroup": {
      "VpcId": "vpc-73cd3c17",
      "CacheSubnetGroupDescription": "New description",
      "Subnets": [
         {
            "SubnetIdentifier": "subnet-42df9c3a",
            "SubnetAvailabilityZone": {
               "Name": "us-west-2a"
            }
         },
         {
            "SubnetIdentifier": "subnet-48fc21a9",
            "SubnetAvailabilityZone": {
               "Name": "us-west-2a"
            }
         }
      ],
      "CacheSubnetGroupName": "mysubnetgroup"
   }
}
```
Subnets and subnet groups

For more information, see the AWS CLI topic modify-cache-subnet-group.

Modifying subnet groups (ElastiCache API)

Using the ElastiCache API, call `ModifyCacheSubnetGroup` with the following parameters:

- `CacheSubnetGroupName=mysubnetgroup`
- Any other parameters whose values you want to change. This example uses `CacheSubnetGroupDescription=New%20description` to change the description of the subnet group.

Example

```
https://elasticache.us-west-2.amazonaws.com/
    ?Action=ModifyCacheSubnetGroup
    &CacheSubnetGroupDescription=New%20description
    &CacheSubnetGroupName=mysubnetgroup
    &SubnetIds.member.1=subnet-42df9c3a
    &SubnetIds.member.2=subnet-48fc21a9
    &SignatureMethod=HmacSHA256
    &SignatureVersion=4
    &Timestamp=20141201T220302Z
    &Version=2014-12-01
    &X-Amz-Algorithm=AWS;4-HMAC-SHA256
    &X-Amz-Credential=<credential>
    &X-Amz-Date=20141201T220302Z
    &X-Amz-Expires=20141201T220302Z
    &X-Amz-Signature=<signature>
    &X-Amz-SignedHeaders=Host
```

Note

When you create a new subnet group, take note the number of available IP addresses. If the subnet has very few free IP addresses, you might be constrained as to how many more nodes you can add to the cluster. To resolve this issue, you can assign one or more subnets to a subnet group so that you have a sufficient number of IP addresses in your cluster's Availability Zone. After that, you can add more nodes to your cluster.
Deleting a subnet group

If you decide that you no longer need your subnet group, you can delete it. You cannot delete a subnet group if it is currently in use by a cluster. You also cannot delete a subnet group on a cluster with Multi-AZ enabled if doing so leaves that cluster with fewer than two subnets. You must first disable Multi-AZ and then delete the subnet.

The following procedures show you how to delete a subnet group.

Deleting a subnet group (Console)

To delete a subnet group

2. In the navigation pane, choose Subnet Groups.
3. In the list of subnet groups, choose the one you want to delete and then choose Delete.
4. When you are asked to confirm this operation, choose Yes, Delete.

Deleting a subnet group (AWS CLI)

Using the AWS CLI, call the command `delete-cache-subnet-group` with the following parameter:

- `--cache-subnet-group-name mysubnetgroup`

For Linux, macOS, or Unix:

```bash
aws elasticache delete-cache-subnet-group \
   --cache-subnet-group-name mysubnetgroup
```

For Windows:

```bash
aws elasticache delete-cache-subnet-group ^
   --cache-subnet-group-name mysubnetgroup
```

This command produces no output.

For more information, see the AWS CLI topic `delete-cache-subnet-group`.

Deleting a subnet group (ElastiCache API)

Using the ElastiCache API, call `DeleteCacheSubnetGroup` with the following parameter:

- `CacheSubnetGroupName=mysubnetgroup`

Example

Line breaks are added for ease of reading.

```plaintext
https://elasticache.us-west-2.amazonaws.com/
   ?Action=DeleteCacheSubnetGroup
   &CacheSubnetGroupName=mysubnetgroup
   &SignatureMethod=HmacSHA256
   &SignatureVersion=4
```

API Version 2015-02-02
This command produces no output.

For more information, see the ElastiCache API topic DeleteCacheSubnetGroup.

Security groups: EC2-Classic

Important
Amazon ElastiCache security groups are only applicable to clusters that are not running in an Amazon Virtual Private Cloud environment (VPC). If you are running in an Amazon Virtual Private Cloud, Security Groups is not available in the console navigation pane. If you are running your ElastiCache nodes in an Amazon VPC, you control access to your clusters with Amazon VPC security groups, which are different from ElastiCache security groups. For more information about using ElastiCache in an Amazon VPC, see Amazon VPCs and ElastiCache security (p. 502).

Amazon ElastiCache allows you to control access to your clusters using ElastiCache security groups. An ElastiCache security group acts like a firewall, controlling network access to your cluster. By default, network access is turned off to your clusters. If you want your applications to access your cluster, you must explicitly enable access from hosts in specific Amazon EC2 security groups. Once ingress rules are configured, the same rules apply to all clusters associated with that security group.

To allow network access to your cluster, create a security group and use the AuthorizeCacheSecurityGroupIngress API operation (CLI: authorize-cache-security-group-ingress) to authorize the desired Amazon EC2 security group (which in turn specifies the Amazon EC2 instances allowed). The security group can be associated with your cluster at the time of creation, or using the ModifyCacheCluster API operation (CLI: modify-cache-cluster).

Important
Access control based on IP range is currently not enabled at the individual cluster level. All clients to a cluster must be within the EC2 network, and authorized via security groups as described previously.

For more information about using ElastiCache with Amazon VPCs, see Amazon VPCs and ElastiCache security (p. 502).

Note that Amazon EC2 instances running in an Amazon VPC can't connect to ElastiCache clusters in EC2-Classic.

Topics
- Creating a security group (p. 534)
- Listing available security groups (p. 536)
- Authorizing network access to an amazon EC2 security group (p. 538)
Creating a security group

This topic is relevant to you only if you are not running in an Amazon VPC. If you are running in an Amazon VPC, see Amazon VPCs and ElastiCache security (p. 502).

To create a security group, you need to provide a name and a description.

The following procedures show you how to create a new security group.

Creating a security group (Console)

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
4. In Basic Details, enter a descriptive name and brief description for the security group. The name and description can be up to 255 characters long, and they can include a-z, A-Z, 0-9, spaces and ._-:/()#,@\[]+=&{}!$*. For VPC, choose the VPC in which to create the security group. The security group can only be used in the VPC in which it is created.
5. You can add security group rules now, or you can add them at any time after you have created the security group. For more information about adding security group rules, see Adding rules to a security group.
6. Choose Create.

Creating a security group (AWS CLI)

At a command prompt, use the create-cache-security-group command with the following parameters:

- --cache-security-group-name – The name of the security group you are creating.
  
  Example: mysecuritygroup
- --description – A description for this security group.

  Example: "My new security group"

For Linux, macOS, or Unix:

```
aws elasticache create-cache-security-group \
  --cache-security-group-name mysecuritygroup \
  --description "My new security group"
```

For Windows:

```
aws elasticache create-cache-security-group ^
  --cache-security-group-name mysecuritygroup ^
  --description "My new security group"
```

For more information, see create-cache-security-group.

Creating a security group (ElastiCache API)

Using the ElastiCache API operation CreateCacheSecurityGroup with the following parameters:

- CacheSecurityGroupName – The name of the security group you are creating.
Example: mysecuritygroup
- Description – A URL encoded description for this security group.

Example: My%20security%20group

Example
Line breaks are added for ease of reading.

```
https://elasticache.us-west-2.amazonaws.com/
  ?Action=CreateCacheSecurityGroup
  &CacheSecurityGroupName=mysecuritygroup
  &Description=My%20security%20group
  &Version=2015-02-02
  &SignatureVersion=4
  &SignatureMethod=HmacSHA256
  &Timestamp=20150202T220302Z
  &X-Amz-Algorithm=&AWS;4-HMAC-SHA256
  &X-Amz-Date=20150202T220302Z
  &X-Amz-SignedHeaders=Host
  &X-Amz-Expires=20150202T220302Z
  &X-Amz-Credential=<credential>
  &X-Amz-Signature=<signature>
```
Listing available security groups

This topic is relevant to you only if you are not running in an Amazon VPC. If you are running in an Amazon VPC, see Amazon VPCs and ElastiCache security (p. 502).

You can list which security groups have been created for your AWS account.

The following procedures show you how to list the available security groups for your AWS account.

Listing available security groups (Console)

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
   
The available security groups appear in the Security Groups list.

Listing available security groups (AWS CLI)

At a command prompt, use the describe-cache-security-groups command to list all available security groups for your AWS account.

```
aws elasticache describe-cache-security-groups
```

JSON output from this command will look something like this.

```
{
  "Marker": "Marker",
  "CacheSecurityGroups": [
  {
    "OwnerId": "OwnerId",
    "CacheSecurityGroupName": "CacheSecurityGroupName",
    "Description": "Description",
    "EC2SecurityGroups": [
      {"Status": "Status",
       "EC2SecurityGroupName": "EC2SecurityGroupName",
       "EC2SecurityGroupOwnerId": "EC2SecurityGroupOwnerId"
      }
    ]
  }
  ]
}
```

For more information, see describe-cache-security-groups.

Listing available security groups (ElastiCache API)

Using the ElastiCache API, call DescribeCacheSecurityGroups.

**Example**

Line breaks are added for ease of reading.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeCacheSecurityGroups
&MaxRecords=100
&Version=2015-02-02
```

API Version 2015-02-02

Authorizing network access to an amazon EC2 security group

This topic is relevant to you only if you are not running in an Amazon VPC. If you are running in an Amazon VPC, see Amazon VPCs and ElastiCache security (p. 502).

If you want to access your cluster from an Amazon EC2 instance, you must grant access to the Amazon EC2 security group that the EC2 instance belongs to. The following procedures show you how to grant access to an Amazon EC2 Security Group.

Important

- Authorizing an Amazon EC2 security group only grants access to your clusters from all EC2 instances belonging to the Amazon EC2 security group.
- It takes approximately one minute for changes to access permissions to take effect.

Authorizing network access to an amazon EC2 security group (Console)

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Security Groups.
3. In the Security Groups list, choose the box to the left of the security group that you want to grant access to.
4. At the bottom of the window, in the EC2 Security Group Name list, choose your Amazon EC2 security group.
5. Choose Add.

Authorizing network access to an amazon EC2 security group (AWS CLI)

At a command prompt, use the authorize-cache-security-group-ingress command to grant access to an Amazon EC2 security group with the following parameters.

- `--cache-security-group-name` – the name of the security group you are granting Amazon EC2 access to.
- `--ec2-security-group-name` – the name of the Amazon EC2 security group that the Amazon EC2 instance belongs to.
- `--ec2-security-group-owner-id` – the id of the owner of the Amazon EC2 security group.

Example

For Linux, macOS, or Unix:

```bash
aws elasticache authorize-cache-security-group-ingress \
  --cache-security-group-name default \n  --ec2-security-group-name myec2group \n  --ec2-security-group-owner-id 987654321021
```

For Windows:

```bash
aws elasticache authorize-cache-security-group-ingress ^
  --cache-security-group-name default ^
  --ec2-security-group-name myec2group ^
  --ec2-security-group-owner-id 987654321021
```

The command should produce output similar to the following:
Identity and access management

For more information, see `authorize-cache-security-group-ingress`.

Authorizing network access to an Amazon EC2 security group (ElastiCache API)

Using the ElastiCache API, call `AuthorizeCacheSecurityGroupIngress` with the following parameters:

- `CacheSecurityGroupName` – the name of the security group you are granting Amazon EC2 access to.
- `EC2SecurityGroupName` – the name of the Amazon EC2 security group that the Amazon EC2 instance belongs to.
- `EC2SecurityGroupOwnerId` – the id of the owner of the Amazon EC2 security group.

Example

```
https://elasticache.us-west-2.amazonaws.com/
?Action=AuthorizeCacheSecurityGroupIngress
&EC2SecurityGroupOwnerId=987654321021
&EC2SecurityGroupName=myec2group
&Version=2015-02-02
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20150202T220302Z
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Date=20150202T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Expires=20150202T220302Z
&X-Amz-Credential=<credential>
&X-Amz-Signature=<signature>
```

For more information, see `AuthorizeCacheSecurityGroupIngress`.

Identity and access management in Amazon ElastiCache

Access to Amazon ElastiCache requires credentials that AWS can use to authenticate your requests. Those credentials must have permissions to access AWS resources, such as an ElastiCache cache cluster or an Amazon Elastic Compute Cloud (Amazon EC2) instance. The following sections provide details on how you can use AWS Identity and Access Management (IAM) and ElastiCache to help secure your resources by controlling who can access them.

- Authentication (p. 540)
Authentication

You can access AWS as any of the following types of identities:

- **AWS account root user** – When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

- **IAM user** – An IAM user is an identity within your AWS account that has specific custom permissions (for example, permissions to create a cluster in ElastiCache). You can use an IAM user name and password to sign in to secure AWS webpages like the AWS Management Console, AWS Discussion Forums, or the AWS Support Center.

In addition to a user name and password, you can also generate access keys for each user. You can use these keys when you access AWS services programmatically, either through one of the several SDKs or by using the AWS Command Line Interface (CLI). The SDK and CLI tools use the access keys to cryptographically sign your request. If you don’t use AWS tools, you must sign the request yourself. ElastiCache supports Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

- **IAM role** – An IAM role is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user in that it is an AWS identity with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. IAM roles with temporary credentials are useful in the following situations:
  - **Federated user access** – Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated users and roles in the IAM User Guide.
  - **AWS service access** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.
  - **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

Access control

You can have valid credentials to authenticate your requests, but unless you have permissions you cannot create or access Amazon ElastiCache resources. For example, you must have permissions to create an ElastiCache cache cluster.
The following sections describe how to manage permissions for Amazon ElastiCache. We recommend that you read the overview first.

- **Overview of managing access permissions to your ElastiCache resources (p. 542)**
- **Using identity-based policies (IAM policies) for Amazon ElastiCache (p. 546)**
Overview of managing access permissions to your ElastiCache resources

Every AWS resource is owned by an AWS account, and permissions to create or access a resource are governed by permissions policies. An account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles). In addition, Amazon ElastiCache also supports attaching permissions policies to resources.

**Note**
An account administrator (or administrator user) is a user with administrator privileges. For more information, see IAM Best Practices in the IAM User Guide.

When granting permissions, you decide who is getting the permissions. You also decide the resources they get permissions for and the specific actions that you want to allow on those resources.

**Topics**
- Amazon ElastiCache resources and operations (p. 542)
- Understanding resource ownership (p. 543)
- Managing access to resources (p. 543)
- Using identity-based policies (IAM policies) for Amazon ElastiCache (p. 546)
- Resource-level permissions (p. 550)
- Using condition keys (p. 551)
- Using Service-Linked Roles for Amazon ElastiCache (p. 567)
- ElastiCache API permissions: Actions, resources, and conditions reference (p. 573)

Amazon ElastiCache resources and operations

In Amazon ElastiCache, the primary resource is a *cache cluster*.

These resources have unique Amazon Resource Names (ARNs) associated with them as shown following.

**Note**
For resource-level permissions to be effective, the resource name on the ARN string should be lower case.

<table>
<thead>
<tr>
<th>Resource type</th>
<th>ARN format</th>
</tr>
</thead>
<tbody>
<tr>
<td>(For Redis 6.0 onward) User</td>
<td>arn:aws:elasticache:us-east-2:123456789012:user:user1</td>
</tr>
</tbody>
</table>
ElastiCache provides a set of operations to work with ElastiCache resources. For a list of available operations, see Amazon ElastiCache Actions.

### Understanding resource ownership

A **resource owner** is the AWS account that created the resource. That is, the resource owner is the AWS account of the principal entity that authenticates the request that creates the resource. A **principal entity** can be the root account, an IAM user, or an IAM role. The following examples illustrate how this works:

- Suppose that you use the root account credentials of your AWS account to create a cache cluster. In this case, your AWS account is the owner of the resource. In ElastiCache, the resource is the cache cluster.
- Suppose that you create an IAM user in your AWS account and grant permissions to create a cache cluster to that user. In this case, the user can create a cache cluster. However, your AWS account, to which the user belongs, owns the cache cluster resource.
- Suppose that you create an IAM role in your AWS account with permissions to create a cache cluster. In this case, anyone who can assume the role can create a cache cluster. Your AWS account, to which the role belongs, owns the cache cluster resource.

### Managing access to resources

A **permissions policy** describes who has access to what. The following section explains the available options for creating permissions policies.

**Note**

This section discusses using IAM in the context of Amazon ElastiCache. It doesn't provide detailed information about the IAM service. For complete IAM documentation, see What Is IAM? in the IAM User Guide. For information about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.
Policies attached to an IAM identity are referred to as identity-based policies (IAM policies). Policies attached to a resource are referred to as resource-based policies.

Topics
- Identity-based policies (IAM policies) (p. 544)
- Specifying policy elements: Actions, effects, resources, and principals (p. 544)
- Specifying conditions in a policy (p. 545)

Identity-based policies (IAM policies)
You can attach policies to IAM identities. For example, you can do the following:

- **Attach a permissions policy to a user or a group in your account** – An account administrator can use a permissions policy that is associated with a particular user to grant permissions. In this case, the permissions are for that user to create an ElastiCache resource, such as a cache cluster, parameter group, or security group.

- **Attach a permissions policy to a role (grant cross-account permissions)** – You can attach an identity-based permissions policy to an IAM role to grant cross-account permissions. For example, the administrator in Account A can create a role to grant cross-account permissions to another AWS account (for example, Account B) or an AWS service as follows:
  1. Account A administrator creates an IAM role and attaches a permissions policy to the role that grants permissions on resources in Account A.
  2. Account A administrator attaches a trust policy to the role identifying Account B as the principal who can assume the role.
  3. Account B administrator can then delegate permissions to assume the role to any users in Account B. Doing this allows users in Account B to create or access resources in Account A. In some cases, you might want to grant an AWS service permissions to assume the role. To support this approach, the principal in the trust policy can also be an AWS service principal.

For more information about using IAM to delegate permissions, see Access Management in the IAM User Guide.

The following is an example policy that allows a user to perform the DescribeCacheClusters action for your AWS account. ElastiCache also supports identifying specific resources using the resource ARNs for API actions. (This approach is also referred to as resource-level permissions).

```json
{
   "Version": "2012-10-17",
   "Statement": [ {
      "Sid": "DescribeCacheClusters",
      "Effect": "Allow",
      "Action": [ "elasticache:DescribeCacheClusters" ],
      "Resource": resource-arn
   } ]
}
```

For more information about using identity-based policies with ElastiCache, see Using identity-based policies (IAM policies) for Amazon ElastiCache (p. 546). For more information about users, groups, roles, and permissions, see Identities (Users, Groups, and Roles in the IAM User Guide).

Specifying policy elements: Actions, effects, resources, and principals
For each Amazon ElastiCache resource (see Amazon ElastiCache resources and operations (p. 542)), the service defines a set of API operations (see Actions). To grant permissions for these API operations,
ElastiCache defines a set of actions that you can specify in a policy. For example, for the ElastiCache snapshot resource, the following actions are defined: CreateCacheCluster, DeleteCacheCluster, and DescribeCacheCluster. Performing an API operation can require permissions for more than one action.

The following are the most basic policy elements:

- **Resource** – In a policy, you use an Amazon Resource Name (ARN) to identify the resource to which the policy applies. For more information, see Amazon ElastiCache resources and operations (p. 542).
- **Action** – You use action keywords to identify resource operations that you want to allow or deny. For example, depending on the specified Effect, the elasticache:CreateCacheCluster permission allows or denies the user permissions to perform the Amazon ElastiCache CreateCacheCluster operation.
- **Effect** – You specify the effect when the user requests the specific action—this can be either allow or deny. If you don’t explicitly grant access to (allow) a resource, access is implicitly denied. You can also explicitly deny access to a resource. For example, you might do this to make sure that a user can’t access a resource, even if a different policy grants access.
- **Principal** – In identity-based policies (IAM policies), the user that the policy is attached to is the implicit principal. For resource-based policies, you specify the user, account, service, or other entity that you want to receive permissions (applies to resource-based policies only).

To learn more about IAM policy syntax and descriptions, see AWS IAM Policy Reference in the IAM User Guide.

For a table showing all of the Amazon ElastiCache API actions, see ElastiCache API permissions: Actions, resources, and conditions reference (p. 573).

**Specifying conditions in a policy**

When you grant permissions, you can use the IAM policy language to specify the conditions when a policy should take effect. For example, you might want a policy to be applied only after a specific date. For more information about specifying conditions in a policy language, see Condition in the IAM User Guide.

To express conditions, you use predefined condition keys. To use ElastiCache-specific condition keys, see Using condition keys (p. 551). There are AWS-wide condition keys that you can use as appropriate. For a complete list of AWS-wide keys, see Available Keys for Conditions in the IAM User Guide.
Using identity-based policies (IAM policies) for Amazon ElastiCache

This topic provides examples of identity-based policies in which an account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles).

**Important**

We recommend that you first read the topics that explain the basic concepts and options to manage access to Amazon ElastiCache resources. For more information, see Overview of managing access permissions to your ElastiCache resources (p. 542).

The sections in this topic cover the following:

- Permissions required to use the Amazon ElastiCache console (p. 547)
- AWS-managed (predefined) policies for Amazon ElastiCache (p. 547)
- Customer-managed policy examples (p. 548)

The following shows an example of a permissions policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowClusterPermissions",
            "Effect": "Allow",
            "Action": [
                "elasticache:CreateCacheCluster",
                "elasticache:CreateReplicationGroup",
                "elasticache:DescribeCacheClusters",
                "elasticache:ModifyCacheCluster",
                "elasticache:RebootCacheCluster"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AllowUserToPassRole",
            "Effect": "Allow",
            "Action": [ "iam:PassRole" ],
            "Resource": "arn:aws:iam::123456789012:role/EC2-roles-for-cluster"
        }
    ]
}
```

The policy has two statements:

- The first statement grants permissions for the Amazon ElastiCache actions (`elasticache:CreateCacheCluster`, `elasticache:DescribeCacheClusters`, `elasticache:ModifyCacheCluster`, and `elasticache:RebootCacheCluster`) on any cache cluster owned by the account.
- The second statement grants permissions for the IAM action (`iam:PassRole`) on the IAM role name specified at the end of the `Resource` value.

The policy doesn't specify the `Principal` element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permissions policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

For a table showing all of the Amazon ElastiCache API actions and the resources that they apply to, see ElastiCache API permissions: Actions, resources, and conditions reference (p. 573).
Permissions required to use the Amazon ElastiCache console

The permissions reference table lists the Amazon ElastiCache API operations and shows the required permissions for each operation. For more information about ElastiCache API operations, see ElastiCache API permissions: Actions, resources, and conditions reference (p. 573).

To use the Amazon ElastiCache console, first grant permissions for additional actions as shown in the following permissions policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Sid": "MinPermsForECConsole",
        "Effect": "Allow",
        "Action": [
            "elasticache:Describe*",
            "elasticache:List*",
            "ec2:DescribeAvailabilityZones",
            "ec2:DescribeVpcs",
            "ec2:DescribeAccountAttributes",
            "ec2:DescribeSecurityGroups",
            "cloudwatch:GetMetricStatistics",
            "cloudwatch:DescribeAlarms",
            "s3:ListAllMyBuckets",
            "sns:ListTopics",
            "sns:ListSubscriptions"
        ],
        "Resource": "*"
    }]
}
```

The ElastiCache console needs these additional permissions for the following reasons:

- Permissions for the ElastiCache actions enable the console to display ElastiCache resources in the account.
- The console needs permissions for the ec2 actions to query Amazon EC2 so it can display Availability Zones, VPCs, security groups, and account attributes.
- The permissions for cloudwatch actions enable the console to retrieve Amazon CloudWatch metrics and alarms, and display them in the console.
- The permissions for sns actions enable the console to retrieve Amazon Simple Notification Service (Amazon SNS) topics and subscriptions, and display them in the console.

AWS-managed (predefined) policies for Amazon ElastiCache

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. Managed policies grant necessary permissions for common use cases so you can avoid having to investigate what permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

The following AWS managed policies, which you can attach to users in your account, are specific to ElastiCache:

- **AmazonElastiCacheReadOnlyAccess** - Grants read-only access to Amazon ElastiCache resources.
- **AmazonElastiCacheFullAccess** - Grants full access to Amazon ElastiCache resources.

