What is Amazon Aurora?

Amazon Aurora (Aurora) is a fully managed relational database engine that’s compatible with MySQL and PostgreSQL. You already know how MySQL and PostgreSQL combine the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases. The code, tools, and applications you use today with your existing MySQL and PostgreSQL databases can be used with Aurora. With some workloads, Aurora can deliver up to five times the throughput of MySQL and up to three times the throughput of PostgreSQL without requiring changes to most of your existing applications.

Aurora includes a high-performance storage subsystem. Its MySQL- and PostgreSQL-compatible database engines are customized to take advantage of that fast distributed storage. The underlying storage grows automatically as needed. An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB). Aurora also automates and standardizes database clustering and replication, which are typically among the most challenging aspects of database configuration and administration.

Aurora is part of the managed database service Amazon Relational Database Service (Amazon RDS). Amazon RDS is a web service that makes it easier to set up, operate, and scale a relational database in the cloud. If you are not already familiar with Amazon RDS, see the Amazon Relational Database Service User Guide.

The following points illustrate how Aurora relates to the standard MySQL and PostgreSQL engines available in Amazon RDS:

- You choose Aurora as the DB engine option when setting up new database servers through Amazon RDS.
- Aurora takes advantage of the familiar Amazon Relational Database Service (Amazon RDS) features for management and administration. Aurora uses the Amazon RDS AWS Management Console interface, AWS CLI commands, and API operations to handle routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair.
- Aurora management operations typically involve entire clusters of database servers that are synchronized through replication, instead of individual database instances. The automatic clustering, replication, and storage allocation make it simple and cost-effective to set up, operate, and scale your largest MySQL and PostgreSQL deployments.
- You can bring data from Amazon RDS for MySQL and Amazon RDS for PostgreSQL into Aurora by creating and restoring snapshots, or by setting up one-way replication. You can use push-button migration tools to convert your existing Amazon RDS for MySQL and Amazon RDS for PostgreSQL applications to Aurora.

Before using Amazon Aurora, you should complete the steps in Setting up your environment for Amazon Aurora (p. 87), and then review the concepts and features of Aurora in Amazon Aurora DB clusters (p. 3).

• High availability for Amazon Aurora (p. 71)
• Replication with Amazon Aurora (p. 73)
• DB instance billing for Aurora (p. 75)
Amazon Aurora DB clusters

An Amazon Aurora DB cluster consists of one or more DB instances and a cluster volume that manages the data for those DB instances. An Aurora cluster volume is a virtual database storage volume that spans multiple Availability Zones, with each Availability Zone having a copy of the DB cluster data. Two types of DB instances make up an Aurora DB cluster:

- **Primary DB instance** – Supports read and write operations, and performs all of the data modifications to the cluster volume. Each Aurora DB cluster has one primary DB instance.

- **Aurora Replica** – Connects to the same storage volume as the primary DB instance and supports only read operations. Each Aurora DB cluster can have up to 15 Aurora Replicas in addition to the primary DB instance. Maintain high availability by locating Aurora Replicas in separate Availability Zones. Aurora automatically fails over to an Aurora Replica in case the primary DB instance becomes unavailable. You can specify the failover priority for Aurora Replicas. Aurora Replicas can also offload read workloads from the primary DB instance.

The following diagram illustrates the relationship between the cluster volume, the primary DB instance, and Aurora Replicas in an Aurora DB cluster.

![Amazon Aurora DB Cluster Diagram](image)

**Note**
The preceding information applies to all the Aurora clusters that use single-master replication. These include provisioned clusters, parallel query clusters, global database clusters, serverless clusters, and all MySQL 8.0-compatible, 5.7-compatible, and PostgreSQL-compatible clusters. Aurora clusters that use multi-master replication have a different arrangement of read/write and read-only DB instances. All DB instances in a multi-master cluster can perform write operations. There isn’t a single DB instance that performs all the write operations, and there aren’t any read-only DB instances. Therefore, the terms *primary instance* and *Aurora Replica* don’t apply to multi-master clusters. When we discuss clusters that might use multi-master replication, we refer to *writer* DB instances and *reader* DB instances.
The Aurora cluster illustrates the separation of compute capacity and storage. For example, an Aurora configuration with only a single DB instance is still a cluster, because the underlying storage volume involves multiple storage nodes distributed across multiple Availability Zones (AZs).
Amazon Aurora versions

Amazon Aurora reuses code and maintains compatibility with the underlying MySQL and PostgreSQL DB engines. However, Aurora has its own version numbers, release cycle, time line for version deprecation, and so on. The following section explains the common points and differences. This information can help you to decide such things as which version to choose and how to verify which features and fixes are available in each version. It can also help you to decide how often to upgrade and how to plan your upgrade process.

Topics
- Relational databases that are available on Aurora (p. 5)
- Differences in version numbers between community databases and Aurora (p. 5)
- Amazon Aurora major versions (p. 6)
- Amazon Aurora minor versions (p. 7)
- Amazon Aurora patch versions (p. 7)
- Learning what's new in each Amazon Aurora version (p. 7)
- Specifying the Amazon Aurora database version for your database cluster (p. 7)
- Default Amazon Aurora versions (p. 8)
- Automatic minor version upgrades (p. 8)
- How long Amazon Aurora major versions remain available (p. 8)
- How often Amazon Aurora minor versions are released (p. 9)
- Long-term support for selected Amazon Aurora minor versions (p. 9)
- Manually controlling if and when your database cluster is upgraded to new versions (p. 9)
- Required Amazon Aurora upgrades (p. 10)
- Testing your DB cluster with a new Aurora version before upgrading (p. 10)

Relational databases that are available on Aurora

The following relational databases are available on Aurora:

- Amazon Aurora MySQL-Compatible Edition. For usage information, see Working with Amazon Aurora MySQL (p. 651). For a detailed list of available versions, see Database engine updates for Amazon Aurora MySQL (p. 991).
- Amazon Aurora PostgreSQL-Compatible Edition. For usage information, see Working with Amazon Aurora PostgreSQL (p. 1019). For a detailed list of available versions, see Amazon Aurora PostgreSQL updates (p. 1412).

Differences in version numbers between community databases and Aurora

Each Amazon Aurora version is compatible with a specific community database version of either MySQL or PostgreSQL. You can find the community version of your database using the `version` function and the Aurora version using the `aurora_version` function.

Examples for Aurora MySQL and Aurora PostgreSQL are shown following.

```sql
mysql> select version();
```

Amazon Aurora minor versions

Aurora versions use the `major.minor.patch` scheme. An Aurora minor version provides incremental community and Aurora-specific improvements to the service, for example new features and fixes.

Aurora minor versions are always mapped to a specific community version. However, some community versions might not have an Aurora equivalent.

Amazon Aurora patch versions

Aurora versions use the `major.minor.patch` scheme. An Aurora patch version includes important fixes added to a minor version after its initial release (for example, Aurora MySQL 2.04.0, 2.04.1, ..., 2.04.9). While each new minor version provides new Aurora features, new patch versions within a specific minor version are primarily used to resolve important issues.

For more information on patching, see Maintaining an Amazon Aurora DB cluster (p. 321).

Learning what's new in each Amazon Aurora version

Each new Aurora version comes with release notes that list the new features, fixes, other enhancements, and so on that apply to each version.

For Aurora MySQL release notes, see Release Notes for Aurora MySQL. For Aurora PostgreSQL release notes, see Release Notes for Aurora PostgreSQL.

Specifying the Amazon Aurora database version for your database cluster

You can specify any currently available version (major and minor) when creating a new DB cluster using the Create database operation in the AWS Management Console, the AWS CLI, or the CreateDBCluster API operation. Not every Aurora database version is available in every AWS Region.

To learn how to create Aurora clusters, see Creating an Amazon Aurora DB cluster (p. 127). To learn how to change the version of an existing Aurora cluster, see Modifying an Amazon Aurora DB cluster (p. 248).
Default Amazon Aurora versions

When a new Aurora minor version contains significant improvements compared to a previous one, it's marked as the default version for new DB clusters. Typically, we release two default versions for each major version per year.

We recommend that you keep your DB cluster upgraded to the most current default minor version, because that version contains the latest security and functionality fixes.

Automatic minor version upgrades

You can stay up to date with Aurora minor versions by turning on Auto minor version upgrade for every DB instance in the Aurora cluster. Aurora only performs the automatic upgrade if all DB instances in your cluster have this setting turned on. Auto minor version upgrades are performed to the default minor version. We typically schedule automatic upgrades twice a year for DB clusters that have the Auto minor version upgrade setting set to Yes. These upgrades are started during the maintenance window that you specify for your cluster.

For more information, see Enabling automatic upgrades between minor Aurora MySQL versions (p. 998) and How to perform minor version upgrades and apply patches (p. 1424).

How long Amazon Aurora major versions remain available

Amazon Aurora major versions remain available at least until community end of life for the corresponding community version. You can use the following dates to plan your testing and upgrade cycles. These dates represent the earliest date that an upgrade to a newer version might be required. If Amazon extends support for an Aurora version for longer than originally stated, we plan to update this table to reflect the later date.

<table>
<thead>
<tr>
<th>Database community version</th>

</tr>
</tbody>
</table>
Before we ask that you upgrade to a newer major version and to help you plan, we provide a reminder at least 12 months in advance. We do so to communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take. We always recommend that you thoroughly test your applications with new database versions before performing a major version upgrade.

After this 12-month period, an automatic upgrade to the subsequent major version might be applied to any database cluster still running the older version. If so, the upgrade is started during scheduled maintenance windows.

**How often Amazon Aurora minor versions are released**

In general, Amazon Aurora minor versions are released quarterly. The release schedule might vary to pick up additional features or fixes.

**Long-term support for selected Amazon Aurora minor versions**

For each Aurora major version, certain minor versions are designated as long-term-support (LTS) versions and made available for at least three years. That is, at least one minor version per major version is made available for longer than the typical 12 months. We generally provide a reminder six months before the end of this period. We do so to communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take.

LTS minor versions include only critical fixes (through patch versions). An LTS version doesn't include new features released after its introduction. Once a year, DB clusters running on an LTS minor version are patched to the latest patch version of the LTS release. We do this patching to help ensure that you benefit from cumulative security and stability fixes. We might patch an LTS minor version more frequently if there are critical fixes, such as for security, that need to be applied.

**Note**

If you want to remain on an LTS minor version for the duration of its lifecycle, make sure to turn off Auto minor version upgrade for your DB instances. To avoid automatically upgrading your DB cluster from the LTS minor version, set Auto minor version upgrade to No on any DB instance in your Aurora cluster.

For the version numbers of all Aurora LTS versions, see Aurora MySQL long-term support (LTS) releases (p. 994) and Aurora PostgreSQL long-term support (LTS) releases (p. 1428).

**Manually controlling if and when your database cluster is upgraded to new versions**

Auto minor version upgrades are performed to the default minor version. We typically schedule automatic upgrades twice a year for DB clusters that have the Auto minor version upgrade setting set to Yes. These upgrades are started during customer-specified maintenance windows. If you want to turn off automatic minor version upgrades, set Auto minor version upgrade to No on any DB instance within an Aurora cluster. Aurora performs an automatic minor version upgrade only if all DB instances in your cluster have the setting turned on.

Because major version upgrades involve some compatibility risk, they don't occur automatically. You must initiate these, except in the case of a major version deprecation, as explained earlier. We always recommend that you thoroughly test your applications with new database versions before performing a major version upgrade.
For more information about upgrading a DB cluster to a new Aurora major version, see Upgrading Amazon Aurora MySQL DB clusters (p. 997) and Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1414).

Required Amazon Aurora upgrades

For certain critical fixes, we might perform a managed upgrade to a newer patch level within the same minor version. These required upgrades happen even if Auto minor version upgrade is turned off. Before doing so, we communicate the detailed upgrade process. Details include the timing of certain milestones, the impact on your DB clusters, and the actions that we recommend that you take. Such managed upgrades are performed automatically. Each such upgrade is started within the cluster maintenance window.

Testing your DB cluster with a new Aurora version before upgrading

You can test the upgrade process and how the new version works with your application and workload. Use one of the following methods:

- Clone your cluster using the Amazon Aurora fast database clone feature. Perform the upgrade and any post-upgrade testing on the new cluster.
- Restore from a cluster snapshot to create a new Aurora cluster. You can create a cluster snapshot yourself from an existing Aurora cluster. Aurora also automatically creates periodic snapshots for you for each of your clusters. You can then initiate a version upgrade for the new cluster. You can experiment on the upgraded copy of your cluster before deciding whether to upgrade your original cluster.

For more information on these ways to create new clusters for testing, see Cloning a volume for an Amazon Aurora DB cluster (p. 280) and Creating a DB cluster snapshot (p. 373).
Regions and Availability Zones

Amazon cloud computing resources are hosted in multiple locations world-wide. These locations are composed of AWS Regions and Availability Zones. Each AWS Region is a separate geographic area. Each AWS Region has multiple, isolated locations known as Availability Zones.

Note
For information about finding the Availability Zones for an AWS Region, see Describe your Availability Zones in the Amazon EC2 documentation.

Amazon operates state-of-the-art, highly-available data centers. Although rare, failures can occur that affect the availability of DB instances that are in the same location. If you host all your DB instances in a single location that is affected by such a failure, none of your DB instances will be available.

It is important to remember that each AWS Region is completely independent. Any Amazon RDS activity you initiate (for example, creating database instances or listing available database instances) runs only in your current default AWS Region. The default AWS Region can be changed in the console, by setting the AWS_DEFAULT_REGION environment variable, or it can be overridden by using the --region parameter with the AWS Command Line Interface (AWS CLI). For more information, see Configuring the AWS Command Line Interface, specifically the sections about environment variables and command line options.

Amazon RDS supports special AWS Regions called AWS GovCloud (US) that are designed to allow US government agencies and customers to move more sensitive workloads into the cloud. The AWS GovCloud (US) Regions address the US government's specific regulatory and compliance requirements. For more information, see What is AWS GovCloud (US)?

To create or work with an Amazon RDS DB instance in a specific AWS Region, use the corresponding regional service endpoint.

Note
Aurora doesn't support Local Zones.

AWS Regions

Each AWS Region is designed to be isolated from the other AWS Regions. This design achieves the greatest possible fault tolerance and stability.
When you view your resources, you see only the resources that are tied to the AWS Region that you specified. This is because AWS Regions are isolated from each other, and we don't automatically replicate resources across AWS Regions.

Region availability

When you work with an Aurora DB cluster using the command line interface or API operations, make sure that you specify its regional endpoint.

Topics

- Aurora MySQL Region availability (p. 12)
- Aurora PostgreSQL Region availability (p. 14)

Aurora MySQL Region availability

The following table shows the AWS Regions where Aurora MySQL is currently available and the endpoint for each Region.

**Availability Zones**

An Availability Zone is an isolated location in a given AWS Region. Each Region has multiple Availability Zones (AZ) designed to provide high availability for the Region. An AZ is identified by the AWS Region code followed by a letter identifier (for example, `us-east-1a`). If you create your VPC and subnets rather than using the default VPC, you define each subnet in a specific AZ. When you create an Aurora DB cluster, Aurora creates the primary instance in one of the subnets in the VPC’s DB subnet group, thus associating that instance with a specific AZ chosen by Aurora.

Each Aurora DB cluster hosts copies of its storage in three separate AZs. Every DB instance in the cluster must be in one of these three AZs. When you create a DB instance in your cluster, Aurora automatically chooses an appropriate AZ if you don’t specify an AZ.

To learn how to specify the AZ when you create a cluster or add instances to it, see [Configure the network for the DB cluster](#).
Local time zone for Amazon Aurora DB clusters

By default, the time zone for an Amazon Aurora DB cluster is Universal Time Coordinated (UTC). You can set the time zone for instances in your DB cluster to the local time zone for your application instead.

To set the local time zone for a DB cluster, set the time zone parameter in the cluster parameter group for your DB cluster to one of the supported values listed later in this section. For Aurora MySQL, the name of this parameter is `time_zone`. For Aurora PostgreSQL, the name of this parameter is `timezone`. When you set the time zone parameter for a DB cluster, all instances in the DB cluster change to use the new local time zone. If other Aurora DB clusters are using the same cluster parameter group, then all instances in those DB clusters change to use the new local time zone also. For information on cluster-level parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 217).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

If you are replicating across AWS Regions, then the replication master DB cluster and the replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the time zone parameter in the parameter groups for both the replication master and the replica.

When you restore a DB cluster from a DB cluster snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB cluster to a point in time, then the local time zone for the restored DB cluster is the time zone setting from the parameter group of the restored DB cluster.

You can set your local time zone to one of the values listed in the following table. For some time zones, time values for certain date ranges can be reported incorrectly as noted in the table. For Australia time zones, the time zone abbreviation returned is an outdated value as noted in the table.

Supported features in Amazon Aurora by AWS Region and Aurora DB engine

Aurora MySQL- and PostgreSQL-compatible database engines support several Amazon Aurora and Amazon RDS features and options. The support varies across specific versions of each database engine, and across AWS Regions. You can use the tables in this section to identify Aurora database engine version support and availability in a given AWS Region for the following features:

Topics
- Backtracking in Aurora (p. 19)
- Aurora global databases (p. 21)
- Aurora machine learning (p. 24)
- Aurora parallel queries (p. 27)
- Amazon RDS Proxy (p. 28)
- Aurora Serverless v2 (p. 31)
- Aurora Serverless v1 (p. 32)
- Data API for Aurora Serverless v1 (p. 33)

Some of these features are Aurora-only capabilities. For example, Aurora Serverless, Aurora global databases, and support for integration with AWS machine learning services aren't supported by Amazon RDS. Other features, such as Amazon RDS Proxy, are supported by both Amazon Aurora and Amazon RDS.

The tables use the following patterns to specify version numbers and level of support:
- Version x.y – The specific version alone is supported.
- Version x.y and higher – The version and all minor versions are also supported. For example, "version 10.11 and higher" means that versions 10.11, 10.11.1, and 10.12 are also supported.
- - – The feature is not currently available for that particular Aurora feature for the given Aurora database engine, or in that specific AWS Region.

Backtracking in Aurora

By using backtracking in Aurora, you return the state of an Aurora cluster to a specific point in time, without restoring data from a backup. It completes within seconds, even for large databases. For more information, see Backtracking an Aurora DB cluster (p. 725).

Aurora backtracking is available for Aurora MySQL only. It's not available for Aurora PostgreSQL.

Aurora global databases

An *Aurora global database* is a single database that spans multiple AWS Regions, enabling low-latency global reads and disaster recovery from any Region-wide outage. It provides built-in fault tolerance for your deployment because the DB instance relies not on a single AWS Region, but upon multiple Regions and different Availability Zones. For more information, see Using Amazon Aurora global databases (p. 151).

Aurora machine learning

Aurora machine learning provides simple, optimized, and secure integration between Aurora and AWS machine learning services without having to build custom integrations or move data around. Aurora exposes ML models as SQL functions, so you don't need to learn new programming languages or tools. Instead, you use standard SQL to build applications that call ML models, pass data to them, and return predictions as query results. For more information, see Using machine learning (ML) capabilities with Amazon Aurora (p. 320).

</tbody>
</table>
Aurora parallel queries

Aurora parallel queries can speed up your queries by up to two orders of magnitude, while maintaining high throughput for your core transactional workload. Using the unique Aurora architecture, parallel queries can push down and parallelize query processing across thousands of CPUs in the Aurora storage layer. By offloading analytical query processing to the Aurora storage layer, parallel queries reduce network, CPU, and buffer pool contention for transactional workloads. For more information, see Working with parallel query for Amazon Aurora MySQL (p. 791). To learn more about Aurora MySQL versions available for parallel queries and any steps you might need to take based on that version to support parallel queries, see Planning for a parallel query cluster (p. 795).

Aurora parallel queries are available for Aurora MySQL only. However, PostgreSQL has its own parallel query feature that is available on Amazon RDS. The capability is enabled by default when a new PostgreSQL instance is created (versions 10.1 and higher). For more information, see PostgreSQL on Amazon RDS.

Amazon RDS Proxy

Amazon RDS Proxy is a fully managed, highly available database proxy that makes applications more scalable by pooling and sharing established database connections. For more information about RDS Proxy, see Using Amazon RDS Proxy (p. 1429).

# Aurora Serverless v2

Aurora Serverless v2 is an on-demand, auto-scaling feature designed to be a cost-effective approach to running intermittent or unpredictable workloads on Amazon Aurora. It automatically starts up, shuts down, and scales capacity up or down, as needed by your applications. The scaling is faster and more granular than with Aurora Serverless v1. With Aurora Serverless v2, each cluster can contain a writer DB instance and multiple reader DB instances. You can combine Aurora Serverless v2 and traditional provisioned DB instances within the same cluster. For more information, see Using Aurora Serverless v2 (p. 1481).

Aurora Serverless v1

Aurora Serverless is an on-demand, auto-scaling feature designed to be a cost-effective approach to running intermittent or unpredictable workloads on Amazon Aurora. It automatically starts up, shuts down, and scales capacity up or down, as needed by your applications, using a single DB instance in each cluster. For more information, see Using Amazon Aurora Serverless v1 (p. 1542).
## Data API for Aurora Serverless v1

The Data API for Aurora Serverless provides a web-services interface to an Aurora Serverless v1 cluster. Instead of managing database connections from client applications, you can run SQL commands against an HTTPS endpoint. For more information, see Using the Data API for Aurora Serverless v1 (p. 1580).

Amazon Aurora connection management

Amazon Aurora typically involves a cluster of DB instances instead of a single instance. Each connection is handled by a specific DB instance. When you connect to an Aurora cluster, the host name and port that you specify point to an intermediate handler called an endpoint. Aurora uses the endpoint mechanism to abstract these connections. Thus, you don’t have to hardcode all the hostnames or write your own logic for load-balancing and rerouting connections when some DB instances aren’t available.

For certain Aurora tasks, different instances or groups of instances perform different roles. For example, the primary instance handles all data definition language (DDL) and data manipulation language (DML) statements. Up to 15 Aurora Replicas handle read-only query traffic.

Using endpoints, you can map each connection to the appropriate instance or group of instances based on your use case. For example, to perform DDL statements you can connect to whichever instance is the primary instance. To perform queries, you can connect to the reader endpoint, with Aurora automatically performing load-balancing among all the Aurora Replicas. For clusters with DB instances of different capacities or configurations, you can connect to custom endpoints associated with different subsets of DB instances. For diagnosis or tuning, you can connect to a specific instance endpoint to examine details about a specific DB instance.

Topics
- Types of Aurora endpoints (p. 36)
- Viewing the endpoints for an Aurora cluster (p. 37)
- Using the cluster endpoint (p. 37)
- Using the reader endpoint (p. 38)
- Using custom endpoints (p. 38)
- Creating a custom endpoint (p. 40)
- Viewing custom endpoints (p. 42)
- Editing a custom endpoint (p. 47)
- Deleting a custom endpoint (p. 49)
- End-to-end AWS CLI example for custom endpoints (p. 50)
- Using the instance endpoints (p. 54)
- How Aurora endpoints work with high availability (p. 54)
Types of Aurora endpoints

An endpoint is represented as an Aurora-specific URL that contains a host address and a port. The following types of endpoints are available from an Aurora DB cluster.

**Cluster endpoint**

A *cluster endpoint* (or *writer endpoint*) for an Aurora DB cluster connects to the current primary DB instance for that DB cluster. This endpoint is the only one that can perform write operations such as DDL statements. Because of this, the cluster endpoint is the one that you connect to when you first set up a cluster or when your cluster only contains a single DB instance.

Each Aurora DB cluster has one cluster endpoint and one primary DB instance.

You use the cluster endpoint for all write operations on the DB cluster, including inserts, updates, deletes, and DDL changes. You can also use the cluster endpoint for read operations, such as queries.

The cluster endpoint provides failover support for read/write connections to the DB cluster. If the current primary DB instance of a DB cluster fails, Aurora automatically fails over to a new primary DB instance. During a failover, the DB cluster continues to serve connection requests to the cluster endpoint from the new primary DB instance, with minimal interruption of service.

The following example illustrates a cluster endpoint for an Aurora MySQL DB cluster.

```
mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com:3306
```

**Reader endpoint**

A *reader endpoint* for an Aurora DB cluster provides load-balancing support for read-only connections to the DB cluster. Use the reader endpoint for read operations, such as queries. By processing those statements on the read-only Aurora Replicas, this endpoint reduces the overhead on the primary instance. It also helps the cluster to scale the capacity to handle simultaneous SELECT queries, proportional to the number of Aurora Replicas in the cluster. Each Aurora DB cluster has one reader endpoint.

If the cluster contains one or more Aurora Replicas, the reader endpoint load-balances each connection request among the Aurora Replicas. In that case, you can only perform read-only statements such as SELECT in that session. If the cluster only contains a primary instance and no Aurora Replicas, the reader endpoint connects to the primary instance. In that case, you can perform write operations through the endpoint.

The following example illustrates a reader endpoint for an Aurora MySQL DB cluster.

```
mydbcluster.cluster-ro-123456789012.us-east-1.rds.amazonaws.com:3306
```

**Custom endpoint**

A *custom endpoint* for an Aurora cluster represents a set of DB instances that you choose. When you connect to the endpoint, Aurora performs load balancing and chooses one of the instances in the group to handle the connection. You define which instances this endpoint refers to, and you decide what purpose the endpoint serves.

An Aurora DB cluster has no custom endpoints until you create one. You can create up to five custom endpoints for each provisioned Aurora cluster. You can't use custom endpoints for Aurora Serverless clusters.

The custom endpoint provides load-balanced database connections based on criteria other than the read-only or read/write capability of the DB instances. For example, you might define a custom endpoint to connect to instances that use a particular AWS instance class or a particular DB parameter group. Then you might tell particular groups of users about this custom endpoint. For example, you might direct internal users to low-capacity instances for report generation or ad hoc (one-time) querying, and direct production traffic to high-capacity instances.
Because the connection can go to any DB instance that is associated with the custom endpoint, we recommend that you make sure that all the DB instances within that group share some similar characteristic. Doing so ensures that the performance, memory capacity, and so on, are consistent for everyone who connects to that endpoint.

This feature is intended for advanced users with specialized kinds of workloads where it isn’t practical to keep all the Aurora Replicas in the cluster identical. With custom endpoints, you can predict the capacity of the DB instance used for each connection. When you use custom endpoints, you typically don’t use the reader endpoint for that cluster.

The following example illustrates a custom endpoint for a DB instance in an Aurora MySQL DB cluster.

myendpoint.cluster-custom-123456789012.us-east-1.rds.amazonaws.com:3306

**Instance endpoint**

An *instance endpoint* connects to a specific DB instance within an Aurora cluster. Each DB instance in a DB cluster has its own unique instance endpoint. So there is one instance endpoint for the current primary DB instance of the DB cluster, and there is one instance endpoint for each of the Aurora Replicas in the DB cluster.

The instance endpoint provides direct control over connections to the DB cluster, for scenarios where using the cluster endpoint or reader endpoint might not be appropriate. For example, your client application might require more fine-grained load balancing based on workload type. In this case, you can configure multiple clients to connect to different Aurora Replicas in a DB cluster to distribute read workloads. For an example that uses instance endpoints to improve connection speed after a failover for Aurora PostgreSQL, see Fast failover with Amazon Aurora PostgreSQL (p. 1202). For an example that uses instance endpoints to improve connection speed after a failover for Aurora MySQL, see MariaDB Connector/J failover support - case Amazon Aurora.