**Note**
You can review these permissions policies by signing in to the IAM console and searching for specific policies there.
You can also create your own custom IAM policies to allow permissions for Amazon ElastiCache API actions. You can attach these custom policies to the IAM users or groups that require those permissions.

**Customer-managed policy examples**

If you are not using a default policy and choose to use a custom-managed policy, ensure one of two things. Either you should have permissions to call `iam:createServiceLinkedRole` (for more information, see Example 5: Allow a user to call IAM CreateServiceLinkedRole API (p. 549)). Or you should have created an ElastiCache service-linked role.

When combined with the minimum permissions needed to use the Amazon ElastiCache console, the example policies in this section grant additional permissions. The examples are also relevant to the AWS SDKs and the AWS CLI. For more information about what permissions are needed to use the ElastiCache console, see Permissions required to use the Amazon ElastiCache console (p. 547).

For instructions on setting up IAM users and groups, see Creating Your First IAM User and Administrators Group in the IAM User Guide.

**Important**
Always test your IAM policies thoroughly before using them in production. Some ElastiCache actions that appear simple can require other actions to support them when you are using the ElastiCache console. For example, `elasticache:createCacheCluster` grants permissions to create ElastiCache cache clusters. However, to perform this operation, the ElastiCache console uses a number of `Describe` and `List` actions to populate console lists.

**Examples**
- Example 1: Allow a user to create and manage security groups (p. 548)
- Example 2: Allow a user read-only access to ElastiCache resources (p. 548)
- Example 3: Allow a user to perform common ElastiCache system administrator tasks (p. 549)
- Example 4: Allow a user to access all ElastiCache API actions (p. 549)
- Example 5: Allow a user to call IAM CreateServiceLinkedRole API (p. 549)

**Example 1: Allow a user to create and manage security groups**

The following policy grants permissions for the security group's specific ElastiCache actions. Typically, you attach this type of permissions policy to the system administrators group.

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Sid": "SecGrpAllows",
        "Effect": "Allow",
        "Action": [
            "elasticache:CreateCacheSecurityGroup",
            "elasticache:DeleteCacheSecurityGroup",
            "elasticache:DescribeCacheSecurityGroup",
            "elasticache:AuthorizeCacheSecurityGroupIngress",
            "elasticache:RevokeCacheSecurityGroupIngress"
        ],
        "Resource": "*"
    }]
}
```

**Example 2: Allow a user read-only access to ElastiCache resources**

The following policy grants permissions ElastiCache actions that allow a user to list resources. Typically, you attach this type of permissions policy to a managers group.

```
{
```

API Version 2015-02-02
548
Example 3: Allow a user to perform common ElastiCache system administrator tasks

Common system administrator tasks include modifying cache clusters, parameters, and parameter groups. A system administrator may also want to get information about the ElastiCache events. The following policy grants a user permissions to perform ElastiCache actions for these common system administrator tasks. Typically, you attach this type of permissions policy to the system administrators group.

```json
{
    "Version": "2012-10-17",
    "Statement":[
        {
            "Sid": "ECUnrestricted",
            "Effect": "Allow",
            "Action": [
                "elasticache:Describe*",
                "elasticache:List*"
            ],
            "Resource": "*"
        }
    ]
}
```

Example 4: Allow a user to access all ElastiCache API actions

The following policy allows a user to access all ElastiCache actions. We recommend that you grant this type of permissions policy only to an administrator user.

```json
{
    "Version": "2012-10-17",
    "Statement":[
        {
            "Sid": "ECUnrestricted",
            "Effect": "Allow",
            "Action": [
                "elasticache:*"
            ],
            "Resource": "*"
        }
    ]
}
```

Example 5: Allow a user to call IAM CreateServiceLinkedRole API

The following policy allows user to call the IAM CreateServiceLinkedRole API. We recommend that you grant this type of permissions policy to the user who invokes mutative ElastiCache operations.

```json
{
    "Version": "2012-10-17",
    "Statement":[
        {
            "Sid": "ECUnrestricted",
            "Effect": "Allow",
            "Action": [
                "elasticache:*"
            ],
            "Resource": "*"
        }
    ]
}
```
Resource-level permissions

You can restrict the scope of permissions by specifying resources in an IAM policy. Many ElastiCache API actions support a resource type that varies depending on the behavior of the action. Every IAM policy statement grants permission to an action that’s performed on a resource. When the action doesn’t act on a named resource, or when you grant permission to perform the action on all resources, the value of the resource in the policy is a wildcard (*). For many API actions, you can restrict the resources that a user can modify by specifying the Amazon Resource Name (ARN) of a resource, or an ARN pattern that matches multiple resources. To restrict permissions by resource, specify the resource by ARN.

ElastiCache Resource ARN Format

Note
For resource-level permissions to be effective, the resource name on the ARN string should be lower case.

- (For Redis 6.0 onward) User – arn:aws:elasticache:us-east-2:123456789012:user:user1

Examples

- Example 1: Allow a user full access to specific ElastiCache resource types (p. 551)
- Example 2: Deny a user access to a replication group. (p. 551)
Example 1: Allow a user full access to specific ElastiCache resource types

The following policy explicitly allows all resources of type subnet group, security group and replication group.

```json
{
    "Sid": "Example1",
    "Effect": "Allow",
    "Action": "elasticache:*",
    "Resource": [
        "arn:aws:elasticache:us-east-1:account-id:subnetgroup:*",
        "arn:aws:elasticache:us-east-1:account-id:securitygroup:*",
        "arn:aws:elasticache:us-east-1:account-id:replicationgroup:*"
    ]
}
```

Example 2: Deny a user access to a replication group.

The following example explicitly denies access to a particular replication group.

```json
{
    "Sid": "Example2",
    "Effect": "Deny",
    "Action": "elasticache:*",
    "Resource": [
        "arn:aws:elasticache:us-east-1:account-id:replicationgroup:name"
    ]
}
```

Using condition keys

You can specify conditions that determine how an IAM policy takes effect. In ElastiCache, you can use the Condition element of a JSON policy to compare keys in the request context with key values that you specify in your policy. For more information, see IAM JSON policy elements: Condition. For a list of global condition keys, see AWS global condition context keys.

Specifying Conditions: Using Condition Keys

To implement fine-grained control, you write an IAM permissions policy that specifies conditions to control a set of individual parameters on certain requests. You then apply the policy to IAM users, groups, or roles that you create using the IAM console.

To apply a condition, you add the condition information to the IAM policy statement. In the following example, you specify the condition that any cache cluster created will be of node type cache.r5.large.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "elasticache:CreateCacheCluster",
                "elasticache:CreateReplicationGroup"
            ],
            "Resource": [
                "arn:aws:elasticache::*:parametergroup:*",
                "arn:aws:elasticache::*:subnetgroup:*
            ]
        },
        ...
    ]
}
```
The following table shows the service-specific condition keys that apply to ElastiCache and the actions that use them.

<table>
<thead>

For more information, see Tag-Based access control policy examples.

For more information on using policy condition operators, see ElastiCache API permissions: Actions, resources, and conditions reference (p. 573).

**Example Policies: Using Conditions for Fine-Grained Parameter Control**

This section shows example policies for implementing fine-grained access control on the previously listed ElastiCache parameters.

1. **elasticache:CacheNodeType**: Specify which NodeType(s) a user can create. Using the provided conditions, the customer can specify a single or a range value for a node type.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "elasticache:CreateCacheCluster",
                "elasticache:CreateReplicationGroup"
            ],
            "Resource": [
                "arn:aws:elasticache::*:parametergroup:*",
                "arn:aws:elasticache::*:subnetgroup:*"
            ]
        },
    ]
}
```
2. `elasticache:NumNodeGroups`: Create a replication group with fewer than 20 node groups.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateCacheCluster",
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
        "arn:aws:elasticache:*:*:parametergroup:*",
        "arn:aws:elasticache:*:*:subnetgroup:*
      ],
      "Condition": {
        "NumericLessThanEquals": {
          "elasticache:NumNodeGroups": "20"
        }
      }
    }
  ]
}
```

3. `elasticache:ReplicasPerNodeGroup`: Specify the replicas per node between 5 and 10.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateCacheCluster",
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
        "arn:aws:elasticache:*:*:replicationgroup:*
      ],
      "Condition": {
        "NumericLessThanEquals": {
          "elasticache:ReplicasPerNodeGroup": "10"
        }
      }
    }
  ]
}
```
Overview of managing access

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "elasticache:CreateCacheCluster",
                "elasticache:CreateReplicationGroup"
            ],
            "Resource": [
                "arn:aws:elasticache:*:*:parametergroup:*",
                "arn:aws:elasticache:*:*:subnetgroup:*
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "elasticache:CreateCacheCluster"
            ],
            "Resource": [
                "arn:aws:elasticache:*:*:cluster:*
            ],
            "Condition": {
                "StringEquals": {
                    "elasticache:EngineVersion": "5.0.6"
                }
            }
        }
    ]
}
```

5. **elasticache:EngineType**: Specify using Redis engine only.
6. elasticache:AtRestEncryptionEnabled: Specify that replication groups would be created only with encryption enabled.
7. elasticache:TransitEncryptionEnabled: Specify that replication groups would be created only with this value set to false.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateCacheCluster",
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
        "arn:aws:elasticache::*:parametergroup:**",
        "arn:aws:elasticache::*:subnetgroup:*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
        "arn:aws:elasticache::*:replicationgroup:**"
      ],
      "Condition": {
        "Bool": {
          "elasticache:TransitEncryptionEnabled": "false"
        }
      }
    }
  ]
}
```

8. elasticache:AutomaticFailoverEnabled: Specify that replication groups would be created only with automatic failover enabled.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateCacheCluster",
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
        "arn:aws:elasticache::*:parametergroup:**",
        "arn:aws:elasticache::*:subnetgroup:*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
```
9. `elasticache:MultiAZEnabled`: Specify that replication groups cannot be created with Multi-AZ disabled.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateCacheCluster",
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
        "arn:aws:elasticache::*:parametergroup:*",
        "arn:aws:elasticache::*:subnetgroup:*"
      ]
    },
    {
      "Effect": "Deny",
      "Action": ["elasticache:CreateReplicationGroup"],
      "Resource": [
        "arn:aws:elasticache::*:replicationgroup:*"
      ],
      "Condition": {
        "Bool": {
          "elasticache:MultiAZEnabled": "false"
        }
      }
    }
  ]
}
```

10. `elasticache:ClusterModeEnabled`: Specify that replication groups can only be created with cluster mode enabled.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateCacheCluster",
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
        "arn:aws:elasticache::*:parametergroup:*",
        "arn:aws:elasticache::*:subnetgroup:*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateCacheCluster",
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
        "arn:aws:elasticache::*:parametergroup:*",
        "arn:aws:elasticache::*:subnetgroup:*"
      ]
    }
  ]
}
```
11 **elasticache:AuthTokenEnabled**: Specify that replication groups can only be created with AUTH token enabled.

```
{
    "Version": "2012-10-17",
    "Statement": [

        {
            "Effect": "Allow",
            "Action": ["elasticache:CreateCacheCluster", "elasticache:CreateReplicationGroup"],
            "Resource": [
                "arn:aws:elasticache::*:*:parametergroup:*",
                "arn:aws:elasticache::*:*:subnetgroup:*
            ],
            "Condition": { "Bool": { "elasticache:ClusterModeEnabled": "true" } }
        },

        {
            "Effect": "Allow",
            "Action": ["elasticache:CreateReplicationGroup"],
            "Resource": ["arn:aws:elasticache::*:*:replicationgroup:*"],
            "Condition": { "Bool": { "elasticache:AuthTokenEnabled": "true" } }
        }
    ]
}
```

12 **elasticache:SnapshotRetentionLimit**: Specify the number of days (or min/max) to keep the snapshot. Below policy enforces storing backups for at least 30 days.

```
{
    "Version": "2012-10-17",
    "Statement": [

        {
            "Effect": "Allow",
            "Action": ["elasticache:CreateCacheCluster", "elasticache:CreateReplicationGroup"]
        }
    ]
}
```
Overview of managing access

13. **elasticache:KmsKeyId**: Specify usage of customer managed AWS KMS keys. This key would complement the At-Rest Encryption one.

14. **elasticache:CacheParameterGroupName**: Specify a non default parameter group with specific parameters from an organization on your clusters. You could also specify a naming pattern for your parameter groups or block delete on a specific parameter group name. Following is an example constraining usage of only "my-org-param-group".
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "elasticache:CreateCacheCluster",
      "elasticache:CreateReplicationGroup"
    ],
    "Resource": [
      "arn:aws:elasticache::*:parametergroup:**",
      "arn:aws:elasticache::*:subnetgroup:**"
    ]
  },
  {
    "Effect": "Allow",
    "Action": [
      "elasticache:CreateReplicationGroup"
    ],
    "Resource": [
      "arn:aws:elasticache::*:cluster:**"
    ],
    "Condition": {
      "StringEquals": {
        "elasticache:CacheParameterGroupName": "my-org-param-group"
      }
    }
  }
]

**elasticache:createcachecluster**: Allowing CreateCacheCluster with cacheNodeType cache.r5.large or cache.r6g.4xlarge and tag Project=XYZ.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateCacheCluster",
        "elasticache:CreateReplicationGroup"
      ],
      "Resource": [
        "arn:aws:elasticache::*:parametergroup:**",
        "arn:aws:elasticache::*:subnetgroup:**"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "elasticache:CreateCacheCluster"
      ],
      "Resource": [
        "arn:aws:elasticache::*:cluster:**"
      ],
      "Condition": {
        "StringEqualsIfExists": {
          "elasticache:CacheNodeType": [
            "cache.r5.large",
            "cache.r6g.4xlarge"
          ]
        }
      },
      "StringEquals": {
        "aws:RequestTag/Project": "XYZ"
      }
    }
  ]
}
```
Note
When creating policies to enforce tags and other condition keys together, the conditional If Exists may be required on condition key elements due to the extra elasticache:AddTagsToResource policy requirements for creation requests with the --tags parameter.

Using Service-Linked Roles for Amazon ElastiCache

Amazon ElastiCache uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to an AWS service, such as Amazon ElastiCache. Amazon ElastiCache service-linked roles are predefined by Amazon ElastiCache. They include all the permissions that the service requires to call AWS services on behalf of your clusters.

A service-linked role makes setting up Amazon ElastiCache easier because you don’t have to manually add the necessary permissions. The roles already exist within your AWS account but are linked to Amazon ElastiCache use cases and have predefined permissions. Only Amazon ElastiCache can assume these roles, and only these roles can use the predefined permissions policy. You can delete the roles only after first deleting their related resources. This protects your Amazon ElastiCache resources because you can’t inadvertently remove necessary permissions to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-Linked Role Permissions for Amazon ElastiCache

Amazon ElastiCache uses the service-linked role named AWSServiceRoleForElastiCache – This policy allows ElastiCache to manage AWS resources on your behalf as necessary for managing your cache.

The AWSServiceRoleForElastiCache service-linked role permissions policy allows Amazon ElastiCache to complete the following actions on the specified resources:
Permission policy:
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AuthorizeSecurityGroupIngress",
        "ec2:CreateNetworkInterface",
        "ec2:CreateSecurityGroup",
        "ec2:DeleteNetworkInterface",
        "ec2:DeleteSecurityGroup",
        "ec2:DescribeAvailabilityZones",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeVpcs",
        "ec2:ModifyNetworkInterfaceAttribute",
        "ec2:RevokeSecurityGroupIngress",
        "cloudwatch:PutMetricData",
        "outposts:GetOutpost",
        "outposts:GetOutpostInstanceTypes",
        "outposts:GetServiceLinkedRoleDeletionStatus",
        "outposts:ListOutposts",
        "outposts:ListSites",
        "application-autoscaling:DeregisterScalableTarget",
        "application-autoscaling:DescribeScalableTargets"
      ],
      "Resource": "*
    }
  ]
}
Alternatively, you can use an AWS managed policy to provide full access to Amazon ElastiCache.

Creating a Service-Linked Role (IAM)

You can create a service-linked role using the IAM console, CLI, or API.

Creating a Service-Linked Role (IAM Console)

You can use the IAM console to create a service-linked role.

To create a service-linked role (console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles. Then choose Create new role.
3. Under Select type of trusted entity choose AWS Service.
4. Under Or select a service to view its use cases, choose ElastiCache.
5. Choose Next: Permissions.
6. Under Policy name, note that the ElastiCacheServiceRolePolicy is required for this role. Choose Next:Tags.
7. Note that tags are not supported for Service-Linked roles. Choose Next:Review.
8. (Optional) For Role description, edit the description for the new service-linked role.
9. Review the role and then choose Create role.

Creating a Service-Linked Role (IAM CLI)

You can use IAM operations from the AWS Command Line Interface to create a service-linked role. This role can include the trust policy and inline policies that the service needs to assume the role.

To create a service-linked role (CLI)

Use the following operation:

```bash
$ aws iam create-service-linked-role --aws-service-name elasticache.amazonaws.com
```

Creating a Service-Linked Role (IAM API)

You can use the IAM API to create a service-linked role. This role can contain the trust policy and inline policies that the service needs to assume the role.

To create a service-linked role (API)

Use the CreateServiceLinkedRole API call. In the request, specify a service name of elasticache.amazonaws.com.

Editing the Description of a Service-Linked Role for Amazon ElastiCache

Amazon ElastiCache does not allow you to edit the AWSServiceRoleForElastiCache service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM.

Editing a Service-Linked Role Description (IAM Console)

You can use the IAM console to edit a service-linked role description.
To edit the description of a service-linked role (console)
1. In the navigation pane of the IAM console, choose Roles.
2. Choose the name of the role to modify.
3. To the far right of Role description, choose Edit.
4. Enter a new description in the box and choose Save.

Editing a Service-Linked Role Description (IAM CLI)
You can use IAM operations from the AWS Command Line Interface to edit a service-linked role description.

To change the description of a service-linked role (CLI)
1. (Optional) To view the current description for a role, use the AWS CLI for IAM operation get-role.
   Example
   
   ```bash
   $ aws iam get-role --role-name AWSServiceRoleForElastiCache
   ```
   Use the role name, not the ARN, to refer to roles with the CLI operations. For example, if a role has the following ARN: arn:aws:iam::123456789012:role/myrole, refer to the role as myrole.
2. To update a service-linked role's description, use the AWS CLI for IAM operation update-role-description.
   For Linux, macOS, or Unix:
   
   ```bash
   $ aws iam update-role-description \
   --role-name AWSServiceRoleForElastiCache \
   --description "new description"
   ```
   For Windows:
   
   ```bash
   $ aws iam update-role-description ^
   --role-name AWSServiceRoleForElastiCache ^
   --description "new description"
   ```

Editing a Service-Linked Role Description (IAM API)
You can use the IAM API to edit a service-linked role description.

To change the description of a service-linked role (API)
1. (Optional) To view the current description for a role, use the IAM API operation GetRole.
   Example
   
   ```html
   https://iam.amazonaws.com/
   ?Action=GetRole
   &RoleName=AWSServiceRoleForElastiCache
   &Version=2010-05-08
   &AUTHPARAMS
   ```
2. To update a role's description, use the IAM API operation UpdateRoleDescription.
Deleting a Service-Linked Role for Amazon ElastiCache

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don’t have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can delete it.

Amazon ElastiCache does not delete the service-linked role for you.

Cleaning Up a Service-Linked Role

Before you can use IAM to delete a service-linked role, first confirm that the role has no resources (clusters or replication groups) associated with it.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles. Then choose the name (not the check box) of the AWSServiceRoleForElastiCache role.
3. On the Summary page for the selected role, choose the Access Advisor tab.
4. On the Access Advisor tab, review recent activity for the service-linked role.

To delete Amazon ElastiCache resources that require AWSServiceRoleForElastiCache (console)

- To delete a cluster, see the following:
  - Using the AWS Management Console (p. 165)
  - Using the AWS CLI (p. 165)
  - Using the ElastiCache API (p. 166)
- To delete a replication group, see the following:
  - Deleting a Replication Group (Console) (p. 296)
  - Deleting a Replication Group (AWS CLI) (p. 296)
  - Deleting a replication group (ElastiCache API) (p. 296)

Deleting a Service-Linked Role (IAM Console)

You can use the IAM console to delete a service-linked role.

To delete a service-linked role (console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles. Then select the check box next to the role name that you want to delete, not the name or row itself.
3. For **Role actions** at the top of the page, choose **Delete role**.

4. In the confirmation dialog box, review the service last accessed data, which shows when each of the selected roles last accessed an AWS service. This helps you to confirm whether the role is currently active. If you want to proceed, choose **Yes, Delete** to submit the service-linked role for deletion.

5. Watch the IAM console notifications to monitor the progress of the service-linked role deletion. Because the IAM service-linked role deletion is asynchronous, after you submit the role for deletion, the deletion task can succeed or fail. If the task fails, you can choose **View details** or **View Resources** from the notifications to learn why the deletion failed.

### Deleting a Service-Linked Role (IAM CLI)

You can use IAM operations from the AWS Command Line Interface to delete a service-linked role.

**To delete a service-linked role (CLI)**

1. If you don't know the name of the service-linked role that you want to delete, enter the following command. This command lists the roles and their Amazon Resource Names (ARNs) in your account.

   ```bash
   $ aws iam get-role --role-name role-name
   ```

   Use the role name, not the ARN, to refer to roles with the CLI operations. For example, if a role has the ARN `arn:aws:iam::123456789012:role/myrole`, you refer to the role as `myrole`.

2. Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `deletion-task-id` from the response to check the status of the deletion task. Enter the following to submit a service-linked role deletion request.

   ```bash
   $ aws iam delete-service-linked-role --role-name role-name
   ```

3. Enter the following to check the status of the deletion task.

   ```bash
   $ aws iam get-service-linked-role-deletion-status --deletion-task-id deletion-task-id
   ```

   The status of the deletion task can be **NOT_STARTED**, **IN_PROGRESS**, **SUCCEEDED**, or **FAILED**. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

### Deleting a Service-Linked Role (IAM API)

You can use the IAM API to delete a service-linked role.

**To delete a service-linked role (API)**

1. To submit a deletion request for a service-linked roll, call `DeleteServiceLinkedRole`. In the request, specify a role name.

   Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `DeletionTaskId` from the response to check the status of the deletion task.

2. To check the status of the deletion, call `GetServiceLinkedRoleDeletionStatus`. In the request, specify the `DeletionTaskId`.

   The status of the deletion task can be **NOT_STARTED**, **IN_PROGRESS**, **SUCCEEDED**, or **FAILED**. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.
ElastiCache API permissions: Actions, resources, and conditions reference

When you set up access control (p. 540) and write permissions policies to attach to an IAM policy (either identity-based or resource-based), use the following table as a reference. The table lists each Amazon ElastiCache API operation and the corresponding actions for which you can grant permissions to perform the action. You specify the actions in the policy's `Action` field, and you specify a resource value in the policy's `Resource` field. Unless indicated otherwise, the resource is required. Some fields include both a required resource and optional resources. When there is no resource ARN, the resource in the policy is a wildcard (*)

You can use condition keys in your ElastiCache policies to express conditions. To see a list of ElastiCache-specific condition keys, along with the actions and resource types to which they apply, see Using condition keys (p. 551). For a complete list of AWS-wide keys, see Available Keys for Conditions in the IAM User Guide.

**Note**

To specify an action, use the `elasticache:` prefix followed by the API operation name (for example, `elasticache:DescribeCacheClusters`).

**Amazon ElastiCache API and required permissions for actions**

**AddTagsToResource**

- **Action**: `elasticache:AddTagsToResource`
- **Resource**: *

**AuthorizeCacheSecurityGroupIngress**

- **Action**: `elasticache:AuthorizeCacheSecurityGroupIngress`
- **Resource**: *

**BatchApplyUpdateAction**

- **Action**: `elasticache:BatchApplyUpdateAction`

**BatchStopUpdateAction**

- **Action**: `elasticache:BatchStopUpdateAction`

**CompleteMigration**

- **Action**: `elasticache:CompleteMigration`
- **Resource**: *

Logging and monitoring in Elasticache

To manage your enterprise caching solution, it's important that you know how your clusters are performing and the resources they're consuming. It's also important that you know the events that are being generated and the costs of your deployment.

Amazon CloudWatch provides metrics for monitoring your cache performance. In addition, cost allocation tags help you monitor and manage costs.

Topics

- Log delivery (p. 579)
- Monitoring use with CloudWatch Metrics (p. 588)
- Logging Amazon ElastiCache API calls with AWS CloudTrail (p. 604)
- Monitoring ElastiCache events (p. 607)
Log delivery

Note
Redis Slow Log is supported for Redis cache clusters and replication groups using engine version 6.0 onward.
Redis Engine Log is supported for Redis cache clusters and replication groups using engine version 6.2 onward.

Log delivery lets you stream Redis SLOWLOG or Redis Engine Log to one of two destinations:

- Amazon Kinesis Data Firehose
- Amazon CloudWatch Logs

You enable and configure log delivery when you create or modify a cluster using ElastiCache APIs. Each log entry will be delivered to the specified destination in one of two formats: JSON or TEXT.

A fixed number of Slow log entries are retrieved from the Redis engine periodically. Depending on the value specified for engine parameter slowlog-max-len, additional slow log entries might not be delivered to the destination.

You can choose to change the delivery configurations or disable log delivery at any time using the AWS console or one of the modify APIs, either modify-cache-cluster or modify-replication-group.

You must set the apply-immediately parameter for all log delivery modifications.

Note
Amazon CloudWatch Logs charges apply when log delivery is enabled, even when logs are delivered directly to Amazon Kinesis Data Firehose. For more information, see Vended Logs section in Amazon CloudWatch Pricing.

Contents of a slow log entry

The ElastiCache for Redis Slow Log contains the following information:

- **CacheClusterId** – The ID of the cache cluster
- **CacheNodeID** – The ID of the cache node
- **Id** – A unique progressive identifier for every slow log entry
- **Timestamp** – The Unix timestamp at which the logged command was processed
- **Duration** – The amount of time needed for its execution, in microseconds
- **Command** – The command used by the client. For example, `set foo bar` where `foo` is the key and `bar` is the value. ElastiCache for Redis replaces the actual key name and value with (2 more arguments) to avoid exposing sensitive data.
- **ClientAddress** – Client IP address and port
- **ClientName** – Client name if set via the CLIENT SETNAME command

Contents of an engine log entry

The ElastiCache for Redis Engine Log contains the following information:

- **CacheClusterId** – The ID of the cache cluster
- **CacheNodeID** – The ID of the cache node
- **Log level** – LogLevel can one of the following: VERBOSE("-"), NOTICE("*"), WARNING("#")
- **Time** – The UTC time of the logged message. Time is in following format: "DD MMM YYYY hh:mm:ss.ms UTC"
Log delivery

- **Role** – Role of the node from where the log is emitted. It can be one of the following: "M" for Primary and "S" for replica.
- **Message** – Redis Engine log message.

Permissions to configure logging

You need to include the following IAM permissions in your IAM user/role policy:

- `logs:CreateLogDelivery`
- `logs:UpdateLogDelivery`
- `logs:DeleteLogDelivery`
- `logs:GetLogDelivery`
- `logs:ListLogDeliveries`

For more information, see [Overview of access management: Permissions and policies](#).

Log type and log format specifications

**Slow log**

Slow log supports both JSON and TEXT

The following shows a JSON format example:

```json
{
  "CacheClusterId": "logslowxxxxmsxj",
  "CacheNodeId": "0001",
  "Id": 296,
  "Timestamp": 1605631822,
  "Duration (us)": 0,
  "Command": "GET ... (1 more arguments)",
  "ClientAddress": "192.168.12.104:55452",
  "ClientName": "logslowxxxxmsxj##"
}
```

The following shows a TEXT format example:

```
logslowxxxxmsxj,0001,1605631822,30,GET ... (1 more arguments),192.168.12.104:55452,logslowxxxxmsxj##
```

**Engine log**

Engine log supports both JSON and TEXT

The following shows a JSON format example:

```json
{
  "CacheClusterId": "xxxxxxxxxxzy-engine-log-test",
  "CacheNodeId": "0001",
  "LogLevel": "VERBOSE",
  "Role": "M",
  "Time": "12 Nov 2020 01:28:57.994 UTC",
  "Message": "Replica is waiting for next BGSAVE before synchronizing with the primary. Check back later"
}
```
The following shows a TEXT format example:

```
xxxxxxxxxxxzy-engine-log-test/0001:M 29 Oct 2020 20:12:20.499 UTC * A slow-running Lua
script detected that is still in execution after 10000 milliseconds.
```

ElastiCache logging destinations

This section describes the logging destinations that you can choose for your ElastiCache logs. Each section provides guidance for configuring logging for the destination type and information about any behavior that’s specific to the destination type. After you’ve configured your logging destination, you can provide its specifications to the ElastiCache logging configuration to start logging to it.

Topics

- Amazon CloudWatch Logs (p. 581)
- Amazon Kinesis Data Firehose (p. 582)

Amazon CloudWatch Logs

- You specify a CloudWatch Logs log group where the logs will be delivered.
- Logs from multiple Redis clusters and replication groups can be delivered to the same log group.
- A new log stream will be created for each node within a cache cluster or replication group and the logs will be delivered to the respective log streams. The log stream name will use the following format: `elasticache/${engine-name}/${cache-cluster-id}/${cache-node-id}/${log-type}`

Permissions to publish logs to CloudWatch Logs

You must have the following permissions settings to configure ElastiCache for Redis to send logs to a CloudWatch Logs log group:

```
{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Action": [
         "logs:CreateLogDelivery",
         "logs:GetLogDelivery",
         "logs:UpdateLogDelivery",
         "logs:DeleteLogDelivery",
         "logs:ListLogDeliveries"
      ],
      "Resource": ["*"],
      "Effect": "Allow",
      "Sid": "ElastiCacheLogging"
   },
   {
      "Sid": "ElastiCacheLoggingCWL",
      "Action": [
         "logs:PutResourcePolicy",
         "logs:DescribeResourcePolicies",
         "logs:DescribeLogGroups"
      ],
      "Resource": [
```
Log delivery

For more information, see Logs sent to CloudWatch Logs.

Amazon Kinesis Data Firehose

- You specify a Kinesis Data Firehose delivery stream where the logs will be delivered.
- Logs from multiple Redis clusters and replication groups can be delivered to the same delivery stream.
- Logs from each node within a cache cluster or replication group will be delivered to the same delivery stream. You can distinguish log messages from different cache nodes based on the cache-cluster-id and cache-node-id included in each log message.
- Log delivery to Kinesis Data Firehose is currently not available in the Asia Pacific (Osaka) Region.

Permissions to publish logs to Kinesis Data Firehose

You must have the following permissions to configure ElastiCache for Redis to send logs to an Amazon Kinesis Data Firehose delivery stream.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "logs:CreateLogDelivery",
                "logs:GetLogDelivery",
                "logs:UpdateLogDelivery",
                "logs:DeleteLogDelivery",
                "logs:ListLogDeliveries"
            ],
            "Resource": ["*"]
        },
        {
            "Sid": "ElastiCacheLogging",
            "Effect": "Allow",
            "Resource": ["*"]
        },
        {
            "Sid": "ElastiCacheLoggingFHSLR",
            "Action": [
                "iam:CreateServiceLinkedRole"
            ],
            "Resource": "*",
            "Effect": "Allow"
        },
        {
            "Sid": "ElastiCacheLoggingFH",
            "Action": [
                "firehose:TagDeliveryStream"
            ],
            "Resource": "Amazon Kinesis Data Firehose delivery stream ARN",
            "Effect": "Allow"
        }
    ]
}
```
Specifying log delivery using the Console

Using the AWS Management Console you can create a Redis (cluster mode disabled) cluster by following the steps at Creating a Redis (cluster mode disabled) cluster (Console) (p. 47) or create a Redis (cluster mode enabled) cluster using the steps at Creating a Redis (cluster mode enabled) cluster (Console) (p. 133). In either case, you configure log delivery by doing the following:

1. Under Advanced Redis settings, choose Logs and then check either Slow logs or Engine logs.
2. Under Log format, choose either Text or JSON.
3. Under Destination Type, choose either CloudWatch Logs or Kinesis Firehose.
4. Under Log destination, choose either Create new and enter either your Amazon S3 bucket name, CloudWatchLogs log group name or your Kinesis Data Firehose stream name, or choose Select existing and then choose either your CloudWatch Logs group name or your Kinesis Data Firehose stream name, When modifying a cluster:

You can choose to either enable/disable log delivery or change either the destination type, format or destination:

1. Sign in to the Console and open the ElastiCache console at https://console.aws.amazon.com/elasticache/.
2. From the navigation pane, choose Redis.
3. From the list of clusters, choose the cluster you want to modify. Choose the Cluster name and not the checkbox beside it.
4. On the Cluster name page, choose the Logs tab.
5. To enable/disable slow logs, choose either Enable slow logs or Disable slow logs.
6. To enable/disable engine logs, choose either Enable engine logs or Disable engine logs.
7. To change your configuration, choose either Modify slow logs or Modify engine logs:
   - Under Destination Type, choose either CloudWatch Logs or Kinesis Firehose.
   - Under Log destination, choose either Create new and enter either your CloudWatchLogs log group name or your Kinesis Data Firehose stream name. Or choose Select existing and then choose either your CloudWatchLogs log group name or your Kinesis Data Firehose stream name.

Specifying log delivery using the AWS CLI

Slow Log

Create a replication group with slow log delivery to CloudWatch Logs.

For Linux, macOS, or Unix:

```bash
aws elasticache create-replication-group \
  --replication-group-id test-slow-log \
  --replication-group-description test-slow-log \
  --engine redis \
  --cache-node-type cache.r5.large \
  --num-cache-clusters 2 \
  --log-delivery-configurations '{
    "LogType":"slow-log",
    "DestinationType":"cloudwatch-logs",
    "DestinationDetails":{
      "CloudWatchLogsDetails":{
```
For Windows:

```
aws elasticache create-replication-group ^
--replication-group-id test-slow-log ^
--replication-group-description test-slow-log ^
--engine redis ^
--cache-node-type cache.r5.large ^
--num-cache-clusters 2 ^
--log-delivery-configurations '{
  "LogType":"slow-log",
  "DestinationType":"cloudwatch-logs",
  "DestinationDetails":{
    "CloudWatchLogsDetails":{
      "LogGroup":"my-log-group"
    }
  },
  "LogFormat":"json"
}'
```

Modify a replication group to deliver slow log to CloudWatch Logs

For Linux, macOS, or Unix:

```
aws elasticache modify-replication-group \
--replication-group-id test-slow-log \
--apply-immediately \
--log-delivery-configurations '{
  "LogType":"slow-log",
  "DestinationType":"cloudwatch-logs",
  "DestinationDetails":{
    "CloudWatchLogsDetails":{
      "LogGroup":"my-log-group"
    }
  },
  "LogFormat":"json"
}'
```

For Windows:

```
aws elasticache modify-replication-group ^
--replication-group-id test-slow-log ^
--apply-immediately ^
--log-delivery-configurations '{
  "LogType":"slow-log",
  "DestinationType":"cloudwatch-logs",
  "DestinationDetails":{
    "CloudWatchLogsDetails":{
      "LogGroup":"my-log-group"
    }
  },
  "LogFormat":"json"
}'
```
Modify a replication group to disable slow log delivery

For Linux, macOS, or Unix:

```
aws elasticache modify-replication-group
  --replication-group-id test-slow-log
  --apply-immediately
  --log-delivery-configurations '{
    "LogType":"slow-log",
    "Enabled":false
  }',
```

For Windows:

```
aws elasticache modify-replication-group
  --replication-group-id test-slow-log
  --apply-immediately
  --log-delivery-configurations '{
    "LogType":"slow-log",
    "Enabled":false
  }',
```

Engine Log

Create a replication group with engine log delivery to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws elasticache create-replication-group
  --replication-group-id test-slow-log
  --replication-group-description test-slow-log
  --engine redis
  --cache-node-type cache.r5.large
  --num-cache-clusters 2
  --log-delivery-configurations '{
    "LogType":"engine-log",
    "DestinationType":"cloudwatch-logs",
    "DestinationDetails":{
      "CloudWatchLogsDetails":{
        "LogGroup":"my-log-group"
      }
    },
    "LogFormat":"json"
  }',
```

For Windows:

```
aws elasticache create-replication-group
  --replication-group-id test-slow-log
  --replication-group-description test-slow-log
  --engine redis
  --cache-node-type cache.r5.large
  --num-cache-clusters 2
  --log-delivery-configurations '{
    "LogType":"engine-log",
    "DestinationType":"cloudwatch-logs",
    "DestinationDetails":{
      "CloudWatchLogsDetails":{
        "LogGroup":"my-log-group"
      }
    },
    "LogFormat":"json"
  }',
```
Modify a replication group to deliver engine log to Kinesis Data Firehose

For Linux, macOS, or Unix:

```bash
aws elasticsearch modify-replication-group \
  --replication-group-id test-slow-log \
  --apply-immediately \
  --log-delivery-configurations ' 
  { 
    "LogType": "engine-log", 
    "DestinationType": "kinesis-firehose", 
    "DestinationDetails": { 
      "KinesisFirehoseDetails": { 
        "DeliveryStream": "test" 
      } 
    }, 
    "LogFormat": "json" 
  }',
```

For Windows:

```bash
aws elasticsearch modify-replication-group ^ 
  --replication-group-id test-slow-log ^ 
  --apply-immediately ^ 
  --log-delivery-configurations ' 
  { 
    "LogType": "engine-log", 
    "DestinationType": "kinesis-firehose", 
    "DestinationDetails": { 
      "KinesisFirehoseDetails": { 
        "DeliveryStream": "test" 
      } 
    }, 
    "LogFormat": "json" 
  }',
```

Modify a replication group to switch to engine format

For Linux, macOS, or Unix:

```bash
aws elasticsearch modify-replication-group \
  --replication-group-id test-slow-log \
  --apply-immediately \
  --log-delivery-configurations ' 
  { 
    "LogType": "engine-log", 
    "LogFormat": "json" 
  }',
```

For Windows:

```bash
aws elasticsearch modify-replication-group ^ 
  --replication-group-id test-slow-log ^ 
  --apply-immediately ^ 
  --log-delivery-configurations ' 
  { 
```
Modify a replication group to disable engine log delivery

For Linux, macOS, or Unix:

```bash
aws elasticache modify-replication-group \
   --replication-group-id test-slow-log \
   --apply-immediately \
   --log-delivery-configurations ' \
   { "LogType":"engine-log", 
   "Enabled":false 
   }'
```

For Windows:

```bash
aws elasticache modify-replication-group ^ \
   --replication-group-id test-slow-log ^ \
   --apply-immediately ^ \
   --log-delivery-configurations ' \
   { "LogType":"engine-log", 
   "Enabled":false 
   }'
```
Monitoring use with CloudWatch Metrics

ElastiCache provides metrics that enable you to monitor your clusters. You can access these metrics through CloudWatch. For more information on CloudWatch, see the CloudWatch documentation.

ElastiCache provides both host-level metrics (for example, CPU usage) and metrics that are specific to the cache engine software (for example, cache gets and cache misses). These metrics are measured and published for each Cache node in 60-second intervals.

**Important**

You should consider setting CloudWatch alarms on certain key metrics, so that you will be notified if your cache cluster's performance starts to degrade. For more information, see Which Metrics Should I Monitor? (p. 598) in this guide.

**Topics**

- Host-Level Metrics (p. 588)
- Metrics for Redis (p. 590)
- Which Metrics Should I Monitor? (p. 598)
- Choosing Metric Statistics and Periods (p. 601)
- Monitoring CloudWatch Cluster and Node Metrics (p. 601)

**Host-Level Metrics**

The AWS/ElastiCache namespace includes the following host-level metrics for individual cache nodes.

**See Also**

- Metrics for Redis (p. 590)

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilization</td>
<td>The percentage of CPU utilization for the entire host. Because Redis is single-threaded, we recommend you monitor EngineCPUUtilization metric for nodes with 4 or more vCPUs.</td>
<td>Percent</td>
</tr>
<tr>
<td>CPUCreditBalance</td>
<td>The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued.</td>
<td>Credits (vCPU-minutes)</td>
</tr>
</tbody>
</table>

   - Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit.

   - The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization.
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUCreditUsage</td>
<td>The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes).</td>
<td>Credits (vCPU-minutes)</td>
</tr>
<tr>
<td>FreeableMemory</td>
<td>The amount of free memory available on the host. This is derived from the RAM, buffers, and cache that the OS reports as freeable.</td>
<td>Bytes</td>
</tr>
<tr>
<td>NetworkBytesIn</td>
<td>The number of bytes the host has read from the network.</td>
<td>Bytes</td>
</tr>
<tr>
<td>NetworkBytesOut</td>
<td>The number of bytes sent out on all network interfaces by the instance.</td>
<td>Bytes</td>
</tr>
<tr>
<td>NetworkPacketsIn</td>
<td>The number of packets received on all network interfaces by the instance. This metric identifies the volume of incoming traffic in terms of the number of packets on a single instance.</td>
<td>Count</td>
</tr>
<tr>
<td>NetworkPacketsOut</td>
<td>The number of packets sent out on all network interfaces by the instance. This metric identifies the volume of outgoing traffic in terms of the number of packets on a single instance.</td>
<td>Count</td>
</tr>
<tr>
<td>NetworkBandwidthInAllowanceExceeded</td>
<td>The number of packets queued or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance.</td>
<td>Count</td>
</tr>
<tr>
<td>NetworkConntrackAllowanceExceeded</td>
<td>The number of packets dropped because connection tracking exceeded the maximum for the instance and new connections could not be established. This can result in packet loss for traffic to or from the instance.</td>
<td>Count</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Unit</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>NetworkLinkLocalAllowanceExceeded</td>
<td>The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service.</td>
<td>Count</td>
</tr>
<tr>
<td>NetworkBandwidthOutAllowanceExceeded</td>
<td>The number of packets queued or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance.</td>
<td>Count</td>
</tr>
<tr>
<td>NetworkPacketsPerSecondAllowanceExceeded</td>
<td>The number of packets queued or dropped because the bidirectional packets per second exceeded the maximum for the instance.</td>
<td>Count</td>
</tr>
<tr>
<td>SwapUsage</td>
<td>The amount of swap used on the host.</td>
<td>Bytes</td>
</tr>
</tbody>
</table>

### Metrics for Redis

The AWS/ElastiCache namespace includes the following Redis metrics.

With the exception of ReplicationLag and EngineCPUUtilization, these metrics are derived from the Redis `info` command. Each metric is calculated at the cache node level.

For complete documentation of the Redis `info` command, see [http://redis.io/commands/info](http://redis.io/commands/info).

**See Also**

- Host-Level Metrics (p. 588)

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveDefragHits</td>
<td>The number of value reallocations per minute performed by the active defragmentation process. This is derived from <code>active_defrag_hits</code> statistic at Redis <code>INFO</code>.</td>
<td>Number</td>
</tr>
<tr>
<td>AuthenticationFailures</td>
<td>The total number of failed attempts to authenticate to Redis using the AUTH command. You can find more information about individual authentication failures using the ACL LOG command. We suggest setting an alarm on this to detect unauthorized access attempts.</td>
<td>Count</td>
</tr>
<tr>
<td>BytesUsedForCache</td>
<td>The total number of bytes allocated by Redis for all purposes, including the dataset, buffers, and so on.</td>
<td>Bytes</td>
</tr>
<tr>
<td>Dimension: Tier=Memory</td>
<td>Dimension: Tier=Memory for Redis clusters using Data tiering (p. 121): The total number of bytes used for cache by memory. This is the value of <code>used_memory</code> statistic at Redis <code>INFO</code>.</td>
<td>Bytes</td>
</tr>
<tr>
<td>Dimension: Tier=SSD</td>
<td>Dimension: Tier=SSD for Redis clusters using Data tiering (p. 121): The total number of bytes used for cache by SSD.</td>
<td>Bytes</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Unit</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>BytesReadFromDisk</td>
<td>The total number of bytes read from disk per minute. Supported only for clusters using Data tiering (p. 121).</td>
<td>Bytes</td>
</tr>
<tr>
<td>BytesWrittenToDisk</td>
<td>The total number of bytes written to disk per minute. Supported only for clusters using Data tiering (p. 121).</td>
<td>Bytes</td>
</tr>
<tr>
<td>CacheHits</td>
<td>The number of successful read-only key lookups in the main dictionary. This is derived from keyspace_hits statistic at Redis INFO.</td>
<td>Count</td>
</tr>
<tr>
<td>CacheMisses</td>
<td>The number of unsuccessful read-only key lookups in the main dictionary. This is derived from keyspace_misses statistic at Redis INFO.</td>
<td>Count</td>
</tr>
<tr>
<td>CommandAuthorizationFailures</td>
<td>The total number of failed attempts by users to run commands they don't have permission to call. You can find more information about individual authentication failures using the ACL LOG command. We suggest setting an alarm on this to detect unauthorized access attempts.</td>
<td>Count</td>
</tr>
<tr>
<td>CacheHitRate</td>
<td>Indicates the usage efficiency of the Redis instance. If the cache ratio is lower than about 0.8, it means that a significant amount of keys are evicted, expired, or don't exist. This is calculated using cache_hits and cache_misses statistics in the following way: cache_hits / (cache_hits + cache_misses).</td>
<td>Percent</td>
</tr>
<tr>
<td>CurrConnections</td>
<td>The number of client connections, excluding connections from read replicas. ElastiCache uses two to four of the connections to monitor the cluster in each case. This is derived from the connected_clients statistic at Redis INFO.</td>
<td>Count</td>
</tr>
<tr>
<td>CurrItems</td>
<td>The number of items in the cache. This is derived from the Redis keyspace statistic, summing all of the keys in the entire keyspace.</td>
<td>Count</td>
</tr>
<tr>
<td>DatabaseMemoryUsagePercentage</td>
<td>Percentage of the memory available for the cluster that is in use. This is calculated using used_memory/maxmemory from Redis INFO.</td>
<td>Percent</td>
</tr>
<tr>
<td>Dimension: Tier=Memory</td>
<td>for clusters using Data tiering (p. 121). The number of items in memory.</td>
<td></td>
</tr>
<tr>
<td>Dimension: Tier=SSD</td>
<td>(solid state drives) for clusters using Data tiering (p. 121). The number of items in SSD.</td>
<td></td>
</tr>
<tr>
<td>CurrVolatileItems</td>
<td>Total number of keys in all databases that have a ttl set. This is derived from the Redis expires statistic, summing all of the keys with a ttl set in the entire keyspace.</td>
<td>Count</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Unit</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------</td>
</tr>
<tr>
<td>DatabaseMemoryUsageCountedForEvictPercentage</td>
<td>Percentage of the memory available for the cluster that is in use excluding memory used for overhead and COB. This is calculated using <code>used_memory-mem_not_counted_for_evict/maxmemory</code> from Redis INFO.</td>
<td>Percent</td>
</tr>
<tr>
<td>DB0AverageTTL</td>
<td>Exposes <code>avg_ttl</code> of DBO from the keyspace statistic of Redis INFO command.</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>EngineCPUUtilization</td>
<td>Provides CPU utilization of the Redis engine thread. Because Redis is single-threaded, you can use this metric to analyze the load of the Redis process itself. The EngineCPUUtilization metric provides a more precise visibility of the Redis process. You can use it in conjunction with the CPUUtilization metric. CPUUtilization exposes CPU utilization for the server instance as a whole, including other operating system and management processes. For larger node types with four vCPUs or more, use the EngineCPUUtilization metric to monitor and set thresholds for scaling.</td>
<td>Percent</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>On an ElastiCache host, background processes monitor the host to provide a managed database experience. These background processes can take up a significant portion of the CPU workload. This is not significant on larger hosts with more than two vCPUs. But it can affect smaller hosts with 2vCPUs or fewer. If you only monitor the EngineCPUUtilization metric, you will be unaware of situations where the host is overloaded with both high CPU usage from Redis and high CPU usage from the background monitoring processes. Therefore, we recommend monitoring the CPUUtilization metric for hosts with two vCPUs or less.</td>
<td></td>
</tr>
<tr>
<td>Evictions</td>
<td>The number of keys that have been evicted due to the maxmemory limit. This is derived from the <code>evicted_keys</code> statistic at Redis INFO.</td>
<td>Count</td>
</tr>
<tr>
<td>GlobalDatastoreReplicationLag</td>
<td>This is the lag between the secondary Region's primary node and the primary Region's primary node. For cluster mode enabled Redis, the lag indicates the maximum delay among the shards.</td>
<td>Seconds</td>
</tr>
<tr>
<td>IsPrimary</td>
<td>Indicates whether the node is the primary node of current shard/cluster. The metric can be either 0 (not primary) or 1 (primary).</td>
<td>Count</td>
</tr>
</tbody>
</table>

</tr>
</tbody>
</table>
The following are aggregations of certain kinds of commands, derived from `info commandstats`. The `commandstats` section provides statistics based on the command type, including the number of calls, the total CPU time consumed by these commands, and the average CPU consumed per command execution. For each command type, the following line is added: `cmdstat_XXX: calls=XXX,usec=XXX,usec_per_call=XXX`.

The latency metrics listed following are calculated using `commandstats` statistic from Redis `INFO`. They are calculated in the following way: `delta(usec)/delta(calls)`. `delta` is calculated as the diff within one minute. Latency is defined as CPU time taken by ElastiCache to process the command. Note that for clusters using data tiering, the time taken to fetch items from SSD is not included in these measurements.

For a full list of available commands, see `redis commands` in the Redis documentation.

</table>
Monitoring use

**Which Metrics Should I Monitor?**

The following CloudWatch metrics offer good insight into ElastiCache performance. In most cases, we recommend that you set CloudWatch alarms for these metrics so that you can take corrective action before performance issues occur.

**Metrics to Monitor**

- CPUUtilization (p. 598)
- EngineCPUUtilization (p. 598)
- SwapUsage (p. 599)
- Evictions (p. 599)
- CurrConnections (p. 599)
- Memory (p. 599)
- Network (p. 599)
- Latency (p. 599)
- Replication (p. 599)

**CPUUtilization**

This is a host-level metric reported as a percentage. For more information, see Host-Level Metrics (p. 588).

For smaller node types with 2vCPUs or less, use the CPUUtilization metric to monitor your workload.

Generally speaking, we suggest you set your threshold at 90% of your available CPU. Because Redis is single-threaded, the actual threshold value should be calculated as a fraction of the node's total capacity. For example, suppose you are using a node type that has two cores. In this case, the threshold for CPUUtilization would be 90/2, or 45%.

You will need to determine your own threshold, based on the number of cores in the cache node that you are using. If you exceed this threshold, and your main workload is from read requests, scale your cache cluster out by adding read replicas. If the main workload is from write requests, depending on your cluster configuration, we recommend that you:

- **Redis (cluster mode disabled) clusters**: scale up by using a larger cache instance type.
- **Redis (cluster mode enabled) clusters**: add more shards to distribute the write workload across more primary nodes.

**Tip**

Instead of using the Host-Level metric CPUUtilization, Redis users might be able to use the Redis metric EngineCPUUtilization, which reports the percentage of usage on the Redis engine core. To see if this metric is available on your nodes and for more information, see Metrics for Redis.

For larger node types with 4vCPUs or more, you may want to use the EngineCPUUtilization metric, which reports the percentage of usage on the Redis engine core. To see if this metric is available on your nodes and for more information, see Metrics for Redis.

**EngineCPUUtilization**

For larger node types with 4vCPUs or more, you may want to use the EngineCPUUtilization metric, which reports the percentage of usage on the Redis engine core. To see if this metric is available on your nodes and for more information, see Metrics for Redis.
For more information, see the **CPUs** section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

**SwapUsage**

This is a host-level metric reported in bytes. For more information, see Host-Level Metrics (p. 588). This metric should not exceed 300 MB. If it does, see the following topics:

- Ensuring that you have enough memory to create a Redis snapshot (p. 221)
- Managing Reserved Memory (p. 223)

**Evictions**

This is a cache engine metric. We recommend that you determine your own alarm threshold for this metric based on your application needs.

**CurrConnections**

This is a cache engine metric. We recommend that you determine your own alarm threshold for this metric based on your application needs.

An increasing number of *CurrConnections* might indicate a problem with your application; you will need to investigate the application behavior to address this issue.

For more information, see the **Connections** section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

**Memory**

Memory is a core aspect of Redis. Understanding the memory utilization of your cluster is necessary to avoid data loss and accommodate future growth of your dataset. Statistics about the memory utilization of a node are available in the memory section of the Redis `INFO` command.

For more information, see the **Memory** section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

**Network**

One of the determining factors for the network bandwidth capacity of your cluster is the node type you have selected. For more information about the network capacity of your node, see Amazon ElastiCache pricing.

For more information, see the **Network** section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

**Latency**

You can measure a command's latency with a set of CloudWatch metrics that provide aggregated latencies per data structure. These latency metrics are calculated using the `commandstats` statistic from the Redis `INFO` command.

For more information, see the **Latency** section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.

**Replication**

The volume of data being replicated is visible via the `ReplicationBytes` metric. Although this metric is representative of the write load on the replication group, it doesn’t provide insights into replication health. For this purpose, you can use the `ReplicationLag` metric.
For more information, see the Replication section at Monitoring best practices with Amazon ElastiCache for Redis using Amazon CloudWatch.
Choosing Metric Statistics and Periods

While CloudWatch will allow you to choose any statistic and period for each metric, not all combinations will be useful. For example, the Average, Minimum, and Maximum statistics for CPUUtilization are useful, but the Sum statistic is not.

All ElastiCache samples are published for a 60 second duration for each individual cache node. For any 60 second period, a cache node metric will only contain a single sample.

For further information on how to retrieve metrics for your cache nodes, see Monitoring CloudWatch Cluster and Node Metrics (p. 601).

Monitoring CloudWatch Cluster and Node Metrics

ElastiCache and CloudWatch are integrated so you can gather a variety of metrics. You can monitor these metrics using CloudWatch.

**Note**
The following examples require the CloudWatch command line tools. For more information about CloudWatch and to download the developer tools, see the CloudWatch product page.

The following procedures show you how to use CloudWatch to gather storage space statistics for an cache cluster for the past hour.

**Note**
The `StartTime` and `EndTime` values supplied in the examples below are for illustrative purposes. You must substitute appropriate start and end time values for your cache nodes.

For information on ElastiCache limits, see AWS Service Limits for ElastiCache.

Monitoring CloudWatch Cluster and Node Metrics (Console)

**To gather CPU utilization statistics for a cache cluster**

2. Select the cache nodes you want to view metrics for.

**Note**
Selecting more than 20 nodes disables viewing metrics on the console.

a. On the **Cache Clusters** page of the AWS Management Console, click the name of one or more cache clusters.
   
   The detail page for the cache cluster appears.

b. Click the **Nodes** tab at the top of the window.

c. On the **Nodes** tab of the detail window, select the cache nodes that you want to view metrics for.
   
   A list of available CloudWatch Metrics appears at the bottom of the console window.

d. Click on the **CPU Utilization** metric.
   
   The CloudWatch console will open, displaying your selected metrics. You can use the **Statistic** and **Period** drop-down list boxes and **Time Range** tab to change the metrics being displayed.

Monitoring CloudWatch Cluster and Node Metrics using the CloudWatch CLI

**To gather CPU utilization statistics for a cache cluster**

API Version 2015-02-02

601
Monitoring CloudWatch Cluster and Node Metrics using the CloudWatch API

To gather CPU utilization statistics for a cache cluster

- Call the CloudWatch API `GetMetricStatistics` with the following parameters (note that the start and end times are shown as examples only; you will need to substitute your own appropriate start and end times):
  - Statistics.member.1=Average
  - Namespace=AWS/ElastiCache
  - StartTime=2013-07-05T00:00:00
  - EndTime=2013-07-06T00:00:00
  - Period=60
  - MeasureName=CPUUtilization
  - Dimensions=CacheClusterId=mycachecluster,CacheNodeId=0002

Example

http://monitoring.amazonaws.com/
?Action=GetMetricStatistics
&SignatureVersion=4
&Version=2014-12-01
&StartTime=2018-07-05T00:00:00
&EndTime=2018-07-06T00:00:00
&Period=3600
&Statistics.member.1=Average
&Dimensions.member.1="CacheClusterId=mycachecluster"
&Dimensions.member.2="CacheNodeId=0002"
&Namespace=AWS;/ElastiCache
&MeasureName=CPUUtilization
&Timestamp=2018-07-07T17%3A48%3A21.746Z
&AWS;AccessKeyId=<AWS; Access Key ID>

Logging Amazon ElastiCache API calls with AWS CloudTrail

Amazon ElastiCache is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon ElastiCache. CloudTrail captures all API calls for Amazon ElastiCache as events, including calls from the Amazon ElastiCache console and from code calls to the Amazon ElastiCache API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon ElastiCache. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to Amazon ElastiCache, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Amazon ElastiCache information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon ElastiCache, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Amazon ElastiCache, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all regions. The trail logs events from all regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Amazon ElastiCache actions are logged by CloudTrail and are documented in the ElastiCache API Reference. For example, calls to the CreateCacheCluster, DescribeCacheCluster and ModifyCacheCluster actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Understanding Amazon ElastiCache log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request
parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `CreateCacheCluster` action.