The following example illustrates an instance endpoint for a DB instance in an Aurora MySQL DB cluster.

mydbinstance.123456789012.us-east-1.rds.amazonaws.com:3306

**Viewing the endpoints for an Aurora cluster**

In the AWS Management Console, you see the cluster endpoint, the reader endpoint, and any custom endpoints in the detail page for each cluster. You see the instance endpoint in the detail page for each instance. When you connect, you must append the associated port number, following a colon, to the endpoint name shown on this detail page.

With the AWS CLI, you see the writer, reader, and any custom endpoints in the output of the `describe-db-clusters` command. For example, the following command shows the endpoint attributes for all clusters in your current AWS Region.

```bash
aws rds describe-db-clusters --query '*[].
{Endpoint:Endpoint,ReaderEndpoint:ReaderEndpoint,CustomEndpoints:CustomEndpoints}'
```

With the Amazon RDS API, you retrieve the endpoints by calling the `DescribeDBClusterEndpoints` function.

**Using the cluster endpoint**

Because each Aurora cluster has a single built-in cluster endpoint, whose name and other attributes are managed by Aurora, you can’t create, delete, or modify this kind of endpoint.
Amazon Aurora User Guide for Aurora

Using the reader endpoint

You use the reader endpoint for read-only connections for your Aurora cluster. This endpoint uses a load-balancing mechanism to help your cluster handle a query-intensive workload. The reader endpoint is the endpoint that you supply to applications that do reporting or other read-only operations on the cluster.

The reader endpoint load-balances connections to available Aurora Replicas in an Aurora DB cluster. It doesn't load-balance individual queries. If you want to load-balance each query to distribute the read workload for a DB cluster, open a new connection to the reader endpoint for each query.

Each Aurora cluster has a single built-in reader endpoint, whose name and other attributes are managed by Aurora. You can't create, delete, or modify this kind of endpoint.

If your cluster contains only a primary instance and no Aurora Replicas, the reader endpoint connects to the primary instance. In that case, you can perform write operations through this endpoint.

Tip
Through RDS Proxy, you can create additional read-only endpoints for an Aurora cluster. These endpoints perform the same kind of load-balancing as the Aurora reader endpoint. Applications can reconnect more quickly to the proxy endpoints than the Aurora reader endpoint if reader instances become unavailable. The proxy endpoints can also take advantage of other proxy features such as multiplexing. For more information, see Using reader endpoints with Aurora clusters (p. 1458).

Using custom endpoints

You use custom endpoints to simplify connection management when your cluster contains DB instances with different capacities and configuration settings.

Previously, you might have used the CNAMES mechanism to set up Domain Name Service (DNS) aliases from your own domain to achieve similar results. By using custom endpoints, you can avoid updating CNAME records when your cluster grows or shrinks. Custom endpoints also mean that you can use encrypted Transport Layer Security/Secure Sockets Layer (TLS/SSL) connections.

Instead of using one DB instance for each specialized purpose and connecting to its instance endpoint, you can have multiple groups of specialized DB instances. In this case, each group has its own custom endpoint. This way, Aurora can perform load balancing among all the instances dedicated to tasks such as reporting or handling production or internal queries. The custom endpoints provide load balancing and high availability for each group of DB instances within your cluster. If one of the DB instances within a group becomes unavailable, Aurora directs subsequent custom endpoint connections to one of the other DB instances associated with the same endpoint.

Topics
- Specifying properties for custom endpoints (p. 39)
- Membership rules for custom endpoints (p. 39)
Specifying properties for custom endpoints

The maximum length for a custom endpoint name is 63 characters. You can see the name format following:

\[\text{endpointName.cluster-custom-customerDnsIdentifier.dnsSuffix}\]

Because custom endpoint names don’t include the name of your cluster, you don’t have to change those names if you rename a cluster. You can’t reuse the same custom endpoint name for more than one cluster in the same region. Give each custom endpoint a name that is unique across the clusters owned by your user ID within a particular region.

Each custom endpoint has an associated type that determines which DB instances are eligible to be associated with that endpoint. Currently, the type can be `READER`, `WRITER`, or `ANY`. The following considerations apply to the custom endpoint types:

- Only DB instances that are read-only Aurora Replicas can be part of a `READER` custom endpoint. The `READER` type applies only to clusters using single-master replication, because those clusters can include multiple read-only DB instances.
- Both read-only Aurora Replicas and the read/write primary instance can be part of an `ANY` custom endpoint. Aurora directs connections to cluster endpoints with type `ANY` to any associated DB instance with equal probability. Because you can’t determine in advance if you are connecting to the primary instance of a read-only Aurora Replica, use this kind of endpoint for read-only connections only. The `ANY` type applies to clusters using any replication topology.
- The `WRITER` type applies only to multi-master clusters, because those clusters can include multiple read/write DB instances.
- If you try to create a custom endpoint with a type that isn’t appropriate based on the replication configuration for a cluster, Aurora returns an error.

Membership rules for custom endpoints

When you add a DB instance to a custom endpoint or remove it from a custom endpoint, any existing connections to that DB instance remain active.

You can define a list of DB instances to include in, or exclude from, a custom endpoint. We refer to these lists as `static` and `exclusion` lists, respectively. You can use the inclusion/exclusion mechanism to further subdivide the groups of DB instances, and to make sure that the set of custom endpoints covers all the DB instances in the cluster. Each custom endpoint can contain only one of these list types.

In the AWS Management Console, the choice is represented by the check box **Attach future instances added to this cluster.** When you keep the check box clear, the custom endpoint uses a static list containing only the DB instances specified on the page. When you choose the check box, the custom endpoint uses an exclusion list. In this case, the custom endpoint represents all DB instances in the cluster (including any that you add in the future) except the ones not selected on the page. The AWS CLI and Amazon RDS API have parameters representing each kind of list. When you use the AWS CLI or Amazon RDS API, you can’t add or remove individual members to the lists; you always specify the entire new list.

Aurora doesn’t change the DB instances specified in the static or exclusion lists when DB instances change roles between primary instance and Aurora Replica due to failover or promotion. For example, a custom endpoint with type `READER` might include a DB instance that was an Aurora Replica and then was promoted to a primary instance. The type of a custom endpoint (`READER`, `WRITER`, or `ANY`) determines what kinds of operations you can perform through that endpoint.
You can associate a DB instance with more than one custom endpoint. For example, suppose that you add a new DB instance to a cluster, or that Aurora adds a DB instance automatically through the autoscaling mechanism. In these cases, the DB instance is added to all custom endpoints for which it is eligible. Which endpoints the DB instance is added to is based on the custom endpoint type of **READER**, **WRITER**, or **ANY**, plus any static or exclusion lists defined for each endpoint. For example, if the endpoint includes a static list of DB instances, newly added Aurora Replicas aren't added to that endpoint. Conversely, if the endpoint has an exclusion list, newly added Aurora Replicas are added to the endpoint, if they aren't named in the exclusion list and their roles match the type of the custom endpoint.

If an Aurora Replica becomes unavailable, it remains associated with any custom endpoints. For example, it remains part of the custom endpoint when it is unhealthy, stopped, rebooting, and so on. However, you can't connect to it through those endpoints until it becomes available again.

### Managing custom endpoints

Because newly created Aurora clusters have no custom endpoints, you must create and manage these objects yourself. You do so using the AWS Management Console, AWS CLI, or Amazon RDS API.

**Note**

You must also create and manage custom endpoints for Aurora clusters restored from snapshots. Custom endpoints are not included in the snapshot. You create them again after restoring, and choose new endpoint names if the restored cluster is in the same region as the original one.

To work with custom endpoints from the AWS Management Console, you navigate to the details page for your Aurora cluster and use the controls under the **Custom Endpoints** section.

To work with custom endpoints from the AWS CLI, you can use these operations:

- `create-db-cluster-endpoint`
- `describe-db-cluster-endpoints`
- `modify-db-cluster-endpoint`
- `delete-db-cluster-endpoint`

To work with custom endpoints through the Amazon RDS API, you can use the following functions:

- `CreateDBClusterEndpoint`
- `DescribeDBClusterEndpoints`
- `ModifyDBClusterEndpoint`
- `DeleteDBClusterEndpoint`

### Creating a custom endpoint

**Console**

To create a custom endpoint with the AWS Management Console, go to the cluster detail page and choose the **Create custom endpoint** action in the **Endpoints** section. Choose a name for the custom endpoint, unique for your user ID and region. To choose a list of DB instances that remains the same even as the cluster expands, keep the check box **Attach future instances added to this cluster** clear. When you choose that check box, the custom endpoint dynamically adds any new instances as you add them to the cluster.
Create custom endpoint

Endpoint name

Endpoint name is case insensitive, First character must be a letter. Can

Endpoint members

Filter database
You can't select the custom endpoint type of ANY or READER in the AWS Management Console. All the custom endpoints you create through the AWS Management Console have a type of ANY.

**AWS CLI**

To create a custom endpoint with the AWS CLI, run the `create-db-cluster-endpoint` command.

The following command creates a custom endpoint attached to a specific cluster. Initially, the endpoint is associated with all the Aurora Replica instances in the cluster. A subsequent command associates it with a specific set of DB instances in the cluster.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample
    --endpoint-type reader
    --db-cluster-identifier cluster_id

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample
    --static-members instance_name_1 instance_name_2
```

For Windows:

```bash
aws rds create-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample
    --endpoint-type reader
    --db-cluster-identifier cluster_id

aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier custom-endpoint-doc-sample
    --static-members instance_name_1 instance_name_2
```

**RDS API**

To create a custom endpoint with the RDS API, run the `CreateDBClusterEndpoint` operation.

**Viewing custom endpoints**

**Console**

To view custom endpoints with the AWS Management Console, go to the cluster detail page for the cluster and look under the **Endpoints** section. This section contains information only about custom endpoints. The details for the built-in endpoints are listed in the main **Details** section. To see the details for a specific custom endpoint, select its name to bring up the detail page for that endpoint.

The following screenshot shows how the list of custom endpoints for an Aurora cluster is initially empty.
After you create some custom endpoints for that cluster, they are shown under the **Endpoints** section.
Clicking through to the detail page shows which DB instances the endpoint is currently associated with.
Viewing custom endpoints
To see the additional detail of whether new DB instances added to the cluster are automatically added to
the endpoint also, open the **Edit** page for the endpoint.

**AWS CLI**

To view custom endpoints with the AWS CLI, run the `describe-db-cluster-endpoints` command.

The following command shows the custom endpoints associated with a specified cluster in a specified
region. The output includes both the built-in endpoints and any custom endpoints.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-cluster-endpoints --region region_name \  
    --db-cluster-identifier cluster_id
```

For Windows:

```bash
aws rds describe-db-cluster-endpoints --region region_name ^  
    --db-cluster-identifier cluster_id
```

The following shows some sample output from a `describe-db-cluster-endpoints` command.
The `EndpointType` of `WRITER` or `READER` denotes the built-in read/write and read-only endpoints
for the cluster. The `EndpointType` of `CUSTOM` denotes endpoints that you create and choose the
associated DB instances. One of the endpoints has a non-empty `StaticMembers` field, denoting that it
is associated with a precise set of DB instances. The other endpoint has a non-empty `ExcludedMembers`
field, denoting that the endpoint is associated with all DB instances other than the ones listed under
`ExcludedMembers`. This second kind of custom endpoint grows to accommodate new instances as you
add them to the cluster.

```json
{
    "DBClusterEndpoints": [
        {
            "Endpoint": "custom-endpoint-demo.cluster-123456789012.ca-central-1.rds.amazonaws.com",
            "Status": "available",
            "DBClusterIdentifier": "custom-endpoint-demo",
            "EndpointType": "WRITER"
        },
        {
            "Endpoint": "custom-endpoint-demo.cluster-ro-123456789012.ca-central-1.rds.amazonaws.com",
            "Status": "available",
            "DBClusterIdentifier": "custom-endpoint-demo",
            "EndpointType": "READER"
        },
        {
            "CustomEndpointType": "ANY",
            "DBClusterEndpointIdentifier": "powers-of-2",
            "ExcludedMembers": [],
            "DBClusterIdentifier": "custom-endpoint-demo",
            "Status": "available",
            "EndpointType": "CUSTOM",
            "Endpoint": "powers-of-2.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com",
            "StaticMembers": [
                "custom-endpoint-demo-04",
                "custom-endpoint-demo-08",
                "custom-endpoint-demo-01",
                "custom-endpoint-demo-02"
            ],
            "DBClusterEndpointResourceIdentifier": "cluster-endpoint-W7PE3TLLFNSHXQFU6J6NV5FHU",
```
Editing a custom endpoint

You can edit the properties of a custom endpoint to change which DB instances are associated with the endpoint. You can also change an endpoint between a static list and an exclusion list. If you need more details about these endpoint properties, see Membership rules for custom endpoints (p. 39).

You can continue connecting to and using a custom endpoint while the changes from an edit action are in progress.

Console

To edit a custom endpoint with the AWS Management Console, you can select the endpoint on the cluster detail page, or bring up the detail page for the endpoint, and choose the Edit action.

RDS API

To view custom endpoints with the RDS API, run the DescribeDBClusterEndpoints.html operation.
Edit endpoint:

Endpoint members

Filter database

DB instance name
AWS CLI

To edit a custom endpoint with the AWS CLI, run the `modify-db-cluster-endpoint` command.

The following commands change the set of DB instances that apply to a custom endpoint and optionally switches between the behavior of a static or exclusion list. The `--static-members` and `--excluded-members` parameters take a space-separated list of DB instance identifiers.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint \
  --static-members db-instance-id-1 db-instance-id-2 db-instance-id-3 \
  --region region_name
```

```bash
aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint \ 
  --excluded-members db-instance-id-4 db-instance-id-5 \ 
  --region region_name
```

For Windows:

```bash
aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint 
  --static-members db-instance-id-1 db-instance-id-2 db-instance-id-3
```

```bash
aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier my-custom-endpoint
  --excluded-members db-instance-id-4 db-instance-id-5
```

RDS API

To edit a custom endpoint with the RDS API, run the `ModifyDBClusterEndpoint` operation.

Deleting a custom endpoint

Console

To delete a custom endpoint with the AWS Management Console, go to the cluster detail page, select the appropriate custom endpoint, and select the **Delete** action.

AWS CLI

To delete a custom endpoint with the AWS CLI, run the `delete-db-cluster-endpoint` command.
The following command deletes a custom endpoint. You don't need to specify the associated cluster, but you must specify the region.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-cluster-endpoint --db-cluster-endpoint-identifier custom-end-point-id \ --region region_name
```

For Windows:

```bash
aws rds delete-db-cluster-endpoint --db-cluster-endpoint-identifier custom-end-point-id ^ --region region_name
```

**RDS API**

To delete a custom endpoint with the RDS API, run the `DeleteDBClusterEndpoint` operation.

**End-to-end AWS CLI example for custom endpoints**

The following tutorial uses AWS CLI examples with Unix shell syntax to show you might define a cluster with several "small" DB instances and a few "big" DB instances, and create custom endpoints to connect to each set of DB instances. To run similar commands on your own system, you should be familiar enough with the basics of working with Aurora clusters and AWS CLI usage to supply your own values for parameters such as region, subnet group, and VPC security group.

This example demonstrates the initial setup steps: creating an Aurora cluster and adding DB instances to it. This is a heterogeneous cluster, meaning not all the DB instances have the same capacity. Most instances use the AWS instance class `db.r4.4xlarge`, but the last two DB instances use `db.r4.16xlarge`. Each of these sample `create-db-instance` commands prints its output to the screen and saves a copy of the JSON in a file for later inspection.

```bash
aws rds create-db-cluster --db-cluster-identifier custom-endpoint-demo --engine aurora \ --engine-version 5.6.10a --master-username $MASTER_USER --master-user-password $MASTER_PW \ --db-subnet-group-name $SUBNET_GROUP --vpc-security-group-ids $VPC_SECURITY_GROUP \ --region $REGION

for i in 01 02 03 04 05 06 07 08
do
  aws rds create-db-instance --db-instance-identifier custom-endpoint-demo-${i} \ --engine aurora --db-cluster-identifier custom-endpoint-demo --db-instance-class db.r4.4xlarge \ --region $REGION \ | tee custom-endpoint-demo-${i}.json
done

for i in 09 10
do
  aws rds create-db-instance --db-instance-identifier custom-endpoint-demo-${i} \ --engine aurora --db-cluster-identifier custom-endpoint-demo --db-instance-class db.r4.16xlarge \ --region $REGION \ | tee custom-endpoint-demo-${i}.json
done
```

The larger instances are reserved for specialized kinds of reporting queries. To make it unlikely for them to be promoted to the primary instance, the following example changes their promotion tier to the lowest priority.
for i in 09 10
do
  aws rds modify-db-instance --db-instance-identifier custom-endpoint-demo-#{i} \
    --region $REGION --promotion-tier 15
done

Suppose that you want to use the two "bigger" instances only for the most resource-intensive queries.
To do this, you can first create a custom read-only endpoint. Then you can add a static list of members
so that the endpoint connects only to those DB instances. Those instances are already in the lowest
promotion tier, making it unlikely either of them will be promoted to the primary instance. If one of
them is promoted to the primary instance, it becomes unreachable through this endpoint because we
specified the READER type instead of the ANY type.

The following example demonstrates the create and modify endpoint commands, and sample JSON
output showing the initial and modified state of the custom endpoint.

```
$ aws rds create-db-cluster-endpoint --region $REGION \
    --db-cluster-identifier custom-endpoint-demo \
    --db-cluster-endpoint-identifier big-instances --endpoint-type reader
{
  "EndpointType": "CUSTOM",
  "Endpoint": "big-instances.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com",
  "DBClusterEndpointIdentifier": "big-instances",
  "DBClusterIdentifier": "custom-endpoint-demo",
  "StaticMembers": [],
  "DBClusterEndpointResourceIdentifier": "cluster-endpoint-W7PE3LLLGNSH6QKFW36J66NV5PHU",
  "ExcludedMembers": [],
  "CustomEndpointType": "READER",
  "Status": "creating",
}
$ aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier big-instances \
    --static-members custom-endpoint-demo-09 custom-endpoint-demo-10 --region $REGION
{
  "EndpointType": "CUSTOM",
  "ExcludedMembers": [],
  "DBClusterEndpointIdentifier": "big-instances",
  "DBClusterIdentifier": "custom-endpoint-demo",
  "DBClusterEndpointResourceIdentifier": "cluster-endpoint-W7PE3LLLGNSH6QKFW36J66NV5PHU",
  "CustomEndpointType": "READER",
  "StaticMembers": [
    "custom-endpoint-demo-10",
    "custom-endpoint-demo-09"
  ],
  "Status": "modifying",
  "Endpoint": "big-instances.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com",
  "DBClusterIdentifier": "custom-endpoint-demo"
}
```

The default READER endpoint for the cluster can connect to either the "small" or "big" DB instances,
making it impractical to predict query performance and scalability when the cluster becomes busy.
To divide the workload cleanly between the sets of DB instances, you can ignore the default READER
endpoint and create a second custom endpoint that connects to all other DB instances. The following
example does so by creating a custom endpoint and then adding an exclusion list. Any other DB
instances you add to the cluster later will be added to this endpoint automatically. The ANY type means
that this endpoint is associated with eight instances in total: the primary instance and another seven
Aurora Replicas. If the example used the READER type, the custom endpoint would only be associated
with the seven Aurora Replicas.
$ aws rds create-db-cluster-endpoint --region $REGION --db-cluster-identifier custom-endpoint-demo \
   --db-cluster-endpoint-identifier small-instances --endpoint-type any
{
  "Status": "creating",
  "DBClusterEndpointIdentifier": "small-instances",
  "CustomEndpointType": "ANY",
  "EndpointType": "CUSTOM",
  "Endpoint": "small-instances.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com",
  "StaticMembers": [],
  "ExcludedMembers": [],
  "DBClusterIdentifier": "custom-endpoint-demo",
  "DBClusterEndpointResourceIdentifier": "cluster-endpoint-6RDDXQOC3AKKZT2PRD7ST37BMY"
}

$ aws rds modify-db-cluster-endpoint --db-cluster-endpoint-identifier small-instances --excluded-members custom-endpoint-demo-09 custom-endpoint-demo-10 --region $REGION
{
  "DBClusterEndpointIdentifier": "small-instances",
  "DBClusterEndpointResourceIdentifier": "cluster-endpoint-6RDDXQOC3AKKZT2PRD7ST37BMY",
  "CustomEndpointType": "ANY",
  "Endpoint": "small-instances.cluster-custom-123456789012.ca-central-1.rds.amazonaws.com",
  "EndpointType": "CUSTOM",
  "ExcludedMembers": ["custom-endpoint-demo-09", "custom-endpoint-demo-10"],
  "StaticMembers": [],
  "DBClusterIdentifier": "custom-endpoint-demo",
  "Status": "modifying"
}

The following example checks the state of the endpoints for this cluster. The cluster still has its original cluster endpoint, with EndpointType of WRITER, which you would still use for administration, ETL, and other write operations. It still has its original READER endpoint, which you wouldn't use because each connection to it might be directed to a "small" or "big" DB instance. The custom endpoints make this behavior predictable, with connections guaranteed to use one of the "small" or "big" DB instances based on the endpoint you specify.

$ aws rds describe-db-cluster-endpoints --region $REGION
{
  "DBClusterEndpoints": [
    {
      "EndpointType": "WRITER",
      "Endpoint": "custom-endpoint-demo.cluster-123456789012.ca-central-1.rds.amazonaws.com",
      "Status": "available",
      "DBClusterIdentifier": "custom-endpoint-demo"
    },
    {
      "EndpointType": "READER",
      "Endpoint": "custom-endpoint-demo.cluster-ro-123456789012.ca-central-1.rds.amazonaws.com",
      "Status": "available",
      "DBClusterIdentifier": "custom-endpoint-demo"
    }
  ]
}
The final examples demonstrate how successive database connections to the custom endpoints connect to the various DB instances in the Aurora cluster. The small-instances endpoint always connects to the db.r4.4xlarge DB instances, which are the lower-numbered hosts in this cluster.
The **big-instances** endpoint always connects to the `db.r4.16xlarge` DB instances, which are the two highest-numbered hosts in this cluster.

```

### Using the instance endpoints

Each DB instance in an Aurora cluster has its own built-in instance endpoint, whose name and other attributes are managed by Aurora. You can't create, delete, or modify this kind of endpoint. You might be familiar with instance endpoints if you use Amazon RDS. However, with Aurora you typically use the writer and reader endpoints more often than the instance endpoints.

In day-to-day Aurora operations, the main way that you use instance endpoints is to diagnose capacity or performance issues that affect one specific instance in an Aurora cluster. While connected to a specific instance, you can examine its status variables, metrics, and so on. Doing this can help you determine what's happening for that instance that's different from what's happening for other instances in the cluster.

In advanced use cases, you might configure some DB instances differently than others. In this case, use the instance endpoint to connect directly to an instance that is smaller, larger, or otherwise has different characteristics than the others. Also, set up failover priority so that this special DB instance is the last choice to take over as the primary instance. We recommend that you use custom endpoints instead of the instance endpoint in such cases. Doing so simplifies connection management and high availability as you add more DB instances to your cluster.

### How Aurora endpoints work with high availability

For clusters where high availability is important, use the writer endpoint for read/write or general-purpose connections and the reader endpoint for read-only connections. The writer and reader endpoints manage DB instance failover better than instance endpoints do. Unlike the instance endpoints, the writer and reader endpoints automatically change which DB instance they connect to if a DB instance in your cluster becomes unavailable.

If the primary DB instance of a DB cluster fails, Aurora automatically fails over to a new primary DB instance. It does so by either promoting an existing Aurora Replica to a new primary DB instance or creating a new primary DB instance. If a failover occurs, you can use the writer endpoint to reconnect to the newly promoted or created primary DB instance, or use the reader endpoint to reconnect to one of
the Aurora Replicas in the DB cluster. During a failover, the reader endpoint might direct connections to the new primary DB instance of a DB cluster for a short time after an Aurora Replica is promoted to the new primary DB instance.

If you design your own application logic to manage connections to instance endpoints, you can manually or programmatically discover the resulting set of available DB instances in the DB cluster. Use the `describe-db-clusters` AWS CLI command or `DescribeDBClusters` RDS API operation to find the DB cluster and reader endpoints, DB instances, whether DB instances are readers, and their promotion tiers. You can then confirm their instance classes after failover and connect to an appropriate instance endpoint.

For more information about failovers, see Fault tolerance for an Aurora DB cluster (p. 72).
Aurora DB instance classes

The DB instance class determines the computation and memory capacity of an Amazon Aurora DB instance. The DB instance class that you need depends on your processing power and memory requirements.

A DB instance class consists of both the DB instance type and the size. For example, db.m6g is a general-purpose DB instance type powered by AWS Graviton2 processors, while db.m6g.2xlarge is a DB instance class within the db.m6g instance type.

For more information about instance class pricing, see Amazon RDS pricing.

Topics
- DB instance class types (p. 56)
- Supported DB engines for DB instance classes (p. 57)
- Determining DB instance class support in AWS Regions (p. 61)
- Hardware specifications for DB instance classes for Aurora (p. 64)

DB instance class types

Amazon Aurora supports three types of instance classes: Aurora Serverless v2, memory optimized, and burstable performance. For more information about Amazon EC2 instance types, see Instance types in the Amazon EC2 documentation.

The following is the Aurora Serverless v2 type available:

- **db.serverless** – A special DB instance class used by Aurora Serverless v2. Aurora adjusts the compute, memory, and network resources dynamically as the workload changes. For usage details, see Using Aurora Serverless v2 (p. 1481).

The following are the memory optimized DB instance classes available:

- **db.x2g** – Instance classes optimized for memory-intensive applications and powered by AWS Graviton2 processors. These offer low cost per GiB of memory.
- **db.r6g** – Instance classes powered by AWS Graviton2 processors. These are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors by completing the same steps as any other DB instance modification.

- **db.r6i** – Instance classes that are ideal for running memory-intensive workloads.
- **db.r5** – Instance classes optimized for memory-intensive applications. These offer improved networking performance. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.r3** – Instance classes that provide memory optimization.

The following are the burstable-performance DB instance classes available:

- **db.t4g** – Burstable instance classes powered by Arm-based AWS Graviton2 processors. These deliver better price performance than previous burstable-performance DB instance classes for a broad set of burstable workloads. T4g instances are configured for Unlimited mode, which means that they can burst beyond the baseline over a 24-hour window for an additional charge. We recommend using these instance classes only for development and test servers, or other nonproduction servers.
• **db.t3** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. T3 instances are configured for Unlimited mode. These instance classes provide more computing capacity than the previous db.t2 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor. We recommend using these instance classes only for development and test servers, or other nonproduction servers.

• **db.t2** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. T2 instances can be configured for Unlimited mode. We recommend using these instance classes only for development and test servers, or other nonproduction servers.

For DB instance class hardware specifications, see [Hardware specifications for DB instance classes for Aurora (p. 64)](#).

**Supported DB engines for DB instance classes**

In the following table, you can find details about supported Amazon Aurora DB instance classes for the Aurora DB engines.

<table>

</tbody>
</table>
Determining DB instance class support in AWS Regions

To determine the DB instance classes supported by each DB engine in a specific AWS Region, you can use the AWS Management Console, the Amazon RDS Pricing page, or the describe-orderable-db-instance-options AWS CLI command.

**Note**
When you perform operations with the AWS CLI, such as creating or modifying a DB cluster, it automatically shows the supported DB instance classes for a specific DB engine, DB engine version, and AWS Region.

Contents
- Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions (p. 61)
- Using the AWS CLI to determine DB instance class support in AWS Regions (p. 62)
  - Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region (p. 62)
  - Listing the DB engine versions that support a specific DB instance class in an AWS Region (p. 63)

Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions

You can use the Amazon RDS Pricing page to determine the DB instance classes supported by each DB engine in a specific AWS Region.

To use the pricing page to determine the DB instance classes supported by each engine in a Region

1. Go to Amazon RDS Pricing.
2. Choose Amazon Aurora.

<table>
<thead>
<tr>
<th>Instance class</th>
<th>Aurora MySQL</th>
<th>Aurora PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.t3.medium</td>
<td>1.14.4 and higher, 3.01.0 and higher</td>
<td>14.3, 13.3, 10.11 and higher</td>
</tr>
<tr>
<td>db.t3.small</td>
<td>1.14.4 and higher; not supported in 3.01.0 and higher</td>
<td>No</td>
</tr>
<tr>
<td>db.t3.micro</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**db.t2 – burstable-performance instance classes**

<table>
<thead>
<tr>
<th>Instance class</th>
<th>Aurora MySQL</th>
<th>Aurora PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.t2.medium</td>
<td>All 1.x and 2.x versions; not supported in 3.01.0 and higher</td>
<td>No</td>
</tr>
<tr>
<td>db.t2.small</td>
<td>All 1.x and 2.x versions; not supported in 3.01.0 and higher</td>
<td>No</td>
</tr>
</tbody>
</table>
3. In **DB Instances**, open **MySQL-Compatible Edition** or **PostgreSQL-Compatible Edition**.

4. To see the DB instance classes available in an AWS Region, choose the AWS Region in **Region** in the appropriate subsection.

### Using the AWS CLI to determine DB instance class support in AWS Regions

You can use the AWS CLI to determine which DB instance classes are supported for specific DB engines and DB engine versions in an AWS Region.

To use the AWS CLI examples in this section, make sure that you enter valid values for the DB engine, DB engine version, DB instance class, and AWS Region. The following table shows the valid DB engine values.

<table>
<thead>
<tr>
<th>Engine name</th>
<th>Engine value in CLI commands</th>
<th>More information about versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.6-compatible Aurora</td>
<td>aurora</td>
<td>Database engine updates for Amazon Aurora MySQL version 1 in the <em>Release Notes for Aurora MySQL</em></td>
</tr>
<tr>
<td>MySQL 5.7-compatible and 8.0-compatible Aurora</td>
<td>aurora-mysql</td>
<td>Database engine updates for Amazon Aurora MySQL version 2 and Database engine updates for Amazon Aurora MySQL version 3 in the <em>Release Notes for Aurora MySQL</em></td>
</tr>
<tr>
<td>Aurora PostgreSQL</td>
<td>aurora-postgresql</td>
<td><em>Release Notes for Aurora PostgreSQL</em></td>
</tr>
</tbody>
</table>

For information about AWS Region names, see [AWS Regions (p. 11)](#).

The following examples demonstrate how to determine DB instance class support in an AWS Region using the `describe-orderable-db-instance-options` AWS CLI command.

#### Topics
- Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region (p. 62)
- Listing the DB engine versions that support a specific DB instance class in an AWS Region (p. 63)

### Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region

To list the DB instance classes that are supported by a specific DB engine version in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options --engine engine --engine-version version \ 
--query "OrderableDBInstanceOptions[0].DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0])" \ 
--output table \ 
--region region
```