```json
{
    "eventVersion": "1.01",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "EXAMPLEEXAMPLEEXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/elasticache-allow",
        "accountId": "123456789012",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "userName": "elasticache-allow"
    },
    "eventTime": "2014-12-01T22:00:35Z",
    "eventSource": "elasticache.amazonaws.com",
    "eventName": "CreateCacheCluster",
    "awsRegion": "us-west-2",
    "sourceIPAddress": "192.0.2.01",
    "userId": "AWS CLI/ElastiCache 1.10 API 2014-12-01",
    "requestParameters": {
        "numCacheNodes": 2,
        "cacheClusterId": "test-memcached",
        "engine": "memcached",

```
Monitoring ElastiCache events

When significant events happen for a cluster, ElastiCache sends notification to a specific Amazon SNS topic. Examples include a failure to add a node, success in adding a node, the modification of a security group, and others. By monitoring for key events, you can know the current state of your clusters and, depending upon the event, be able to take corrective action.

Topics

- Managing ElastiCache Amazon SNS notifications (p. 607)
- Viewing ElastiCache events (p. 611)
- Event Notifications and Amazon SNS (p. 614)

Managing ElastiCache Amazon SNS notifications

You can configure ElastiCache to send notifications for important cluster events using Amazon Simple Notification Service (Amazon SNS). In these examples, you will configure a cluster with the Amazon Resource Name (ARN) of an Amazon SNS topic to receive notifications.

Note

This topic assumes that you've signed up for Amazon SNS and have set up and subscribed to an Amazon SNS topic. For information on how to do this, see the Amazon Simple Notification Service Developer Guide.

Adding an Amazon SNS topic

The following sections show you how to add an Amazon SNS topic using the AWS Console, the AWS CLI, or the ElastiCache API.

Adding an Amazon SNS topic (Console)

The following procedure shows you how to add an Amazon SNS topic for a cluster. To add an Amazon SNS topic for a replication group, in step 2, instead of choosing a cluster, choose a replication group then follow the same remaining steps.
Monitoring events

Note
This process can also be used to modify the Amazon SNS topic.

To add or modify an Amazon SNS topic for a cluster (Console)

2. In Clusters, choose the cluster for which you want to add or modify an Amazon SNS topic ARN.
3. Choose Modify.
4. In Modify Cluster under Topic for SNS Notification, choose the SNS topic you want to add, or choose Manual ARN input and type the ARN of the Amazon SNS topic.
5. Choose Modify.

Adding an Amazon SNS topic (AWS CLI)

To add or modify an Amazon SNS topic for a cluster, use the AWS CLI command modify-cache-cluster.

The following code example adds an Amazon SNS topic arn to my-cluster.

For Linux, macOS, or Unix:

```bash
```

For Windows:

```bash
```

For more information, see modify-cache-cluster.

Adding an Amazon SNS topic (ElastiCache API)

To add or modify an Amazon SNS topic for a cluster, call the ModifyCacheCluster action with the following parameters:

- CacheClusterId=my-cluster
- TopicArn=arn%3Aaws%3Asns%3Aus-west-2%3A565419523791%3AElastiCacheNotifications

Example

```
https://elasticache.amazon.com/
?Action=ModifyCacheCluster
&ApplyImmediately=false
&CacheClusterId=my-cluster
&NotificationTopicArn=arn%3Aaws%3Asns%3Aus-west-2%3A565419523791%3AElastiCacheNotifications
&Version=2014-12-01
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20141201T220302Z
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
```

API Version 2015-02-02
For more information, see ModifyCacheCluster.

## Enabling and disabling Amazon SNS notifications

You can turn notifications on or off for a cluster. The following procedures show you how to disable Amazon SNS notifications.

### Enabling and disabling Amazon SNS notifications (Console)

**To disable Amazon SNS notifications using the AWS Management Console**

2. To see a list of your clusters running Redis, in the navigation pane choose Redis.
3. Choose the box to the left of the cluster you want to modify notification for.
4. Choose Modify.
5. In Modify Cluster under Topic for SNS Notification, choose Disable Notifications.
6. Choose Modify.

### Enabling and disabling Amazon SNS notifications (AWS CLI)

To disable Amazon SNS notifications, use the command `modify-cache-cluster` with the following parameters:

For Linux, macOS, or Unix:

```
aws elasticache modify-cache-cluster \
  --cache-cluster-id my-cluster \
  --notification-topic-status inactive
```

For Windows:

```
aws elasticache modify-cache-cluster ^
  --cache-cluster-id my-cluster ^
  --notification-topic-status inactive
```

### Enabling and disabling Amazon SNS notifications (ElastiCache API)

To disable Amazon SNS notifications, call the `ModifyCacheCluster` action with the following parameters:

- `CacheClusterId=my-cluster`
- `NotificationTopicStatus=inactive`

This call returns output similar to the following:

**Example**

[https://elasticache.us-west-2.amazonaws.com/](https://elasticache.us-west-2.amazonaws.com/)
?Action=ModifyCacheCluster
&ApplyImmediately=false
&CacheClusterId=my-cluster
&NotificationTopicStatus=inactive
&Version=2014-12-01
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&Timestamp=20141201T220302Z
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Date=20141201T220302Z
&X-Amz-SignedHeaders=Host
&X-Amz-Expires=20141201T220302Z
&X-Amz-Credential=<credential>
&X-Amz-Signature=<signature>
Viewing ElastiCache events

ElastiCache logs events that relate to your cluster instances, security groups, and parameter groups. This information includes the date and time of the event, the source name and source type of the event, and a description of the event. You can easily retrieve events from the log using the ElastiCache console, the AWS CLI describe-events command, or the ElastiCache API action DescribeEvents.

The following procedures show you how to view all ElastiCache events for the past 24 hours (1440 minutes).

Viewing ElastiCache events (Console)

The following procedure displays events using the ElastiCache console.

To view events using the ElastiCache console

2. To see a list of all available events, in the navigation pane, choose Events.

On the Events screen each row of the list represents one event and displays the event source, the event type (cache-cluster, cache-parameter-group, cache-security-group, or cache-subnet-group), the GMT time of the event, and a description of the event.

Using the Filter you can specify whether you want to see all events, or just events of a specific type in the event list.

Viewing ElastiCache events (AWS CLI)

To generate a list of ElastiCache events using the AWS CLI, use the command describe-events. You can use optional parameters to control the type of events listed, the time frame of the events listed, the maximum number of events to list, and more.

The following code lists up to 40 cache cluster events.

```
aws elasticache describe-events --source-type cache-cluster --max-items 40
```

The following code lists all events for the past 24 hours (1440 minutes).

```
aws elasticache describe-events --source-type cache-cluster --duration 1440
```

The output from the describe-events command looks something like this.

```
aws elasticache describe-events --source-type cache-cluster --max-items 40
{
    "Events": [
        {
            "SourceIdentifier": "my-mem-cluster",
            "SourceType": "cache-cluster",
            "Message": "Finished modifying number of nodes from 1 to 3",

Monitoring events

For more information, such as available parameters and permitted parameter values, see describe-events.

Viewing ElastiCache events (ElastiCache API)

To generate a list of ElastiCache events using the ElastiCache API, use the DescribeEvents action. You can use optional parameters to control the type of events listed, the time frame of the events listed, the maximum number of events to list, and more.

The following code lists the 40 most recent cache-cluster events.

https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeEvents
&MaxRecords=40
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&SourceType=cache-cluster
&Timestamp=20150202T192317Z
&Version=2015-02-02
&X-Amz-Credential=<credential>

The following code lists the cache-cluster events for the past 24 hours (1440 minutes).

https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeEvents
&Duration=1440
&SignatureVersion=4
&SignatureMethod=HmacSHA256
&SourceType=cache-cluster
&Timestamp=20150202T192317Z
&Version=2015-02-02
&X-Amz-Credential=<credential>

The above actions should produce output similar to the following.

<DescribeEventsResponse xmlns="http://elasticache.amazonaws.com/doc/2015-02-02/">
  <DescribeEventsResult>
    <Events>
      <Event>
        <Message>Cache cluster created</Message>
        <SourceType>cache-cluster</SourceType>
        <Date>2015-02-02T18:22:18.202Z</Date>
        <SourceIdentifier>mem01</SourceIdentifier>
      </Event>
      (...output omitted...)
    </Events>
  </DescribeEventsResult>
  <ResponseMetadata>
    <RequestId>e21c81b4-b9cd-11e3-8a16-7978bb24ffdf</RequestId>
  </ResponseMetadata>
</DescribeEventsResponse>

For more information, such as available parameters and permitted parameter values, see DescribeEvents.
Event Notifications and Amazon SNS

ElastiCache can publish messages using Amazon Simple Notification Service (SNS) when significant events happen on a cache cluster. This feature can be used to refresh the server-lists on client machines connected to individual cache node endpoints of a cache cluster.

**Note**
For more information on Amazon Simple Notification Service (SNS), including information on pricing and links to the Amazon SNS documentation, see the Amazon SNS product page.

Notifications are published to a specified Amazon SNS topic. The following are requirements for notifications:

- Only one topic can be configured for ElastiCache notifications.
- The AWS account that owns the Amazon SNS topic must be the same account that owns the cache cluster on which notifications are enabled.
- The Amazon SNS topic you are publishing to cannot be encrypted.

**Note**
It is possible to attach an encrypted (at-rest) Amazon SNS topic to the cluster. However, the status of the topic from the ElastiCache console will show as inactive, which effectively disassociates the topic from the cluster when ElastiCache pushes messages to the topic.
- The Amazon SNS topic has to be in the same Region as the ElastiCache cluster.

ElastiCache Events

The following ElastiCache events trigger Amazon SNS notifications. For information on event details, see Viewing ElastiCache events (p. 611).

<table>
<thead>
<tr>
<th>Event Name</th>
<th>Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ElastiCache:AddCacheNodeComplete</td>
<td>ElastiCache:AddCacheNodeComplete: cache-cluster</td>
<td>A cache node has been added to the cache cluster and is ready for use.</td>
</tr>
<tr>
<td>ElastiCache:AddCacheNodeFailed due to insufficient free IP addresses</td>
<td>ElastiCache:AddCacheNodeFailed: cluster-name</td>
<td>A cache node could not be added because there are not enough available IP addresses.</td>
</tr>
<tr>
<td>ElastiCache:CacheClusterParametersChanged</td>
<td>ElastiCache:CacheClusterParametersChanged: cluster-name</td>
<td>One or more cache cluster parameters have been changed.</td>
</tr>
<tr>
<td>ElastiCache:CacheClusterProvisioningComplete</td>
<td>ElastiCache:CacheClusterProvisioningComplete: cluster-name-0001-005</td>
<td>The provisioning of a cache cluster is completed, and the cache nodes in the cache cluster are ready to use.</td>
</tr>
<tr>
<td>ElastiCache:CacheClusterProvisioningFailed due to incompatible network state</td>
<td>ElastiCache:CacheClusterProvisioningFailed: cluster-name</td>
<td>An attempt was made to launch a new cache cluster into a nonexistent virtual private cloud (VPC).</td>
</tr>
<tr>
<td>Event Name</td>
<td>Message</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| ElastiCache:CacheClusterSecurityGroupModified  | ElastiCache:CacheClusterSecurityGroupModified : cluster-name | One of the following events has occurred:  
• The list of cache security groups authorized for the cache cluster has been modified.  
• One or more new EC2 security groups have been authorized on any of the cache security groups associated with the cache cluster.  
• One or more EC2 security groups have been revoked from any of the cache security groups associated with the cache cluster. |
| ElastiCache:CacheNodeReplaceStarted           | ElastiCache:CacheNodeReplaceStarted : cluster-name | ElastiCache has detected that the host running a cache node is degraded or unreachable and has started replacing the cache node.  

**Note**  
The DNS entry for the replaced cache node is not changed.  

In most instances, you do not need to refresh the server-list for your clients when this event occurs. However, some cache client libraries may stop using the cache node even after ElastiCache has replaced the cache node; in this case, the application should refresh the server-list when this event occurs. |
## Monitoring events

<table>

Compliance validation for Amazon ElastiCache

Third-party auditors assess the security and compliance of AWS services as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, and HIPAA.

To learn whether ElastiCache or other AWS services are in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- **Architecting for HIPAA Security and Compliance Whitepaper** – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

  **Note**
  Not all AWS services are HIPAA eligible. For more information, see the HIPAA Eligible Services Reference.

- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **Evaluating Resources with Rules** in the AWS Config Developer Guide – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
- **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

You can use Amazon ElastiCache for Redis to build HIPAA-compliant applications. To help do this, you can enable at-rest encryption, in-transit encryption, and Redis AUTH when you create a Redis cluster using ElastiCache for Redis versions 3.2.6, 4.0.10, or later. You can store healthcare-related information, including protected health information (PHI), under an executed Business Associate Agreement (BAA) with AWS. AWS Services in Scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see the following topics:

- AWS Cloud Compliance
- HIPAA Compliance
- AWS Services in Scope by Compliance Program
- ElastiCache for Redis compliance (p. 619)
- Data security in Amazon ElastiCache (p. 470)
- Authenticating users with the Redis AUTH command (p. 478)

Self-service security updates for compliance

ElastiCache offers a self-service software update feature called Service Updates by using the console, API, and CLI. Using this feature, you can manage security updates on your Redis clusters on-demand and in real-time. This feature allows you to control when you update Redis clusters with the latest required security fixes, minimizing the impact on your business.

Security updates are released by using the Service Updates feature. They are specified by the Update Type field of value security update. The Service Update has corresponding Severity and Recommended Apply by Date fields. In order to maintain compliance of your Redis clusters, you must apply the available updates by the Recommended Apply by Date. The field SLA Met reflects your Redis cluster’s compliance status.

Note

If you do not apply the Service Update by the recommended date or when the Service Update expires, ElastiCache will not take any action to apply the update on your behalf.

You are notified of the Service Updates applicable to your Redis clusters by an announcement on the Redis console, email, Amazon SNS, CloudWatch events (AWS Health Service). For more information on Self-Service Maintenance see Self-service updates in Amazon ElastiCache (p. 626).

CloudWatch events and AWS Health Dashboard are not supported in the following regions:

• us-gov-west-1
• us-gov-east-1
• cn-north-1
• cn-northwest-1

ElastiCache for Redis FedRAMP compliance

The AWS FedRAMP Compliance program includes Amazon ElastiCache for Redis as a FedRAMP-authorized service. If you are a federal or commercial customer, you can use the service to process and store sensitive workloads in AWS US East and US West with data up to the moderate impact level. You can use the service for sensitive workloads in the AWS GovCloud (US) Region’s authorization boundary with data up to the high impact level.

You can request access to the AWS FedRAMP Security Packages through the FedRAMP PMO or your AWS Sales Account Manager or, they can be downloaded through AWS Artifact at AWS Artifact.
Requirements

To enable FedRAMP support on your ElastiCache for Redis cluster, your cluster and nodes within the cluster must satisfy the following requirements.

- **Engine version requirements** – Your cluster must be running ElastiCache for Redis 3.2.6, 4.0.10 and later for both cluster mode enabled and disabled to qualify for FedRAMP compliance.
  
  - Starting with ElastiCache for Redis versions 3.2.6, 4.0.10 and later for both cluster mode enabled and disabled, you can also enable additional data security features such as:
    - ElastiCache for Redis in-transit encryption (TLS) (p. 471)
    - At-Rest Encryption in ElastiCache for Redis (p. 483)
    - Authenticating users with the Redis AUTH command (p. 478)

- **Node type requirements** – Your cluster must be running a current-generation node type — M4, M5, M6g, T2, T3, T4g, R4, R5 or R6g. For more information, see the following:
  
  - Supported node types (p. 99)
  - Choosing your node size (p. 127)

- **FIPS Endpoints requirements** – Your ElastiCache for Redis clusters can be created using the FIPS endpoints available in the following regions:

<table>
<thead>
<tr>
<th>Region Name/Region</th>
<th>FIPS Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio) Region</td>
<td>elasticache-fips.us-east-2.amazonaws.com</td>
</tr>
<tr>
<td>us-east-2</td>
<td></td>
</tr>
<tr>
<td>US East (N. Virginia) Region</td>
<td>elasticache-fips.us-east-1.amazonaws.com</td>
</tr>
<tr>
<td>us-east-1</td>
<td></td>
</tr>
<tr>
<td>US West (N. California) Region</td>
<td>elasticache-fips.us-west-1.amazonaws.com</td>
</tr>
<tr>
<td>us-west-1</td>
<td></td>
</tr>
<tr>
<td>US West (Oregon) Region</td>
<td>elasticache-fips.us-west-2.amazonaws.com</td>
</tr>
<tr>
<td>us-west-2</td>
<td></td>
</tr>
<tr>
<td>AWS GovCloud (US-West)</td>
<td>elasticache-fips.us-gov-west-1.amazonaws.com</td>
</tr>
<tr>
<td>us-gov-west-1</td>
<td></td>
</tr>
</tbody>
</table>

- **Security Updates Requirement** – You must regularly update your Redis cluster by the Recommended Apply by Date. You can update the cluster in real-time and on-demand to ensure no impact to your business. For more information, see Self-service updates in Amazon ElastiCache (p. 626).

HIPAA eligibility

The AWS HIPAA Compliance program includes Amazon ElastiCache for Redis as a HIPAA eligible service. To use ElastiCache for Redis in compliance with HIPAA, you need to set up a Business Associate Agreement (BAA) with AWS. In addition, your cluster and the nodes within your cluster must satisfy the requirements for engine version, node type, and data security listed following.

Requirements

To enable HIPAA support on your ElastiCache for Redis cluster, your cluster and nodes within the cluster must satisfy the following requirements.
• **Engine version requirements** – Your cluster must be running one of the following ElastiCache for Redis versions to qualify for HIPAA eligibility.
  • ElastiCache for Redis version 6.0 (enhanced) (p. 190) or higher.
  • ElastiCache for Redis version 5.0.0 (enhanced) (p. 192) or higher.
  • ElastiCache for Redis version 4.0.10 (enhanced) (p. 193)
  • ElastiCache for Redis version 3.2.6 (enhanced) (p. 194)

• **Node type requirements** – Your cluster must be running a current-generation node type—M4, M5, M6g, T2, T3, T4g, R4, R5, R6g or R6gd. For more information, see the following:
  • Supported node types (p. 99)
  • Choosing your node size (p. 127)

• **Data security requirements** – Your cluster must enable in-transit encryption, at-rest encryption, and Redis AUTH. For more information, see the following:
  • ElastiCache for Redis in-transit encryption (TLS) (p. 471)
  • At-Rest Encryption in ElastiCache for Redis (p. 483)
  • Authenticating users with the Redis AUTH command (p. 478)

• **Security Updates Requirement** – You must update your Redis cluster with the latest Service Updates of type security by the Recommended Apply by Date. You can update the cluster in real-time and on-demand to ensure no impact to your business. For more information, see Self-service updates in Amazon ElastiCache (p. 626).

By implementing these requirements, ElastiCache for Redis can be used to store, process, and access Protected Health Information (PHI) in compliance with HIPAA.

For general information about AWS Cloud and HIPAA eligibility, see the following:

• HIPAA Compliance
• Architecting for HIPAA Security and Compliance on Amazon Web Services
• Security Updates Requirement – You must regularly update your Redis cluster by the Recommended Apply by Date. You can update the cluster in real-time and on-demand to ensure no impact to your business. For more information, see Self-service updates in Amazon ElastiCache (p. 626).

### ElastiCache for Redis PCI DSS compliance

The AWS PCI DSS Compliance program includes Amazon ElastiCache for Redis as a PCI-compliant service. The PCI DSS 3.2 Compliance Package can be downloaded through AWS Artifact. For more information, see AWS PCI DSS Compliance Program.

**Requirements**

To enable PCI DSS support on your ElastiCache for Redis cluster, your cluster and nodes within the cluster must satisfy the following requirements.

• **Engine version requirements** – Your cluster must be running ElastiCache for Redis 3.2.6, 4.0.10 and later for both cluster mode enabled and disabled.

• **Node type requirements** – Your cluster must be running a current-generation node type—M4, M5, M6g, T2, T3, T4g, R4, R5, R6g or R6gd. For more information, see the following:
  • Supported node types (p. 99)
  • Choosing your node size (p. 127)

• **Security Updates Requirement** – You must regularly update your Redis cluster by the Recommended Apply by Date. You can update the cluster in real-time and on-demand to ensure no impact to your business. For more information, see Self-service updates in Amazon ElastiCache (p. 626).
ElastiCache for Redis also offers Data Security Controls to further secure the cluster to store, process, and transmit sensitive financial data like Customer Cardholder Data (CHD) when using the service.

**Data security options** – For more information, see the following:

- ElastiCache for Redis in-transit encryption (TLS) (p. 471)
- At-Rest Encryption in ElastiCache for Redis (p. 483)
- Authenticating users with the Redis AUTH command (p. 478)

**Create and seed a new compliant cluster**

To create a compliant cluster, create a new cluster and make sure that your choices fulfill the requirements for the compliance you want. These requirements can include engine version, node type, encryption, and if needed FIPS endpoints. If you choose, you can seed a new compliant cluster with data from an existing cluster as you’re creating it. For more information, see the following:

- Creating a cluster (p. 130)
- Creating a Redis replication group from scratch (p. 272)
- Seeding a new cluster with an externally created backup (p. 337)

**More information**

For general information about AWS Cloud compliance, see the following:

- Self-service security updates for compliance (p. 619)
- Self-service updates in Amazon ElastiCache (p. 626)
- AWS Cloud Compliance
- Shared Responsibility Model
- AWS Services in Scope by Compliance Program
- AWS HIPAA Compliance Program
- Architecting for HIPAA Security and Compliance on Amazon Web Services
- AWS PCI DSS Compliance Program

**Resilience in Amazon ElastiCache**

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see [AWS Global Infrastructure](https://aws.amazon.com/global-infrastructure/).

In addition to the AWS global infrastructure, Amazon ElastiCache offers several features to help support your data resiliency and backup needs.

**Topics**

- Mitigating Failures (p. 623)
Mitigating Failures

When planning your Amazon ElastiCache implementation, you should plan so that failures have a minimal impact upon your application and data. The topics in this section cover approaches you can take to protect your application and data from failures.

Topics
- Mitigating Failures when Running Redis (p. 623)
- Recommendations (p. 625)

Mitigating Failures when Running Redis

When running the Redis engine, you have the following options for minimizing the impact of a node or Availability Zone failure.

Mitigating Node Failures

To mitigate the impact of Redis node failures, you have the following options:

Topics
- Mitigating Failures: Redis Append Only Files (AOF) (p. 623)
- Mitigating Failures: Redis Replication Groups (p. 624)

Mitigating Failures: Redis Append Only Files (AOF)

When AOF is enabled for Redis, whenever data is written to your Redis cluster, a corresponding transaction record is written to a Redis append only file (AOF). If your Redis process restarts, ElastiCache creates a replacement cluster and provisions it. You can then run the AOF against the cluster to repopulate it with data.

Some of the shortcomings of using Redis AOF to mitigate cluster failures are the following:

- It is time-consuming.
  
  Creating and provisioning a cluster can take several minutes. Depending on the size of the AOF, running it against the cluster adds even more time when your application can't access your cluster for data. This forces your application to hit the database directly.

- The AOF can get big.
  
  Because every write to your cluster is written to a transaction record, AOFs can become very large, larger than the .rdb file for the dataset in question. Because ElastiCache relies on the local instance store, which is limited in size, enabling AOF can cause out-of-disk-space issues. You can avoid out-of-disk-space issues by using a replication group with Multi-AZ enabled.

- Using AOF can't protect you from all failure scenarios.
  
  For example, if a node fails due to a hardware fault in an underlying physical server, ElastiCache will provision a new node on a different server. In this case, the AOF is not available and can't be used to recover the data.

For more information, see Append only files (AOF) in ElastiCache for Redis (p. 345).
Mitigating Failures: Redis Replication Groups

A Redis replication group is comprised of a single primary node which your application can both read from and write to, and from 1 to 5 read-only replica nodes. Whenever data is written to the primary node it is also asynchronously updated on the read replica nodes.

When a read replica fails

1. ElastiCache detects the failed read replica.
2. ElastiCache takes the failed node offline.
3. ElastiCache launches and provisions a replacement node in the same AZ.
4. The new node synchronizes with the primary node.

During this time your application can continue reading and writing using the other nodes.

Redis Multi-AZ

You can enable Multi-AZ on your Redis replication groups. Whether you enable Multi-AZ or not, a failed primary will be detected and replaced automatically. How this takes place varies whether or not Multi-AZ is or is not enabled.

When Multi-AZ is enabled

1. ElastiCache detects the primary node failure.
2. ElastiCache promotes the read replica node with the least replication lag to primary node.
3. The other replicas sync with the new primary node.
4. ElastiCache spins up a read replica in the failed primary's AZ.
5. The new node syncs with the newly promoted primary.

Failing over to a replica node is generally faster than creating and provisioning a new primary node. This means your application can resume writing to your primary node sooner than if Multi-AZ were not enabled.

For more information, see Minimizing downtime in ElastiCache for Redis with Multi-AZ (p. 253).

When Multi-AZ is disabled

1. ElastiCache detects primary failure.
2. ElastiCache takes the primary offline.
3. ElastiCache creates and provisions a new primary node to replace the failed primary.
4. ElastiCache syncs the new primary with one of the existing replicas.
5. When the sync is finished, the new node functions as the cluster's primary node.

During steps 1 through 4 of this process, your application can't write to the primary node. However, your application can continue reading from your replica nodes.

For added protection, we recommend that you launch the nodes in your replication group in different Availability Zones (AZs). If you do this, an AZ failure will only impact the nodes in that AZ and not the others.

For more information, see High availability using replication groups (p. 246).
Mitigating Availability Zone Failures

To mitigate the impact of an Availability Zone failure, locate your nodes in as many Availability Zones as possible.

No matter how many nodes you have, if they are all located in the same Availability Zone, a catastrophic failure of that AZ results in your losing all your cache data. However, if you locate your nodes in multiple AZs, a failure of any AZ results in your losing only the nodes in that AZ.

Any time you lose a node you can experience a performance degradation since read operations are now shared by fewer nodes. This performance degradation will continue until the nodes are replaced. Because your data is not partitioned across Redis nodes, you risk some data loss only when the primary node is lost.

For information on specifying the Availability Zones for Redis nodes, see Creating a Redis (cluster mode disabled) cluster (Console) (p. 47).

For more information on regions and Availability Zones, see Choosing regions and availability zones (p. 87).

Recommendations

There are two types of failures you need to plan for, individual node failures and broad Availability Zone failures. The best failure mitigation plan will address both kinds of failures.

Minimizing the Impact of Failures

To minimize the impact of a node failure, we recommend that your implementation use multiple nodes in each shard and distribute the nodes across multiple Availability Zones.

When running Redis, we recommend that you enable Multi-AZ on your replication group so that ElastiCache will automatically fail over to a replica if the primary node fails.

Minimizing the Impact of Availability Zone Failures

To minimize the impact of an Availability Zone failure, we recommend launching your nodes in as many different Availability Zones as are available. Spreading your nodes evenly across AZs will minimize the impact in the unlikely event of an AZ failure.

Other precautions

If you’re running Redis, then in addition to the above, we recommend that you schedule regular backups of your cluster. Backups (snapshots) create a .rdb file you can use to restore your cluster in case of failure or corruption. For more information, see Backup and restore for ElastiCache for Redis (p. 310).

Infrastructure security in AWS Elasticache

As a managed service, AWS Elasticache is protected by the AWS global network security procedures that are described in the Security and Compliance section at AWS Architecture Center.

You use AWS published API calls to access Elasticache through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.
Self-service updates in Amazon ElastiCache

Amazon ElastiCache monitors your fleet of Redis clusters and nodes to determine whether service updates are applicable as they become available. Typically, you set up a predefined maintenance window so that ElastiCache can apply these updates. However, in some cases you might find this approach too rigid and likely to constrain your operational flows.

With self-service updates, you control when and which updates are applied. You can also monitor the progress of these updates to your selected Redis clusters in real time.

Depending on the type of service update, you can choose to stop an update to remaining nodes and clusters. You can select a group of clusters (including the ones that were partially updated) to apply the service updates anytime until the service update expires.

Managing the service updates

ElastiCache service updates are released on a regular basis. If you have one or more qualifying clusters for those service updates, you receive notifications through email, SNS, ElastiCache events, the Personal Health Dashboard (PHD), and Amazon CloudWatch events. The updates are also displayed on the Service Updates page on the ElastiCache console. By using this dashboard, you can view all the service updates and their status for your ElastiCache Redis fleet. This page provides an audit log that you can use when reviewing your Redis fleet for service updates.

Note
Using this log can prove important when reviewing your fleet for compliance. For more information, see Self-service security updates for compliance (p. 619).

You control when to apply an update, regardless of the recommendation. At a minimum, we strongly recommend that you apply any updates of type security to ensure that your Redis clusters are always up-to-date with current security patches. It is also recommended to apply updates of type engine to ensure that your clusters run the latest ElastiCache patch for a given engine version as well as the latest Redis OSS versions released by ElastiCache.

To view the up-to-date status of all your Redis clusters, you can choose Service Update Status. This view also shows the clusters for which the update is not applicable. In addition, you might find updates that you applied to Redis clusters exceed their estimated update time. In this case, you can stop them and reapply them at a time that better suits your business needs.

For more information, see Amazon ElastiCache maintenance help page.

The following sections explore these options in detail.

Topics
- Applying the self-service updates (p. 626)
- Stopping the self-service updates (p. 632)

Applying the self-service updates

You can start applying the service updates to your Redis fleet from the time that the updates have an available status until they have an expired status. Service updates of the type security are cumulative. In other words, any nonexpired updates that you haven't applied yet are included with your latest update. Service updates of the type engine are cumulative and may also contain security updates.

Note
You can apply only those service updates that have an available status, even if the recommended apply by date is past due.
For more information about reviewing your ElastiCache fleet and applying any service-specific updates to applicable Redis clusters, see Applying the service updates using the console for Redis (p. 627).

When a new service update is available for one or more of your Redis clusters, you can use the ElastiCache console, API, or AWS CLI to apply the update. The following sections explain the options that you can use to apply updates.

**Applying the service updates using the console**

You can apply the service updates using one of the following console options.

**Topics**

- Applying the service updates using the console for Redis (p. 627)
- Applying the service updates using the service updates list (p. 630)

**Applying the service updates using the console for Redis**

Choose this to view **Update Status** for individual Redis clusters, and then choose **Apply**, **View**, or **Stop** for the service updates. If a service update is available, the console displays a banner at the top of the Redis page, as shown following.

If you choose **Apply Now**, you can choose to apply the service update to all or a subset of the applicable clusters in this workflow, as shown following.

**Note**

If you choose **Dismiss**, the console stops displaying the banner for that console session. However, the banner reappears the next time that you refresh your session.
On the Apply Updates Now page, you can use these options:

- **Auto-Update after Due Date**: If this attribute is yes, after the Recommended apply by Date has passed, ElastiCache schedules clusters yet to be updated in the appropriate maintenance window. Updates are applied along with other applicable updates. You can continue to apply the updates until the update expiration date.

  If this attribute is no and you don't apply the self-service update before it expires, ElastiCache doesn't automatically apply the service update for you. If your cluster is part of one or more ElastiCache-supported compliance programs and isn't updated, it remains out of compliance until the next cumulative update becomes available.

- The **Nodes Updated** ratio value for your Redis cluster and the **Estimated Update Time** value help you plan your maintenance schedule. If service updates exceed the estimated time constraints for your business flows, you can stop updates and reapply them at a later date. For more information, see Stopping the self-service updates (p. 632).
• If you choose to apply the service updates to any or all available Redis clusters, choose **Confirm**. If you choose this, you then view the **Service Updates** page, where you can monitor the status of your service update.

• If you choose **Cancel**, you can explore further options, as explained following.

On the ElastiCache dashboard, you can check **Update Status** for each of your Redis clusters, as shown following.

**Update Status** displays one of the following:

• **update available**: An update is available to apply to this cluster.

• **not-applied**: An update is available but not yet applied.

• **scheduling**: The update date is being scheduled.

• **scheduled**: The update date has been scheduled.

• **waiting-to-start**: The update process will soon begin.

• **in-progress**: The update is being applied to this cluster, rendering it unavailable for the duration of the value in **Estimated Update Time**.

• **stopping**: An in-progress update has been interrupted before completion.

• **stopped**: The update has been terminated.

If you stop an in-progress update on a Redis cluster, some nodes might be updated while others are not. The **stopping** process doesn't roll back any changes to already updated nodes. You can reapply
the update to those nodes that still have an available status at your convenience if the update doesn't have anExpired status.

- **complete**: The update has been successfully applied.
- **up to date**: The cluster doesn't have any outstanding active service updates and your cluster is compliant. For more information about compliance, see Self-service security updates for compliance (p. 619).

**Applying the service updates using the service updates list**

To view the list of individual service updates and their status, along with other information, choose the Service Updates List tab.

In Service Updates List, you can view the following:

- **Service Update Name**: A unique identifier for the service update.
- **Status**: The status of the update, which is one of the following:
  - **available**: The update is available for requisite Redis clusters.
  - **complete**: The update has been applied and all Redis clusters are compliant. For more information, see Self-service security updates for compliance (p. 619).
  - **cancelled**: The update has been canceled and is no longer necessary.
  - **expired**: The update is no longer available to apply.
- **Severity**: The priority of applying the update:
  - **critical**: We recommend that you apply this update immediately (within 14 days or less).
  - **important**: We recommend that you apply this update as soon as your business flow allows (within 30 days or less).
  - **medium**: We recommend that you apply this update as soon as you can (within 60 days or less).
  - **low**: We recommend that you apply this update as soon as you can (within 90 days or less).
- **Update Type**: The currently supported update types:
• **security-update**: Upgrade to improve the security, reliability, and operational performance on ElastiCache nodes.

• **engine-update**: Upgrade to improve the security, reliability, and operational performance of ElastiCache nodes. It can include ElastiCache engine related fixes or Redis engine version upgrades.

• **Release Date**: When the update is released and available to apply on your Redis fleet.

• **Recommended Apply By Date**: ElastiCache guidance date to apply the updates by.

Choosing an individual update provides additional details, including the following:

• **Update Description**: Provides details on the service update.

• **Update Expiration Date**: The date when the service update expires and no longer is available. Any updates that aren't applied before their expiration date are cumulatively rolled into the next update.

**Important**

We strongly recommend that you apply updates of type **security** as soon as you can. Doing this helps ensure that your Redis clusters are always up-to-date with the latest security patches and are compliant. For more information, see [Self-service security updates for compliance (p. 619)](#).

To view the list of individual service updates in relation to the applicable Redis clusters, choose the **Service Update Status** tab.

In the **Service Updates Status** list, you can view the following:

• **Service Update Name**: Detailed information about the service update.

• **Cluster Name**: The list of your Redis clusters that are eligible for the update.

• **Nodes Updated**: The ratio of individual nodes within a specific cluster that were updated or remain available for the specific service update.

• **Update Severity**: The priority of applying the update:
  - **critical**: We recommend that you apply this update immediately (within 14 days or less).
  - **important**: We recommend that you apply this update as soon as you can (within 30 days or less).
  - **medium**: We recommend that you apply this update as soon as you can (within 60 days or less).
  - **low**: We recommend that you apply this update as soon as you can (within 90 days or less).

• **Update Type**: The currently supported update types:
  - **security-update**: Upgrade to improve the security, reliability, and operational performance on ElastiCache nodes.
  - **engine-update**: Upgrade to improve the security, reliability, and operational performance of ElastiCache nodes. It can include ElastiCache engine related fixes or Redis engine version upgrades.
Managing the service updates

- **Service Update Status**: The status of the update, which is one of the following:
  - **available**: The update is available for requisite Redis clusters.
  - **complete**: The update has been applied and all Redis clusters are compliant.
  - **canceled**: The update has been canceled and is no longer necessary.
  - **expired**: The update is no longer available to apply.

- **Service Update SLA Met**: This reflects whether your cluster is compliant.
  - **yes**: All available updates have been applied to this cluster and available nodes by the apply-by date.
  - **no**: If no, at least one node in the replication group has not been updated by the recommended apply-by date. This typically happens when a service update is applied and then stopped.

  **Note**
  If you stop the progress of a service update on a cluster, any nodes that are already updated have a **complete** status. Any nodes that have an **In Progress** or **Stopping** status revert to a **Stopped** status, and the **Service Update SLA Met** status changes to **no**.

- **N/A**: The replication group was created after the recommended apply-by date.

- **Cluster Status Modified Date**: The latest date that the update status was changed for a cluster.

  **Note**
  The **Show Previous Updates** check box, if selected, displays a list of previous updates that are no longer available.

**Applying the service updates using the AWS CLI**

After you receive notification that service updates are available, you can inspect and apply them using the AWS CLI:

- To retrieve a description of the service updates that are available, run the following command:
  ```bash
  aws elasticache describe-service-updates --service-update-status available
  ```
  For more information, see `DescribeServiceUpdates`.

- To view update actions that have a **not-applied** or **stopped** status, run the following command:
  ```bash
  aws elasticache describe-update-actions --service-update-name sample-service-update --update-action-status not-applied stopped
  ```
  For more information, see `DescribeUpdateActions`.

- To apply a service update on a list of replication groups, run the following command:
  ```bash
  aws elasticache batch-apply-update-action --service-update-name sample-service-update --replication-group-ids my-replication-group-1 my-replication-group-2
  ```
  For more information, see `BatchApplyUpdateAction`.

**Stopping the self-service updates**

You may stop updates to Redis clusters if needed. For example, you might want to stop updates if you have an unexpected surge to your Redis clusters that are undergoing updates. Or you might want to stop updates if they’re taking too long and interrupting your business flow at a peak time.

  **Note**
  If the service update in progress is of **engine** update type and it includes a Redis engine version update, it will not be possible to stop the upgrade once the operation started. This is to ensure
your cluster runs the same Redis engine version across all nodes. Service update description will describe the type of Redis engine version update. It can also be found in the PHD, SNS or Email notifications.

The Stopping operation immediately interrupts all updates to those clusters and any nodes that are yet to be updated. It continues to completion any nodes that have an in progress status. However, it ceases updates to other nodes in the same cluster that have an update available status and reverts them to a Stopping status.

When the Stopping workflow is complete, the nodes that have a Stopping status change to a Stopped status. Depending on the workflow of the update, some clusters won't have any nodes updated. Other clusters might include some nodes that are updated and others that still have an update available status.

You can return later to finish the update process as your business flows permit. In this case, choose the applicable clusters that you want to complete updates on, and then choose Apply Now. For more information, see Applying the service updates using the console for Redis (p. 627).

**Stopping the service updates using the console**

You can interrupt a service update using the Redis console. The following demonstrates how to do this:

- After a service update has progressed on a selected Redis cluster, the ElastiCache console displays the View/Stop Update tab at the top of the Redis dashboard.

- To interrupt the update, choose Stop Update.
When you stop the update, choose the Redis cluster and examine the status. It reverts to a **Stopping** status, as shown following, and eventually a **Stopped** status.
Stopping the service updates using the AWS CLI

You can interrupt a service update using the AWS CLI. The following code example shows how to do this.

```
aws elasticache batch-stop-update-action --service-update-name sample-service-update --replication-group-ids my-replication-group-1 my-replication-group-2
```

For more information, see `BatchStopUpdateAction`.