For Windows:

```bash
aws rds describe-orderable-db-instance-options --engine engine --engine-version version ^
```
Determining DB instance class support in AWS Regions

The output also shows the engine modes that are supported for each DB instance class.

For example, the following command lists the supported DB instance classes for version 13.6 of the Aurora PostgreSQL DB engine in US East (N. Virginia).

For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --engine-version 13.6 --query "OrderableDBInstanceOptions[].{DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}" --output table --region region
```

For Windows:

```bash
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --engine-version 13.6 --query "OrderableDBInstanceOptions[].{DBInstanceClass:DBInstanceClass,SupportedEngineModes:SupportedEngineModes[0]}" --output table --region region
```

Listing the DB engine versions that support a specific DB instance class in an AWS Region

To list the DB engine versions that support a specific DB instance class in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class --query "OrderableDBInstanceOptions[].{EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}" --output table --region region
```

For Windows:

```bash
aws rds describe-orderable-db-instance-options --engine engine --db-instance-class DB_instance_class --query "OrderableDBInstanceOptions[].{EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}" --output table --region region
```

The output also shows the engine modes that are supported for each DB engine version.

For example, the following command lists the DB engine versions of the Aurora PostgreSQL DB engine that support the db.r5.large DB instance class in US East (N. Virginia).

For Linux, macOS, or Unix:

```bash
aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-instance-class db.r5.large --query "OrderableDBInstanceOptions[].{EngineVersion:EngineVersion,SupportedEngineModes:SupportedEngineModes[0]}" --output table --region region
```
Hardware specifications for DB instance classes for Aurora

The following terminology is used to describe hardware specifications for DB instance classes:

**vCPU**

The number of virtual central processing units (CPUs). A *virtual CPU* is a unit of capacity that you can use to compare DB instance classes. Instead of purchasing or leasing a particular processor to use for several months or years, you are renting capacity by the hour. Our goal is to make a consistent and specific amount of CPU capacity available, within the limits of the actual underlying hardware.

**ECU**

The relative measure of the integer processing power of an Amazon EC2 instance. To make it easy for developers to compare CPU capacity between different instance classes, we have defined an Amazon EC2 Compute Unit. The amount of CPU that is allocated to a particular instance is expressed in terms of these EC2 Compute Units. One ECU currently provides CPU capacity equivalent to a 1.0–1.2 GHz 2007 Opteron or 2007 Xeon processor.

**Memory (GiB)**

The RAM, in gibibytes, allocated to the DB instance. There is often a consistent ratio between memory and vCPU. As an example, take the db.r4 instance class, which has a memory to vCPU ratio similar to the db.r5 instance class. However, for most use cases the db.r5 instance class provides better, more consistent performance than the db.r4 instance class.

**Max. Bandwidth (Mbps)**

The maximum bandwidth in megabits per second. Divide by 8 to get the expected throughput in megabytes per second.

*Note*

This figure refers to I/O bandwidth for local storage within the DB instance. It doesn't apply to communication with the Aurora cluster volume.

**Network Performance**

The network speed relative to other DB instance classes.

In the following table, you can find hardware details about the Amazon RDS DB instance classes for Aurora.

For information about Aurora DB engine support for each DB instance class, see Supported DB engines for DB instance classes (p. 57).

** The r3.8xlarge instance doesn't have dedicated EBS bandwidth and therefore doesn't offer EBS optimization. On this instance, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

Amazon Aurora storage and reliability

Following, you can learn about the Aurora storage subsystem. Aurora uses a distributed and shared storage architecture that is an important factor in performance, scalability, and reliability for Aurora clusters.

Topics
- Overview of Aurora storage (p. 67)
- What the cluster volume contains (p. 67)
- How Aurora storage automatically resizes (p. 67)
- How Aurora data storage is billed (p. 68)
- Amazon Aurora reliability (p. 68)

Overview of Aurora storage

Aurora data is stored in the cluster volume, which is a single, virtual volume that uses solid state drives (SSDs). A cluster volume consists of copies of the data across three Availability Zones in a single AWS Region. Because the data is automatically replicated across Availability Zones, your data is highly durable with less possibility of data loss. This replication also ensures that your database is more available during a failover. It does so because the data copies already exist in the other Availability Zones and continue to serve data requests to the DB instances in your DB cluster. The amount of replication is independent of the number of DB instances in your cluster.

Aurora uses separate local storage for nonpersistent, temporary files. This includes files that are used for such purposes as sorting large data sets during query processing, and building indexes. For more information, see Temporary storage limits for Aurora MySQL (p. 724) and Temporary storage limits for Aurora PostgreSQL (p. 1147).

What the cluster volume contains

The Aurora cluster volume contains all your user data, schema objects, and internal metadata such as the system tables and the binary log. For example, Aurora stores all the tables, indexes, binary large objects (BLOBs), stored procedures, and so on for an Aurora cluster in the cluster volume.

The Aurora shared storage architecture makes your data independent from the DB instances in the cluster. For example, you can add a DB instance quickly because Aurora doesn't make a new copy of the table data. Instead, the DB instance connects to the shared volume that already contains all your data. You can remove a DB instance from a cluster without removing any of the underlying data from the cluster. Only when you delete the entire cluster does Aurora remove the data.

How Aurora storage automatically resizes

Aurora cluster volumes automatically grow as the amount of data in your database increases. The maximum size for an Aurora cluster volume is 128 tebibytes (TiB) or 64 TiB, depending on the DB engine version. For details about the maximum size for a specific version, see Amazon Aurora size limits (p. 1758). This automatic storage scaling is combined with a high-performance and highly distributed storage subsystem. These make Aurora a good choice for your important enterprise data when your main objectives are reliability and high availability.
To display the volume status, see Displaying volume status for an Aurora MySQL DB cluster (p. 747) or Displaying volume status for an Aurora PostgreSQL DB cluster (p. 1152). For ways to balance storage costs against other priorities, Storage scaling (p. 274) describes how to monitor the Amazon Aurora metrics AuroraVolumeBytesLeftTotal and VolumeBytesUsed in CloudWatch.

When Aurora data is removed, the space allocated for that data is freed. Examples of removing data include dropping or truncating a table. This automatic reduction in storage usage helps you to minimize storage charges.

Note
The storage limits and dynamic resizing behavior discussed here applies to persistent tables and other data stored in the cluster volume. Data for temporary tables is stored in the local DB instance and its maximum size depends on the instance class that you use.

Some storage features, such as the maximum size of a cluster volume and automatic resizing when data is deleted, depend on the Aurora version of your cluster. For more information, see Storage scaling (p. 274). You can also learn how to avoid storage issues and how to monitor the allocated storage and free space in your cluster.

How Aurora data storage is billed

Even though an Aurora cluster volume can grow up to 128 tebibytes (TiB), you are only charged for the space that you use in an Aurora cluster volume. In earlier Aurora versions, the cluster volume could reuse space that was freed up when you deleted data, but the allocated storage space would never decrease. Starting in Aurora MySQL 2.09.0 and 1.23.0, and Aurora PostgreSQL 3.3.0 and 2.6.0, when Aurora data is removed, such as by dropping a table or database, the overall allocated space decreases by a comparable amount. Thus, you can reduce storage charges by deleting tables, indexes, databases, and so on that you no longer need.

Tip
For earlier versions without the dynamic resizing feature, resetting the storage usage for a cluster involved doing a logical dump and restoring to a new cluster. That operation can take a long time for a substantial volume of data. If you encounter this situation, consider upgrading your cluster to a version that supports volume shrinking.

For pricing information about Aurora data storage, see Amazon RDS for Aurora Pricing.

For information about how to minimize storage charges by monitoring storage usage for your cluster, see Storage scaling (p. 274). For pricing information about Aurora data storage, see Amazon RDS for Aurora pricing.

Amazon Aurora reliability

Aurora is designed to be reliable, durable, and fault tolerant. You can architect your Aurora DB cluster to improve availability by doing things such as adding Aurora Replicas and placing them in different Availability Zones, and also Aurora includes several automatic features that make it a reliable database solution.

Topics
- Storage auto-repair (p. 68)
- Survivable page cache (p. 69)
- Crash recovery (p. 69)

Storage auto-repair

Because Aurora maintains multiple copies of your data in three Availability Zones, the chance of losing data as a result of a disk failure is greatly minimized. Aurora automatically detects failures in the disk
volumes that make up the cluster volume. When a segment of a disk volume fails, Aurora immediately repairs the segment. When Aurora repairs the disk segment, it uses the data in the other volumes that make up the cluster volume to ensure that the data in the repaired segment is current. As a result, Aurora avoids data loss and reduces the need to perform a point-in-time restore to recover from a disk failure.

**Survivable page cache**

In Aurora, each DB instance's page cache is managed in a separate process from the database, which allows the page cache to survive independently of the database. (The page cache is also called the InnoDB buffer pool on Aurora MySQL and the buffer cache on Aurora PostgreSQL.)

In the unlikely event of a database failure, the page cache remains in memory, which keeps current data pages “warm” in the page cache when the database restarts. This provides a performance gain by bypassing the need for the initial queries to execute read I/O operations to “warm up” the page cache.

For Aurora MySQL, page cache behavior when rebooting and failing over is the following:

- Versions earlier than 2.10 – When the writer DB instance reboots, the page cache on the writer instance survives, but reader DB instances lose their page caches.
- Version 2.10 and higher – You can reboot the writer instance without rebooting the reader instances.
  - If the reader instances don’t reboot when the writer instance reboots, they don’t lose their page caches.
  - If the reader instances reboot when the writer instance reboots, they do lose their page caches.
- When a reader instance reboots, the page caches on the writer and reader instances both survive.
- When the DB cluster fails over, the effect is similar to when a writer instance reboots. On the new writer instance (previously the reader instance) the page cache survives, but on the reader instance (previously the writer instance), the page cache doesn’t survive.

For Aurora PostgreSQL, you can use cluster cache management to preserve the page cache of a designated reader instance that becomes the writer instance after failover. For more information, see Fast recovery after failover with cluster cache management for Aurora PostgreSQL (p. 1209).

**Crash recovery**

Aurora is designed to recover from a crash almost instantaneously and continue to serve your application data without the binary log. Aurora performs crash recovery asynchronously on parallel threads, so that your database is open and available immediately after a crash.

For more information about crash recovery, see Fault tolerance for an Aurora DB cluster (p. 72).

The following are considerations for binary logging and crash recovery on Aurora MySQL:

- Enabling binary logging on Aurora directly affects the recovery time after a crash, because it forces the DB instance to perform binary log recovery.
- The type of binary logging used affects the size and efficiency of logging. For the same amount of database activity, some formats log more information than others in the binary logs. The following settings for the binlog_format parameter result in different amounts of log data:
  - **ROW** – The most log data
  - **STATEMENT** – The least log data
  - **MIXED** – A moderate amount of log data that usually provides the best combination of data integrity and performance

The amount of binary log data affects recovery time. If there is more data logged in the binary logs, the DB instance must process more data during recovery, which increases recovery time.
Aurora security

Security for Amazon Aurora is managed at three levels:

• To control who can perform Amazon RDS management actions on Aurora DB clusters and DB instances, you use AWS Identity and Access Management (IAM). When you connect to AWS using IAM credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon Aurora (p. 1653).

If you are using IAM to access the Amazon RDS console, you must first log on to the AWS Management Console with your IAM user credentials, and then go to the Amazon RDS console at https://console.aws.amazon.com/rds.

• Aurora DB clusters must be created in a virtual private cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora DB clusters in a VPC, you use a VPC security group. You can make these endpoint and port connections using Transport Layer Security (TLS)/Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see Amazon VPC VPCs and Amazon Aurora (p. 1728).

• To authenticate logins and permissions for an Amazon Aurora DB cluster, you can take either of the following approaches, or a combination of them.

  • You can take the same approach as with a stand-alone DB instance of MySQL or PostgreSQL. Techniques for authenticating logins and permissions for stand-alone DB instances of MySQL or PostgreSQL, such as using SQL commands or modifying database schema tables, also work with Aurora. For more information, see Security with Amazon Aurora MySQL (p. 681) or Security with Amazon Aurora PostgreSQL (p. 1019).

  • You can use IAM database authentication.

    With IAM database authentication, you authenticate to your Aurora DB cluster by using an IAM user or IAM role and an authentication token. An authentication token is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see IAM database authentication (p. 1682).

  • You can use Kerberos authentication for Aurora PostgreSQL.

    You can use Kerberos to authenticate users when they connect to your Aurora PostgreSQL DB cluster. In this case, your DB cluster works with AWS Directory Service for Microsoft Active Directory to enable Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple DB
Using SSL with Aurora DB clusters

Amazon Aurora DB clusters support Secure Sockets Layer (SSL) connections from applications using the same process and public key as Amazon RDS DB instances. For more information, see Security with Amazon Aurora MySQL (p. 681), Security with Amazon Aurora PostgreSQL (p. 1019), or Using TLS/SSL with Aurora Serverless v1 (p. 1545).

High availability for Amazon Aurora

The Amazon Aurora architecture involves separation of storage and compute. Aurora includes some high availability features that apply to the data in your DB cluster. The data remains safe even if some or all of the DB instances in the cluster become unavailable. Other high availability features apply to the DB instances. These features help to make sure that one or more DB instances are ready to handle database requests from your application.

Topics

- High availability for Aurora data (p. 71)
- High availability for Aurora DB instances (p. 71)
- High availability across AWS Regions with Aurora global databases (p. 72)
- Fault tolerance for an Aurora DB cluster (p. 72)

High availability for Aurora data

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single AWS Region. Aurora stores these copies regardless of whether the instances in the DB cluster span multiple Availability Zones. For more information on Aurora, see Managing an Amazon Aurora DB cluster (p. 243).

When data is written to the primary DB instance, Aurora synchronously replicates the data across Availability Zones to six storage nodes associated with your cluster volume. Doing so provides data redundancy, eliminates I/O freezes, and minimizes latency spikes during system backups. Running a DB instance with high availability can enhance availability during planned system maintenance, and help protect your databases against failure and Availability Zone disruption. For more information on Availability Zones, see Regions and Availability Zones (p. 11).

High availability for Aurora DB instances

For a cluster using single-master replication, after you create the primary instance, you can create up to 15 read-only Aurora Replicas. The Aurora Replicas are also known as reader instances.

During day-to-day operations, you can offload some of the work for read-intensive applications by using the reader instances to process `SELECT` queries. When a problem affects the primary instance, one of these reader instances takes over as the primary instance. This mechanism is known as failover. Many Aurora features apply to the failover mechanism. For example, Aurora detects database problems and activates the failover mechanism automatically when necessary. Aurora also has features that reduce the time for failover to complete. Doing so minimizes the time that the database is unavailable for writing during a failover.
To use a connection string that stays the same even when a failover promotes a new primary instance, you connect to the cluster endpoint. The cluster endpoint always represents the current primary instance in the cluster. For more information about the cluster endpoint, see Amazon Aurora connection management (p. 35).

Tip
Within each AWS Region, Availability Zones (AZs) represent locations that are distinct from each other to provide isolation in case of outages. We recommend that you distribute the primary instance and reader instances in your DB cluster over multiple Availability Zones to improve the availability of your DB cluster. That way, an issue that affects an entire Availability Zone doesn’t cause an outage for your cluster.
You can set up a Multi-AZ cluster by making a simple choice when you create the cluster. The choice is simple whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also make an existing Aurora cluster into a Multi-AZ cluster by adding a new reader instance and specifying a different Availability Zone.

High availability across AWS Regions with Aurora global databases

For high availability across multiple AWS Regions, you can set up Aurora global databases. Each Aurora global database spans multiple AWS Regions, enabling low latency global reads and disaster recovery from outages across an AWS Region. Aurora automatically handles replicating all data and updates from the primary AWS Region to each of the secondary Regions. For more information, see Using Amazon Aurora global databases (p. 151).

Fault tolerance for an Aurora DB cluster

An Aurora DB cluster is fault tolerant by design. The cluster volume spans multiple Availability Zones (AZs) in a single AWS Region, and each Availability Zone contains a copy of the cluster volume data. This functionality means that your DB cluster can tolerate a failure of an Availability Zone without any loss of data and only a brief interruption of service.

If the primary instance in a DB cluster using single-master replication fails, Aurora automatically fails over to a new primary instance in one of two ways:

- By promoting an existing Aurora Replica to the new primary instance
- By creating a new primary instance

If the DB cluster has one or more Aurora Replicas, then an Aurora Replica is promoted to the primary instance during a failure event. A failure event results in a brief interruption, during which read and write operations fail with an exception. However, service is typically restored in less than 120 seconds, and often less than 60 seconds. To increase the availability of your DB cluster, we recommend that you create at least one or more Aurora Replicas in two or more different Availability Zones.

Tip
In Aurora MySQL 2.10 and higher, you can improve availability during a failover by having more than one reader DB instance in a cluster. In Aurora MySQL 2.10 and higher, Aurora restarts only the writer DB instance and the failover target during a failover. Other reader DB instances in the cluster remain available to continue processing queries through connections to the reader endpoint.

You can customize the order in which your Aurora Replicas are promoted to the primary instance after a failure by assigning each replica a priority. Priorities range from 0 for the first priority to 15 for the last priority. If the primary instance fails, Amazon RDS promotes the Aurora Replica with the better priority to the new primary instance. You can modify the priority of an Aurora Replica at any time. Modifying the priority doesn’t trigger a failover.
More than one Aurora Replica can share the same priority, resulting in promotion tiers. If two or more Aurora Replicas share the same priority, then Amazon RDS promotes the replica that is largest in size. If two or more Aurora Replicas share the same priority and size, then Amazon RDS promotes an arbitrary replica in the same promotion tier.

If the DB cluster doesn’t contain any Aurora Replicas, then the primary instance is recreated in the same AZ during a failure event. A failure event results in an interruption during which read and write operations fail with an exception. Service is restored when the new primary instance is created, which typically takes less than 10 minutes. Promoting an Aurora Replica to the primary instance is much faster than creating a new primary instance.

Suppose that the primary instance in your cluster is unavailable because of an outage that affects an entire AZ. In this case, the way to bring a new primary instance online depends on whether your cluster uses a Multi-AZ configuration:

- If your provisioned or Aurora Serverless v2 cluster contains any reader instances in other AZs, Aurora uses the failover mechanism to promote one of those reader instances to be the new primary instance.
- If your provisioned or Aurora Serverless v2 cluster only contains a single DB instance, or if the primary instance and all reader instances are in the same AZ, make sure to manually create one or more new DB instances in another AZ.
- If your cluster uses Aurora Serverless v1, Aurora automatically creates a new DB instance in another AZ. However, this process involves a host replacement and thus takes longer than a failover.

Note
Amazon Aurora also supports replication with an external MySQL database, or an RDS MySQL DB instance. For more information, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 842).

Replication with Amazon Aurora

There are several replication options with Aurora. Each Aurora DB cluster has built-in replication between multiple DB instances in the same cluster. You can also set up replication with your Aurora cluster as the source or the target. When you replicate data into or out of an Aurora cluster, you can choose between built-in features such as Aurora global databases or the traditional replication mechanisms for the MySQL or PostgreSQL DB engines. You can choose the appropriate options based on which one provides the right combination of high availability, convenience, and performance for your needs. The following sections explain how and when to choose each technique.

Topics
- Aurora Replicas (p. 73)
- Replication with Aurora MySQL (p. 74)
- Replication with Aurora PostgreSQL (p. 75)

Aurora Replicas

When you create a second, third, and so on DB instance in an Aurora provisioned DB cluster, Aurora automatically sets up replication from the writer DB instance to all the other DB instances. These other DB instances are read-only and are known as Aurora Replicas. We also refer to them as reader instances when discussing the ways that you can combine writer and reader DB instances within a cluster.

Aurora Replicas have two main purposes. You can issue queries to them to scale the read operations for your application. You typically do so by connecting to the reader endpoint of the cluster. That way, Aurora can spread the load for read-only connections across as many Aurora Replicas as you have in
the cluster. Aurora Replicas also help to increase availability. If the writer instance in a cluster becomes unavailable, Aurora automatically promotes one of the reader instances to take its place as the new writer.

An Aurora DB cluster can contain up to 15 Aurora Replicas. The Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an AWS Region.

The data in your DB cluster has its own high availability and reliability features, independent of the DB instances in the cluster. If you aren't familiar with Aurora storage features, see Overview of Aurora storage (p. 67). The DB cluster volume is physically made up of multiple copies of the data for the DB cluster. The primary instance and the Aurora Replicas in the DB cluster all see the data in the cluster volume as a single logical volume.

As a result, all Aurora Replicas return the same data for query results with minimal replica lag. This lag is usually much less than 100 milliseconds after the primary instance has written an update. Replica lag varies depending on the rate of database change. That is, during periods where a large amount of write operations occur for the database, you might see an increase in replica lag.

Aurora Replicas work well for read scaling because they are fully dedicated to read operations on your cluster volume. Write operations are managed by the primary instance. Because the cluster volume is shared among all DB instances in your DB cluster, minimal additional work is required to replicate a copy of the data for each Aurora Replica.

To increase availability, you can use Aurora Replicas as failover targets. That is, if the primary instance fails, an Aurora Replica is promoted to the primary instance. There is a brief interruption during which read and write requests made to the primary instance fail with an exception. When this happens, some of the Aurora Replicas might be rebooted, depending on the DB engine version. For information about the rebooting behavior of different Aurora DB engine versions, see Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance (p. 329). Promoting an Aurora Replica this way is much faster than recreating the primary instance. If your Aurora DB cluster doesn't include any Aurora Replicas, then your DB cluster isn't available while your DB instance is recovering from the failure.

For high-availability scenarios, we recommend that you create one or more Aurora Replicas. These should be of the same DB instance class as the primary instance and in different Availability Zones for your Aurora DB cluster. For more information about Aurora Replicas as failover targets, see Fault tolerance for an Aurora DB cluster (p. 72).

You can't create an encrypted Aurora Replica for an unencrypted Aurora DB cluster. You can't create an unencrypted Aurora Replica for an encrypted Aurora DB cluster.

Tip
You can use Aurora Replicas within an Aurora cluster as your only form of replication to keep your data highly available. You can also combine the built-in Aurora replication with the other types of replication. Doing so can help to provide an extra level of high availability and geographic distribution of your data.

For details on how to create an Aurora Replica, see Adding Aurora Replicas to a DB cluster (p. 270).

**Replication with Aurora MySQL**

In addition to Aurora Replicas, you have the following options for replication with Aurora MySQL:

- Aurora MySQL DB clusters in different AWS Regions.
  - You can replicate data across multiple Regions by using an Aurora global database. For details, see High availability across AWS Regions with Aurora global databases (p. 72)
  - You can create an Aurora read replica of an Aurora MySQL DB cluster in a different AWS Region, by using MySQL binary log (binlog) replication. Each cluster can have up to five read replicas created this way, each in a different Region.
• Two Aurora MySQL DB clusters in the same Region, by using MySQL binary log (binlog) replication.
• An RDS for MySQL DB instance as the source of data and an Aurora MySQL DB cluster, by creating an Aurora read replica of an RDS for MySQL DB instance. Typically, you use this approach for migration to Aurora MySQL, rather than for ongoing replication.

For more information about replication with Aurora MySQL, see Single-master replication with Amazon Aurora MySQL (p. 827).