Troubleshooting

The following items must be verified while troubleshooting persistent connectivity issues with ElastiCache:

**Topics**
- Security groups (p. 635)
- Network ACLs (p. 635)
- Route tables (p. 637)
- DNS resolution (p. 637)
- Identifying issues with server-side diagnostics (p. 637)
- Network connectivity validation (p. 641)
- Network-related limits (p. 642)
- CPU Usage (p. 643)
- Connections being terminated from the server side (p. 645)
- Client-side troubleshooting for Amazon EC2 instances (p. 646)
- Dissecting the time taken to complete a single request (p. 646)

**Security groups**

Security Groups are virtual firewalls protecting your ElastiCache client (EC2 instance, AWS Lambda function, Amazon ECS container, etc.) and ElastiCache cluster. Security groups are stateful, meaning that after the incoming or outgoing traffic is allowed, the responses for that traffic will be automatically authorized in the context of that specific security group.

The stateful feature requires the security group to keep track of all authorized connections, and there is a limit for tracked connections. If the limit is reached, new connections will fail. Please refer to the troubleshooting section for help on how to identify if the limits has been hit on the client or Elasticache side.

You can have a single security groups assigned at the same time to the client and ElastiCache cluster, or individual security groups for each.

For both cases, you need to allow the TCP outbound traffic on the ElastiCache port from the source and the inbound traffic on the same port to ElastiCache. The default port is 11211 for Memcached and 6379 for Redis. By default, security groups allow all outbound traffic. In this case, only the inbound rule in the target security group is required.

For more information, see `Access patterns for accessing an ElastiCache cluster in an Amazon VPC`.

**Network ACLs**

Network Access Control Lists (ACLs) are stateless rules. The traffic must be allowed in both directions (Inbound and Outbound) to succeed. Network ACLs are assigned to subnets, not specific resources. It is
possible to have the same ACL assigned to ElastiCache and the client resource, especially if they are in the same subnet.

By default, network ACLs allow all traffic. However, it is possible to customize them to deny or allow traffic. Additionally, the evaluation of ACL rules is sequential, meaning that the rule with the lowest number matching the traffic will allow or deny it. The minimum configuration to allow the Redis traffic is:

Client side Network ACL:

- **Inbound Rules:**
  - Rule number: preferably lower than any deny rule;
  - Type: Custom TCP Rule;
  - Protocol: TCP
  - Port Range: 1024-65535
  - Source: 0.0.0.0/0 (or create individual rules for the ElastiCache cluster subnets)
  - Allow/Deny: Allow

- **Outbound Rules:**
  - Rule number: preferably lower than any deny rule;
  - Type: Custom TCP Rule;
  - Protocol: TCP
  - Port Range: 6379
  - Source: 0.0.0.0/0 (or the ElastiCache cluster subnets. Keep in mind that using specific IPs may create issues in case of failover or scaling the cluster)
  - Allow/Deny: Allow

ElastiCache Network ACL:

- **Inbound Rules:**
  - Rule number: preferably lower than any deny rule;
  - Type: Custom TCP Rule;
  - Protocol: TCP
  - Port Range: 6379
  - Source: 0.0.0.0/0 (or create individual rules for the ElastiCache cluster subnets)
  - Allow/Deny: Allow

- **Outbound Rules:**
  - Rule number: preferably lower than any deny rule;
  - Type: Custom TCP Rule;
  - Protocol: TCP
  - Port Range: 1024-65535
  - Source: 0.0.0.0/0 (or the ElastiCache cluster subnets. Keep in mind that using specific IPs may create issues in case of failover or scaling the cluster)
  - Allow/Deny: Allow

For more information, see Network ACLs.
Route tables

Similarly to Network ACLs, each subnet can have different route tables. If clients and the ElastiCache cluster are in different subnets, make sure that their route tables allow them to reach each other.

More complex environments, involving multiple VPCs, dynamic routing, or network firewalls, may become difficult to troubleshoot. See Network connectivity validation (p. 641) to confirm that your network settings are appropriate.

DNS resolution

ElastiCache provides the service endpoints based on DNS names. The endpoints available are Configuration, Primary, Reader, and Node endpoints. For more information, see Finding Connection Endpoints.

In case of failover or cluster modification, the address associated to the endpoint name may change and will be automatically updated.

Custom DNS settings (i.e., not using the VPC DNS service) may not be aware of the ElastiCache-provided DNS names. Make sure that your system can successfully resolve the ElastiCache endpoints using system tools like dig (as shown following) or nslookup.

```
$ dig +short example.xxxxxx.ng.0001.use1.cache.amazonaws.com
example-001.xxxxxx.0001.use1.cache.amazonaws.com.
1.2.3.4
```

You can also force the name resolution through the VPC DNS service:

```
$ dig +short example.xxxxxx.ng.0001.use1.cache.amazonaws.com @169.254.169.253
example-001.tihewd.0001.use1.cache.amazonaws.com.
1.2.3.4
```

Identifying issues with server-side diagnostics

CloudWatch metrics and run-time information from the ElastiCache engine are common sources or information to identify potential sources of connection issues. A good analysis commonly starts with the following items:

- **CPU usage**: Redis is a multi-threaded application. However, execution of each command happens in a single (main) thread. For this reason, ElastiCache provides the metrics CPUUtilization and EngineCPUUtilization. EngineCPUUtilization provides the CPU utilization dedicated to the Redis process, and CPUUtilization the usage across all vCPUs. Nodes with more than one vCPU usually have different values for CPUUtilization and EngineCPUUtilization, the second being commonly higher. High EngineCPUUtilization can be caused by an elevated number of requests or complex operations that take a significant amount of CPU time to complete. You can identify both with the following:
  - Elevated number of requests: Check for increases on other metrics matching the EngineCPUUtilization pattern. Useful metrics are:
    - CacheHits and CacheMisses: the number of successful requests or requests that didn't find a valid item in the cache. If the ratio of misses compared to hits is high, the application is wasting time and resources with unfruitful requests.
    - SetTypeCmds and GetTypeCmds: These metrics correlated with EngineCPUUtilization can help to understand if the load is significantly higher for write requests, measured by SetTypeCmds, or reads, measured by GetTypeCmds. If the load is predominantly reads, using multiple read-replicas can balance the requests across multiple nodes and spare the primary for writes. In cluster mode-disabled clusters, the use of read-replicas can be done by creating an
additional connection configuration in the application using the ElastiCache reader endpoint. For more information, see Finding Connection Endpoints. The read operations must be submitted to this additional connection. Write operations will be done through the regular primary endpoint. In cluster mode-enabled, it is advisable to use a library that supports read replicas natively. With the right flags, the library will be able to automatically discover the cluster topology, the replica nodes, enable the read operations through the READONLY Redis command, and submit the read requests to the replicas.

- Elevated number of connections:
  - CurrConnections and NewConnections: CurrConnection is the number of established connections at the moment of the datapoint collection, while NewConnections shows how many connections were created in the period.

  Creating and handling connections implies significant CPU overhead. Additionally, the TCP three-way handshake required to create new connections will negatively affect the overall response times.

  An ElastiCache node with thousands of NewConnections per minute indicates that a connection is created and used by just a few commands, which is not optimal. Keeping connections established and reusing them for new operations is a best practice. This is possible when the client application supports and properly implements connection pooling or persistent connections. With connection pooling, the number of currConnections does not have big variations, and the NewConnections should be as low as possible. Redis provides optimal performance with small number of currConnections. Keeping currConnection in the order of tens or hundreds minimizes the usage of resources to support individual connections like client buffers and CPU cycles to serve the connection.

- Network throughput:
  - Determine the bandwidth: ElastiCache nodes have network bandwidth proportional to the node size. Since applications have different characteristics, the results can vary according to the workload. As examples, applications with high rate of small requests tend to affect more the CPU usage than the network throughput while bigger keys will cause higher network utilization. For that reason, it is advisable to test the nodes with the actual workload for a better understanding of the limits.

  Simulating the load from the application would provide more accurate results. However, benchmark tools can give a good idea of the limits.

  - For cases where the requests are predominantly reads, using replicas for read operations will alleviate the load on the primary node. If the use-case is predominantly writes, the use of many replicas will amplify the network usage. For every byte written to the primary node, N bytes will be sent to the replicas, being N the number of replicas. The best practice for write intensive workloads are using ElastiCache for Redis with cluster mode-enabled so the writes can be balanced across multiple shards, or scale-up to a node type with more network capabilities.

  - The CloudWatch metrics NetworkBytesIn and NetworkBytesOut provide the amount of data coming into or leaving the node, respectively. ReplicationBytes is the traffic dedicated to data replication.

For more information, see Network-related limits (p. 642).

- Complex commands: Redis commands are served on a single thread, meaning that requests are served sequentially. A single slow command can affect other requests and connections, culminating in time-outs. The use of commands that act upon multiple values, keys, or data types must be done carefully. Connections can be blocked or terminated depending on the number of parameters, or size of its input or output values.

  A notorious example is the KEYS command. It sweeps the entire keyspace searching for a given pattern and blocks the execution of other commands during its execution. Redis uses the “Big O” notation to describe its commands complexity.
Keys command has O(N) time complexity, N being the number of keys in the database. Therefore, the larger the number of keys, the slower the command will be. `KEYS` can cause trouble in different ways: If no search pattern is used, the command will return all key names available. In databases with thousand or million of items, a huge output will be created and flood the network buffers.

If a search pattern is used, only the keys matching the pattern will return to the client. However, the engine still sweeps the entire keyspace searching for it, and the time to complete the command will be the same.

An alternative for `KEYS` is the `SCAN` command. It iterates over the keyspace and limits the iterations in a specific number of items, avoiding prolonged blocks on the engine.

Scan has the `COUNT` parameter, used to set the size of the iteration blocks. The default value is 10 (10 items per iteration).

Depending on the number of items in the database, small `COUNT` values blocks will require more iterations to complete a full scan, and bigger values will keep the engine busy for longer at each iteration. While small count values will make `SCAN` slower on big databases, larger values can cause the same issues mentioned for `KEYS`.

As an example, running the `SCAN` command with count value as 10 will requires 100,000 repetitions on a database with 1 million keys. If the average network round-trip time is 0.5 milliseconds, approximately 50,000 milliseconds (50 seconds) will be spent transferring requests.

On the other hand, if the count value were 100,000, a single iteration would be required and only 0.5 ms would be spent transferring it. However, the engine would be entirely blocked for other operations until the command finishes sweeping all the keyspace.

Besides `KEYS`, several other commands are potentially harmful if not used correctly. To see a list of all commands and their respective time complexity, go to https://redis.io/commands.

Examples of potential issues:

- Lua scripts: Redis provides an embedded Lua interpreter, allowing the execution of scripts on the server-side. Lua scripts on Redis are executed on engine level and are atomic by definition, meaning that no other command or script will be allowed to run while a script is in execution. Lua scripts provide the possibility of running multiple commands, decision-making algorithms, data parsing, and others directly on the Redis engine. While the atomicity of scripts and the chance of offloading the application are tempting, scripts must be used with care and for small operations. On ElastiCache, the execution time of Lua scripts is limited to 5 seconds. Scripts that haven’t written to the keyspace will be automatically terminated after the 5 seconds period. To avoid data corruption and inconsistencies, the node will failover if the script execution hasn’t completed in 5 seconds and had any write during its execution. Transactions are the alternative to guarantee consistency of multiple related key modifications in Redis. A transaction allows the execution of a block of commands, watching existing keys for modifications. If any of the watched keys changes before the completion of the transaction, all modifications are discarded.

- Mass deletion of items: The `DEL` command accepts multiple parameters, which are the key names to be deleted. Deletion operations are synchronous and will take significant CPU time if the list of parameters is big, or contains a big list, set, sorted set, or hash (data structures holding several sub-items). In other words, even the deletion of a single key can take significant time if it has many elements. The alternative to `DEL` is `UNLINK`, which is an asynchronous command available since Redis 4. `UNLINK` must be preferred over `DEL` whenever possible. Starting on ElastiCache for Redis 6x, the `lazyfree-lazy-user-del` parameter makes the `DEL` command behave like `UNLINK` when enabled. For more information, see Redis 6.0 Parameter Changes.

- Commands acting upon multiple keys: `DEL` was mentioned before as a command that accepts multiple arguments and its execution time will be directly proportional to that. However, Redis provides many more commands that work similarly. As examples, `MSET` and `MGET` allow the insertion or retrieval of multiple String keys at once. Their usage may be beneficial to reduce the
Identifying issues with server-side diagnostics

network latency inherent to multiple individual \texttt{SET} or \texttt{GET} commands. However, an extensive list of parameters will affect CPU usage.

While CPU utilization alone is not the cause for connectivity issues, spending too much time to process a single or few commands over multiple keys may cause failure of other requests and increase overall CPU utilization.

The number of keys and their size will affect the command complexity and consequently completion time.

Other examples of commands that can act upon multiple keys: \texttt{HMGET, HMSET, MSETNX, PFCOUNT, PFMERGE, SDIFF, SDIFFSTORE, SINTER, SINTERSTORE, UNION, UNIONSTORE, TOUCH, ZDIFF, ZDIFFSTORE, ZINTER or ZINTERSTORE}.

- Commands acting upon multiple data types: Redis also provides commands that act upon one or multiple keys, regardless of their data type. ElastiCache for Redis provides the metric \texttt{KeyBasedCmds} to monitor such commands. This metric sums the execution of the following commands in the selected period:
  - \textbf{O(N)} complexity:
    - \texttt{KEYS}
  - \textbf{O(1)}
    - \texttt{EXISTS}
    - \texttt{OBJECT}
    - \texttt{PTTL}
    - \texttt{RANDOMKEY}
    - \texttt{TTL}
    - \texttt{TYPE}
    - \texttt{EXPIRE}
    - \texttt{EXPIREAT}
    - \texttt{MOVE}
    - \texttt{PERSIST}
    - \texttt{PEXPIRE}
    - \texttt{PEXPIREAT}
    - \texttt{UNLINK} \texttt{(O(N)} to reclaim memory. However the memory-reclaiming task happens in a separated thread and does not block the engine

- Different complexity times depending on the data type:
  - \texttt{DEL}
  - \texttt{DUMP}
  - \texttt{RENAME} is considered a command with \texttt{O(1)} complexity, but executes \texttt{DEL} internally. The execution time will vary depending on the size of the renamed key.
  - \texttt{RENAMENX}
  - \texttt{RESTORE}
  - \texttt{SORT}

- Big hashes: Hash is a data type that allows a single key with multiple key-value sub-items. Each hash can store 4.294.967.295 items and operations on big hashes can become expensive. Similarly to \texttt{KEYS}, hashes have the \texttt{HKEYS} command with \texttt{O(N)} time complexity, \textit{N} being the number of items in the hash. \texttt{HSCAN} must be preferred over \texttt{HKEYS} to avoid long running commands. \texttt{HDEL}, \texttt{HGETALL}, \texttt{HMGET}, \texttt{HMSET} and \texttt{HVALS} are commands that should be used with caution on big hashes.

- Other big data-structures: Besides hashes, other data structures can be CPU intensive. Sets, Lists, Sorted Sets, and Hyperloglogs can also take significant time to be manipulated depending on
Network connectivity validation

After reviewing the network configurations related to DNS resolution, security groups, network ACLs, and route tables, the connectivity can be validated with the VPC Reachability Analyzer and system tools.

Reachability Analyzer will test the network connectivity and confirm if all the requirements and permissions are satisfied. For the tests below you will need the ENI ID (Elastic Network Interface Identification) of one of the ElastiCache nodes available in your VPC. You can find it by doing the following:

1. Go to https://console.aws.amazon.com/ec2/v2/home?#NIC:
2. Filter the interface list by your Elasticache cluster name or the IP address got from the DNS validations previously.
3. Write down or otherwise save the ENI ID. If multiple interfaces are shown, review the description to confirm that they belong to the right ElastiCache cluster and choose one of them.
4. Proceed to the next step.
5. Create an analyze path at https://console.aws.amazon.com/vpc/home?#ReachabilityAnalyzer and choose the following options:
   - Source Type: Choose instance if your ElastiCache client runs on an Amazon EC2 instance or Network Interface if it uses another service, such as AWS Fargate Amazon ECS with awsvpc network, AWS Lambda, etc), and the respective resource ID (EC2 instance or ENI ID);
   - Destination Type: Choose Network Interface and select the Elasticache ENI from the list.
   - Destination port: specify 6379 for ElastiCache for Redis or 11211 for ElastiCache for Memcached. Those are the ports defined with the default configuration and this example assumes that they are not changed.
   - Protocol: TCP

Create the analyze path and wait a few moments for the result. If the status is unreachable, open the analysis details and review the Analysis explorer for details where the requests were blocked.

If the reachability tests passed, proceed to the verification on the OS level.

To validate the TCP connectivity on the ElastiCache service port: On Amazon Linux, Nping is available in the package nmap and can test the TCP connectivity on the ElastiCache port, as well as providing the network round-trip time to establish the connection. Use this to validate the network connectivity and the current latency to the ElastiCache cluster, as shown following:

```
# sudo nping --tcp -p 6379 example.xxxxxx.ng.0001.use1.cache.amazonaws.com
Starting Nping 0.6.40 ( http://nmap.org/nping ) at 2020-12-30 16:48 UTC
SENT (0.0495s) TCP ...
(Output suppressed )
Max rtt: 0.937ms | Min rtt: 0.318ms | Avg rtt: 0.449ms
Raw packets sent: 5 (220B) | Rcvd: 5 (220B) | Lost: 0 (0.00%)
Nping done: 1 IP address pinged in 4.08 seconds
```

By default, nping sends 5 probes with a delay of 1 second between them. You can use the option “-c” to increase the number of probes and “--delay” to change the time to send a new test.
If the tests with `nping` fail and the *VPC Reachability Analyzer* tests passed, ask your system administrator to review possible Host-based firewall rules, asymmetric routing rules, or any other possible restriction on the operating system level.

On the ElastiCache console, check if *Encryption in-transit* is enabled in your ElastiCache cluster details. If in-transit encryption is enabled, confirm if the TLS session can be established with the following command:

```
openssl s_client -connect example.xxxxxx.use1.cache.amazonaws.com:6379
```

An extensive output is expected if the connection and TLS negotiation are successful. Check the return code available in the last line, the value must be 0 (ok). If openssl returns something different, check the reason for the error at [https://www.openssl.org/docs/man1.0.2/man1/verify.html#DIAGNOSTICS](https://www.openssl.org/docs/man1.0.2/man1/verify.html#DIAGNOSTICS).

If all the infrastructure and operating system tests passed but your application is still unable to connect to ElastiCache, check if the application configurations are compliant with the ElastiCache settings. Common mistakes are:

- Your application does not support ElastiCache cluster mode, and ElastiCache has cluster-mode enabled;
- Your application does not support TLS/SSL, and ElastiCache has in-transit encryption enabled;
- Application supports TLS/SSL but does not have the right configuration flags or trusted certification authorities;

## Network-related limits

- **Maximum number of connections:** There are hard limits for simultaneous connections. Each ElastiCache node allows up to 65,000 simultaneous connections across all clients. This limit can be monitored through the *CurrConnections* metrics on CloudWatch. However, clients also have their limits for outbound connections. On Linux, check the allowed ephemeral port range with the command:

  ```
  # sysctl net.ipv4.ip_local_port_range
  net.ipv4.ip_local_port_range = 32768 60999
  ```

  In the previous example, 28231 connections will be allowed from the same source, to the same destination IP (ElastiCache node) and port. The following command shows how many connections exist for a specific Elasticache node (IP 1.2.3.4):

  ```
  ss --numeric --tcp state connected "dst 1.2.3.4 and dport == 6379" | grep -vE '^State' | wc -l
  ```

  If the number is too high, your system may become overloaded trying to process the connection requests. It is advisable to consider implementing techniques like connection pooling or persistent connections to better handle the connections. Whenever possible, configure the connection pool to limit the maximum number of connections to a few hundred. Also, back-off logic to handle time-outs or other connection exceptions would be advisable to avoid connection churn in case of issues.

- **Network traffic limits:** Check the following CloudWatch metrics for Redis to identify possible network limits being hit on the ElastiCache node:

  - `NetworkBandwidthInAllowanceExceeded` / `NetworkBandwidthOutAllowanceExceeded`: Network packets shaped because the throughput exceeded the aggregated bandwidth limit.

    It is important to note that every byte written to the primary node will be replicated to N replicas, N being the number of replicas. Clusters with small node types, multiple replicas, and intensive write...
requests may not be able to cope with the replication backlog. For such cases, it's a best practice to scale-up (change node type), scale-out (add shards in cluster-mode enabled clusters), reduce the number of replicas, or minimize the number of writes.

- **NetworkConntrackAllowanceExceeded**: Packets shaped because the maximum number of connections tracked across all security groups assigned to the node has been exceeded. New connections will likely fail during this period.

- **NetworkPackets PerSecondAllowanceExceeded**: Maximum number of packets per second exceeded. Workloads based on a high rate of very small requests may hit this limit before the maximum bandwidth.

The metrics above are the ideal way to confirm nodes hitting their network limits. However, limits are also identifiable by plateaus on network metrics.

If the plateaus are observed for extended periods, they will be likely followed by replication lag, increase on bytes Used for cache, drop on freeable memory, high swap and CPU usage. Amazon EC2 instances also have network limits that can tracked through ENA driver metrics. Linux instances with enhanced networking support and ENA drivers 2.2.10 or newer can review the limit counters with the command:

```
# ethtool -S eth0 | grep "allowance_exceeded"
```

## CPU Usage

The CPU usage metric is the starting point of investigation, and the following items can help to narrow down possible issues on the ElastiCache side:

- **Redis SlowLogs**: The ElastiCache default configuration retains the last 128 commands that took over 10 milliseconds to complete. The history of slow commands is kept during the engine runtime and will be lost in case of failure or restart. If the list reaches 128 entries, old events will be removed to open room for new ones. The size of the list of slow events and the execution time considered slow can be modified via the parameters `slowlog-max-len` and `slowlog-log-slower-than` in a custom parameter group. The slowlogs list can be retrieved by running `SLOWLOG GET 128` on the engine, 128 being the last 128 slow commands reported. Each entry has the following fields:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1)</td>
<td>(integer)</td>
<td>1</td>
<td>Sequential ID</td>
<td></td>
</tr>
<tr>
<td>2)</td>
<td>(integer)</td>
<td>1609010767</td>
<td>Timestamp (Unix epoch time) of the Event</td>
<td></td>
</tr>
<tr>
<td>3)</td>
<td>(integer)</td>
<td>4823378</td>
<td>Time in microseconds to complete the command.</td>
<td></td>
</tr>
<tr>
<td>4)</td>
<td>1)</td>
<td>&quot;keys&quot;</td>
<td>Command</td>
<td></td>
</tr>
<tr>
<td>5)</td>
<td>2) **</td>
<td>&quot;**</td>
<td>Arguments</td>
<td></td>
</tr>
<tr>
<td>6)</td>
<td>3) &quot;1.2.3.4:57004&quot;</td>
<td>Source</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The event above happened on December 26, at 19:26:07 UTC, took 4.8 seconds (4.823ms) to complete and was caused by the `KEYS` command requested from the client 1.2.3.4.

On Linux, the timestamp can be converted with the command date:

```
$ date --date='@1609010767'
Sat Dec 26 19:26:07 UTC 2020
```

With Python:

```
>>> from datetime import datetime
>>> datetime.fromtimestamp(1609010767)
datetime.datetime(2020, 12, 26, 19, 26, 7)
```
Or on Windows with PowerShell:

```
PS D:\Users\user> [datetimeoffset]::FromUnixTimeSeconds('1609010767')
DateTime      : 12/26/2020 7:26:07 PM
UtcDateTime   : 12/26/2020 7:26:07 PM
LocalDateTime : 12/26/2020 2:26:07 PM
Date          : 12/26/2020 12:00:00 AM
Day           : 26
DayOfWeek     : Saturday
DayOfYear     : 361
Hour          : 19
Millisecond   : 0
Minute        : 26
Month         : 12
Offset        : 00:00:00
UtcTicks      : 637446075670000000
TimeOfDay     : 19:26:07
Year          : 2020
```

Many slow commands in a short period of time (same minute or less) is a reason for concern. Review the nature of commands and how they can be optimized (see previous examples). If commands with $O(1)$ time complexity are frequently reported, check the other factors for high CPU usage mentioned before.