Replication with Aurora PostgreSQL

In addition to Aurora Replicas, you have the following options for replication with Aurora PostgreSQL:
• An Aurora primary DB cluster in one Region and up to five read-only secondary DB clusters in different Regions by using an Aurora global database. Aurora PostgreSQL doesn't support cross-Region Aurora Replicas. However, you can use Aurora global database to scale your Aurora PostgreSQL DB cluster’s read capabilities to more than one AWS Region and to meet availability goals. For more information, see Using Amazon Aurora global databases (p. 151).
• Two Aurora PostgreSQL DB clusters in the same Region, by using PostgreSQL's logical replication feature.
• An RDS for PostgreSQL DB instance as the source of data and an Aurora PostgreSQL DB cluster, by creating an Aurora read replica of an RDS for PostgreSQL DB instance. Typically, you use this approach for migration to Aurora PostgreSQL, rather than for ongoing replication.

For more information about replication with Aurora PostgreSQL, see Replication with Amazon Aurora PostgreSQL (p. 1225).

DB instance billing for Aurora

Amazon RDS provisioned instances in an Amazon Aurora cluster are billed based on the following components:
• DB instance hours (per hour) – Based on the DB instance class of the DB instance (for example, db.t2.small or db.m4.large). Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is billed in one second increments, with a minimum of 10 minutes. For more information, see Aurora DB instance classes (p. 56).
• Storage (per GiB per month) – Storage capacity that you have provisioned to your DB instance. If you scale your provisioned storage capacity within the month, your bill is prorated. For more information, see Amazon Aurora storage and reliability (p. 67).
• I/O requests (per 1 million requests per month) – Total number of storage I/O requests that you have made in a billing cycle.
• Backup storage (per GiB per month) – Backup storage is the storage that is associated with automated database backups and any active database snapshots that you have taken. Increasing your backup retention period or taking additional database snapshots increases the backup storage consumed by your database. Per second billing doesn't apply to backup storage (metered in GB-month).

For more information, see Backing up and restoring an Amazon Aurora DB cluster (p. 368).
• Data transfer (per GB) – Data transfer in and out of your DB instance from or to the internet and other AWS Regions.

Amazon RDS provides the following purchasing options to enable you to optimize your costs based on your needs:
• **On-Demand Instances** – Pay by the hour for the DB instance hours that you use. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is now billed in one second increments, with a minimum of 10 minutes.

• **Reserved Instances** – Reserve a DB instance for a one-year or three-year term and get a significant discount compared to the on-demand DB instance pricing. With Reserved Instance usage, you can launch, delete, start, or stop multiple instances within an hour and get the Reserved Instance benefit for all of the instances.

• **Aurora Serverless v2** – Aurora Serverless v2 provides on-demand capacity where the billing unit is Aurora capacity unit (ACU) hours instead of DB instance hours. Aurora Serverless v2 capacity increases and decreases, within a range that you specify, depending on the load on your database. You can configure a cluster where all the capacity is Aurora Serverless v2, or a combination of Aurora Serverless v2 and on-demand or reserved provisioned instances. For information about how Aurora Serverless v2 ACUs work, see How Aurora Serverless v2 works (p. 1483).

For Aurora pricing information, see the [Aurora pricing page](https://aws.amazon.com/aurora/pricing/).

**Topics**

- On-Demand DB instances for Aurora (p. 77)
- Reserved DB instances for Aurora (p. 78)
On-Demand DB instances for Aurora

Amazon RDS on-demand DB instances are billed based on the class of the DB instance (for example, db.t2.small or db.m4.large). For Amazon RDS pricing information, see the Amazon RDS product page.

Billing starts for a DB instance as soon as the DB instance is available. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. Amazon RDS usage is billed in one-second increments, with a minimum of 10 minutes. In the case of billable configuration change, such as scaling compute or storage capacity, you're charged a 10-minute minimum. Billing continues until the DB instance terminates, which occurs when you delete the DB instance or if the DB instance fails.

If you no longer want to be charged for your DB instance, you must stop or delete it to avoid being billed for additional DB instance hours. For more information about the DB instance states for which you are billed, see Viewing DB instance status in an Aurora cluster (p. 441).

Stopped DB instances

While your DB instance is stopped, you're charged for provisioned storage, including Provisioned IOPS. You are also charged for backup storage, including storage for manual snapshots and automated backups within your specified retention window. You aren't charged for DB instance hours.

Multi-AZ DB instances

If you specify that your DB instance should be a Multi-AZ deployment, you're billed according to the Multi-AZ pricing posted on the Amazon RDS pricing page.
Reserved DB instances for Aurora

Using reserved DB instances, you can reserve a DB instance for a one- or three-year term. Reserved DB instances provide you with a significant discount compared to on-demand DB instance pricing. Reserved DB instances are not physical instances, but rather a billing discount applied to the use of certain on-demand DB instances in your account. Discounts for reserved DB instances are tied to instance type and AWS Region.

The general process for working with reserved DB instances is: First get information about available reserved DB instance offerings, then purchase a reserved DB instance offering, and finally get information about your existing reserved DB instances.

Overview of reserved DB instances

When you purchase a reserved DB instance in Amazon RDS, you purchase a commitment to getting a discounted rate, on a specific DB instance type, for the duration of the reserved DB instance. To use an Amazon RDS reserved DB instance, you create a new DB instance just like you do for an on-demand instance. The new DB instance that you create must match the specifications of the reserved DB instance. If the specifications of the new DB instance match an existing reserved DB instance for your account, you are billed at the discounted rate offered for the reserved DB instance. Otherwise, the DB instance is billed at an on-demand rate.

You can modify a reserved DB instance. If the modification is within the specifications of the reserved DB instance, part or all of the discount still applies to the modified DB instance. If the modification is outside the specifications, such as changing the instance class, the discount no longer applies. For more information, see Size-flexible reserved DB instances (p. 79).

For more information about reserved DB instances, including pricing, see Amazon RDS reserved instances.

Offering types

Reserved DB instances are available in three varieties—No Upfront, Partial Upfront, and All Upfront—that let you optimize your Amazon RDS costs based on your expected usage.

No Upfront

This option provides access to a reserved DB instance without requiring an upfront payment. Your No Upfront reserved DB instance bills a discounted hourly rate for every hour within the term, regardless of usage, and no upfront payment is required. This option is only available as a one-year reservation.

Partial Upfront

This option requires a part of the reserved DB instance to be paid upfront. The remaining hours in the term are billed at a discounted hourly rate, regardless of usage. This option is the replacement for the previous Heavy Utilization option.

All Upfront

Full payment is made at the start of the term, with no other costs incurred for the remainder of the term regardless of the number of hours used.

If you are using consolidated billing, all the accounts in the organization are treated as one account. This means that all accounts in the organization can receive the hourly cost benefit of reserved DB instances that are purchased by any other account. For more information about consolidated billing, see Amazon RDS reserved DB instances in the AWS Billing and Cost Management User Guide.
Size-flexible reserved DB instances

When you purchase a reserved DB instance, one thing that you specify is the instance class, for example db.r5.large. For more information about instance classes, see Aurora DB instance classes (p. 56).

If you have a DB instance, and you need to scale it to larger capacity, your reserved DB instance is automatically applied to your scaled DB instance. That is, your reserved DB instances are automatically applied across all DB instance class sizes. Size-flexible reserved DB instances are available for DB instances with the same AWS Region and database engine. Size-flexible reserved DB instances can only scale in their instance class type. For example, a reserved DB instance for a db.r5.large can apply to a db.r5.xlarge, but not to a db.r6g.large, because db.r5 and db.r6g are different instance class types.

Reserved DB instance benefits also apply for both Multi-AZ and Single-AZ configurations. Flexibility means that you can move freely between configurations within the same DB instance class type. For example, you can move from a Single-AZ deployment running on one large DB instance (four normalized units) to a Multi-AZ deployment running on two small DB instances (2*2 = 4 normalized units).

Size-flexible reserved DB instances are available for the following Aurora database engines:

- Aurora MySQL
- Aurora PostgreSQL

You can compare usage for different reserved DB instance sizes by using normalized units. For example, one unit of usage on two db.r3.large DB instances is equivalent to eight normalized units of usage on one db.r3.small. The following table shows the number of normalized units for each DB instance size.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Single-AZ normalized units</th>
<th>Multi-AZ normalized units</th>
</tr>
</thead>
<tbody>
<tr>
<td>micro</td>
<td>0.5</td>
<td>1</td>
</tr>
<tr>
<td>small</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>medium</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>large</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>xlarge</td>
<td>8</td>
<td>16</td>
</tr>
<tr>
<td>2xlarge</td>
<td>16</td>
<td>32</td>
</tr>
<tr>
<td>4xlarge</td>
<td>32</td>
<td>64</td>
</tr>
<tr>
<td>8xlarge</td>
<td>64</td>
<td>128</td>
</tr>
<tr>
<td>10xlarge</td>
<td>80</td>
<td>160</td>
</tr>
<tr>
<td>12xlarge</td>
<td>96</td>
<td>192</td>
</tr>
<tr>
<td>16xlarge</td>
<td>128</td>
<td>256</td>
</tr>
<tr>
<td>24xlarge</td>
<td>192</td>
<td>384</td>
</tr>
</tbody>
</table>

For example, suppose that you purchase a db.t2.medium reserved DB instance, and you have two running db.t2.small DB instances in your account in the same AWS Region. In this case, the billing benefit is applied in full to both instances.
Alternatively, if you have one `db.t2.large` instance running in your account in the same AWS Region, the billing benefit is applied to 50 percent of the usage of the DB instance.

**Reserved DB instance billing example**

The price for a reserved DB instance doesn't include regular costs associated with storage, backups, and I/O. The following example illustrates the total cost per month for a reserved DB instance:

- An Aurora MySQL reserved Single-AZ `db.r4.large` DB instance class in US East (N. Virginia) at a cost of $0.19 per hour, or $138.70 per month
- Aurora storage at a cost of $0.10 per GiB per month (assume $45.60 per month for this example)
- Aurora I/O at a cost of $0.20 per 1 million requests (assume $20 per month for this example)
- Aurora backup storage at $0.021 per GiB per month (assume $30 per month for this example)

Add all of these options ($138.70 + $45.60 + $20 + $30) with the reserved DB instance, and the total cost per month is $234.30.

If you chose to use an on-demand DB instance instead of a reserved DB instance, an Aurora MySQL Single-AZ `db.r4.large` DB instance class in US East (N. Virginia) costs $0.29 per hour, or $217.50 per month. So, for an on-demand DB instance, add all of these options ($217.50 + $45.60 + $20 + $30), and the total cost per month is $313.10. You save nearly $79 per month by using the reserved DB instance.
Deleting a reserved DB instance

The terms for a reserved DB instance involve a one-year or three-year commitment. You can't cancel a reserved DB instance. However, you can delete a DB instance that is covered by a reserved DB instance discount. The process for deleting a DB instance that is covered by a reserved DB instance discount is the same as for any other DB instance.

You're billed for the upfront costs regardless of whether you use the resources.

If you delete a DB instance that is covered by a reserved DB instance discount, you can launch another DB instance with compatible specifications. In this case, you continue to get the discounted rate during the reservation term (one or three years).

Working with reserved DB instances

You can use the AWS Management Console, the AWS CLI, and the RDS API to work with reserved DB instances.

Console

You can use the AWS Management Console to work with reserved DB instances as shown in the following procedures.

To get pricing and information about available reserved DB instance offerings

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Reserved instances**.
3. Choose **Purchase Reserved DB Instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Multi-AZ deployment**, choose whether you want a Multi-AZ deployment.
   
   **Note**
   
   Reserved Amazon Aurora instances always have the **Multi-AZ deployment** option set to no. When you create an Amazon Aurora DB cluster from your reserved DB instance, the DB cluster is automatically created as Multi-AZ. You must purchase a reserved DB instance for each DB instance you plan to use, including Aurora Replicas.
7. For **Term**, choose the length of time you want the DB instance reserved.
8. For **Offering type**, choose the offering type.
   
   After you select the offering type, you can see the pricing information.

   **Important**
   
   Choose **Cancel** to avoid purchasing the reserved DB instance and incurring any charges.

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering as shown in the following procedure.

To purchase a reserved DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Reserved instances**.

3. Choose **Purchase Reserved DB Instance**.

4. For **Product description**, choose the DB engine and licensing type.

5. For **DB instance class**, choose the DB instance class.

6. For **Multi-AZ deployment**, choose whether you want a Multi-AZ deployment.

   **Note**
   
   Reserved Amazon Aurora instances always have the **Multi-AZ deployment** option set to **No**. When you create an Amazon Aurora DB cluster from your reserved DB instance, the DB cluster is automatically created as Multi-AZ. You must purchase a reserved DB instance for each DB instance you plan to use, including Aurora Replicas.

7. For **Term**, choose the length of time you want the DB instance reserved.

8. For **Offering type**, choose the offering type.

After you choose the offering type, you can see the pricing information.
9. (Optional) You can assign your own identifier to the reserved DB instances that you purchase to help you track them. For **Reserved Id**, type an identifier for your reserved DB instance.

10. Choose **Continue**.

   The **Purchase Reserved DB Instances** dialog box appears, with a summary of the reserved DB instance attributes that you've selected and the payment due.

   ![Purchase Reserved DB Instances Dialog Box](image.png)

11. On the confirmation page, review your reserved DB instance. If the information is correct, choose **Order** to purchase the reserved DB instance.

   Alternatively, choose **Back** to edit your reserved DB instance.

After you have purchased reserved DB instances, you can get information about your reserved DB instances as shown in the following procedure.

**To get information about reserved DB instances for your AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

2. In the **Navigation** pane, choose **Reserved instances**.
The reserved DB instances for your account appear. To see detailed information about a particular reserved DB instance, choose that instance in the list. You can then see detailed information about that instance in the detail pane at the bottom of the console.

AWS CLI

You can use the AWS CLI to work with reserved DB instances as shown in the following examples.

Example of getting available reserved DB instance offerings

To get information about available reserved DB instance offerings, call the AWS CLI command `describe-reserved-db-instances-offerings`.

```
aws rds describe-reserved-db-instances-offerings
```

This call returns output similar to the following:

<table>
<thead>
<tr>
<th>OFFERING</th>
<th>OfferingId</th>
<th>Class</th>
<th>Multi-AZ</th>
<th>Duration</th>
<th>Fixed Price</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>438012d3-4052-4cc7-b2e3-8d3372e0e706</td>
<td>db.r3.large</td>
<td>y</td>
<td>1y</td>
<td>1820.00 USD</td>
</tr>
<tr>
<td></td>
<td>649fd0c8-cf6d-47a0-bfa6-060f8e75e95f</td>
<td>db.r3.small</td>
<td>n</td>
<td>1y</td>
<td>227.50 USD</td>
</tr>
<tr>
<td></td>
<td>123456cd-ab1c-47a0-bfa6-12345667232f</td>
<td>db.r3.small</td>
<td>n</td>
<td>1y</td>
<td>162.00 USD</td>
</tr>
<tr>
<td></td>
<td>123456cd-ab1c-47a0-bfa6-12345667232d</td>
<td>db.r3.large</td>
<td>y</td>
<td>1y</td>
<td>700.00 USD</td>
</tr>
<tr>
<td></td>
<td>123456cd-ab1c-17d0-bfa6-12345667234e</td>
<td>db.r3.xlarge</td>
<td>n</td>
<td>1y</td>
<td>4242.00 USD</td>
</tr>
</tbody>
</table>

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering.

To purchase a reserved DB instance, use the AWS CLI command `purchase-reserved-db-instances-offering` with the following parameters:

- `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase. See the preceding example to get the offering ID.
- `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.

Example of purchasing a reserved DB instance

The following example purchases the reserved DB instance offering with ID `649fd0c8-cf6d-47a0-bfa6-060f8e75e95f`, and assigns the identifier of `MyReservation`.

For Linux, macOS, or Unix:

```
aws rds purchase-reserved-db-instances-offering
  --reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f
  --reserved-db-instance-id MyReservation
```
For Windows:

```
aws rds purchase-reserved-db-instances-offering ^
--reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f ^
--reserved-db-instance-id MyReservation
```

The command returns output similar to the following:

```
RESERVATION  ReservationId      Class        Multi-AZ  Start Time                Duration
Fixed Price  Usage Price  Count  State            Description  Offering Type
RESERVATION  MyReservation      db.r3.small  y         2011-12-19T00:30:23.247Z  1y
455.00 USD   0.092 USD    1      payment-pending  mysql        Partial  Upfront
```

After you have purchased reserved DB instances, you can get information about your reserved DB instances.

To get information about reserved DB instances for your AWS account, call the AWS CLI command `describe-reserved-db-instances`, as shown in the following example.

**Example of getting your reserved DB instances**

```
aws rds describe-reserved-db-instances
```

The command returns output similar to the following:

```
RESERVATION  ReservationId     Class        Multi-AZ  Start Time                Duration
Fixed Price  Usage Price  Count  State    Description  Offering Type
RESERVATION  MyReservation     db.r3.small  y         2011-12-09T23:37:44.720Z  1y
455.00 USD   0.092 USD    1      retired  mysql        Partial  Upfront
```

**RDS API**

You can use the RDS API to work with reserved DB instances:

- To get information about available reserved DB instance offerings, call the Amazon RDS API operation `DescribeReservedDB InstancesOfferings`.
- After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering. Call the `PurchaseReservedDBInstancesOffering` RDS API operation with the following parameters:
  - `--reserved-db-instances-offering-id` – The ID of the offering that you want to purchase.
  - `--reserved-db-instance-id` – You can assign your own identifier to the reserved DB instances that you purchase to help track them.
- After you have purchased reserved DB instances, you can get information about your reserved DB instances. Call the `DescribeReservedDBInstances` RDS API operation.

**Viewing the billing for your reserved DB instances**

You can view the billing for your reserved DB instances in the Billing Dashboard in the AWS Management Console.

**To view reserved DB instance billing**

1. Sign in to the AWS Management Console.
2. From the account menu at the upper right, choose Billing Dashboard.
3. Choose **Bill Details** at the upper right of the dashboard.
4. Under **AWS Service Charges**, expand **Relational Database Service**.
5. Expand the AWS Region where your reserved DB instances are, for example **US West (Oregon)**.

Your reserved DB instances and their hourly charges for the current month are shown under **Amazon Relational Database Service for Database Engine Reserved Instances**.

The reserved DB instance in this example was purchased All Upfront, so there are no hourly charges.
6. Choose the **Cost Explorer** (bar graph) icon next to the **Reserved Instances** heading.

The Cost Explorer displays the **Monthly EC2 running hours costs and usage** graph.
7. Clear the **Usage Type Group** filter to the right of the graph.
8. Choose the time period and time unit for which you want to examine usage costs.

The following example shows usage costs for on-demand and reserved DB instances for the year to date by month.

The reserved DB instance costs from January through June 2021 are monthly charges for a Partial Upfront instance, while the cost in August 2021 is a one-time charge for an All Upfront instance.

The reserved instance discount for the Partial Upfront instance expired in June 2021, but the DB instance wasn't deleted. After the expiration date, it was simply charged at the on-demand rate.
Setting up your environment for Amazon Aurora

Before you use Amazon Aurora for the first time, complete the following tasks.

Topics

• Get an AWS account and your root user credentials (p. 87)
• Create an IAM user (p. 87)
• Sign in as an IAM user (p. 88)
• Create IAM user access keys (p. 89)
• Determine requirements (p. 89)
• Provide access to the DB cluster in the VPC by creating a security group (p. 90)

If you already have an AWS account, know your Aurora requirements, and prefer to use the defaults for IAM and VPC security groups, skip ahead to Getting started with Amazon Aurora (p. 93).

Get an AWS account and your root user credentials

To access AWS, you must sign up for an AWS account.

To sign up for an AWS account

2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing My Account.

Create an IAM user

If your account already includes an IAM user with full AWS administrative permissions, you can skip this section.

When you first create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account.

Important
We strongly recommend that you do not use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the AWS General Reference.
To create an administrator user for yourself and add the user to an administrators group (console)

1. Sign in to the IAM console as the account owner by choosing Root user and entering your AWS account email address. On the next page, enter your password.
   
   **Note**
   
   We strongly recommend that you adhere to the best practice of using the Administrator IAM user that follows and securely lock away the root user credentials. Sign in as the root user only to perform a few account and service management tasks.

2. In the navigation pane, choose Users and then choose Add users.

3. For User name, enter Administrator.

4. Select the check box next to AWS Management Console access. Then select Custom password, and then enter your new password in the text box.

5. (Optional) By default, AWS requires the new user to create a new password when first signing in. You can clear the check box next to User must create a new password at next sign-in to allow the new user to reset their password after they sign in.

6. Choose Next: Permissions.

7. Under Set permissions, choose Add user to group.

8. Choose Create group.

9. In the Create group dialog box, for Group name enter Administrators.

10. Choose Filter policies, and then select AWS managed - job function to filter the table contents.

11. In the policy list, select the check box for AdministratorAccess. Then choose Create group.
   
   **Note**
   
   You must activate IAM user and role access to Billing before you can use the AdministratorAccess permissions to access the AWS Billing and Cost Management console. To do this, follow the instructions in step 1 of the tutorial about delegating access to the billing console.

12. Back in the list of groups, select the check box for your new group. Choose Refresh if necessary to see the group in the list.

13. Choose Next: Tags.

14. (Optional) Add metadata to the user by attaching tags as key-value pairs. For more information about using tags in IAM, see Tagging IAM entities in the IAM User Guide.

15. Choose Next: Review to see the list of group memberships to be added to the new user. When you are ready to proceed, choose Create user.

You can use this same process to create more groups and users and to give your users access to your AWS account resources. To learn about using policies that restrict user permissions to specific AWS resources, see Access management and Example policies.

### Sign in as an IAM user

Sign in to the IAM console by choosing IAM user and entering your AWS account ID or account alias. On the next page, enter your IAM user name and your password.

**Note**

For your convenience, the AWS sign-in page uses a browser cookie to remember your IAM user name and account information. If you previously signed in as a different user, choose the sign-in link beneath the button to return to the main sign-in page. From there, you can enter your AWS account ID or account alias to be redirected to the IAM user sign-in page for your account.
Create IAM user access keys

Access keys consist of an access key ID and secret access key, which are used to sign programmatic requests that you make to AWS. If you don't have access keys, you can create them from the AWS Management Console. As a best practice, do not use the AWS account root user access keys for any task where it's not required. Instead, create a new administrator IAM user with access keys for yourself.

The only time that you can view or download the secret access key is when you create the keys. You cannot recover them later. However, you can create new access keys at any time. You must also have permissions to perform the required IAM actions. For more information, see Permissions required to access IAM resources in the IAM User Guide.

To create access keys for an IAM user

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Users.
3. Choose the name of the user whose access keys you want to create, and then choose the Security credentials tab.
4. In the Access keys section, choose Create access key.
5. To view the new access key pair, choose Show. You will not have access to the secret access key again after this dialog box closes. Your credentials will look something like this:
   - Access key ID: AKIAIOSFODNN7EXAMPLE
   - Secret access key: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
6. To download the key pair, choose Download .csv file. Store the keys in a secure location. You will not have access to the secret access key again after this dialog box closes.
   Keep the keys confidential in order to protect your AWS account and never email them. Do not share them outside your organization, even if an inquiry appears to come from AWS or Amazon.com. No one who legitimately represents Amazon will ever ask you for your secret key.
7. After you download the .csv file, choose Close. When you create an access key, the key pair is active by default, and you can use the pair right away.

Determine requirements

The basic building block of Aurora is the DB cluster. One or more DB instances can belong to a DB cluster. A DB cluster provides a network address called the cluster endpoint. Your applications connect to the cluster endpoint exposed by the DB cluster whenever they need to access the databases created in that DB cluster. The information you specify when you create the DB cluster controls configuration elements such as memory, database engine and version, network configuration, security, and maintenance periods.

Before you create a DB cluster and a security group, you must know your DB cluster and network needs. Here are some important things to consider:

- Resource requirements – What are the memory and processor requirements for your application or service? You will use these settings when you determine what DB instance class you will use when
you create your DB cluster. For specifications about DB instance classes, see Aurora DB instance classes (p. 56).

- **VPC, subnet, and security group** – Your DB cluster will be in a virtual private cloud (VPC). Security group rules must be configured to connect to a DB cluster. The following list describes the rules for each VPC option:
  - **Default VPC** — If your AWS account has a default VPC in the AWS Region, that VPC is configured to support DB clusters. If you specify the default VPC when you create the DB cluster:
    - Make sure to create a VPC security group that authorizes connections from the application or service to the Aurora DB cluster. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 3: Create a VPC security group (p. 1738).
    - You must specify the default DB subnet group. If this is the first DB cluster you have created in the AWS Region, Amazon RDS will create the default DB subnet group when it creates the DB cluster.
  - **User-defined VPC** — If you want to specify a user-defined VPC when you create a DB cluster:
    - Make sure to create a VPC security group that authorizes connections from the application or service to the Aurora DB cluster. Use the **Security Group** option on the VPC console or the AWS CLI to create VPC security groups. For information, see Step 3: Create a VPC security group (p. 1738).
    - The VPC must meet certain requirements in order to host DB clusters, such as having at least two subnets, each in a separate availability zone. For information, see Amazon VPC VPCs and Amazon Aurora (p. 1728).
    - You must specify a DB subnet group that defines which subnets in that VPC can be used by the DB cluster. For information, see the DB Subnet Group section in Working with a DB cluster in a VPC (p. 1728).
  - **High availability**: Do you need failover support? On Aurora, a Multi-AZ deployment creates a primary instance and Aurora Replicas. You can configure the primary instance and Aurora Replicas to be in different Availability Zones for failover support. We recommend Multi-AZ deployments for production workloads to maintain high availability. For development and test purposes, you can use a non-Multi-AZ deployment. For more information, see High availability for Amazon Aurora (p. 71).
  - **IAM policies**: Does your AWS account have policies that grant the permissions needed to perform Amazon RDS operations? If you are connecting to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management for Amazon Aurora (p. 1653).
  - **Open ports**: What TCP/IP port will your database be listening on? The firewall at some companies might block connections to the default port for your database engine. If your company firewall blocks the default port, choose another port for the new DB cluster. Note that once you create a DB cluster that listens on a port you specify, you can change the port by modifying the DB cluster.
  - **AWS Region**: What AWS Region do you want your database in? Having the database close in proximity to the application or web service could reduce network latency. For more information, see Regions and Availability Zones (p. 11).

Once you have the information you need to create the security group and the DB cluster, continue to the next step.

### Provide access to the DB cluster in the VPC by creating a security group

Your DB cluster will be created in a VPC. Security groups provide access to the DB cluster in the VPC. They act as a firewall for the associated DB cluster, controlling both inbound and outbound traffic at the cluster level. DB clusters are created by default with a firewall and a default security group that prevents
access to the DB cluster. You must therefore add rules to a security group that enable you to connect to
your DB cluster. Use the network and configuration information you determined in the previous step to
create rules to allow access to your DB cluster.

For example, if you have an application that will access a database on your DB cluster in a VPC, you must
add a custom TCP rule that specifies the port range and IP addresses that application will use to access
the database. If you have an application on an Amazon EC2 instance, you can use the VPC security group
you set up for the Amazon EC2 instance.