- **Latency metrics:** ElastiCache for Redis provides CloudWatch metrics to monitor the average latency for different classes of commands. The datapoint is calculated by dividing the total number of executions of commands in the category by the total execution time in the period. It is important to understand that latency metric results are an aggregate of multiple commands. A single command can cause unexpected results, like timeouts, without significant impact on the metrics. For such cases, the slowlog events would be a more accurate source of information. The following list contains the latency metrics available and the respective commands that affect them.
  - **EvalBasedCmdsLatency:** related to Lua Script commands, `eval`, `evalsha`;
  - **GeoSpatialBasedCmdsLatency:** `geodist`, `geohash`, `geopos`, `georadius`, `georadiusbymember`, `geoadd`;
  - **GetTypeCmdsLatency:** Read commands, regardless of data type;
  - **HashBasedCmdsLatency:** `hexists`, `hget`, `hgetall`, `hkeys`, `hlen`, `hmget`, `hvals`, `hstrlen`, `hdel`, `hincrby`, `hincrbyfloat`, `hmset`, `hset`, `hsetnx`;
  - **HyperLogLogBasedCmdsLatency:** `pfselftest`, `pfcount`, `pfdebug`, `pfadd`, `pmerge`;
  - **KeyBasedCmdsLatency:** Commands that can act upon different data types: `dump`, `exists`, `keys`, `object`, `pttl`, `randomkey`, `ttl`, `type`, `del`, `expire`, `expireat`, `move`, `persist`, `pexpire`, `pxexpireat`, `rename`, `renamenx`, `restoreK`, `sort`, `unlink`;
  - **ListBasedCmdsLatency:** `lindex`, `llen`, `lrange`, `blpop`, `brpop`, `brpoplpush`, `linsert`, `lpop`, `lpush`, `lpushx`, `lrem`, `lset`, `ltrim`, `rpop`, `rpoplpush`, `rpush`, `rpushx`;
  - **PubSubBasedCmdsLatency:** `psubscribe`, `publish`, `pubsub`, `punsubscribe`, `subscribe`, `unsubscribe`;
  - **SetBasedCmdsLatency:** `scard`, `sdiff`, `sinter`, `sismember`, `smembers`, `srandmember`, `sunion`, `sadd`, `sdiffstore`, `sinterstore`, `smove`, `spop`, `zrem`, `zunionstore`;
  - **SetTypeCmdsLatency:** Write commands, regardless of data-type;
  - **SortedSetBasedCmdsLatency:** `zcard`, `zcount`, `zrange`, `zrangebyscore`, `zrank`, `zrevrange`, `zrevrangebyscore`, `zrevrank`, `zscore`, `zrangebylex`, `zrevrangebylex`, `zlexcount`, `zadd`, `zincrby`, `zinterstore`, `zrem`, `zremrangebyrank`, `zremrangebyscore`, `zunionstore`, `zremrangebylex`, `zpopmax`, `zpopmin`, `bzpopmin`, `bzpopmax`;

API Version 2015-02-02
644
Connections being terminated from the server side

The default ElastiCache for Redis configuration keeps the client connections established indefinitely. However, in some cases connection termination may be desirable. For example:

- Bugs in the client application may cause connections to be forgotten and kept established with an idle state. This is called "connection leak" and the consequence is a steady increase on the number of established connections observed on the CurrConnections metric. This behavior can result in saturation on the client or ElastiCache side. When an immediate fix is not possible from the client side, some administrators set a "timeout" value in their ElastiCache parameter group. The timeout is the time in seconds allowed for idle connections to persist. If the client doesn't submit any request in the period, the Redis engine will terminate the connection as soon as the connection reaches the timeout value. Small timeout values may result in unnecessary disconnections and clients will need handle them properly and reconnect, causing delays.

- The memory used to store keys is shared with client buffers. Slow clients with big requests or responses may demand a significant amount of memory to handle its buffers. The default ElastiCache for Redis configurations does not restrict the size of regular client output buffers. If the maxmemory limit is hit, the engine will try to evict items to fulfill the buffer usage. In extreme low memory conditions, ElastiCache for Redis might choose to disconnect clients that consume large client output buffers in order to free memory and retain the cluster's health.

It is possible to limit the size of client buffers with custom configurations and clients hitting the limit will be disconnected. However, clients should be able to handle unexpected disconnections. The parameters to handle buffers size for regular clients are the following:

- client-query-buffer-limit: Maximum size of a single input request;
- client-output-buffer-limit-normal-soft-limit: Soft limit for client connections. The connection will be terminated if stays above the soft limit for more than the time in seconds defined on client-output-buffer-limit-normal-soft-seconds or if it hits the hard limit;
- client-output-buffer-limit-normal-hard-limit: A connection hitting this limit will be immediately terminated.
Besides the regular client buffers, the following options control the buffer for replica nodes and Pub/Sub (Publish/Subscribe) clients:

- client-output-buffer-limit-replica-hard-limit;
- client-output-buffer-limit-replica-soft-seconds;
- client-output-buffer-limit-replica-hard-limit;
- client-output-buffer-limit-pubsub-soft-limit;
- client-output-buffer-limit-pubsub-soft-seconds;
- client-output-buffer-limit-pubsub-hard-limit;

**Client-side troubleshooting for Amazon EC2 instances**

The load and responsiveness on the client side can also affect the requests to ElastiCache. EC2 instance and operating system limits need to be carefully reviewed while troubleshooting intermittent connectivity or timeout issues. Some key points to observe:

- **CPU:**
  - EC2 instance CPU usage: Make sure the CPU hasn’t been saturated or near to 100 percent. Historical analysis can be done via CloudWatch, however keep in mind that data points granularity is either 1 minute (with detailed monitoring enabled) or 5 minutes;
  - If using burstable EC2 instances, make sure that their CPU credit balance hasn’t been depleted. This information is available on the CPUCreditBalance CloudWatch metric.
  - Short periods of high CPU usage can cause timeouts without reflecting on 100 percent utilization on CloudWatch. Such cases require real-time monitoring with operating-system tools like top, ps and mpstat.

- **Network**
  - Check if the Network throughput is under acceptable values according to the instance capabilities. For more information, see Amazon EC2 Instance Types
  - On instances with the ena Enhanced Network driver, check the ena statistics for timeouts or exceeded limits. The following statistics are useful to confirm network limits saturation:
    - bw_in_allowance_exceeded / bw_out_allowance_exceeded: number of packets shaped due to excessive inbound or outbound throughput;
    - conntrack_allowance_exceeded: number of packets dropped due to security groups connection tracking limits. New connections will fail when this limit is saturated;
    - linklocal_allowance_exceeded: number of packets dropped due to excessive requests to instance meta-data, NTP via VPC DNS. The limit is 1024 packets per second for all the services;
    - pps_allowance_exceeded: number of packets dropped due to excessive packets per second ratio. The PPS limit can be hit when the network traffic consists on thousands or millions of very small requests per second. ElastiCache traffic can be optimized to make better use of network packets via pipelines or commands that do multiple operations at once like MGET instead of GET.

**Dissecting the time taken to complete a single request**

- On the network: Tcpdump and Wireshark (tshark on the command line) are handy tools to understand how much time the request took to travel the network, hit the ElastiCache engine and get a return. The following example highlights a single request created with the following command:
$ echo ping | nc example.xxxxxx.ng.0001.use1.cache.amazonaws.com 6379
  +PONG

In parallel to the command above, tcpdump was in execution and returned:

$ sudo tcpdump -i any -nn port 6379 -tt

tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on any, link-type LINUX_SLL (Linux cooked), capture size 262144 bytes
1609428918.917869 IP 172.31.11.40966 > 172.31.11.247.6379: Flags [S], seq 177032944, win 26883, options [mss 8961,sackOK,TS val 177032944 ecr 0,nop,wscale 7], length 0

1609428918.918300 IP 172.31.11.142.40966 > 172.31.11.247.6379: Flags [.], seq 6, ack 7, win 211, options [nop,nop,TS val 27819441 ecr 3788576332], length 0
1609428918.918302 IP 172.31.11.142.40966 > 172.31.11.247.6379: Flags [.], seq 8, ack 7, win 227, options [nop,nop,TS val 27819441 ecr 3788576332], length 0
1609428918.918307 IP 172.31.11.247.6379 > 172.31.11.142.40966: Flags [.], ack 9, win 211, options [nop,nop,TS val 27819441 ecr 3788576332], length 0
^C
10 packets captured
10 packets received by filter
0 packets dropped by kernel

From the output above we can confirm that the TCP three-way handshake was completed in 222 microseconds (918091 - 917869) and the ping command was submitted and returned in 173 microseconds (918295 - 918122).

It took 438 microseconds (918307 - 917869) from requesting to closing the connection. Those results would confirm that network and engine response times are good and the investigation can focus on other components.

On the operating system: Strace can help identifying time gaps on the OS level. The analysis of actual applications would be way more extensive and specialized application profilers or debuggers are advisable. The following example just shows if the base operating system components are working as expected, otherwise further investigation may be required. Using the same Redis PING command with strace we get:

$ echo ping | strace -f -tttt -r -e trace=execve,socket,open,recvfrom,sendto nc example.xxxxxx.ng.0001.use1.cache.amazonaws.com (http://example.xxxxxx.ng.0001.use1.cache.amazonaws.com/) 6379
1609430221.697712 (+ 0.000000) execve("/usr/bin/nc", ["nc", "example.xxxxxx.ng.0001.use1.cache.amazonaws.com", "6379"]
1609430221.708955 (+ 0.011231) socket(AF_UNIX, SOCK_STREAM|SOCK_CLOEXEC|SOCK_NONBLOCK, 0) = 3
In the example above, the command took a little more than 54 milliseconds to complete (752110 - 697712 = 54398 microseconds).

A significant amount of time, approximately 20ms, was taken to instantiate nc and do the name resolution (from 697712 to 717890), after that, 2ms were required to create the TCP socket (745659 to 747858), and 0.4 ms (747858 to 748330) to submit and receive the response for the request.
Quotas for ElastiCache

Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Unless otherwise noted, each quota is Region-specific. You can request increases for some quotas, and other quotas cannot be increased.

To view the quotas for ElastiCache, open the Service Quotas console. In the navigation pane, choose AWS services and select ElastiCache.

To request a quota increase, see Requesting a Quota Increase in the Service Quotas User Guide. If the quota is not yet available in Service Quotas, use the limit increase form.

Your AWS account has the following quotas related to ElastiCache.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nodes per Region</td>
<td>300</td>
</tr>
<tr>
<td>Nodes per cluster per instance type (Redis cluster mode enabled)</td>
<td>90</td>
</tr>
<tr>
<td>Nodes per shard (Redis cluster mode disabled)</td>
<td>6</td>
</tr>
<tr>
<td>Parameter groups per Region</td>
<td>150</td>
</tr>
<tr>
<td>Security groups per Region</td>
<td>50</td>
</tr>
<tr>
<td>Subnet groups per Region</td>
<td>150</td>
</tr>
<tr>
<td>Subnets per subnet group</td>
<td>20</td>
</tr>
<tr>
<td>Users per user group</td>
<td>100</td>
</tr>
<tr>
<td>Maximum number of users</td>
<td>1000</td>
</tr>
<tr>
<td>Maximum number of user groups</td>
<td>100</td>
</tr>
</tbody>
</table>
Using the ElastiCache API

This section provides task-oriented descriptions of how to use and implement ElastiCache operations. For a complete description of these operations, see the Amazon ElastiCache API Reference

Topics
- Using the query API (p. 650)
- Available libraries (p. 652)
- Troubleshooting applications (p. 653)

Using the query API

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named Action.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the \texttt{param.n} notation. Values of \texttt{n} are integers starting from 1.

Query request authentication

You can only send Query requests over HTTPS and you must include a signature in every Query request. This section describes how to create the signature. The method described in the following procedure is known as \textit{signature version 4}.

The following are the basic steps used to authenticate requests to AWS. This assumes you are registered with AWS and have an Access Key ID and Secret Access Key.

\textbf{Query authentication process}

\begin{enumerate}
\item The sender constructs a request to AWS.
\item The sender calculates the request signature, a Keyed-Hashing for Hash-based Message Authentication Code (HMAC) with a SHA-1 hash function, as defined in the next section of this topic.
\item The sender of the request sends the request data, the signature, and Access Key ID (the key-identifier of the Secret Access Key used) to AWS.
\end{enumerate}
4. AWS uses the Access Key ID to look up the Secret Access Key.
5. AWS generates a signature from the request data and the Secret Access Key using the same algorithm used to calculate the signature in the request.
6. If the signatures match, the request is considered to be authentic. If the comparison fails, the request is discarded, and AWS returns an error response.

**Note**

If a request contains a Timestamp parameter, the signature calculated for the request expires 15 minutes after its value.
If a request contains an Expires parameter, the signature expires at the time specified by the Expires parameter.

**To calculate the request signature**

1. Create the canonicalized query string that you need later in this procedure:
   a. Sort the UTF-8 query string components by parameter name with natural byte ordering. The parameters can come from the GET URI or from the POST body (when Content-Type is application/x-www-form-urlencoded).
   b. URL encode the parameter name and values according to the following rules:
      i. Do not URL encode any of the unreserved characters that RFC 3986 defines. These unreserved characters are A-Z, a-z, 0-9, hyphen (-), underscore (_), period (.), and tilde (~).
      ii. Percent encode all other characters with %XY, where X and Y are hex characters 0-9 and uppercase A-F.
      iii. Percent encode extended UTF-8 characters in the form %XY%ZA....
      iv. Percent encode the space character as %20 (and not +, as common encoding schemes do).
   c. Separate the encoded parameter names from their encoded values with the equals sign (=) (ASCII character 61), even if the parameter value is empty.
   d. Separate the name-value pairs with an ampersand (&) (ASCII code 38).
2. Create the string to sign according to the following pseudo-grammar (the "\n" represents an ASCII newline).

   ```plaintext
   StringToSign = HTTPVerb + "\n" + 
   ValueOfHostHeaderInLowercase + "\n" + 
   HTTPRequestURI + "\n" + 
   CanonicalizedQueryString <from the preceding step>
   ```

   The HTTPRequestURI component is the HTTP absolute path component of the URI up to, but not including, the query string. If the HTTPRequestURI is empty, use a forward slash (/).
3. Calculate an RFC 2104-compliant HMAC with the string you just created, your Secret Access Key as the key, and SHA256 or SHA1 as the hash algorithm.

   For more information, see [https://www.ietf.org/rfc/rfc2104.txt](https://www.ietf.org/rfc/rfc2104.txt).
4. Convert the resulting value to base64.
5. Include the value as the value of the Signature parameter in the request.

For example, the following is a sample request (linebreaks added for clarity).

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeCacheClusters
```
For the preceding query string, you would calculate the HMAC signature over the following string.

GET

```
elasticache.amazonaws.com
Action=DescribeCacheClusters
&CacheClusterIdentifier=myCacheCluster
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-12-01
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20141201/us-west-2/elasticache/aws4_request
&X-Amz-Date=20141201T223649Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
content-type: application/x-amz-json-1_0
host: elasticache.us-west-2.amazonaws.com
user-agent: CacheServicesAPICommand_Client
x-amz-content-sha256: 4f4c7c3e4f6b7f78e6a0236c9143f915ffa56
x-amz-date: 20141201T223649Z
```

The result is the following signed request.

```
https://elasticache.us-west-2.amazonaws.com/
?Action=DescribeCacheClusters
&CacheClusterIdentifier=myCacheCluster
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-12-01
&X-Amz-Algorithm=&AWS;4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20141201/us-west-2/elasticache/aws4_request
&X-Amz-Date=20141201T223649Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=2877960fced9040b41b4feaca835fd5cfeb9264f768e6a0236c9143f915ffa56
```

For detailed information on the signing process and calculating the request signature, see the topic Signature Version 4 Signing Process and its subtopics.

Available libraries

AWS provides software development kits (SDKs) for software developers who prefer to build applications using language-specific APIs instead of the Query API. These SDKs provide basic functions (not included in the APIs), such as request authentication, request retries, and error handling so that it is easier to get started. SDKs and additional resources are available for the following programming languages:

- Java
- Windows and .NET
- PHP
- Python
- Ruby

For information about other languages, see Sample Code & Libraries.
Amazon ElastiCache for Redis User Guide
Troubleshooting applications

Troubleshooting applications
ElastiCache provides speciﬁc and descriptive errors to help you troubleshoot problems while interacting
with the ElastiCache API.

Retrieving errors
Typically, you want your application to check whether a request generated an error before you spend any
time processing results. The easiest way to ﬁnd out if an error occurred is to look for an Error node in
the response from the ElastiCache API.
XPath syntax provides a simple way to search for the presence of an Error node, as well as an easy way
to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module
to determine if an error occurred during a request. If an error occurred, the code prints the ﬁrst error
code and message in the response.
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find("//Error") )
{print "There was an error processing your request:\n", " Error code: ",
$xp->findvalue("//Error[1]/Code"), "\n", " ",
$xp->findvalue("//Error[1]/Message"), "\n\n"; }

Troubleshooting tips
We recommend the following processes to diagnose and resolve problems with the ElastiCache API.
• Verify that ElastiCache is running correctly.
To do this, simply open a browser window and submit a query request to the ElastiCache service (such
as https://elasticache.amazonaws.com). A MissingAuthenticationTokenException or 500 Internal
Server Error conﬁrms that the service is available and responding to requests.
• Check the structure of your request.
Each ElastiCache operation has a reference page in the ElastiCache API Reference. Double-check that
you are using parameters correctly. To give you ideas regarding what might be wrong, look at the
sample requests or user scenarios to see if those examples are doing similar operations.
• Check the forum.
ElastiCache has a discussion forum where you can search for solutions to problems others have
experienced along the way. To view the forum, see

Setting up the ElastiCache command line interface
This section describes the prerequisites for running the command line tools, where to get the command
line tools, how to set up the tools and their environment, and includes a series of common examples of
tool usage.
Follow the instructions in this topic only if you are going to the AWS CLI for ElastiCache.

Important

The Amazon ElastiCache Command Line Interface (CLI) does not support any ElastiCache
improvements after API version 2014-09-30. To use newer ElastiCache functionality from the
command line, use the AWS Command Line Interface.
API Version 2015-02-02
653


Prerequisites

This document assumes that you can work in a Linux/UNIX or Windows environment. The Amazon ElastiCache command line tools also work on Mac OS X, which is a UNIX-based environment; however, no specific Mac OS X instructions are included in this guide.

As a convention, all command line text is prefixed with a generic PROMPT> command line prompt. The actual command line prompt on your machine is likely to be different. We also use $ to indicate a Linux/UNIX specific command and C:\> for a Windows specific command. The example output resulting from the command is shown immediately thereafter without any prefix.

The Java runtime environment

The command line tools used in this guide require Java version 5 or later to run. Either a JRE or JDK installation is acceptable. To view and download JREs for a range of platforms, including Linux/UNIX and Windows, see Java SE Downloads.

Setting the Java home variable

The command line tools depend on an environment variable (JAVA_HOME) to locate the Java Runtime. This environment variable should be set to the full path of the directory that contains a subdirectory named bin which in turn contains the executable java (on Linux and UNIX) or java.exe (on Windows) executable.

To set the Java Home variable

1. Set the Java Home variable.

   • On Linux and UNIX, enter the following command:

     $ export JAVA_HOME=<PATH>

   • On Windows, enter the following command:

     C:\> set JAVA_HOME=<PATH>

2. Confirm the path setting by running $JAVA_HOME/bin/java -version and checking the output.

   • On Linux/UNIX, you will see output similar to the following:

     
     $ $JAVA_HOME/bin/java -version
     java version "1.6.0_23"
     Java(TM) SE Runtime Environment (build 1.6.0_23-b05)
     Java HotSpot(TM) Client VM (build 19.0-b09, mixed mode, sharing)

   • On Windows, you will see output similar to the following:
Getting the command line tools

The command line tools are available as a ZIP file on the ElastiCache Developer Tools web site. These tools are written in Java, and include shell scripts for Windows 2000/XP/Vista/Windows 7, Linux/UNIX, and Mac OSX. The ZIP file is self-contained and no installation is required; simply download the zip file and unzip it to a directory on your local machine.

Setting up the tools

The command line tools depend on an environment variable (AWS_ELASTICACHE_HOME) to locate supporting libraries. You need to set this environment variable before you can use the tools. Set it to the path of the directory you unzipped the command line tools into. This directory is named ElastiCacheCli-A.B.nnnn (A, B and n are version/release numbers), and contains subdirectories named bin and lib.

To set the AWS_ELASTICACHE_HOME environment variable

- Open a command line window and enter one of the following commands to set the AWS_ELASTICACHE_HOME environment variable.
  - On Linux and UNIX, enter the following command:
    ```
    $ export AWS_ELASTICACHE_HOME=<path-to-tools>
    ```
  - On Windows, enter the following command:
    ```
    C:\> set AWS_ELASTICACHE_HOME=<path-to-tools>
    ```

To make the tools easier to use, we recommend that you add the tools’ BIN directory to your system PATH. The rest of this guide assumes that the BIN directory is in your system path.

To add the tools’ BIN directory to your system path

- Enter the following commands to add the tools’ BIN directory to your system PATH.
  - On Linux and UNIX, enter the following command:
    ```
    $ export PATH=$PATH:&AWS_ELASTICACHE_HOME/bin
    ```
  - On Windows, enter the following command:
    ```
    C:\> set PATH=%PATH%;%AWS_ELASTICACHE_HOME\bin
    ```

Note

The Windows environment variables are reset when you close the command window. You might want to set them permanently. Consult the documentation for your version of Windows for more information.
Note
Paths that contain a space must be wrapped in double quotes, for example:
"C:\Program Files\Java"

Providing credentials for the tools

The command line tools need the AWS Access Key and Secret Access Key provided with your AWS account. You can get them using the command line or from a credential file located on your local system.

The deployment includes a template file ${AWS_ELASTICACHE_HOME}/credential-file-path.template that you need to edit with your information. Following are the contents of the template file:

```
AWSAccessKeyId=<Write your AWS access ID>
AWSSecretKey=<Write your AWS secret key>
```

Important
On UNIX, limit permissions to the owner of the credential file:

```
$ chmod 600 <the file created above>
```

With the credentials file setup, you'll need to set the AWS_CREDENTIAL_FILE environment variable so that the ElastiCache tools can find your information.

To set the AWS_CREDENTIAL_FILE environment variable

1. Set the environment variable:
   - On Linux and UNIX, update the variable using the following command:

   ```
   $ export AWS_CREDENTIAL_FILE=<the file created above>
   ```
   - On Windows, set the variable using the following command:

   ```
   C:\> set AWS_CREDENTIAL_FILE=<the file created above>
   ```

2. Check that your setup works properly, run the following command:

   ```
   elasticache --help
   ```

   You should see the usage page for all ElastiCache commands.

Environmental variables

Environment variables can be useful for scripting, configuring defaults or temporarily overriding them.

In addition to the AWS_CREDENTIAL_FILE environment variable, most API tools included with the ElastiCache Command Line Interface support the following variables:

- **EC2_REGION** — The AWS region to use.
- **AWS_ELASTICACHE_URL** — The URL to use for the service call. Not required to specify a different regional endpoint if EC2_REGION is specified or the --region parameter is passed.
The following examples show how to set the environmental variable EC2_REGION to configure the region used by the API tools:

Linux, OS X, or Unix