You can configure connectivity between an Amazon EC2 instance a DB cluster when you create
the DB cluster. For more information, see Configure automatic network connectivity with an EC2
instance (p. 127).

**Tip**

You can set up network connectivity between an Amazon EC2 instance and a DB cluster
automatically when you create the DB cluster. For more information, see Configure automatic
network connectivity with an EC2 instance (p. 127).

For more information about creating a VPC for use with Aurora, see Tutorial: Create a VPC for use with
a DB cluster (IPv4 only) (p. 1743). For information about common scenarios for accessing a DB instance,
see Scenarios for accessing a DB cluster in a VPC (p. 1738).

**To create a VPC security group**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://
console.aws.amazon.com/vpc.

   **Note**
   Make sure you are in the VPC console, not the RDS console.

2. In the top right corner of the AWS Management Console, choose the AWS Region where you want
to create your VPC security group and DB cluster. In the list of Amazon VPC resources for that AWS
Region, you should see at least one VPC and several subnets. If you don’t, you don’t have a default
VPC in that AWS Region.

3. In the navigation pane, choose **Security Groups**.

4. Choose **Create security group**.

   The **Create security group** page appears.

5. In **Basic details**, enter the **Security group name** and **Description**. For **VPC**, choose the VPC that you
want to create your DB cluster in.

6. In **Inbound rules**, choose **Add rule**.

   a. For **Type**, choose **Custom TCP**.

   b. For **Port range**, enter the port value to use for your DB cluster.

   c. For **Source**, choose a security group name or type the IP address range (CIDR value) from where
you access the DB cluster. If you choose **My IP**, this allows access to the DB cluster from the IP
address detected in your browser.

7. If you need to add more IP addresses or different port ranges, choose **Add rule** and enter the
information for the rule.

8. (Optional) In **Outbound rules**, add rules for outbound traffic. By default, all outbound traffic is
allowed.

9. Choose **Create security group**.

You can use the VPC security group you just created as the security group for your DB cluster when you
create it.
Note
If you use a default VPC, a default subnet group spanning all of the VPC's subnets is created for you. When you create a DB cluster, you can select the default VPC and use default for DB Subnet Group.

Once you have completed the setup requirements, you can create a DB cluster using your requirements and security group by following the instructions in Creating an Amazon Aurora DB cluster (p. 127). For information about getting started by creating a DB cluster that uses a specific DB engine, see Getting started with Amazon Aurora (p. 93).
Creating a DB cluster and connecting to a database on an Aurora MySQL DB cluster

The easiest way to create an Aurora MySQL DB cluster is to use the AWS Management Console. After you create the DB cluster, you can use standard MySQL utilities, such as MySQL Workbench, to connect to a database on the DB cluster.

Important
Before you can create or connect to a DB cluster, you must complete the tasks in Setting up your environment for Amazon Aurora (p. 87).

Topics
• Create an Aurora MySQL DB cluster (p. 93)
• Connect to an instance in a DB cluster (p. 98)
• Delete the sample DB cluster, DB subnet group, and VPC (p. 100)

Create an Aurora MySQL DB cluster

Before you create a DB cluster, you must first have a virtual private cloud (VPC) based on the Amazon VPC service and an Amazon RDS DB subnet group. Your VPC must have at least one subnet in each of at least two Availability Zones. You can use the default VPC for your AWS account, or you can create your own VPC. The Amazon RDS console is designed to make it easy for you to create your own VPC for use with Amazon Aurora or use an existing VPC with your Aurora DB cluster.

In some cases, you might want to create a VPC and DB subnet group for use with your Aurora DB cluster yourself, rather than having Amazon RDS create them. If so, follow the instructions in Tutorial: Create
a VPC for use with a DB cluster (IPv4 only) (p. 1743). Otherwise, follow the instructions in this topic to create your DB cluster and have Amazon RDS create a VPC and DB subnet group for you.

You can use Easy create to create an Aurora MySQL-Compatible Edition DB cluster with the RDS console. With Easy create, you specify only the DB engine type, size, and DB cluster identifier. Easy create uses the default settings for the other configuration options. When you use Standard create instead of Easy create, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

In this tutorial, you use Easy create to create an Aurora MySQL-Compatible Edition DB cluster.

**Note**
For information about creating DB clusters with Standard create, see Creating an Amazon Aurora DB cluster (p. 127).

To create an Aurora MySQL DB cluster with Easy create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB cluster.
   Aurora is not available in all AWS Regions. For a list of AWS Regions where Aurora is available, see Region availability (p. 12).
3. In the navigation pane, choose Databases.
4. Choose Create database and make sure that Easy Create is chosen.

5. For Engine type, choose Amazon Aurora.
6. For Edition, choose Amazon Aurora with MySQL compatibility.
7. For DB instance size, choose Dev/Test.
8. For DB cluster identifier, enter a name for the DB cluster, or leave the default name.

The Create database page should look similar to the following image.
9. For Master username, enter a name for the user, or leave the default name (admin). This user name and its password give you control over the Aurora MySQL DB cluster.

To use an automatically generated password for the DB cluster, make sure that the Auto generate a password box is selected.
To choose your own password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.

- To change settings with **No** in that column, use **Standard create**.
• To change settings with Yes in that column, either use Standard create, or modify the DB cluster after it is created to change the settings.

The following are important considerations for changing the default settings:

• If you want the DB cluster to use a specific VPC, subnet group, and security group, use Standard create to specify these resources. You might have created these resources when you were setting up for Amazon RDS. For more information, see Setting up your environment for Amazon Aurora (p. 87).

• If you want to be able to access the DB cluster from a client outside of its VPC, use Standard create to set Public access to Yes.

If the DB cluster should be private, leave Public access set to No.

11. Choose Create database.

If you chose to use an automatically generated password, the View credential details button appears on the Databases page.

To view the user name and password for the DB cluster, choose View credential details.

To connect to the DB cluster as the master user, use the user name and password that appear.

Important
You can't view the master user password again. If you don't record it, you might have to change it.

If you need to change the master user password after the DB cluster is available, you can modify the DB cluster to do so. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 248).

12. For Databases, choose the name of the new Aurora MySQL DB cluster.

On the RDS console, the details for new DB cluster appear. The DB cluster and its DB instance have a status of Creating until the DB cluster is ready to use. When the state changes to Available for both, you can connect to the DB cluster. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB cluster is available.
Connect to an instance in a DB cluster

After Amazon RDS provisions your DB cluster and creates the primary instance, you can use any standard SQL client application to connect to a database on the DB cluster. In the following procedure, you connect to a database on the Aurora MySQL DB cluster using MySQL monitor commands.

To connect to a database on an Aurora MySQL DB cluster using the MySQL monitor

1. Install a SQL client that you can use to connect to the DB cluster.

You can connect to an Aurora MySQL DB cluster by using tools like the MySQL command line utility. For more information on using the MySQL client, see `mysql - the MySQL command-line client` in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the Download MySQL Workbench page.

For more information on using MySQL, see the MySQL documentation. For information about installing MySQL (including the MySQL client), see Installing and upgrading MySQL.

If your DB cluster is publicly accessible, you can install the SQL client outside of the VPC. If your DB cluster is private, you typically install the SQL client on a resource inside the VPC, such as an Amazon EC2 instance.

2. Make sure that your DB cluster is associated with a security group that provides access to it. For more information, see Setting up your environment for Amazon Aurora (p. 87).

If you didn't specify the appropriate security group when you created the DB cluster, you can modify the DB cluster to change its security group. For more information, see Modifying an Amazon Aurora DB cluster (p. 248).

If your DB cluster is publicly accessible, make sure its associated security group has inbound rules for the IP addresses that you want to access it. If your DB cluster is private, make sure its associated security group has inbound rules for the security group of each resource that you want to access it, such as the security group of an Amazon EC2 instance.

3. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

4. Choose Databases and then choose the DB cluster name to show its details. On the Connectivity & security tab, copy the value for the Endpoint name of the Writer instance endpoint. Also, note the port number for the endpoint.
5. Enter the following command at a command prompt on a client computer to connect to a database on an Aurora MySQL DB cluster using the MySQL monitor. Use the cluster endpoint to connect to the primary instance, and the master user name that you created previously. (You are prompted for a password.) If you supplied a port value other than 3306, use that for the \(-P\) parameter instead.

```prompt
PROMPT> mysql -h <cluster endpoint> -P 3306 -u <myusername> -p
```

You should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 350
Server version: 5.6.10-log MySQL Community Server (GPL)
Type 'help;' or '\'h' for help. Type '\c' to clear the buffer.
mysql>
```

For more information about connecting to the DB cluster, see Connecting to an Amazon Aurora MySQL DB cluster (p. 207). If you can't connect to your DB cluster, see Can't connect to Amazon RDS DB instance (p. 1760).
Delete the sample DB cluster, DB subnet group, and VPC

After you have connected to the sample DB cluster that you created, you can delete the DB cluster, DB subnet group, and VPC (if you created a VPC).

To delete a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases and then choose the DB instance associated with the DB cluster.
3. For Actions, choose Delete.
4. Choose Delete.

After all of the DB instances associated with a DB cluster are deleted, the DB cluster is deleted automatically.

To delete a DB subnet group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Subnet groups and then choose the DB subnet group.
3. Choose Delete.
4. Choose Delete.

To delete a VPC

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose Your VPCs and then choose the VPC that was created for this procedure.
3. For Actions, choose Delete VPC.
4. Choose Delete.

Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster

The easiest way to create an Aurora PostgreSQL DB cluster is to use the Amazon RDS console. After you create the DB cluster, you can use standard PostgreSQL utilities, such as pgAdmin, to connect to a database on the DB cluster.

Important
Before you can create or connect to a DB cluster, you must complete the tasks in Setting up your environment for Amazon Aurora (p. 87).

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources that you use. You can delete these resources after you complete the tutorial if they are no longer needed.
Create an Aurora PostgreSQL DB cluster

Before you create a DB cluster, make sure first to have a virtual private cloud (VPC) based on the Amazon VPC service and an Amazon RDS DB subnet group. Your VPC must have at least one subnet in each of at least two Availability Zones. You can use the default VPC for your AWS account, or you can create your own VPC. The Amazon RDS console is designed to make it easy for you to create your own VPC for use with Amazon Aurora or use an existing VPC with your Aurora DB cluster.

In some cases, you might want to create a VPC and DB subnet group for use with your Amazon Aurora DB cluster yourself, rather than having Amazon RDS create them. If so, follow the instructions in Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 1743). Otherwise, follow the instructions in this topic to create your DB cluster and have Amazon RDS create a VPC and DB subnet group for you.

You can use Easy create to create an Aurora PostgreSQL DB cluster with the AWS Management Console. With Easy create, you specify only the DB engine type, size, and DB cluster identifier. Easy create uses the default settings for the other configuration options. When you use Standard create instead of Easy create, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

In this example, you use Easy create to create an Aurora PostgreSQL DB cluster.

**Note**
For information about creating DB clusters with Standard create, see Creating an Amazon Aurora DB cluster (p. 127).

To create an Aurora PostgreSQL DB cluster with Easy create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB cluster.
   
   Aurora is not available in all AWS Regions. For a list of AWS Regions where Aurora is available, see Region availability (p. 12).
3. In the navigation pane, choose Databases.
4. Choose Create database and make sure that Easy Create is chosen.
   
   ![Create database](image)

5. For Engine type, choose Amazon Aurora.
7. For **DB instance size**, choose **Dev/Test**.
8. For **DB cluster identifier**, enter a name for the DB cluster, or leave the default name.
9. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.
10. To use an automatically generated master password for the DB cluster, make sure that the **Auto generate a password** box is selected.

To enter your master password, clear the **Auto generate a password** box, and then enter the same password in **Master password** and **Confirm password**.

11. (Optional) Open **View default settings for Easy create**.

You can examine the default settings used with **Easy create**. The **Editable after database is created** column shows which options you can change after database creation.
• To change settings with No in that column, use Standard create.
• To change settings with Yes in that column, either use Standard create, or modify the DB cluster after it is created to change the settings.

The following are important considerations for changing the default settings:

• If you want the DB cluster to use a specific VPC, subnet group, and security group, use Standard create to specify these resources. You might have created these resources when you were setting up for Amazon RDS. For more information, see Setting up your environment for Amazon Aurora (p. 87).

• If you want to be able to access the DB cluster from a client outside of its VPC, use Standard create to set Public access to Yes.

If the DB cluster should be private, leave Public access set to No.

12. Choose Create database.

If you chose to use an automatically generated password, the View credential details button appears on the Databases page.

To view the master user name and password for the DB cluster, choose View credential details.

To connect to the DB cluster as the master user, use the user name and password that appear.

**Important**
You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB cluster is available, you can modify the DB cluster to do so. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 248).

13. For Databases, choose the name of the new Aurora PostgreSQL DB cluster.

On the RDS console, the details for new DB cluster appear. The DB cluster and its DB instance have a status of Creating until the DB cluster is ready to use. When the state changes to Available for both, you can connect to the DB cluster. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB cluster is available.
Connect to an instance in an Aurora PostgreSQL DB cluster

After Amazon RDS provisions your DB cluster and creates the primary instance, you can use any standard SQL client application to connect to a database on the DB cluster.

To connect to a database on an Aurora PostgreSQL DB cluster

1. Make sure that your DB cluster is associated with a security group that provides access to it. For more information, see Setting up your environment for Amazon Aurora (p. 87).

   If you didn’t specify the appropriate security group when you created the DB cluster, you can modify the DB cluster to change its security group. For more information, see Modifying an Amazon Aurora DB cluster (p. 248).

   If your DB cluster is publicly accessible, make sure its associated security group has inbound rules for the IP addresses that you want to access it. If your DB cluster is private, make sure its associated security group has inbound rules for the security group of each resource that you want to access it, such as the security group of an Amazon EC2 instance.

2. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

3. Choose Databases and then choose the DB cluster name to show its details. On the Connectivity & security tab, copy the value for the Endpoint name of the Writer instance endpoint. Also, note the port number for the endpoint.

4. If your client computer has PostgreSQL installed, you can use a local instance of psql to connect to an Aurora PostgreSQL DB cluster. To connect to your Aurora PostgreSQL DB cluster using psql, provide host information and access credentials.
The following format is used to connect to an Aurora PostgreSQL DB cluster.

```bash
psql --host=DB_instance_endpoint --port=port --username=master_user_name --password --dbname=database_name
```

For example, the following command connects to a database called `mypgdb` on an Aurora PostgreSQL DB cluster called `mypostgresql` using fictitious credentials.

```bash
psql --host=database-1.123456789012.us-west-1.rds.amazonaws.com --port=5432 --username=awsuser --password --dbname=postgres
```

For more information about connecting to the DB cluster using the endpoint and port, see Connecting to an Amazon Aurora PostgreSQL DB cluster (p. 212). If you can't connect to your DB cluster, see Can't connect to Amazon RDS DB instance (p. 1760).

Delete the sample DB cluster, DB subnet group, and VPC

After you have connected to the sample DB cluster that you created, you can delete the DB cluster, DB subnet group, and VPC (if you created a VPC).

**To delete a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases** and then choose the DB instance associated with the DB cluster.
3. For **Actions**, choose **Delete**.
4. Choose **Delete**.

   After all of the DB instances associated with a DB cluster are deleted, the DB cluster is deleted automatically.

**To delete a DB subnet group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Subnet groups** and then choose the DB subnet group.
3. Choose **Delete**.
4. Choose **Delete**.

**To delete a VPC**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Your VPCs** and then choose the VPC that was created for this procedure.
3. For **Actions**, choose **Delete VPC**.
4. Choose **Delete**.
Tutorial: Create a web server and an Amazon Aurora DB cluster

This tutorial helps you install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is an Aurora MySQL DB cluster. Both the Amazon EC2 instance and the DB cluster run in a virtual private cloud (VPC) based on the Amazon VPC service.

**Important**
There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

**Note**
This tutorial works with Amazon Linux and might not work for other versions of Linux such as Ubuntu.

In the tutorial that follows, you specify the VPC, subnets, and security groups when you create the DB cluster. You also specify them when you create the EC2 instance to host your web server. The VPC, subnets, and security groups are required for the DB cluster and the web server to communicate. After the VPC is set up, this tutorial shows you how to create the DB cluster and install the web server. You connect your web server to your DB cluster in the VPC using the DB cluster writer endpoint.

1. Complete the tasks in Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 1743).
   
   Before you begin this tutorial, make sure that you have a VPC with both public and private subnets, and corresponding security groups. If you don't have these, complete the following tasks in the tutorial:
   
   a. Create a VPC with private and public subnets (p. 1744)
   b. Create a VPC security group for a public web server (p. 1744)
   c. Create a VPC security group for a private DB cluster (p. 1745)
   d. Create a DB subnet group (p. 1746)

2. Create an Amazon Aurora DB cluster (p. 108)

3. Create an EC2 instance and install a web server (p. 113)

The following diagram shows the configuration when the tutorial is complete.
Create an Amazon Aurora DB cluster

In this step, you create an Amazon Aurora MySQL DB cluster that maintains the data used by a web application.

**Important**
Before you begin this step, you must have a VPC with both public and private subnets, and corresponding security groups. If you don't have these, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 1743). Complete the steps in Create a VPC with private and public subnets (p. 1744), Create a VPC security group for a public web server (p. 1744), and Create a VPC security group for a private DB cluster (p. 1745).

**To create an Aurora MySQL DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create the DB cluster. This example uses the US West (Oregon) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, shown following, make sure that the **Standard create** option is chosen, and then choose **Amazon Aurora**. Keep the default values for **Version** and the other engine options.
6. In the **Templates** section, choose **Dev/Test**.

7. In the **Availability and durability** section, use the default values.

8. In the **Settings** section, set these values:

   - **DB cluster identifier** – `tutorial-db-cluster`
   - **Master username** – `tutorial_user`
   - **Auto generate a password** – Disable the option.
   - **Master password** – Choose a password.
   - **Confirm password** – Retype the password.
9. In the **Instance configuration** section, set these values:
   - **Burstable classes (includes t classes)**
   - **db.t3.micro**

10. In the **Connectivity** section, set these values:
• **Virtual private cloud (VPC)** – Choose n existing VPC with both public and private subnets, such as the tutorial-vpc (vpc-identifier) created in Create a VPC with private and public subnets (p. 1744).

  **Note**
  The VPC must have subnets in different Availability Zones.

• **Subnet group** – Choose a DB subnet group for the VPC, such as the tutorial-db-subnet-group created in Create a DB subnet group (p. 1746).

• **Public access** – Choose **No**.

• **VPC security group** – Select Choose existing.

• **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as the tutorial-db-securitygroup created in Create a VPC security group for a private DB cluster (p. 1745).

  Remove other security groups, such as the default security group, by choosing the X associated with each.

• **Availability Zone** – Choose **us-west-2a**.

  To avoid cross-AZ traffic, make sure the DB cluster and the EC2 instance are in the same Availability Zone.

• Open **Additional configuration**, and make sure **Database port** uses the default value **3306**.
11. Open the **Additional configuration** section, and enter `sample` for **Initial database name**. Keep the default settings for the other options.

12. To create your Aurora MySQL DB cluster, choose **Create database**.
Your new DB cluster appears in the Databases list with the status Creating.

13. Wait for the Status of your new DB cluster to show as Available. Then choose the DB cluster name to show its details.

14. In the Connectivity & security section, view the Endpoint and Port of the writer DB instance.

Note the endpoint and port for your writer DB instance. You use this information to connect your web server to your DB cluster.

15. Complete Create an EC2 instance and install a web server (p. 113).

Create an EC2 instance and install a web server

In this step, you create a web server to connect to the Amazon Aurora DB cluster that you created in Create an Amazon Aurora DB cluster (p. 108).

Launch an EC2 instance

First, you create an Amazon EC2 instance in the public subnet of your VPC.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose EC2 Dashboard, and then choose Launch instance, as shown following.
3. Make sure you have opted into the new launch experience.
4. Under Name and tags, for Name, enter tutorial-web-server.
5. Under Application and OS Images (Amazon Machine Image), choose Amazon Linux, and then choose the Amazon Linux 2 AMI. Keep the defaults for the other choices.
6. Under **Instance type**, choose **t2.micro**.

7. Under **Key pair (login)**, choose a **Key pair name** to use an existing key pair. To create a new key pair for the Amazon EC2 instance, choose **Create new key pair** and then use the **Create key pair** window to create it.

For more information about creating a new key pair, see Create a key pair in the Amazon EC2 User Guide for Linux Instances.

8. For **Network settings**, choose **Edit**.

9. Under **Network settings**, set these values and keep the other values as their defaults:

   - **VPC (required)** – Choose the VPC with both public and private subnets that you chose for the DB cluster, such as the vpc-identifier | tutorial-vpc created in Create a VPC with private and public subnets (p. 1744).

   - **Subnet** – Choose an existing public subnet, such as subnet-identifier tutorial-subnet-public1-us-west-2a created in Create a VPC security group for a public web server (p. 1744).

   - **Auto-assign public IP** – Choose Enable.

   - **Firewall (security groups)** – Choose Select an existing security group.

   - **Common security groups** – Choose choose an existing security group, such as the tutorial-securitygroup created in Create a VPC security group for a public web server (p. 1744). Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.
• **Advanced network configuration** – Leave the default values.

10. Leave the default values for the remaining sections.

11. Review a summary of your instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.

12. On the **Launch Status** page, shown following, note the identifier for your new EC2 instance, for example: `i-0288d65fd4470b6a9`. 

---

The network configuration settings are shown in the following image:
13. Choose **View all instances** to find your instance.
14. Wait until **Instance State** for your instance is **running** before continuing.

**Install an Apache web server with PHP and MariaDB**

Next, you connect to your EC2 instance and install the web server.

**To connect to your EC2 instance and install the Apache web server with PHP**

1. Connect to the EC2 instance that you created earlier by following the steps in [Connect to your Linux instance](#).
2. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

   **Note**
   The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

   ```bash
   sudo yum update -y
   ```

3. After the updates complete, install the PHP software using the `amazon-linux-extras install` command. This command installs multiple software packages and related dependencies at the same time.

   ```bash
   sudo amazon-linux-extras install php8.0 mariadb10.5
   ```

   If you receive an error stating `sudo: amazon-linux-extras: command not found`, then your instance was not launched with an Amazon Linux 2 AMI (perhaps you are using the Amazon Linux AMI instead). You can view your version of Amazon Linux using the following command.

   ```bash
   grep -r -A 100000000 CentOS-Base /etc/* | wc -l
   ```
Create a web server

```bash
cat /etc/system-release
```

For more information, see Updating instance software.

4. Install the Apache web server.

```bash
sudo yum install -y httpd
```

5. Start the web server with the command shown following.

```bash
sudo systemctl start httpd
```

You can test that your web server is properly installed and started. To do this, enter the public Domain Name System (DNS) name of your EC2 instance in the address bar of a web browser, for example: `http://ec2-42-8-168-21.us-west-1.compute.amazonaws.com`. If your web server is running, then you see the Apache test page.

If you don't see the Apache test page, check your inbound rules for the VPC security group that you created in Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 1743). Make sure that your inbound rules include a rule allowing HTTP (port 80) access for the IP address you use to connect to the web server.

**Note**
The Apache test page appears only when there is no content in the document root directory, `/var/www/html`. After you add content to the document root directory, your content appears at the public DNS address of your EC2 instance instead of the Apache test page.

6. Configure the web server to start with each system boot using the `systemctl` command.

```bash
sudo systemctl enable httpd
```

To allow `ec2-user` to manage files in the default root directory for your Apache web server, modify the ownership and permissions of the `/var/www` directory. There are many ways to accomplish this task. In this tutorial, you add `ec2-user` to the `apache` group, to give the `apache` group ownership of the `/var/www` directory and assign write permissions to the group.

**To set file permissions for the Apache web server**

1. Add the `ec2-user` user to the `apache` group.

```bash
sudo usermod -a -G apache ec2-user
```

2. Log out to refresh your permissions and include the new `apache` group.

```bash
exit
```

3. Log back in again and verify that the `apache` group exists with the `groups` command.

```bash
groups
```

Your output looks similar to the following:

```
ec2-user adm wheel apache systemd-journal
```
4. Change the group ownership of the /var/www directory and its contents to the apache group.

```
sudo chown -R ec2-user:apache /var/www
```

5. Change the directory permissions of /var/www and its subdirectories to add group write permissions and set the group ID on subdirectories created in the future.

```
sudo chmod 2775 /var/www
find /var/www -type d -exec sudo chmod 2775 {} \;
```

6. Recursively change the permissions for files in the /var/www directory and its subdirectories to add group write permissions.

```
find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

**Note**
A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of web pages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption. For more information, see Tutorial: Configure SSL/TLS with the Amazon Linux AMI in the Amazon EC2 User Guide.

## Connect your Apache web server to your DB cluster

Next, you add content to your Apache web server that connects to your Amazon Aurora DB cluster.

### To add content to the Apache web server that connects to your DB cluster

1. While still connected to your EC2 instance, change the directory to /var/www and create a new subdirectory named inc.

```
cd /var/www
mkdir inc
cd inc
```

2. Create a new file in the inc directory named dbinfo.inc, and then edit the file by calling nano (or the editor of your choice).

```
>dbinfo.inc
nano dbinfo.inc
```

3. Add the following contents to the dbinfo.inc file. Here, `db_instance_endpoint` is DB cluster writer endpoint, without the port, and `master_password` is the master password for your DB cluster.

   **Note**
   We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.

```
<?php
```
4. Save and close the `dbinfo.inc` file.
5. Change the directory to `/var/www/html`.

```bash
cd /var/www/html
```
6. Create a new file in the `html` directory named `SamplePage.php`, and then edit the file by calling `nano` (or the editor of your choice).

```bash
>SamplePage.php
nano SamplePage.php
```
7. Add the following contents to the `SamplePage.php` file:

```
<?php include '../inc/dbinfo.inc'; ?>
<html>
<body>
<h1>Sample page</h1>
<?php
/* Connect to MySQL and select the database. */
$connection = mysqli_connect(DB_SERVER, DB_USERNAME, DB_PASSWORD);
if (mysqli_connect_errno()) echo "Failed to connect to MySQL: " .
mysqli_connect_error();
$database = mysqli_select_db($connection, DB_DATABASE);
/* Ensure that the EMPLOYEES table exists. */
VerifyEmployeesTable($connection, DB_DATABASE);
/* If input fields are populated, add a row to the EMPLOYEES table. */
$employee_name = htmlentities($_POST['NAME']);
$employee_address = htmlentities($_POST['ADDRESS']);
if (strlen($employee_name) || strlen($employee_address)) {
    AddEmployee($connection, $employee_name, $employee_address);
}
?>
<!-- Input form -->
<form action="<?PHP echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
<table border="0">
<tr>
    <td>NAME</td>
    <td>ADDRESS</td>
</tr>
</form>
```

**Note**

We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.
Create a web server

```php
<?php

// Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
  <tr>
    <td>ID</td>
    <td>NAME</td>
    <td>ADDRESS</td>
  </tr>
  <?php
    $result = mysqli_query($connection, "SELECT * FROM EMPLOYEES");
    while($query_data = mysqli_fetch_row($result)) {
      echo "<tr>",
      echo "<td>\$query_data[0], "</td>",
      echo "<td>\$query_data[1], "</td>",
      echo "<td>\$query_data[2], "</td>";
      echo "</tr>";
    }
  ?>
</table>

<!-- Clean up. -->
<?php
  mysqli_free_result($result);
  mysqli_close($connection);
?>
</body>
</html>

/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
  $n = mysqli_real_escape_string($connection, $name);
  $a = mysqli_real_escape_string($connection, $address);
  $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";
  if(!mysqli_query($connection, $query)) echo("<p>Error adding employee data.</p>");
}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
  if(!TableExists("EMPLOYEES", $connection, $dbName)) {
    $query = "CREATE TABLE EMPLOYEES (ID int(11) UNSIGNED AUTO_INCREMENT PRIMARY KEY, NAME VARCHAR(45),
```
ADDRESS VARCHAR(90)
);

if(mysql_query($connection, $query)) echo("<p>Error creating table.</p>");
}

/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
    $t = mysql_real_escape_string($connection, $tableName);
    $d = mysql_real_escape_string($connection, $dbName);

    $checktable = mysql_query($connection,
        "SELECT TABLE_NAME FROM information_schema.TABLES WHERE TABLE_NAME = '{$t}' AND TABLE_SCHEMA = '{$d}'");

    if(mysql_num_rows($checktable) > 0) return true;
    return false;
}

8. Save and close the SamplePage.php file.

You can use SamplePage.php to add data to your DB cluster. The data that you add is then displayed on the page. To verify that the data was inserted into the table, you can install MySQL client on the Amazon EC2 instance, connect to the DB cluster, and query the table.