```bash
$ export EC2_REGION=us-west-1
```

Windows

```bash
$ set EC2_REGION=us-west-1
```

**Amazon ElastiCache error messages**

The following error messages are returned by Amazon ElastiCache. You may receive other error messages that are returned by ElastiCache, other AWS services, or by Redis. For descriptions of error messages from sources other than ElastiCache, see the documentation from the source that is generating the error message.

- Cluster node quota exceeded (p. 657)
- Customer's node quota exceeded (p. 657)
- Manual snapshot quota exceeded (p. 657)
- Insufficient cache cluster capacity (p. 658)

**Error Message:** *Cluster node quota exceeded. Each cluster can have at most %n nodes in this region.*

**Cause:** You attempted to create or modify a cluster with the result that the cluster would have more than %n nodes.

**Solution:** Change your request so that the cluster does not have more than %n nodes. Or, if you need more than %n nodes, make your request using the Amazon ElastiCache Node request form.

For more information, see Amazon ElastiCache Limits in Amazon Web Services General Reference.

**Error Messages:** *Customer node quota exceeded. You can have at most %n nodes in this region Or, You have already reached your quota of %n nodes in this region.*

**Cause:** You attempted to create or modify a cluster with the result that your account would have more than %n nodes across all clusters in this region.

**Solution:** Change your request so that the total nodes in the region across all clusters for this account does not exceed %n. Or, if you need more than %n nodes, make your request using the Amazon ElastiCache Node request form.

For more information, see Amazon ElastiCache Limits in Amazon Web Services General Reference.

**Error Messages:** *The maximum number of manual snapshots for this cluster taken within 24 hours has been reached or The maximum number of manual snapshots for this node taken within 24 hours has been reached its quota of %n*

**Cause:** You attempted to take a manual snapshot of a cluster when you have already taken the maximum number of manual snapshots allowed in a 24-hour period.
**Solution:** Wait 24 hours to attempt another manual snapshot of the cluster. Or, if you need to take a manual snapshot now, take the snapshot of another node that has the same data, such as a different node in a cluster.

**Error Messages:** InsufficientCacheClusterCapacity

**Cause:** AWS does not currently have enough available On-Demand capacity to service your request.

**Solution:**
- Wait a few minutes and then submit your request again; capacity can shift frequently.
- Submit a new request with a reduced number of nodes or shards (node groups). For example, if you're making a single request to launch 15 nodes, try making 3 requests of 5 nodes, or 15 requests for 1 node instead.
- If you're launching a cluster, submit a new request without specifying an Availability Zone.
- If you're launching a cluster, submit a new request using a different node type (which you can scale up at a later stage). For more information, see Scaling ElastiCache for Redis clusters (p. 345).

---

**Notifications**

This topic covers ElastiCache notifications that you might be interested in. A notification is a situation or event that, in most cases, is temporary, lasting only until a solution is found and implemented. Notifications generally have a start date and a resolution date, after which the notification is no longer relevant. Any one notification might or might not be relevant to you. We recommend an implementation guideline that, if followed, improves the performance of your cluster.

Notifications do not announce new or improved ElastiCache features or functionality.

**General ElastiCache notifications**

Currently there are no outstanding ElastiCache notifications that are not engine specific.

**ElastiCache for Redis specific notifications**

There are currently no outstanding ElastiCache for Redis notifications.
ElastiCache for Redis Documentation

- **API version:** 2015-02-02
- **Latest documentation update:** January 24, 2022

The following table describes important changes in each release of the *ElastiCache for Redis User Guide* after March 2018. For notification about updates to this documentation, you can subscribe to the RSS feed.

**Recent ElastiCache for Redis Updates**

<table>
<thead>
<tr>
<th>update-history-change</th>
<th>update-history-description</th>
<th>update-history-date</th>
</tr>
</thead>
<tbody>
<tr>
<td>ElastiCache now supports PrivateLink (p. 659)</td>
<td>AWS PrivateLink allows you to privately access ElastiCache API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. For more information, see Amazon ElastiCache API and interface VPC endpoints (AWS PrivateLink) for Redis or Amazon ElastiCache API and interface VPC endpoints (AWS PrivateLink) for Memcached.</td>
<td>January 24, 2022</td>
</tr>
<tr>
<td>ElastiCache for Redis now supports Redis 6.2 and Data Tiering (p. 659)</td>
<td>Amazon ElastiCache for Redis introduces the next version of the Redis engine supported by Amazon ElastiCache. ElastiCache for Redis 6.2 includes performance improvements for TLS-enabled clusters using x86 node types with 8 vCPUs or more or Graviton2 node types with 4 vCPUs or more. ElastiCache for Redis also introduces data tiering. You can use data tiering as a lower-cost way to scale your clusters to up to hundreds of terabytes of capacity. For more information, see ElastiCache for Redis version 6.2 (enhanced) and Data tiering.</td>
<td>November 23, 2021</td>
</tr>
<tr>
<td>Support for Auto Scaling (p. 659)</td>
<td>ElastiCache for Redis now supports Auto Scaling. ElastiCache for Redis auto scaling is the ability to increase or decrease the desired shards.</td>
<td>August 19, 2021</td>
</tr>
</tbody>
</table>
or replicas in your ElastiCache for Redis service automatically. ElastiCache leverages the Application Auto Scaling service to provide this functionality. For more information, see Auto Scaling ElastiCache for Redis clusters.

Support for delivery of Redis Slow logs (p. 659)  
ElastiCache now lets you stream Redis SLOWLOG to one of two destinations: Amazon Kinesis Data Firehose or Amazon CloudWatch Logs. For more information, see Log delivery.  
April 22, 2021

Support for tagging resources and condition keys (p. 659)  
ElastiCache now supports tagging to help you manage your clusters and other ElastiCache resources. For more information, see Tagging your ElastiCache resources. ElastiCache also introduces support for condition keys. You can specify conditions that determine how an IAM policy takes effect. For more information, see Using condition keys.  
April 7, 2021

ElastiCache is now available on AWS Outposts (p. 659)  
AWS Outposts bring native AWS services, infrastructure, and operating models to virtually any data center, co-location space, or on-premises facility. You can deploy ElastiCache on Outposts to set up, operate, and use cache on-premises, just as you would in the cloud. For more information, see Using Outposts for Redis or Using Outposts for Memcached.  
October 8, 2020

ElastiCache now supports Redis 6 (p. 659)  
Amazon ElastiCache for Redis introduces the next version of the Redis engine supported by Amazon ElastiCache. This version includes authenticating users with role-based access control, versionless support, client-side caching, and significant operational improvements. For more information, see ElastiCache for Redis Version 6.0 (Enhanced).

<tbody>
<tr>
<td>ElastiCache now supports Local Zones (p. 659)</td>
<td>A Local Zone is an extension of an AWS Region that is geographically close to your users. You can extend any virtual private cloud (VPC) from a parent AWS Region into Local Zones by creating a new subnet and assigning it to a Local Zone. For more information, see <a href="#">Using Local Zones</a>.</td>
<td>September 25, 2020</td>
</tr>
<tr>
<td>ElastiCache for Redis now supports scaling your Redis Cluster environment up to 500 nodes or 500 shards (p. 659)</td>
<td>The Redis Cluster mode makes configurations possible that you can use to partition your data across multiple shards and offers better scalability, performance, and availability. This feature is available on Amazon ElastiCache for Redis version 5.0.6 onwards in all AWS Regions and for all existing and new ElastiCache for Redis Cluster environments. For more information, see <a href="#">Redis Nodes and Shards</a>.</td>
<td>August 13, 2020</td>
</tr>
<tr>
<td>ElastiCache now supports resource-level permissions (p. 659)</td>
<td>You can now restrict the scope of a user's permissions by specifying ElastiCache resources in an AWS Identity and Access Management (IAM) policy. For more information, see <a href="#">Resource-level permissions</a>.</td>
<td>August 12, 2020</td>
</tr>
<tr>
<td>ElastiCache for Redis adds additional Amazon CloudWatch metrics (p. 659)</td>
<td>ElastiCache for Redis now supports new CloudWatch metrics, including <code>PubSubCmds</code> and <code>HyperLogLogBasedCmds</code>. For a full list, see <a href="#">Metrics for Redis</a>.</td>
<td>June 10, 2020</td>
</tr>
<tr>
<td>ElastiCache now supports auto-update of ElastiCache clusters (p. 659)</td>
<td>Amazon ElastiCache now supports auto-update of ElastiCache clusters after the &quot;recommended apply by date&quot; of service update has passed. ElastiCache will use your maintenance window to schedule the auto-update of applicable clusters. For more information, see <a href="#">Self-service updates</a>.</td>
<td>May 13, 2020</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>------</td>
</tr>
<tr>
<td>ElastiCache for Redis now supports Global Datastore for Redis (p. 659)</td>
<td>The Global Datastore for Redis feature offers fully managed, fast, reliable, and secure replication across AWS Regions. Using this feature, you can create cross-Region read replica clusters for ElastiCache for Redis to enable low-latency reads and disaster recovery across AWS Regions. You can create, modify, and describe a global datastore. You can also add or remove AWS Regions from your global datastore and promote an AWS Region as primary within a global datastore. For more information, see Replication Across AWS Regions Using Global Datastore.</td>
<td>March 16, 2020</td>
</tr>
<tr>
<td>ElastiCache for Redis now supports Redis version 5.0.6 (p. 659)</td>
<td>For more information, see ElastiCache for Redis Version 5.0.6 (Enhanced).</td>
<td>December 18, 2019</td>
</tr>
<tr>
<td>Amazon ElastiCache now supports T3-Standard cache nodes (p. 659)</td>
<td>You can now launch the next generation general-purpose burstable T3-Standard cache nodes in Amazon ElastiCache. Amazon EC2's T3-Standard instances provide a baseline level of CPU performance with the ability to burst CPU usage at any time until the accrued credits are exhausted. For more information, see Supported Node Types.</td>
<td>November 12, 2019</td>
</tr>
<tr>
<td>Amazon ElastiCache now supports modifying the AUTH token on an existing ElastiCache for Redis server (p. 659)</td>
<td>ElastiCache for Redis 5.0.5 now enables you to modify authentication tokens by setting and rotating new tokens. You can now modify active tokens while they're in use. You can also add brand-new tokens to existing clusters enabled with encryption in transit that were previously set up without authentication tokens. This is a two-step process by which you can set and rotate the token without interrupting client requests. This feature is currently not supported on AWS CloudFormation. For more information, see Authenticating Users with the Redis AUTH Command.</td>
<td>October 30, 2019</td>
</tr>
</tbody>
</table>
| **ElastiCache for Redis now supports online data migration from Redis on Amazon EC2**  
| (p. 659) | You can now use Online Migration to migrate your data from self-hosted Redis on Amazon EC2 to Amazon ElastiCache. For more information, see Online Migration to ElastiCache. | October 28, 2019 |
| **ElastiCache for Redis now supports Redis version 5.0.5**  
| (p. 659) | This update includes online configuration changes for ElastiCache for Redis of autofailover clusters during all planned operations. For more information, see ElastiCache for Redis Version 5.0.5 (Enhanced). | September 23, 2019 |
| **ElastiCache for Redis introduces online vertical scaling for Redis Cluster mode.**  
| (p. 659) | You can now scale up or scale down your sharded Redis Cluster on demand. ElastiCache for Redis resizes your cluster by changing the node type, while the cluster continues to stay online and serve incoming requests. For more information, see Online Vertical Scaling by Modifying Node Type. | August 20, 2019 |
| **ElastiCache for Redis now allows users to use a single reader endpoint for your Amazon ElastiCache for Redis cluster.**  
| (p. 659) | This feature allows you to direct all read traffic to your ElastiCache for Redis cluster through a single, cluster-level endpoint to take advantage of load balancing and higher availability. For more information, see Finding connection endpoints. | June 13, 2019 |
| **ElastiCache for Redis now allows users to apply service updates on their own schedule**  
| (p. 659) | With this feature, you can choose to apply available service updates at a time of your choosing and not just during maintenance windows. This will minimize service interruptions, particularly during peak business flows, and help ensure you remain compliant if your cluster is in ElastiCache-supported compliance programs. For more information, see Self-Service Updates in Amazon ElastiCache and Self-Service Security Updates for Compliance. | June 4, 2019 |
| **ElastiCache for Redis now supports Redis version 5.0.4, including engine stability guarantee in special conditions.**  
<p>| (p. 659) | This also includes improved Hyperloglog error handling and other enhancements. For more information, see Redis 5.0.4 release notes. | May 15, 2019 |</p>

<td>June 14, 2018</td>
</tr>
<tr>
<td>User Guide restructure (p. 659)</td>
<td>The single ElastiCache User Guide is now restructured so that there are separate user guides for Redis (ElastiCache for Redis User Guide) and for Memcached (ElastiCache for Memcached User Guide). The documentation structure in the AWS CLI Command Reference: elasticache section and the Amazon ElastiCache API Reference remain unchanged.</td>
<td>April 20, 2018</td>
</tr>
</tbody>
</table>
Support for EngineCPUUtilization metric

ElastiCache for Redis added a new metric, EngineCPUUtilization, which reports the percentage of your CPU's capacity that is currently being used. For more information, see Metrics for Redis.

April 9, 2018

The following table describes the important changes to the *ElastiCache for Redis User Guide* before March 2018.

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date Changed</th>
</tr>
</thead>
</table>
| Support for Asia Pacific (Osaka-local) Region. | ElastiCache added support for the Asia Pacific (Osaka-local) Region. The Asia Pacific (Osaka) Region currently supports a single Availability Zone and is by invitation only. For more information, see the following:  
  • Supported regions & endpoints (p. 88)  
  • Supported node types (p. 99) | February 12, 2018 |
| Support for EU (Paris). | ElastiCache added support for the EU (Paris) Region. For more information, see the following:  
  • Supported regions & endpoints (p. 88)  
  • Supported node types (p. 99) | December 18, 2017 |
| Support for China (Ningxia) Region | Amazon ElastiCache added support for China (Ningxia) Region. For more information, see the following:  
  • Supported regions & endpoints (p. 88)  
  • Supported node types (p. 99) | December 11, 2017 |
| Support for Service Linked Roles | This release of ElastiCache added support for Service Linked Roles (SLR). For more information, see the following:  
  • Using Service-Linked Roles for Amazon ElastiCache (p. 567)  
  • Set up your permissions (new ElastiCache users only) (p. 43) | December 7, 2017 |
| Support for R4 node types | This release of ElastiCache added support R4 node types in all AWS Regions supported by ElastiCache. You can purchase R4 node types as On-Demand or as Reserved Cache Nodes. For more information, see the following:  
  • Supported node types (p. 99)  
  • Redis node-type specific parameters (p. 465) | November 20, 2017 |
<p>| ElastiCache for Redis 3.2.10 and Amazon ElastiCache for Redis adds support for ElastiCache for Redis 3.2.10. ElastiCache for Redis | November 9, 2017 |</p>

<tr>
<td>Enhanced Redis restore</td>
<td>ElastiCache adds enhanced Redis backup and restore with cluster resizing. This feature supports restoring a backup to a cluster with a different number of shards than the cluster used to create the backup. (For the API and CLI, this feature can restore a different number of node groups rather than a different number of shards.) This update also supports different Redis slot configurations. For more information, see Restoring from a backup with optional cluster resizing (p. 334).</td>
<td>March 15, 2017</td>
</tr>
</tbody>
</table>
| New Redis memory management parameter | ElastiCache adds a new Redis parameter, reserved-memory-percent, which makes managing your reserved memory easier. This parameter is available on all versions of ElastiCache for Redis. For more information, see the following:  
  - Managing Reserved Memory (p. 223)  
  - New parameters for Redis 3.2.4 (p. 452) | March 15, 2017 |
| Support for EU West (London) Region | ElastiCache adds support for EU (London) Region. Only node types T2 and M4 are currently supported. For more information, see the following:  
  - Supported regions & endpoints (p. 88)  
  - Supported node types (p. 99) | December 13, 2016 |
| Support for Canada (Montreal) Region | ElastiCache adds support for the Canada (Montreal) Region. Only node type M4 and T2 are currently supported in this AWS Region. For more information, see the following:  
  - Supported regions & endpoints (p. 88)  
  - Supported node types (p. 99) | December 8, 2016 |
| Support for M4 and R3 node types | ElastiCache adds support for R3 and M4 node types in South America (São Paulo) Region and M4 node types in China (Beijing) Region. For more information, see the following:  
  - Supported regions & endpoints (p. 88)  
  - Supported node types (p. 99) | November 1, 2016 |
| US East 2 (Ohio) Region support | ElastiCache adds support for the US East (Ohio) Region (us-east-2) with M4, T2, and R3 node types. For more information, see the following:  
  - Supported regions & endpoints (p. 88)  
  - Supported node types (p. 99) | October 17, 2016 |
<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date Changed</th>
</tr>
</thead>
</table>
| Support for Redis Cluster | ElastiCache adds support for Redis Cluster (enhanced). Customers using Redis Cluster, can partition their data across up to 15 shards (node groups). Each shard supports replication with up to 5 read replicas per shard. Redis Cluster automatic failover times are about one fourth as long as those of earlier versions. This release includes a redesigned management console that uses terminology in keeping with industry usage. For more information, see the following:  
  • Comparing Memcached and Redis  
  • ElastiCache for Redis components and features (p. 10) — note the sections on Nodes, Shards, Clusters, and Replication.  
  • ElastiCache for Redis terminology (p. 32) | October 12, 2016 |
| M4 node type support | ElastiCache adds support for the M4 family of node types in most AWS Regions supported by ElastiCache. You can purchase M4 node types as On-Demand or as Reserved Cache Nodes. For more information, see the following:  
  • Supported node types (p. 99)  
  • Redis node-type specific parameters (p. 465) | August 3, 2016 |
| Mumbai Region support | ElastiCache adds support for the Asia Pacific (Mumbai) Region. For more information, see the following:  
  • Supported node types (p. 99)  
  • Redis node-type specific parameters (p. 465) | June 27, 2016 |
| Snapshot export | ElastiCache adds the ability to export a Redis snapshot so you can access it from outside ElastiCache. For more information, see the following:  
  • Exporting a backup (p. 328) in the Amazon ElastiCache User Guide  
  • CopySnapshot in the Amazon ElastiCache API Reference | May 26, 2016 |
<p>| Node type scale up | ElastiCache adds the ability to scale up your Redis node type. For more information, see Scaling ElastiCache for Redis clusters (p. 345). | March 24, 2016 |
| Easy engine upgrade | ElastiCache adds the ability to easily upgrade your Redis cache engine. For more information, see Upgrading engine versions (p. 198). | March 22, 2016 |</p>

</tr>
</tbody>
</table>
| Support for Redis 2.8.24 | ElastiCache adds support for Redis version 2.8.24 with improvements added since Redis 2.8.23. Improvements include bug fixes and support for logging bad memory access addresses. For more information, see the following:  
  - ElastiCache for Redis version 2.8.24 (enhanced) (p. 195)  
  - Redis 2.8 Release Notes | January 20, 2016 |
| Support for Asia Pacific (Seoul) Region | ElastiCache adds support for the Asia Pacific (Seoul) (ap-northeast-2) Region with t2, m3, and r3 node types. | January 6, 2016 |
| Amazon ElastiCache console change. | Because the newer Redis versions provide a better and more stable user experience, Redis versions 2.6.13, 2.8.6, and 2.8.19 are no longer listed in the ElastiCache Management Console. For other options and more information, see Supported ElastiCache for Redis versions (p. 189). | December 15, 2015 |
| Support for Redis 2.8.23. | ElastiCache adds support for Redis version 2.8.23 with improvements added since Redis 2.8.22. Improvements include bug fixes and support for the new parameter close-on-slave-write which, if enabled, disconnects clients who attempt to write to a read-only replica. For more information, see ElastiCache for Redis version 2.8.23 (enhanced) (p. 196). | November 13, 2015 |
### Change Description

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date Changed</th>
</tr>
</thead>
</table>
| **Support for Redis 2.8.22.** | ElastiCache adds support for Redis version 2.8.22 with ElastiCache added enhancements and improvements since version 2.8.21. Improvements include:  
- Implementation of a forkless save process that enables a successful save when low available memory could cause a forked save to fail.  
- Additional CloudWatch metrics — `SaveInProgress` and `ReplicationBytes`.  
- To enable partial synchronizations, the Redis parameter `repl-backlog-size` now applies to all clusters.  

For a complete list of changes and more information, see ElastiCache for Redis version 2.8.22 (enhanced) (p. 196). | September 28, 2015 |
| **Support for Redis 2.8.21** | ElastiCache adds support for Redis version 2.8.21 and Redis improvements since version 2.8.19. This Redis release includes several bug fixes. For more information, see Redis 2.8 release notes. | July 29, 2015 |
| **New topic: Accessing ElastiCache from outside AWS** | Added new topic on how to access ElastiCache resources from outside AWS. For more information, see Accessing ElastiCache resources from outside AWS (p. 171). | July 9, 2015 |

For more information and actions you can take when a node is scheduled for replacement, see ElastiCache’s Event Notifications and Amazon SNS (p. 614). | June 11, 2015 |
<table>

<tr>
<th>Change</th>
<th>Description</th>
<th>Date Changed</th>
</tr>
</thead>
</table>
| Support for Redis v. 2.8.19. | ElastiCache adds support for Redis version 2.8.19 and Redis improvements since version 2.8.6. This support includes support for:  
• The HyperLogLog data structure, with the Redis commands PFADD, PFCOUNT, and PFMERGE.  
• Lexicographic range queries with the new commands ZRANGEBYLEX, ZLEXCOUNT, and ZREMRANGEBYLEX.  
• Introduced a number of bug fixes, namely preventing a primary node from sending stale data to replica nodes by failing the primary SYNC when a background save (bgsave) child process terminates unexpectedly.  
For more information on HyperLogLog, see Redis new data structure: the HyperLogLog.  
For more information on PFADD, PFCOUNT, and PFMERGE, see the Redis Documentation and click HyperLogLog. | March 11, 2015 |
<p>| Support for cost allocation tags | ElastiCache adds support for cost allocation tags. For more information, see Monitoring costs with cost allocation tags (p. 210). | February 9, 2015 |
| Support for Europe (Frankfurt) Region | ElastiCache adds support for the Europe (Frankfurt) (eu-central-1) Region. | January 19, 2015 |
| Multi-AZ support for Redis replication groups | ElastiCache adds support for Multi-AZ from the primary node to a read replica in a Redis replication group. ElastiCache monitors the health of the replication group. If the primary fails, ElastiCache automatically promotes a replica to primary, then replaces the replica. For more information, see Minimizing downtime in ElastiCache for Redis with Multi-AZ (p. 253). | October 24, 2014 |
| AWS CloudTrail logging of API calls supported | ElastiCache adds support for using AWS CloudTrail to log all ElastiCache API calls. For more information, see Logging Amazon ElastiCache API calls with AWS CloudTrail (p. 604). | September 15, 2014 |
| New instance sizes supported | ElastiCache adds support for additional General Purpose (T2) instances. For more information, see Configuring engine parameters using parameter groups (p. 423). | September 11, 2014 |</p>

<tbody>
<tr>
<td>New instance sizes supported</td>
<td>ElastiCache adds support for additional General Purpose (M3) instances and Memory Optimized (R3) instances. For more information, see Configuring engine parameters using parameter groups (p. 423).</td>
<td>July 1, 2014</td>
</tr>
<tr>
<td>Backup and restore for Redis clusters</td>
<td>In this release, ElastiCache allows customers to create snapshots of their Redis clusters, and create new clusters using these snapshots. A backup is a copy of the cluster at a specific moment in time, and consists of cluster metadata and all of the data in the Redis cache. Backups are stored in Amazon S3, and customers can restore the data from a snapshot into a new cluster at any time. For more information, see Backup and restore for ElastiCache for Redis (p. 310).</td>
<td>April 24, 2014</td>
</tr>
<tr>
<td>Redis 2.8.6</td>
<td>ElastiCache supports Redis 2.8.6, in addition to Redis 2.6.13. With Redis 2.8.6, customers can improve the resiliency and fault tolerance of read replicas, with support for partial resynchronization, and a user-defined minimum number of read replicas that must be available at all times. Redis 2.8.6 also offers full support for publish-and-subscribe, where clients can be notified of events that occur on the server.</td>
<td>March 13, 2014</td>
</tr>
<tr>
<td>Redis cache engine</td>
<td>ElastiCache offers Redis cache engine software, in addition to Memcached. Customers who currently use Redis can “seed” a new ElastiCache Redis cache cluster with their existing data from a Redis snapshot file, easing migration to a managed ElastiCache environment. To support Redis replication capabilities, the ElastiCache API now supports replication groups. Customers can create a replication group with a primary Redis cache node, and add one or more read replica nodes that automatically stay synchronized with cache data in the primary node. Read-intensive applications can be offloaded to a read replica, reducing the load on the primary node. Read replicas can also guard against data loss in the event of a primary cache node failure.</td>
<td>September 3, 2013</td>
</tr>
<tr>
<td>Support for default Amazon Virtual Private Cloud (VPC)</td>
<td>In this release, ElastiCache is fully integrated with Amazon Virtual Private Cloud (VPC). For new customers, cache clusters are created in an Amazon VPC by default. For more information, see Amazon VPCs and ElastiCache security (p. 502).</td>
<td>January 8, 2013</td>
</tr>
<tr>
<td>Support for Amazon Virtual Private Cloud (VPC)</td>
<td>In this release, ElastiCache clusters can be launched in Amazon Virtual Private Cloud (VPC). By default, new customers’ cache clusters are created in an Amazon VPC automatically; existing customers can migrate to Amazon VPC at their own pace. For more information, see Amazon VPCs and ElastiCache security (p. 502).</td>