For information about connecting to a DB cluster, see Connecting to an Amazon Aurora DB cluster (p. 207).

To make sure that your DB cluster is as secure as possible, verify that sources outside of the VPC can’t connect to your DB cluster.

After you have finished testing your web server and your database, you should delete your DB cluster and your Amazon EC2 instance.

- To delete a DB cluster, follow the instructions in Deleting Aurora DB clusters and DB instances (p. 345). You don’t need to create a final snapshot.
- To terminate an Amazon EC2 instance, follow the instruction in Terminate your instance in the Amazon EC2 User Guide.
Amazon Aurora tutorials and sample code

The AWS documentation includes several tutorials that guide you through common Amazon Aurora use cases. Many of these tutorials show you how to use Amazon Aurora with other AWS services. In addition, you can access sample code in GitHub.

**Note**
You can find more tutorials at the AWS Database Blog. For information about training, see AWS Training and Certification.

**Topics**
- Tutorials in this guide (p. 123)
- Tutorials in other AWS guides (p. 123)
- Tutorials and sample code in GitHub (p. 124)

**Tutorials in this guide**

The following tutorials in this guide show you how to perform common tasks with Amazon Aurora:

- **Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 1743)**
  Learn how to include a DB cluster in an Amazon virtual private cloud (VPC) that shares data with a web server that is running on an Amazon EC2 instance in the same VPC.

- **Tutorial: Create a VPC for use with a DB cluster (dual-stack mode) (p. 1748)**
  Learn how to include a DB cluster in an Amazon virtual private cloud (VPC) that shares data with an Amazon EC2 instance in the same VPC. In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode.

- **Tutorial: Create a web server and an Amazon Aurora DB cluster (p. 107)**
  Learn how to install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is an Aurora MySQL DB cluster. Both the Amazon EC2 instance and the DB cluster run in an Amazon VPC.

- **Tutorial: Restore an Amazon Aurora DB cluster from a DB cluster snapshot (p. 419)**
  Learn how to restore a DB cluster from a DB cluster snapshot.

- **Tutorial: Use tags to specify which Aurora DB clusters to stop (p. 357)**
  Learn how to use tags to specify which Aurora DB clusters to stop.

- **Tutorial: Log DB instance state changes using Amazon EventBridge (p. 587)**
  Learn how to log a DB instance state change using Amazon EventBridge and AWS Lambda.

**Tutorials in other AWS guides**

The following tutorials in other AWS guides show you how to perform common tasks with Amazon Aurora:
**Note**
Some of the tutorials use Amazon RDS DB instances, but they can be adapted to use Aurora DB clusters.

- **Tutorial: Aurora Serverless** in the *AWS AppSync Developer Guide*
  Learn how to use AWS AppSync to provide a data source for executing SQL commands against Aurora Serverless DB clusters with the Data API enabled. You can use AWS AppSync resolvers to execute SQL statements against the Data API with GraphQL queries, mutations, and subscriptions.

- **Tutorial: Rotating a Secret for an AWS Database** in the *AWS Secrets Manager User Guide*
  Learn how to create a secret for an AWS database and configure the secret to rotate on a schedule. You trigger one rotation manually, and then confirm that the new version of the secret continues to provide access.

- **Tutorial: Configuring a Lambda function to access Amazon RDS in an Amazon VPC** in the *AWS Lambda Developer Guide*
  Learn how to create a Lambda function to access a database, create a table, add a few records, and retrieve the records from the table. You also learn how to invoke the Lambda function and verify the query results.

- **Tutorials and samples** in the *AWS Elastic Beanstalk Developer Guide*
  Learn how to deploy applications that use Amazon RDS databases with AWS Elastic Beanstalk.

- **Using Data from an Amazon RDS Database to Create an Amazon ML Datasource** in the *Amazon Machine Learning Developer Guide*
  Learn how to create an Amazon Machine Learning (Amazon ML) datasource object from data stored in a MySQL DB instance.

- **Manually Enabling Access to an Amazon RDS Instance in a VPC** in the *Amazon QuickSight User Guide*
  Learn how to enable Amazon QuickSight access to an Amazon RDS DB instance in a VPC.

**Tutorials and sample code in GitHub**

The following tutorials and sample code in GitHub show you how to perform common tasks with Amazon Aurora:

**Note**
Some of the tutorials use Amazon RDS DB instances, but they can be adapted to use Aurora DB clusters.

- **Creating a Job Posting Site using Amazon Aurora and Amazon Translation Services**
  Learn how to create a web application that stores and queries data by using Amazon Aurora, Elastic Beanstalk, and SDK for Java 2.x. The application created in this AWS tutorial is a job posting web application that lets an employer, an administrator, or human resources staff alert employees or the public about a job opening within a company.

- **Creating the Amazon Relational Database Service item tracker**
  Learn how to create an application that tracks and reports on work items using Amazon RDS, Amazon Simple Email Service, Elastic Beanstalk, and SDK for Java 2.x.

- **SDK for Go code samples for Amazon RDS**
  View a collection of SDK for Go code samples for Amazon RDS and Aurora.

- **SDK for Java 2.x code samples for Amazon RDS**
View a collection of SDK for Java 2.x code samples for Amazon RDS and Aurora.

- **SDK for PHP code samples for Amazon RDS**

View a collection of SDK for PHP code samples for Amazon RDS and Aurora.

- **SDK for Ruby code samples for Amazon RDS**

View a collection of SDK for Ruby code samples for Amazon RDS and Aurora.
Configuring your Amazon Aurora DB cluster

This section shows how to set up your Aurora DB cluster. Before creating an Aurora DB cluster, decide on the DB instance class that will run the DB cluster. Also, decide where the DB cluster will run by choosing an AWS Region. Next, create the DB cluster. If you have data outside of Aurora, you can migrate the data into an Aurora DB cluster.

Topics

- Creating an Amazon Aurora DB cluster (p. 127)
- Creating Amazon Aurora resources with AWS CloudFormation (p. 150)
- Using Amazon Aurora global databases (p. 151)
- Connecting to an Amazon Aurora DB cluster (p. 207)
- Working with parameter groups (p. 215)
- Migrating data to an Amazon Aurora DB cluster (p. 242)
Creating an Amazon Aurora DB cluster

An Amazon Aurora DB cluster consists of a DB instance, compatible with either MySQL or PostgreSQL, and a cluster volume that holds the data for the DB cluster, copied across three Availability Zones as a single, virtual volume. By default, an Aurora DB cluster contains a primary DB instance that performs reads and writes, and, optionally, up to 15 Aurora Replicas (reader DB instances). For more information about Aurora DB clusters, see Amazon Aurora DB clusters (p. 3).

Following, you can find out how to create an Aurora DB cluster. To get started, first see DB cluster prerequisites (p. 127).

For simple instructions on connecting to your Aurora DB cluster, see Connecting to an Amazon Aurora DB cluster (p. 207).

Topics
• DB cluster prerequisites (p. 127)
• Creating a DB cluster (p. 131)
• Settings for Aurora DB clusters (p. 137)
• Settings that don't apply to Amazon Aurora for DB clusters (p. 147)
• Settings that don't apply to Amazon Aurora DB instances (p. 148)

DB cluster prerequisites

Important
Before you can create an Aurora DB cluster, you must complete the tasks in Setting up your environment for Amazon Aurora (p. 87).

The following are prerequisites to complete before creating a DB cluster.

Topics
• Configure the network for the DB cluster (p. 127)
• Additional prerequisites (p. 130)

Configure the network for the DB cluster

You can create an Amazon Aurora DB cluster only in a virtual private cloud (VPC) based on the Amazon VPC service, in an AWS Region that has at least two Availability Zones. The DB subnet group that you choose for the DB cluster must cover at least two Availability Zones. This configuration ensures that your DB cluster always has at least one DB instance available for failover, in the unlikely event of an Availability Zone failure.

If you plan to set up connectivity between your new DB cluster and an EC2 instance in the same VPC, you can do so during DB cluster creation. If you plan to connect to your DB cluster from resources other than EC2 instances in the same VPC, you can configure the network connections manually.

Topics
• Configure automatic network connectivity with an EC2 instance (p. 127)
• Configure the network manually (p. 130)

Configure automatic network connectivity with an EC2 instance

When you create an Aurora DB cluster, you can use the AWS Management Console to set up connectivity between an Amazon EC2 instance and the new DB cluster. When you do so, RDS configures your VPC and
network settings automatically. The DB cluster is created in the same VPC as the EC2 instance so that the EC2 instance can access the DB cluster.

The following are requirements for connecting an EC2 instance with the DB cluster:

- The EC2 instance must exist in the AWS Region before you create the DB cluster.
  
  If no EC2 instances exist in the AWS Region, the console provides a link to create one.
- Currently, the DB cluster can't be an Aurora Serverless DB cluster or part of an Aurora global database.
- The user who is creating the DB instance must have permissions to perform the following operations:
  
  ec2:AssociateRouteTable
  ec2:AuthorizeSecurityGroupEgress
  ec2:CreateRouteTable
  ec2:CreateSubnet
  ec2:CreateSecurityGroup
  ec2:DescribeInstances
  ec2:DescribeNetworkInterfaces
  ec2:DescribeRouteTables
  ec2:DescribeSecurityGroups
  ec2:DescribeSubnets
  ec2:ModifyNetworkInterfaceAttribute
  ec2:RevokeSecurityGroupEgress

Using this option creates a private DB cluster. The DB cluster uses a DB subnet group with only private subnets to restrict access to resources within the VPC.

To connect an EC2 instance to the DB cluster, choose **Connect to an EC2 compute resource** in the **Connectivity** section on the **Create database** page.

When you choose **Connect to an EC2 compute resource**, RDS sets the following options automatically. You can't change these settings unless you choose not to set up connectivity with an EC2 instance by choosing **Don't connect to an EC2 compute resource**.
Network type

RDS sets network type to IPv4. Currently, dual-stack mode isn't supported when you set up a connection between an EC2 instance and the DB cluster.

Virtual Private Cloud (VPC)

RDS sets the VPC to the one associated with the EC2 instance.

DB subnet group

A DB subnet group with a private subnet in each Availability Zone in the AWS Region is required. If a DB subnet group that meets this requirement exists, RDS uses the existing DB subnet group.

If a DB subnet group that meets this requirement doesn't exist, RDS uses an available private subnet in each Availability Zone to create a DB subnet group using the private subnets. If a private subnet isn't available in an Availability Zone, RDS creates a private subnet in the Availability Zone and then creates the DB subnet group.

When a private subnet is available, RDS uses the route table associated with it and adds any subnets it creates to this route table. When no private subnet is available, RDS creates a route table with no internet gateway access and adds the subnets it creates to the route table.

Public access

RDS chooses No so that the DB cluster isn't publicly accessible.

For security, it is a best practice to keep the database private and make sure it isn't accessible from the internet.

VPC security group (firewall)

RDS creates a new security group that is associated with the DB cluster. The security group is named rds-ec2-n, where n is a number. This security group includes an inbound rule with the EC2 VPC security group (firewall) as the source. This security group that is associated with the DB cluster allows the EC2 instance to access the DB cluster.

RDS also creates a new security group that is associated with the EC2 instance. The security group is named ec2-rds-n, where n is a number. This security group includes an outbound rule with the VPC security group of the DB cluster as the source. This security group allows the DB cluster to send traffic to the EC2 instance.

You can add another new security group by choosing Create new and typing the name of the new security group.

You can add existing security groups by choosing Choose existing and selecting security groups to add.

Availability Zone

When you don't create an Aurora Replica in Availability & durability during DB cluster creation (Single-AZ deployment), RDS chooses the Availability Zone of the EC2 instance.

When you create an Aurora Replica during DB cluster creation (Multi-AZ deployment), RDS chooses the Availability Zone of the EC2 instance for one DB instance in the DB cluster. RDS randomly chooses a different Availability Zone for the other DB instance in the DB cluster. Either the primary DB instance or the Aurora Replica is created in the same Availability Zone as the EC2 instance. There is the possibility of cross Availability Zone costs if the primary DB instance and EC2 instance are in different Availability Zones.
For more information about these settings, see Settings for Aurora DB clusters (p. 137).

If you make any changes to these settings after the DB cluster is created, the changes might affect the connection between the EC2 instance and the DB cluster.

**Configure the network manually**

If you plan to connect to your DB cluster from resources other than EC2 instances in the same VPC, you can configure the network connections manually. If you use the AWS Management Console to create your DB cluster, you can have Amazon RDS automatically create a VPC for you. Or you can use an existing VPC or create a new VPC for your Aurora DB cluster. Whichever approach you take, your VPC must have at least one subnet in each of at least two Availability Zones for you to use it with an Amazon Aurora DB cluster.

By default, Amazon RDS creates the primary DB instance and the Aurora Replica in the Availability Zones automatically for you. To choose a specific Availability Zone, you need to change the Availability & durability Multi-AZ deployment setting to **Don’t create an Aurora Replica**. Doing so exposes an Availability Zone setting that lets you choose from among the Availability Zones in your VPC. However, we strongly recommend that you keep the default setting and let Amazon RDS create a Multi-AZ deployment and choose Availability Zones for you. By doing so, your Aurora DB cluster is created with the fast failover and high availability features that are two of Aurora's key benefits.

If you don't have a default VPC or you haven't created a VPC, you can have Amazon RDS automatically create a VPC for you when you create a DB cluster using the console. Otherwise, you must do the following:

- Create a VPC with at least one subnet in each of at least two of the Availability Zones in the AWS Region where you want to deploy your DB cluster. For more information, see Working with a DB cluster in a VPC (p. 1728) and Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 1743).
- Specify a VPC security group that authorizes connections to your DB cluster. For more information, see Provide access to the DB cluster in the VPC by creating a security group (p. 90) and Controlling access with security groups (p. 1720).
- Specify an RDS DB subnet group that defines at least two subnets in the VPC that can be used by the DB cluster. For more information, see Working with DB subnet groups (p. 1729).

For information on VPCs, see Amazon VPC VPCs and Amazon Aurora (p. 1728). For a tutorial that configures the network for a private DB cluster, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 1743).

**Additional prerequisites**

Before you create your DB cluster, consider the following additional prerequisites:

- If you are connecting to AWS using AWS Identity and Access Management (IAM) credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see Identity and access management for Amazon Aurora (p. 1653).

  If you are using IAM to access the Amazon RDS console, you must first sign on to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at https://console.aws.amazon.com/rds/.

- If you want to tailor the configuration parameters for your DB cluster, you must specify a DB cluster parameter group and DB parameter group with the required parameter settings. For information about creating or modifying a DB cluster parameter group or DB parameter group, see Working with parameter groups (p. 215).

- Determine the TCP/IP port number to specify for your DB cluster. The firewalls at some companies block connections to the default ports (3306 for MySQL, 5432 for PostgreSQL) for Aurora. If your
Creating a DB cluster

You can create an Aurora DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

You can create a DB instance running MySQL with the AWS Management Console with *Easy create* enabled or not enabled. With *Easy create* enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. *Easy create* uses the default setting for other configuration options. With *Easy create* not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

*Note*

For this example, *Standard create* is enabled, and *Easy create* isn't enabled. For information about creating an Aurora MySQL DB cluster with *Easy create* enabled, see Getting started with Amazon Aurora (p. 93).

**To create an Aurora DB cluster using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you want to create the DB cluster.

   Aurora is not available in all AWS Regions. For a list of AWS Regions where Aurora is available, see Region availability (p. 12).
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. In **Choose a database creation method**, choose **Standard create**.
6. In **Engine options**, choose **Amazon Aurora**.
### Engine options

<table>
<thead>
<tr>
<th>Engine type</th>

</table>

**Edition**
- Amazon Aurora MySQL-Compatible Edition
- Amazon Aurora PostgreSQL-Compatible Edition

7. In **Edition**, choose one of the following:
   - **Amazon Aurora with MySQL compatibility**
   - **Amazon Aurora with PostgreSQL compatibility**

8. Choose one of the following in **Capacity type**:
   - **Provisioned**
     - For more information, see Amazon Aurora DB clusters (p. 3).
   - **Serverless**
     - For more information, see Using Aurora Serverless v2 (p. 1481) and Using Amazon Aurora Serverless v1 (p. 1542).

10. In **Templates**, choose the template that matches your use case.
11. To enter your master password, do the following:
   a. In the **Settings** section, open **Credential Settings**.
   b. Clear the **Auto generate a password** check box.
   c. (Optional) Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.
By default, the new DB instance uses an automatically generated password for the master user.

12. (Optional) Set up a connection to a compute resource for this DB cluster.

You can configure connectivity between an Amazon EC2 instance and the new DB cluster during DB cluster creation. For more information, see Configure automatic network connectivity with an EC2 instance (p. 127).

13. For the remaining sections, specify your DB cluster settings. For information about each setting, see Settings for Aurora DB clusters (p. 137).

If you chose to use an automatically generated password, the View credential details button appears on the Databases page.

To view the master user name and password for the DB cluster, choose View credential details.

To connect to the DB instance as the master user, use the user name and password that appear.

**Important**
You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see Modifying an Amazon Aurora DB cluster (p. 248).

15. For Databases, choose the name of the new Aurora DB cluster.

On the RDS console, the details for new DB cluster appear. The DB cluster and its DB instance have a status of creating until the DB cluster is ready to use.
Creating a DB cluster

When the state changes to available for both, you can connect to the DB cluster. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB cluster is available.

To view the newly created cluster, choose Databases from the navigation pane in the Amazon RDS console. Then choose the DB cluster to show the DB cluster details. For more information, see Viewing an Amazon Aurora DB cluster (p. 433).

On the Connectivity & security tab, note the port and the endpoint of the writer DB instance. Use the endpoint and port of the cluster in your JDBC and ODBC connection strings for any application that performs write or read operations.

AWS CLI

Note
Before you can create an Aurora DB cluster using the AWS CLI, you must fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see DB cluster prerequisites (p. 127).

You can use the AWS CLI to create an Aurora MySQL DB cluster or an Aurora PostgreSQL DB cluster.

To create an Aurora MySQL DB cluster using the AWS CLI

When you create an Aurora MySQL DB cluster or DB instance, ensure that you specify the correct value for the --engine option value based on the MySQL compatibility of the DB cluster or DB instance.
• When you create an Aurora MySQL 8.0-compatible or 5.7-compatible DB cluster or DB instance, you specify `aurora-mysql` for the `--engine` option.

• When you create an Aurora MySQL 5.6-compatible DB cluster or DB instance, you specify `aurora` for the `--engine` option.

Complete the following steps:

1. Identify the DB subnet group and VPC security group ID for your new DB cluster, and then call the `create-db-cluster` AWS CLI command to create the Aurora MySQL DB cluster.

   For example, the following command creates a new MySQL 8.0–compatible DB cluster named `sample-cluster`.

   **For Linux, macOS, or Unix:**
   ```bash
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql
   --engine-version 8.0 --master-username user-name --master-user-password password
   --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

   **For Windows:**
   ```bash
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql
   --engine-version 8.0 --master-username user-name --master-user-password password
   --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

   The following command creates a new MySQL 5.7–compatible DB cluster named `sample-cluster`.

   **For Linux, macOS, or Unix:**
   ```bash
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql
   --engine-version 5.7.12 --master-username user-name --master-user-password password
   --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

   **For Windows:**
   ```bash
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-mysql
   --engine-version 5.7.12 --master-username user-name --master-user-password password
   --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

   The following command creates a new MySQL 5.6–compatible DB cluster named `sample-cluster`.

   **For Linux, macOS, or Unix:**
   ```bash
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora
   --engine-version 5.6.10a --master-username user-name --master-user-password password
   --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```

   **For Windows:**
   ```bash
   aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora
   --engine-version 5.6.10a --master-username user-name --master-user-password password
   --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
   ```
2. If you use the console to create a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to create a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

Call the `create-db-instance` AWS CLI command to create the primary instance for your DB cluster. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

For example, the following command creates a new MySQL 5.7–compatible or MySQL 8.0–compatible DB instance named sample-instance.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance --db-cluster-identifier sample-cluster --engine aurora --db-instance-class db.r5.large
```

For Windows:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance --db-cluster-identifier sample-cluster --engine aurora --db-instance-class db.r5.large
```

The following command creates a new MySQL 5.6–compatible DB instance named sample-instance.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance --db-cluster-identifier sample-cluster --engine aurora --db-instance-class db.r5.large
```

For Windows:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance --db-cluster-identifier sample-cluster --engine aurora --db-instance-class db.r5.large
```

To create an Aurora PostgreSQL DB cluster using the AWS CLI

1. Identify the DB subnet group and VPC security group ID for your new DB cluster, and then call the `create-db-cluster` AWS CLI command to create the Aurora PostgreSQL DB cluster.

For example, the following command creates a new DB cluster named sample-cluster.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql --master-username user-name --master-user-password password --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

For Windows:

```bash
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql --master-username user-name --master-user-password password --db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```
Available settings

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora-postgresql ^
--master-username user-name --master-user-password password ^
--db-subnet-group-name mysubnetgroup --vpc-security-group-ids sg-c7e5b0d2
```

2. If you use the console to create a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to create a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

Call the `create-db-instance` AWS CLI command to create the primary instance for your DB cluster. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier sample-instance \
--db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class db.r4.large
```

For Windows:

```
aws rds create-db-instance --db-instance-identifier sample-instance ^
--db-cluster-identifier sample-cluster --engine aurora-postgresql --db-instance-class db.r4.large
```

**RDS API**

**Note**
Before you can create an Aurora DB cluster using the AWS CLI, you must fulfill the required prerequisites, such as creating a VPC and an RDS DB subnet group. For more information, see DB cluster prerequisites (p. 127).

Identify the DB subnet group and VPC security group ID for your new DB cluster, and then call the `CreateDBCluster` operation to create the DB cluster.

When you create an Aurora MySQL DB cluster or DB instance, ensure that you specify the correct value for the `Engine` parameter value based on the MySQL compatibility of the DB cluster or DB instance.

- When you create an Aurora MySQL 5.7 DB cluster or DB instance, you must specify `aurora-mysql` for the `Engine` parameter.
- When you create an Aurora MySQL 5.6 DB cluster or DB instance, you must specify `aurora` for the `Engine` parameter.

When you create an Aurora PostgreSQL DB cluster or DB instance, specify `aurora-postgresql` for the `Engine` parameter.

**Settings for Aurora DB clusters**

The following table contains details about settings that you choose when you create an Aurora DB cluster.
### Available settings

**Note**
Additonal settings are available if you are creating an Aurora Serverless v1 DB cluster. For information about these settings, see [Creating an Aurora Serverless v1 DB cluster](p. 1558). Also, some settings aren’t available for Aurora Serverless v1 because of Aurora Serverless v1 limitations. For more information, see [Limitations of Aurora Serverless v1](p. 1543).

<table>
<thead>
<tr>
<th>Console setting</th>
<th>Setting description</th>
<th>CLI option and RDS API parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto minor version upgrade</strong></td>
<td>Choose <strong>Enable auto minor version upgrade</strong> if you want to enable your Aurora DB cluster to receive preferred minor version upgrades to the DB engine automatically when they become available. The Auto minor version upgrade setting applies to both Aurora PostgreSQL and Aurora MySQL DB clusters. For Aurora MySQL version 1 and version 2 clusters, this setting upgrades the clusters to a maximum version of 1.22.2 and 2.07.2, respectively. For more information about engine updates for Aurora PostgreSQL, see [Amazon Aurora PostgreSQL updates](p. 1412). For more information about engine updates for Aurora MySQL, see [Database engine updates for Amazon Aurora MySQL](p. 991).</td>
<td>Set this value for every DB instance in your Aurora cluster. If any DB instance in your cluster has this setting turned off, the cluster isn't automatically upgraded. Using the AWS CLI, run <code>create-db-instance</code> and set the `--auto-minor-version-upgrade</td>
</tr>
<tr>
<td><strong>AWS KMS key</strong></td>
<td>Only available if <strong>Encryption</strong> is set to <strong>Enable encryption</strong>. Choose the AWS KMS key to use for encrypting this DB cluster. For more information, see [Encrypting Amazon Aurora resources](p. 1638).</td>
<td>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--kms-key-id</code> option. Using the RDS API, call <code>CreateDBCluster</code> and set the <code>KmsKeyId</code> parameter.</td>
</tr>
<tr>
<td><strong>Backtrack</strong></td>
<td>Applies only to Aurora MySQL. Choose <strong>Enable Backtrack</strong> to enable backtracking or <strong>Disable Backtrack</strong> to disable backtracking. Using backtracking, you can rewind a DB cluster to a specific time, without creating a new DB cluster. It is disabled by default. If you enable backtracking, also specify the amount of time that you want to be able to backtrack your DB cluster (the target backtrack window). For more information, see [Backtracking an Aurora DB cluster](p. 725).</td>
<td>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--backtrack-window</code> option. Using the RDS API, call <code>CreateDBCluster</code> and set the <code>BacktrackWindow</code> parameter.</td>

<td><strong>Database port</strong></td>
<td>Specify the port for applications and utilities to use to access the database. Aurora MySQL DB clusters default to the default MySQL port, 3306, and Aurora PostgreSQL DB clusters default to the default PostgreSQL port, 5432. The firewalls at some companies block connections to these default ports. If your company firewall blocks the default port, choose another port for the new DB cluster.</td>
<td>Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--port</code> option. Using the RDS API, call <code>CreateDBCluster</code> and set the <code>Port</code> parameter.</td>
</tr>
</tbody>
</table>
| **DB cluster identifier**| Enter a name for your DB cluster that is unique for your account in the AWS Region that you chose. This identifier is used in the cluster endpoint address for your DB cluster. For information on the cluster endpoint, see Amazon Aurora connection management (p. 35). The DB cluster identifier has the following constraints:  
  - It must contain from 1 to 63 alphanumeric characters or hyphens.  
  - Its first character must be a letter.  
  - It cannot end with a hyphen or contain two consecutive hyphens.  
  - It must be unique for all DB clusters per AWS account, per AWS Region.                                                  | Using the AWS CLI, run `create-db-cluster` and set the `--db-cluster-identifier` option. Using the RDS API, call `CreateDBCluster` and set the `DBClusterIdentifier` parameter. |
<p>| <strong>DB cluster parameter group</strong> | Choose a DB cluster parameter group. Aurora has a default DB cluster parameter group you can use, or you can create your own DB cluster parameter group. For more information about DB cluster parameter groups, see Working with parameter groups (p. 215). | Using the AWS CLI, run <code>create-db-cluster</code> and set the <code>--db-cluster-parameter-group-name</code> option. Using the RDS API, call <code>CreateDBCluster</code> and set the <code>DBClusterParameterGroupName</code> parameter. |
| <strong>DB instance class</strong>     | Applies only to the provisioned capacity type. Choose a DB instance class that defines the processing and memory requirements for each instance in the DB cluster. For more information about DB instance classes, see Aurora DB instance classes (p. 56). | Set this value for every DB instance in your Aurora cluster. Using the AWS CLI, run <code>create-db-instance</code> and set the <code>--db-instance-class</code> option. Using the RDS API, call <code>CreateDBInstance</code> and set the <code>DBInstanceClass</code> parameter. |</p>

</table>
| **Maintenance window** | Choose Select window and specify the weekly time range during which system maintenance can occur. Or choose No preference for Amazon RDS to assign a period randomly. | Using the AWS CLI, run `create-db-cluster` and set the `--preferred-maintenance-window` option.    
Using the RDS API, call `CreateDBCluster` and set the `PreferredMaintenanceWindow` parameter. |
| **Master password**    | Enter a password to log on to your DB cluster:  
• For Aurora MySQL, the password must contain 8–41 printable ASCII characters.  
• For Aurora PostgreSQL, it must contain 8–128 printable ASCII characters.  
• It can't contain /, ,, @, or a space. | Using the AWS CLI, run `create-db-cluster` and set the `--master-user-password` option.     
Using the RDS API, call `CreateDBCluster` and set the `MasterUserPassword` parameter.       |
| **Master username**    | Enter a name to use as the master user name to log on to your DB cluster:  
• For Aurora MySQL, the name must contain 1–16 alphanumeric characters.  
• For Aurora PostgreSQL, it must contain 1–63 alphanumeric characters.  
• The first character must be a letter.  
• The name can't be a reserved word by the database engine. | Using the AWS CLI, run `create-db-cluster` and set the `--master-username` option.        
Using the RDS API, call `CreateDBCluster` and set the `MasterUsername` parameter.          |
| **Multi-AZ deployment** | Applies only to the provisioned capacity type. Determine if you want to create Aurora Replicas in other Availability Zones for failover support. If you choose Create Replica in Different Zone, then Amazon RDS creates an Aurora Replica for you in your DB cluster in a different Availability Zone than the primary instance for your DB cluster. For more information about multiple Availability Zones, see Regions and Availability Zones (p. 11). | Using the AWS CLI, run `create-db-cluster` and set the `--availability-zones` option.        
Using the RDS API, call `CreateDBCluster` and set the `AvailabilityZones` parameter.        |

</tbody>
</table>
## Console setting | Setting description | CLI option and RDS API parameter
--- | --- | ---
**VPC security group** | Choose Create new to have Amazon RDS create a VPC security group for you. Or choose Choose existing and specify one or more VPC security groups to secure network access to the DB cluster. When you choose Create new in the RDS console, a new security group is created with an inbound rule that allows access to the DB instance from the IP address detected in your browser. For more information, see DB cluster prerequisites (p. 127). | Using the AWS CLI, run `create-db-cluster` and set the `--vpc-security-group-ids` option. Using the RDS API, call `CreateDBCluster` and set the `VpcSecurityGroupIds` parameter.

### Settings that don't apply to Amazon Aurora for DB clusters

The following settings in the AWS CLI command `create-db-cluster` and the RDS API operation `CreateDBCluster` don't apply to Amazon Aurora DB clusters.

**Note**  
The AWS Management Console doesn't show these settings for Aurora DB clusters.

<table>
<thead>
<tr>
<th>AWS CLI setting</th>
<th>RDS API setting</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--allocated-storage</code></td>
<td><code>AllocatedStorage</code></td>
</tr>
<tr>
<td><code>--db-cluster-instance-class</code></td>
<td><code>DBClusterInstanceClass</code></td>

Creating Amazon Aurora resources with AWS CloudFormation

Amazon Aurora is integrated with AWS CloudFormation, a service that helps you to model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want (such as DB clusters and DB cluster parameter groups), and AWS CloudFormation provisions and configures those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your Aurora resources consistently and repeatedly. Describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

Aurora and AWS CloudFormation templates

To provision and configure resources for Aurora and related services, you must understand AWS CloudFormation templates. Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you’re unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the AWS CloudFormation User Guide.

Aurora supports creating resources in AWS CloudFormation. For more information, including examples of JSON and YAML templates for these resources, see the RDS resource type reference in the AWS CloudFormation User Guide.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- AWS CloudFormation

- AWS CloudFormation API Reference
- AWS CloudFormation Command Line Interface User Guide
Using Amazon Aurora global databases

Amazon Aurora global databases span multiple AWS Regions, enabling low latency global reads and providing fast recovery from the rare outage that might affect an entire AWS Region. An Aurora global database has a primary DB cluster in one Region, and up to five secondary DB clusters in different Regions.

Topics
- Overview of Amazon Aurora global databases (p. 151)
- Advantages of Amazon Aurora global databases (p. 152)
- Limitations of Amazon Aurora global databases (p. 152)
- Getting started with Amazon Aurora global databases (p. 154)
- Managing an Amazon Aurora global database (p. 175)
- Connecting to an Amazon Aurora global database (p. 180)
- Using write forwarding in an Amazon Aurora global database (p. 181)
- Using failover in an Amazon Aurora global database (p. 192)
- Monitoring an Amazon Aurora global database (p. 202)
- Using Amazon Aurora global databases with other AWS services (p. 205)
- Upgrading an Amazon Aurora global database (p. 206)

Overview of Amazon Aurora global databases

By using an Amazon Aurora global database, you can run your globally distributed applications using a single Aurora database that spans multiple AWS Regions.

An Aurora global database consists of one primary AWS Region where your data is written, and up to five read-only secondary AWS Regions. You issue write operations directly to the primary DB cluster in the primary AWS Region. Aurora replicates data to the secondary AWS Regions using dedicated infrastructure, with latency typically under a second.

In the following diagram, you can find an example Aurora global database that spans two AWS Regions.

You can scale up each secondary cluster independently, by adding one or more Aurora Replicas (read-only Aurora DB instances) to serve read-only workloads.

Only the primary cluster performs write operations. Clients that perform write operations connect to the DB cluster endpoint of the primary DB cluster. As shown in the diagram, Aurora global database uses the cluster storage volume and not the database engine for replication. To learn more, see Overview of Aurora storage (p. 67).
Aurora global databases are designed for applications with a worldwide footprint. The read-only secondary DB clusters (AWS Regions) allow you to support read operations closer to application users. By using features such as write forwarding, you can also configure an Aurora MySQL–based global database so that secondary clusters send data to the primary. For more information, see Using write forwarding in an Amazon Aurora global database (p. 181).

An Aurora global database supports two different approaches to failover. To recover your Aurora global database after an outage in the primary Region, you use the manual unplanned failover process. With this process, you fail over your primary to another Region (cross-Region failover). For more information about this process, see Recovering an Amazon Aurora global database from an unplanned outage (p. 193).

For planned operational procedures such as maintenance, you use managed planned failover. With this feature, you can relocate the primary cluster of a healthy Aurora global database to one of its secondary Regions with no data loss. To learn more, see Performing managed planned failovers for Amazon Aurora global databases (p. 194).

Advantages of Amazon Aurora global databases

By using Aurora global databases, you can get the following advantages:

- **Global reads with local latency** – If you have offices around the world, you can use an Aurora global database to keep your main sources of information updated in the primary AWS Region. Offices in your other Regions can access the information in their own Region, with local latency.

- **Scalable secondary Aurora DB clusters** – You can scale your secondary clusters by adding more read-only instances (Aurora Replicas) to a secondary AWS Region. The secondary cluster is read-only, so it can support up to 16 read-only Aurora Replica instances rather than the usual limit of 15 for a single Aurora cluster.

- **Fast replication from primary to secondary Aurora DB clusters** – The replication performed by an Aurora global database has little performance impact on the primary DB cluster. The resources of the DB instances are fully devoted to serve application read and write workloads.

- **Recovery from Region-wide outages** – The secondary clusters allow you to make an Aurora global database available in a new primary AWS Region more quickly (lower RTO) and with less data loss (lower RPO) than traditional replication solutions.

Limitations of Amazon Aurora global databases

The following limitations currently apply to Aurora global databases:

- Aurora global databases are available in certain AWS Regions and for specific Aurora MySQL and Aurora PostgreSQL versions only. For more information, see Aurora global databases (p. 21).

- Aurora global databases have certain configuration requirements for supported Aurora DB instance classes, maximum number of AWS Regions, and so on. For more information, see Configuration requirements of an Amazon Aurora global database (p. 154).

- Managed planned failover for Aurora global databases requires one of the following Aurora database engines:
  - Aurora MySQL with MySQL 8.0 compatibility, version 3.01.0 and higher
  - Aurora MySQL with MySQL 5.7 compatibility, version 2.09.1 and higher
  - Aurora MySQL with MySQL 5.6 compatibility, version 1.23.1 and higher
  - Aurora PostgreSQL versions 13.3 and higher, 12.4 and higher, 11.9 and higher, and 10.14 and higher
  - Aurora global databases currently don't support the following Aurora features:
    - Aurora multi-master clusters
• Aurora Serverless v1
• Backtracking in Aurora
• Amazon RDS Proxy
• Automatic minor version upgrade doesn't apply to Aurora MySQL and Aurora PostgreSQL clusters that are part of an Aurora global database. Note that you can specify this setting for a DB instance that is part of a global database cluster, but the setting has no effect.
• Aurora global databases currently don't support Aurora Auto Scaling for secondary DB clusters.
• You can start database activity streams on Aurora global databases running the following Aurora MySQL and Aurora PostgreSQL versions only.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Primary AWS Region</th>
<th>Secondary AWS Regions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL 5.7</td>
<td>version 2.08 and higher</td>
<td>version 2.08 and higher</td>
</tr>
<tr>
<td>Aurora PostgreSQL</td>
<td>version 13.3 and higher</td>
<td>version 13.3 and higher</td>
</tr>
<tr>
<td></td>
<td>version 12.4 and higher</td>
<td>version 12.4 and higher</td>
</tr>
<tr>
<td></td>
<td>version 11.7 and higher</td>
<td>version 11.9 and higher</td>
</tr>
<tr>
<td></td>
<td>version 10.11 and higher</td>
<td>version 10.14 and higher</td>
</tr>
</tbody>
</table>

For information about database activity streams, see Monitoring Amazon Aurora with Database Activity Streams (p. 619).

• The following limitations currently apply to upgrading Aurora global databases:
  • You can’t apply a custom parameter group to the global database cluster while you’re performing a major version upgrade of that Aurora global database. You create your custom parameter groups in each Region of the global cluster and you apply them manually to the Regional clusters after the upgrade.
  • With an Aurora global database based on Aurora PostgreSQL, you can’t perform a major version upgrade of the Aurora DB engine if the recovery point objective (RPO) feature is turned on. For information about the RPO feature, see Managing RPOs for Aurora PostgreSQL–based global databases (p. 198).

For information about upgrading an Aurora global database, see Upgrading an Amazon Aurora global database (p. 206).

• You can’t stop or start the Aurora DB clusters in your Aurora global database individually. To learn more, see Stopping and starting an Amazon Aurora DB cluster (p. 244).

• Aurora Replicas attached to the secondary Aurora DB cluster can restart under certain circumstances. If the primary AWS Region’s writer DB instance restarts or fails over, Aurora Replicas in secondary Regions also restart. The secondary cluster is then unavailable until all replicas are back in sync with the primary DB cluster’s writer instance. This behavior is expected, as documented in Replication with Amazon Aurora (p. 73). Be sure that you understand the impacts to your Aurora global database before making changes to your primary DB cluster. To learn more, see Recovering an Amazon Aurora global database from an unplanned outage (p. 193).

• Aurora PostgreSQL–based DB clusters running in an Aurora global database have the following limitations:
  • Cluster cache management isn’t supported for Aurora PostgreSQL DB clusters that are part of Aurora global databases.
  • If the primary DB cluster of your Aurora global database is based on a replica of an Amazon RDS PostgreSQL instance, you can’t create a secondary cluster. Don’t attempt to create a secondary from that cluster using the AWS Management Console, the AWS CLI, or the CreateDBCluster API operation. Attempts to do so time out, and the secondary cluster isn’t created.
We recommend that you create secondary DB clusters for your Aurora global databases by using the same version of the Aurora DB engine as the primary. For more information, see Creating an Amazon Aurora global database (p. 155).

Getting started with Amazon Aurora global databases

To get started with Aurora global databases, first decide which Aurora DB engine you want to use and in which AWS Regions. Only specific versions of the Aurora MySQL and Aurora PostgreSQL database engines in certain AWS Regions support Aurora global databases. For the complete list, see Aurora global databases (p. 21).

You can create an Aurora global database in one of the following ways:

- **Create a new Aurora global database with new Aurora DB clusters and Aurora DB instances** – You can do this by following the steps in Creating an Amazon Aurora global database (p. 155). After you create the primary Aurora DB cluster, you then add the secondary AWS Region by following the steps in Adding an AWS Region to an Amazon Aurora global database (p. 168).

- **Use an existing Aurora DB cluster that supports the Aurora global database feature and add an AWS Region to it** – You can do this only if your existing Aurora DB cluster uses a DB engine version that supports the Aurora global mode or is global-compatible. For some DB engine versions, this mode is explicit, but for others, it's not.

  Check whether you can choose Add region for Action on the AWS Management Console when your Aurora DB cluster is selected. If you can, you can use that Aurora DB cluster for your Aurora global cluster. For more information, see Adding an AWS Region to an Amazon Aurora global database (p. 168).

Before creating an Aurora global database, we recommend that you understand all configuration requirements.

**Topics**

- Configuration requirements of an Amazon Aurora global database (p. 154)
- Creating an Amazon Aurora global database (p. 155)
- Adding an AWS Region to an Amazon Aurora global database (p. 168)
- Creating a headless Aurora DB cluster in a secondary Region (p. 172)
- Using a snapshot for your Amazon Aurora global database (p. 174)

Configuration requirements of an Amazon Aurora global database

An Aurora global database spans at least two AWS Regions. The primary AWS Region supports an Aurora DB cluster that has one writer Aurora DB instance. A secondary AWS Region runs a read-only Aurora DB cluster made up entirely of Aurora Replicas. At least one secondary AWS Region is required, but an Aurora global database can have up to five secondary AWS Regions. The table lists the maximum Aurora DB clusters, Aurora DB instances, and Aurora Replicas allowed in an Aurora global database.

<table>
<thead>
<tr>
<th>Description</th>
<th>Primary AWS Region</th>
<th>Secondary AWS Regions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora DB clusters</td>
<td>1</td>
<td>5 (maximum)</td>
</tr>
</tbody>
</table>
### Getting started with Aurora global databases

<table>
<thead>
<tr>
<th>Description</th>
<th>Primary AWS Region</th>
<th>Secondary AWS Regions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Writer instances</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Read-only instances (Aurora replicas), per Aurora DB cluster</td>
<td>15 (max)</td>
<td>16 (total)</td>
</tr>
<tr>
<td>Read-only instances (max allowed, given actual number of secondary Regions)</td>
<td>15 - $s$</td>
<td>$s$ = total number of secondary AWS Regions</td>
</tr>
</tbody>
</table>

The Aurora DB clusters that make up an Aurora global database have the following specific requirements:

- **DB instance class requirements** – An Aurora global database requires DB instance classes that are optimized for memory-intensive applications. For information about the memory optimized DB instance classes, see DB instance classes. We recommend that you use a db.r5 or higher instance class.

- **AWS Region requirements** – An Aurora global database needs a primary Aurora DB cluster in one AWS Region, and at least one secondary Aurora DB cluster in a different Region. You can create up to five secondary (read-only) Aurora DB clusters, and each must be in a different Region. In other words, no two Aurora DB clusters in an Aurora global database can be in the same AWS Region.

- **Naming requirements** – The names you choose for each of your Aurora DB clusters must be unique, across all AWS Regions. You can't use the same name for different Aurora DB clusters even though they're in different Regions.

Before you can follow the procedures in this section, you need an AWS account. Complete the setup tasks for working with Amazon Aurora. For more information, see Setting up your environment for Amazon Aurora (p. 87). You also need to complete other preliminary steps for creating any Aurora DB cluster. To learn more, see Creating an Amazon Aurora DB cluster (p. 127).

### Creating an Amazon Aurora global database

In some cases, you might have an existing Aurora provisioned DB cluster running an Aurora database engine that's global-compatible. If so, you can add another AWS Region to it to create your Aurora global database. To do so, see Adding an AWS Region to an Amazon Aurora global database (p. 168).

To create an Aurora global database by using the AWS Management Console, the AWS CLI, or the RDS API, use the following steps.

**Console**

The steps for creating an Aurora global database begin by signing in to an AWS Region that supports the Aurora global database feature. For a complete list, see Aurora global databases (p. 21).

One of the following steps is choosing a virtual private cloud (VPC) based on Amazon VPC for your Aurora DB cluster. To use your own VPC, we recommend that you create it in advance so it's available for you to choose. At the same time, create any related subnets, and as needed a subnet group and security group. To learn how, see Tutorial: Create an Amazon VPC for use with a DB instance.

For general information about creating an Aurora DB cluster, see Creating an Amazon Aurora DB cluster (p. 127).

**To create an Aurora global database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Create database**. On the **Create database** page, do the following:
   - For the database creation method, choose **Standard create**. (Don't choose Easy create.)
   - For **Engine type** in the **Engine options** section, choose **Amazon Aurora**.

Continue creating your Aurora global database by using the steps from the following procedures:

- Creating a global database using Aurora MySQL (p. 156)
- Creating a global database using Aurora PostgreSQL (p. 160)

**Creating a global database using Aurora MySQL**

The following steps apply to all versions of Aurora MySQL except for Aurora MySQL 5.6.10a. To use Aurora MySQL 5.6.10a for your Aurora global database, see Using Aurora MySQL 5.6.10a for an Aurora global database (p. 158).

**To create an Aurora global database using Aurora MySQL**

Complete the **Create database** page.

1. For **Engine options**, choose the following:
   a. For **Edition**, choose **Amazon Aurora MySQL-Compatible Edition**.
   b. Leave **Replication features** set to the default (single-master replication).
   c. Expand **Show filters**, and then turn on **Show versions that support the global database feature**.
   d. For **Engine version**, choose the version of Aurora MySQL that you want to use for your Aurora global database.
Getting started with Aurora global databases

2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate for your use case. Don't use Dev/Test in production environments.

3. For **Settings**, do the following:
   
   a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.
   
   b. Enter your own password for the `admin` user account for the DB instance, or have Aurora generate one for you. If you choose to autogenerate a password, you get an option to copy the password.

4. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a `db.r5` or higher instance class.
5. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different Availability Zone (AZ) for you. If you don't create an Aurora Replica now, you need to do it later.

6. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.

7. Complete the **Database authentication** settings. To simplify the process, you can choose **Password authentication** now and set up AWS Identity and Access Management (IAM) later.

8. For **Additional configuration**, do the following:
   a. Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.
      
      Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.
   b. Clear the **Enable backtrack** check box if it's selected. Aurora global databases don't support backtracking. Otherwise, accept the other default settings for **Additional configuration**.

9. Choose **Create database**.

   It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. You can tell when the Aurora DB cluster is ready to use as the primary DB cluster in an Aurora global database by its status. When that's so, its status and that of the writer and replica node is **Available**, as shown following.

When your primary DB cluster is available, create the Aurora global database by adding a secondary cluster to it. To do this, follow the steps in **Adding an AWS Region to an Amazon Aurora global database** (p. 168).

**Using Aurora MySQL 5.6.10a for an Aurora global database**

The following steps apply to the 5.6.10a version of Aurora MySQL only. For other versions of Aurora MySQL, see **Creating a global database using Aurora MySQL** (p. 156).

**To create an Aurora global database using Aurora MySQL 5.6.10a**

Complete the **Create database** page.

1. For **Engine options**, choose the following:
b. Leave **Replication features** set to the default (single-master replication).

c. Expand **Show filters**, and then turn on **Show versions that support the global database feature**.

d. For **Engine version**, choose **Aurora (MySQL 5.6) global_10a**.

2. For **Templates**, choose **Production**.

3. For **Global database settings**, do the following:

   a. For **Global database identifier**, enter a meaningful name.

   b. For **Credentials Settings**, enter your own password for the `admin` user account for the DB instance, or have Aurora generate one for you. If you choose Auto generate a password, you get an option to copy the password.

4. For **Encryption**, enable or disable encryption as needed.

5. The remaining sections of the **Create database** page configure the **Primary region settings**. Complete these as follows:

   a. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a db.r5 or higher instance class.

   b. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different AZ for you. If you don't create an Aurora Replica now, you need to do it later.
c. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.

d. For **Encryption key**, choose the key to use. If you didn't choose **Encryption** earlier, disregard this option.

e. Complete the **Database authentication** settings. To simplify the process, you can choose **Password authentication** now and set up IAM later.

f. For **Additional configuration**, do the following:

   i. For **DB instance identifier**, enter a name for the database instance, or use the default provided. This is the writer instance for the Aurora primary DB cluster for this Aurora global database.

   ii. For **DB cluster identifier**, enter a meaningful name or accept the default provided.

   iii. Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.

   iv. You can accept all other default settings for **Additional configuration**.

g. Choose **Create database**.

It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. You can tell when the Aurora DB cluster is ready to use as the primary DB cluster in an Aurora global database by its status. When that's so, its status and that of the writer and replica node is **Available**, as shown following.

This Aurora global database still needs a secondary Aurora DB cluster. You can add that now, by following the steps in **Adding an AWS Region to an Amazon Aurora global database (p. 168)**.

**Creating a global database using Aurora PostgreSQL**

**To create an Aurora global database using Aurora PostgreSQL**

Complete the **Create database** page.

1. For **Engine options**, choose the following:

   a. For **Edition**, choose **Amazon Aurora PostgreSQL-Compatible Edition**.
b. Expand **Show filters**, and then turn on **Show versions that support the global database feature**.

c. For **Engine version**, choose the version of Aurora PostgreSQL that you want to use for your Aurora global database.

<table>
<thead>
<tr>
<th>Engine type</th>
<th>Edition</th>
<th>Engine version</th>
<th>Require version support for the following database features.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora</td>
<td>Amazon Aurora MySQL-Compatible Edition</td>
<td>Show versions that support the global database feature</td>
<td></td>
</tr>
</tbody>
</table>
| Amazon Aurora PostgreSQL-Compatible Edition | Show versions that support the global database feature  
Show versions that support Serverless v2  
Show versions that support the pBabybfith feature for PostgreSQL  
Show versions that support biabits feature for MySQL |
| PostgreSQL | Aurora PostgreSQL (compatible with PostgreSQL 11.9) | |

2. For **Templates**, choose **Production**. Or you can choose Dev/Test if appropriate. Don’t use Dev/Test in production environments.

3. For **Settings**, do the following:

   a. Enter a meaningful name for the DB cluster identifier. When you finish creating the Aurora global database, this name identifies the primary DB cluster.

   b. Enter your own password for the default admin account for the DB cluster, or have Aurora generate one for you. If you choose Auto generate a password, you get an option to copy the password.
4. For **DB instance class**, choose `db.r5.large` or another memory optimized DB instance class. We recommend that you use a `db.r5` or higher instance class.

```
Instance configuration

<table>
<thead>
<tr>
<th>DB instance class</th>
<th>Memory optimized classes (includes t classes)</th>
<th>Burstable classes (includes t classes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.r5.large</td>
<td>16 GB RAM, 16,608 MB/s, 4,750 Mbps</td>
<td></td>
</tr>
</tbody>
</table>
```

5. For **Availability & durability**, we recommend that you choose to have Aurora create an Aurora Replica in a different AZ for you. If you don't create an Aurora Replica now, you need to do it later.

6. For **Connectivity**, choose the virtual private cloud (VPC) based on Amazon VPC that defines the virtual networking environment for this DB instance. You can choose the defaults to simplify this task.

7. (Optional) Complete the **Database authentication** settings. Password authentication is always enabled. To simplify the process, you can skip this section and set up IAM or password and Kerberos authentication later.

8. For **Additional configuration**, do the following:

   a. Enter a name for **Initial database name** to create the primary Aurora DB instance for this cluster. This is the writer node for the Aurora primary DB cluster.

      Leave the defaults selected for the DB cluster parameter group and DB parameter group, unless you have your own custom parameter groups that you want to use.

   b. Accept all other default settings for **Additional configuration**, such as Encryption, Log exports, and so on.

9. Choose **Create database**.

   It can take several minutes for Aurora to complete the process of creating the Aurora DB instance, its Aurora Replica, and the Aurora DB cluster. When the cluster is ready to use, the Aurora DB cluster and its writer and replica nodes display **Available** status. This becomes the primary DB cluster of your Aurora global database, after you add a secondary.
When your primary DB cluster is available, create one or more secondary clusters by following the steps in Adding an AWS Region to an Amazon Aurora global database (p. 168).

**AWS CLI**

The AWS CLI commands in the procedures following accomplish the following tasks:

1. Create an Aurora global database, giving it a name and specifying the Aurora database engine type that you plan to use.
2. Create an Aurora DB cluster for the Aurora global database.
3. Create the Aurora DB instance for the cluster.
4. Create an Aurora DB instance for the Aurora DB cluster.
5. Create a second DB instance for Aurora DB cluster. This is a reader to complete the Aurora DB cluster.
6. Create a second Aurora DB cluster in another Region and then add it to your Aurora global database, by following the steps in Adding an AWS Region to an Amazon Aurora global database (p. 168).

Follow the procedure for your Aurora database engine.

**CLI examples**

- Creating a global database using Aurora MySQL (p. 163)
- Creating a global database using Aurora PostgreSQL (p. 166)

**Creating a global database using Aurora MySQL**

**To create an Aurora global database using Aurora MySQL**

1. Use the `create-global-cluster` CLI command, passing the name of the AWS Region, Aurora database engine and version. Choose your parameters from those shown in the table for the version of Aurora MySQL that you want to use.

Other options for Aurora MySQL depend on the version of the Aurora MySQL database engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Aurora MySQL version 1</th>
<th>Aurora MySQL version 2 and 3</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--engine</code></td>
<td>aurora</td>
<td>aurora-mysql</td>
</tr>
<tr>
<td><code>--engine-mode</code></td>
<td>global</td>
<td>-</td>
</tr>
</tbody>
</table>
### Getting started with Aurora global databases

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Aurora MySQL version 1</th>
<th>Aurora MySQL version 2 and 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>--engine-version</td>
<td>5.6.10a, 5.6.mysql_aurora.1.22.0, 5.7.mysql_aurora.2.07.0, 5.6.mysql_aurora.1.22.2, 5.7.mysql_aurora.2.07.3, 5.6.mysql_aurora.1.22.1, 5.7.mysql_aurora.2.07.2, 5.6.mysql_aurora.1.23.0, 5.7.mysql_aurora.2.08.0, 5.6.mysql_aurora.1.23.1, 5.7.mysql_aurora.2.08.1, 5.7.mysql_aurora.2.08.2, 5.7.mysql_aurora.2.08.3, 5.7.mysql_aurora.2.09.0, 5.7.mysql_aurora.2.08.4, 8.0.mysql_aurora.3.01.0, and later versions</td>
<td></td>
</tr>
</tbody>
</table>

For Linux, macOS, or Unix:

```bash
aws rds create-global-cluster --region primary_region \ 
  --global-cluster-identifier global_database_id \ 
  --engine aurora \ 
  --engine-version version # optional
```

For Windows:

```bash
aws rds create-global-cluster ^
  --global-cluster-identifier global_database_id ^
  --engine aurora ^
  --engine-version version # optional
```

This creates an "empty" Aurora global database, with just a name (identifier) and Aurora database engine. It can take a few minutes for the Aurora global database to be available. Before going to the next step, use the `describe-global-clusters` CLI command to see if it's available.

```bash
aws rds describe-global-clusters --region primary_region --global-cluster-identifier global_database_id
```

When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the `create-db-cluster` CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier`.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster \ 
  --region primary_region \ 
  --db-cluster-identifier db_cluster_id \ 
  --master-username userid \ 
  --master-user-password password \ 
  --engine { aurora | aurora-mysql } \ 
  --engine-mode global # Required for --engine-version 5.6.10a only \ 
  --engine-version version \ 
  --global-cluster-identifier global_database_id
```

For Windows:
Getting started with Aurora global databases

aws rds create-db-cluster
  --region primary_region
  --db-cluster-identifier db_cluster_id
  --master-username userid
  --master-user-password password
  --engine { aurora | aurora-mysql }
  --engine-mode global # Required for --engine-version 5.6.10a only
  --engine-version version
  --global-cluster-identifier global_database_id

Other options for Aurora MySQL depend on the version of the Aurora MySQL database engine.

Use the describe-db-clusters AWS CLI command to confirm that the Aurora DB cluster is ready. To single out a specific Aurora DB cluster, use --db-cluster-identifier parameter. Or you can leave out the Aurora DB cluster name in the command to get details about all your Aurora DB clusters in the given Region.

aws rds describe-db-clusters --region primary_region --db-cluster-identifier db_cluster_id

When the response shows "Status": "available" for the cluster, it’s ready to use.

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the create-db-instance CLI command. Give the command your Aurora DB cluster's name, and specify the configuration details for the instance. You don't need to pass the --master-username and --master-user-password parameters in the command, because it gets those from the Aurora DB cluster.

For the --db-instance-class, you can use only those from the memory optimized classes, such as db.r5.large. We recommend that you use a db.r5 or higher instance class. For information about these classes, see DB instance classes.

For Linux, macOS, or Unix:

aws rds create-db-instance
  --db-cluster-identifier db_cluster_id
  --db-instance-class instance_class
  --db-instance-identifier db_instance_id
  --engine { aurora | aurora-mysql }
  --engine-mode global # Required for --engine-version 5.6.10a only
  --engine-version version
  --region primary_region

For Windows:

aws rds create-db-instance
  --db-cluster-identifier db_cluster_id
  --db-instance-class instance_class
  --db-instance-identifier db_instance_id
  --engine { aurora | aurora-mysql }
  --engine-mode global # Required for --engine-version 5.6.10a only
  --engine-version version
  --region primary_region

The create-db-instance operation might take some time to complete. Check the status to see if the Aurora DB instance is available before continuing.

aws rds describe-db-clusters --db-cluster-identifier sample_secondary_db_cluster
When the command returns a status of "available," you can create another Aurora DB instance for your primary DB cluster. This is the reader instance (the Aurora Replica) for the Aurora DB cluster.

4. To create another Aurora DB instance for the cluster, use the `create-db-instance` CLI command.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
  --db-cluster-identifier sample_secondary_db_cluster
  --db-instance-class instance_class
  --db-instance-identifier sample_replica_db
  --engine aurora
```

For Windows:

```bash
aws rds create-db-instance ^
  --db-cluster-identifier sample_secondary_db_cluster ^
  --db-instance-class instance_class ^
  --db-instance-identifier sample_replica_db ^
  --engine aurora
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the `describe-db-instances` CLI command.

At this point, you have an Aurora global database with its primary Aurora DB cluster containing a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in Adding an AWS Region to an Amazon Aurora global database (p. 168).

Creating a global database using Aurora PostgreSQL

When you create Aurora objects for an Aurora global database by using the following commands, it can take a few minutes for each to become available. We recommend that after completing any given command, you check the specific Aurora object’s status to make sure that the status is available.

To do so, use the `describe-global-clusters` CLI command.

```bash
aws rds describe-global-clusters --region primary_region
  --global-cluster-identifier global_database_id
```

To create an Aurora global database using Aurora PostgreSQL

1. Use the `create-global-cluster` CLI command.

For Linux, macOS, or Unix:

```bash
aws rds create-global-cluster --region primary_region
  --global-cluster-identifier global_database_id
  --engine aurora-postgresql
  --engine-version version # optional
```

For Windows:

```bash
aws rds create-global-cluster ^
  --global-cluster-identifier global_database_id ^
  --engine aurora-postgresql ^
  --engine-version version # optional
```
When the Aurora global database is available, you can create its primary Aurora DB cluster.

2. To create a primary Aurora DB cluster, use the `create-db-cluster` CLI command. Include the name of your Aurora global database by using the `--global-cluster-identifier`.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster \
--region primary_region \
--db-cluster-identifier db_cluster_id \
--master-username userid \
--master-user-password password \
--engine aurora-postgresql \
--engine-version version \
--global-cluster-identifier global_database_id
```

For Windows:

```bash
aws rds create-db-cluster ^
--region primary_region  ^
--db-cluster-identifier db_cluster_id ^
--master-username userid ^
--master-user-password password ^
--engine aurora-postgresql ^
--engine-version version ^
--global-cluster-identifier global_database_id
```

Check that the Aurora DB cluster is ready. When the response from the following command shows "Status": "available" for the Aurora DB cluster, you can continue.

```bash
aws rds describe-db-clusters --region primary_region --db-cluster-identifier db_cluster_id
```

3. Create the DB instance for your primary Aurora DB cluster. To do so, use the `create-db-instance` CLI command.

- Pass the name of your Aurora DB cluster with the `--db-instance-identifier` parameter.

You don't need to pass the `--master-username` and `--master-user-password` parameters in the command, because it gets those from the Aurora DB cluster.

For the `--db-instance-class`, you can use only those from the memory optimized classes, such as `db.r5.large`. We recommend that you use a `db.r5` or higher instance class. For information about these classes, see DB instance classes.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
--db-cluster-identifier db_cluster_id \
--db-instance-class instance_class \
--db-instance-identifier db_instance_id \
--engine aurora-postgresql \
--engine-version version \
--region primary_region
```

For Windows:

```bash
aws rds create-db-instance ^
```
4. Check the status of the Aurora DB instance before continuing.

```
aws rds describe-db-clusters --db-cluster-identifier sample_secondary_db_cluster
```

If the response shows that Aurora DB instance status is "available," you can create another Aurora DB instance for your primary DB cluster.

5. To create an Aurora Replica for Aurora DB cluster, use the `create-db-instance` CLI command.

For Linux, macOS, or Unix:

```
aws rds create-db-instance
  --db-cluster-identifier sample_secondary_db_cluster
  --db-instance-class instance_class
  --db-instance-identifier sample_replica_db
  --engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance
  --db-cluster-identifier sample_secondary_db_cluster
  --db-instance-class instance_class
  --db-instance-identifier sample_replica_db
  --engine aurora-postgresql
```

When the DB instance is available, replication begins from the writer node to the replica. Before continuing, check that the DB instance is available with the `describe-db-instances` CLI command.

Your Aurora global database exists, but it has only its primary Region with an Aurora DB cluster made up of a writer DB instance and an Aurora Replica. You can now add a read-only Aurora DB cluster in a different Region to complete your Aurora global database. To do so, follow the steps in Adding an AWS Region to an Amazon Aurora global database (p. 168).

RDS API

To create an Aurora global database with the RDS API, run the **CreateGlobalCluster** operation.

**Adding an AWS Region to an Amazon Aurora global database**

An Aurora global database needs at least one secondary Aurora DB cluster in a different AWS Region than the primary Aurora DB cluster. You can attach up to five secondary DB clusters to your Aurora global database. For each secondary DB cluster that you add to your Aurora global database, reduce the number of Aurora Replicas allowed to the primary DB cluster by one.

For example, if your Aurora global database has 5 secondary Regions, your primary DB cluster can have only 10 (rather than 15) Aurora Replicas. For more information, see Configuration requirements of an Amazon Aurora global database (p. 154).

The number of Aurora Replicas (reader instances) in the primary DB cluster determines the number of secondary DB clusters you can add. The total number of reader instances in the primary DB cluster
plus the number of secondary clusters can't exceed 15. For example, if you have 14 reader instances in the primary DB cluster and 1 secondary cluster, you can't add another secondary cluster to the global database.

**Note**
For Aurora MySQL version 3, when you create a secondary cluster, make sure that the value of `lower_case_table_names` matches the value in the primary cluster. This setting is a database parameter that affects how the server handles identifier case sensitivity. For more information about database parameters, see *Working with parameter groups* (p. 215).

**Console**

**To add an AWS Region to an Aurora global database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane of the AWS Management Console, choose **Databases**.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is **Available**.
4. For **Actions**, choose **Add region**.

5. On the **Add a region** page, choose the secondary AWS Region.

You can't choose an AWS Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.

6. Complete the remaining fields for the secondary Aurora cluster in the new AWS Region. These are the same configuration options as for any Aurora DB cluster instance, except for the following option for Aurora MySQL–based Aurora global databases only:
• Enable read replica write forwarding – This optional setting lets your Aurora global database's secondary DB clusters forward write operations to the primary cluster. For more information, see Using write forwarding in an Amazon Aurora global database (p. 181).

7. Add region.

After you finish adding the Region to your Aurora global database, you can see it in the list of Databases in the AWS Management Console as shown in the screenshot.

AWS CLI

To add a secondary AWS Region to an Aurora global database

1. Use the create-db-cluster CLI command with the name (--global-cluster-identifier) of your Aurora global database. For other parameters, do the following:

2. For --region, choose a different AWS Region than that of your Aurora primary Region.

3. Do one of the following:

   • For an Aurora global database based on Aurora MySQL5.6.10a only, use the following parameters:
     • --engine – aurora
     • --engine-mode – global
     • --engine-version – 5.6.10a
For an Aurora global database based on other Aurora DB engines, choose specific values for the `--engine` and `--engine-version` parameters. These values are the same as those for the primary Aurora DB cluster in your Aurora global database.

The following table displays current options.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Aurora MySQL 5.6</th>
<th>Aurora MySQL 5.7</th>
<th>Aurora PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--engine</code></td>
<td><code>aurora</code></td>
<td><code>aurora-mysql</code></td>
<td><code>aurora-postgresql</code></td>
</tr>
<tr>
<td><code>--engine-version</code></td>
<td>5.6.mysql_aurora.1.22.0, 5.6.mysql_aurora.1.22.1, 5.6.mysql_aurora.1.22.2, 5.6.mysql_aurora.1.22.3, 5.6.mysql_aurora.1.23.0, 5.6.mysql_aurora.1.23.1</td>
<td>5.7.mysql_aurora.2.07.0, 5.7.mysql_aurora.2.07.1, 5.7.mysql_aurora.2.07.2, 5.7.mysql_aurora.2.07.3, 5.7.mysql_aurora.2.08.0, 5.7.mysql_aurora.2.08.1, 5.7.mysql_aurora.2.08.2, 5.7.mysql_aurora.2.08.3, 5.7.mysql_aurora.2.09.0 (and later)</td>
<td>10.11 (and later), 11.7 (and later), 12.4 (and later)</td>
</tr>
</tbody>
</table>

4. For an encrypted cluster, specify your primary AWS Region as the `--source-region` for encryption.

The following example creates a new Aurora DB cluster and attaches it to an Aurora global database as a read-only secondary Aurora DB cluster. In the last step, an Aurora DB instance is added to the new Aurora DB cluster.

For Linux, macOS, or Unix:

```
aws rds --region secondary_region \
create-db-cluster \
  --db-cluster-identifier secondary_cluster_id \
  --global-cluster-identifier global_database_id \
  --engine { aurora | aurora-mysql | aurora-postgresql } \
  --engine-version version
aws rds --region secondary_region \
create-db-instance \
  --db-instance-class instance_class \
  --db-cluster-identifier secondary_cluster_id \
  --db-instance-identifier db_instance_id \
  --engine { aurora | aurora-mysql | aurora-postgresql }
```

For Windows:

```
aws rds --region secondary_region ^
create-db-cluster ^
  --db-cluster-identifier secondary_cluster_id ^
  --global-cluster-identifier global_database_id ^
  --engine { aurora | aurora-mysql | aurora-postgresql } ^
  --engine-version version
aws rds --region secondary_region ^
create-db-instance ^
  --db-instance-class instance_class ^
  --db-cluster-identifier secondary_cluster_id ^
  --db-instance-identifier db_instance_id ^
  --engine { aurora | aurora-mysql | aurora-postgresql }
```
RDS API

To add a new AWS Region to an Aurora global database with the RDS API, run the CreateDBCluster operation. Specify the identifier of the existing global database using the GlobalClusterIdentifier parameter.

Creating a headless Aurora DB cluster in a secondary Region

Although an Aurora global database requires at least one secondary Aurora DB cluster in a different AWS Region than the primary, you can use a headless configuration for the secondary cluster. A headless secondary Aurora DB cluster is one without a DB instance. This type of configuration can lower expenses for an Aurora global database. In an Aurora DB cluster, compute and storage are decoupled. Without the DB instance, you're not charged for compute, only for storage. If it's set up correctly, a headless secondary's storage volume is kept in-sync with the primary Aurora DB cluster.

You add the secondary cluster as you normally do when creating an Aurora global database. However, after the primary Aurora DB cluster begins replication to the secondary, you delete the Aurora read-only DB instance from the secondary Aurora DB cluster. This secondary cluster is now considered "headless" because it no longer has a DB instance. Yet, the storage volume is kept in sync with the primary Aurora DB cluster.

Warning
With Aurora PostgreSQL, to create a headless cluster in a secondary AWS Region, use the AWS CLI or RDS API to add the secondary AWS Region. Skip the step to create the reader DB instance for the secondary cluster. Currently, creating a headless cluster isn't supported in the RDS Console. For the CLI and API procedures to use, see Adding an AWS Region to an Amazon Aurora global database (p. 168).

Creating a reader DB instance in a secondary Region and subsequently deleting it could lead to an Aurora PostgreSQL vacuum issue on the primary Region's writer DB instance. If you encounter this issue, restart the primary Region's writer DB instance after you delete the secondary Region's reader DB instance.

To add a headless secondary Aurora DB cluster to your Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane of the AWS Management Console, choose Databases.
3. Choose the Aurora global database that needs a secondary Aurora DB cluster. Ensure that the primary Aurora DB cluster is Available.
4. For Actions, choose Add region.
5. On the Add a region page, choose the secondary AWS Region.

   You can't choose an AWS Region that already has a secondary Aurora DB cluster for the same Aurora global database. Also, it can't be the same Region as the primary Aurora DB cluster.

6. Complete the remaining fields for the secondary Aurora cluster in the new AWS Region. These are the same configuration options as for any Aurora DB cluster instance.

   For an Aurora MySQL–based Aurora global database, disregard the Enable read replica write forwarding option. This option has no function after you delete the reader instance.

7. Add region. After you finish adding the Region to your Aurora global database, you can see it in the list of Databases in the AWS Management Console as shown in the screenshot.
8. Check the status of the secondary Aurora DB cluster and its reader instance before continuing, by using the AWS Management Console or the AWS CLI. For example:

```
# aws rds describe-db-clusters --db-cluster-identifier secondary-cluster-id --query '[].[].[Status]' --output text
```

It can take several minutes for the status of a newly added secondary Aurora DB cluster to change from creating to available. When the Aurora DB cluster is available, you can delete the reader instance.

9. Select the reader instance in the secondary Aurora DB cluster, and then choose Delete.

After deleting the reader instance, the secondary cluster remains part of the Aurora global database. It has no instance associated with it, as shown following.
You can use this headless secondary Aurora DB cluster to manually recover your Amazon Aurora global database from an unplanned outage in the primary AWS Region (p. 193) if such an outage occurs.

Using a snapshot for your Amazon Aurora global database

You can restore a snapshot of an Aurora DB cluster or from an Amazon RDS DB instance to use as the starting point for your Aurora global database. You restore the snapshot and create a new Aurora provisioned DB cluster at the same time. You then add another AWS Region to the restored DB cluster, thus turning it into an Aurora global database. Any Aurora DB cluster that you create using a snapshot in this way becomes the primary cluster of your Aurora global database.

The snapshot that you use can be from a provisioned or from a serverless Aurora DB cluster.

**Note**

You can't create a provisioned Aurora DB cluster from a snapshot made from an Aurora MySQL 5.6.10a–based global database. A snapshot from an Aurora MySQL 5.6.10a–based global database can only be restored as an Aurora global database.

During the restore process, choose the same DB engine type as the snapshot. For example, suppose that you want to restore a snapshot that was made from an Aurora Serverless DB cluster running Aurora PostgreSQL. In this case, you create an Aurora PostgreSQL DB cluster using that same Aurora DB engine and version.

The restored DB cluster assumes the role of primary cluster for Aurora global database when you add an AWS Regions to it. All data contained in this primary cluster is replicated to any secondary clusters that you add to your Aurora global database.
Managing an Amazon Aurora global database

With the exception of the managed planned failover process, you perform most management operations on the individual clusters that make up an Aurora global database. When you choose **Group related resources** on the **Databases** page in the console, you see the primary cluster and secondary clusters grouped under the associated global database. To find the AWS Regions where a global database's DB clusters are running, its Aurora DB engine and version, and its identifier, use its **Configuration** tab.

The managed planned failover process is available to Aurora global database objects only, not for a single Aurora DB cluster. To learn more, see **Performing managed planned failovers for Amazon Aurora global databases** (p. 194).

To recover an Aurora global database from an unplanned outage in its primary Region, see **Using failover in an Amazon Aurora global database** (p. 192).

**Topics**

- Modifying an Amazon Aurora global database (p. 175)
- Modifying parameters for an Aurora global database (p. 176)
- Removing a cluster from an Amazon Aurora global database (p. 177)
- Deleting an Amazon Aurora global database (p. 179)

**Modifying an Amazon Aurora global database**

The **Databases** page in the AWS Management Console lists all your Aurora global databases, showing the primary cluster and secondary clusters for each one. The Aurora global database has its own
configuration settings. Specifically, it has AWS Regions associated with its primary and secondary clusters, as shown in the screenshot following.

When you make changes to the Aurora global database, you have a chance to cancel changes, as shown in the following screenshot.

When you choose **Continue**, you confirm the changes.

**Modifying parameters for an Aurora global database**

You can configure the Aurora DB cluster parameter groups independently for each Aurora cluster within the Aurora global database. Most parameters work the same as for other kinds of Aurora clusters. We recommend that you keep settings consistent among all the clusters in a global database. Doing this helps to avoid unexpected behavior changes if you promote a secondary cluster to be the primary.

For example, use the same settings for time zones and character sets to avoid inconsistent behavior if a different cluster takes over as the primary cluster.
Removing a cluster from an Amazon Aurora global database

You can remove Aurora DB clusters from your Aurora global database for several different reasons. For example, you might want to remove an Aurora DB cluster from an Aurora global database if the primary cluster becomes degraded or isolated. It then becomes a standalone provisioned Aurora DB cluster that could be used to create a new Aurora global database. To learn more, see Recovering an Amazon Aurora global database from an unplanned outage (p. 193).

You also might want to remove Aurora DB clusters because you want to delete an Aurora global database that you no longer need. You can’t delete the Aurora global database until after you remove (detach) all associated Aurora DB clusters, leaving the primary for last. For more information, see Deleting an Amazon Aurora global database (p. 179).

When an Aurora DB cluster is detached from the Aurora global database, it’s no longer synchronized with the primary. It becomes a standalone provisioned Aurora DB cluster with full read/write capabilities.

You can remove Aurora DB clusters from your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To remove an Aurora cluster from an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the cluster on the Databases page.
3. For Actions, choose Remove from Global.

You see a prompt to confirm that you want to detach the secondary from the Aurora global database.
4. Choose **Remove and promote** to remove the cluster from the global database.

The Aurora DB cluster is no longer serving as a secondary in the Aurora global database, and is no longer synchronized with the primary DB cluster. It is a standalone Aurora DB cluster with full read/write capability.

After you remove or delete all secondary clusters, then you can remove the primary cluster the same way. You can’t detach (remove) the primary Aurora DB cluster from an Aurora global database until after you remove all secondary clusters.

The Aurora global database might remain in the **Databases** list, with zero Regions and AZs. You can delete if you no longer want to use this Aurora global database. For more information, see Deleting an Amazon Aurora global database (p. 179).

**AWS CLI**

To remove an Aurora cluster from an Aurora global database, run the `remove-from-global-cluster` CLI command with the following parameters:

- `--global-cluster-identifier` – The name (identifier) of your Aurora global database.
- `--db-cluster-identifier` – The name of each Aurora DB cluster to remove from the Aurora global database. Remove all secondary Aurora DB clusters before removing the primary.

The following examples first remove a secondary cluster and then the primary cluster from an Aurora global database.

For Linux, macOS, or Unix:

```
aws rds --region secondary_region \
    remove-from-global-cluster \
    --db-cluster-identifier secondary_cluster_ARN \
    --global-cluster-identifier global_database_id
```

```
aws rds --region primary_region \
```
remove-from-global-cluster
  --db-cluster-identifier primary_cluster_ARN
  --global-cluster-identifier global_database_id

Repeat the `remove-from-global-cluster --db-cluster-identifier secondary_cluster_ARN` command for each secondary AWS Region in your Aurora global database.

For Windows:

```
aws rds --region secondary_region
  remove-from-global-cluster
    --db-cluster-identifier secondary_cluster_ARN
    --global-cluster-identifier global_database_id

aws rds --region primary_region
  remove-from-global-cluster
    --db-cluster-identifier primary_cluster_ARN
    --global-cluster-identifier global_database_id
```

Repeat the `remove-from-global-cluster --db-cluster-identifier secondary_cluster_ARN` command for each secondary AWS Region in your Aurora global database.

RDS API

To remove an Aurora cluster from an Aurora global database with the RDS API, run the `RemoveFromGlobalCluster` action.

Deleting an Amazon Aurora global database

Because an Aurora global database typically holds business-critical data, you can't delete the global database and its associated clusters in a single step. To delete an Aurora global database, do the following:

- Remove all secondary DB clusters from the Aurora global database. Each cluster becomes a standalone Aurora DB cluster. To learn how, see Removing a cluster from an Amazon Aurora global database (p. 177).
- From each standalone Aurora DB cluster, delete all Aurora Replicas.
- Remove the primary DB cluster from the Aurora global database. This becomes a standalone Aurora DB cluster.
- From the Aurora primary DB cluster, first delete all Aurora Replicas, then delete the writer DB instance.

Deleting the writer instance from the newly standalone Aurora DB cluster also typically removes the Aurora DB cluster and the Aurora global database.

For more general information, see Deleting a DB instance from an Aurora DB cluster (p. 350).

To delete an Aurora global database, you can use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To delete an Aurora global database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases and find the Aurora global database you want to delete in the listing.
3. Confirm that all clusters are removed from the Aurora global database. The Aurora global database should show 0 Regions and AZs and a size of 0 clusters.

   If the Aurora global database contains any Aurora DB clusters, you can't delete it. If necessary, detach the primary and secondary Aurora DB clusters from the Aurora global database. For more information, see Removing a cluster from an Amazon Aurora global database (p. 177).

4. Choose your Aurora global database in the list, and then choose **Delete** from the Actions menu.

![AWS CLI](Image)

**AWS CLI**

To delete an Aurora global database, run the `delete-global-cluster` CLI command with the name of the AWS Region and the Aurora global database identifier, as shown in the following example.

For Linux, macOS, or Unix:

```bash
aws rds --region primary_region delete-global-cluster \
   --global-cluster-identifier global_database_id
```

For Windows:

```bash
aws rds --region primary_region delete-global-cluster ^
   --global-cluster-identifier global_database_id
```

**RDS API**

To delete a cluster that is part of an Aurora global database, run the `DeleteGlobalCluster` API operation.

**Connecting to an Amazon Aurora global database**

How you connect to an Aurora global database depends on whether you need to write to the database or read from the database:

- For read-only requests or queries, you connect to the reader endpoint for the Aurora cluster in your AWS Region.
- To run data manipulation language (DML) or data definition language (DDL) statements, you connect to the cluster endpoint for the primary cluster. This endpoint might be in a different AWS Region than your application.

When you view an Aurora global database in the console, you can see all the general-purpose endpoints associated with all of its clusters. The following screenshot shows an example. There is a single cluster endpoint associated with the primary cluster that you use for write operations. The primary cluster and each secondary cluster has a reader endpoint that you use for read-only queries. To minimize latency, choose whichever reader endpoint is in your AWS Region or the AWS Region closest to you. The following shows an Aurora MySQL example.
Using write forwarding in an Amazon Aurora global database

You can reduce the number of endpoints that you need to manage for applications running on your Aurora global database, by using write forwarding. This feature of Aurora MySQL lets secondary clusters in an Aurora global database forward SQL statements that perform write operations to the primary cluster. The primary cluster updates the source and then propagates resulting changes back to all secondary AWS Regions.

The write forwarding configuration saves you from implementing your own mechanism to send write operations from a secondary AWS Region to the primary Region. Aurora handles the cross-Region networking setup. Aurora also transmits all necessary session and transactional context for each statement. The data is always changed first on the primary cluster and then replicated to the secondary clusters in the Aurora global database. This way, the primary cluster is the source of truth and always has an up-to-date copy of all your data.

**Note**
Write forwarding requires Aurora MySQL version 2.08.1 or later.

**Topics**
- Enabling write forwarding (p. 181)
- Checking if a secondary cluster has write forwarding enabled (p. 183)
- Application and SQL compatibility with write forwarding (p. 184)
- Isolation and consistency for write forwarding (p. 185)
- Running multipart statements with write forwarding (p. 188)
- Transactions with write forwarding (p. 188)
- Configuration parameters for write forwarding (p. 188)
- Amazon CloudWatch metrics for write forwarding (p. 189)

**Enabling write forwarding**

By default, write forwarding isn't enabled when you add a secondary cluster to an Aurora global database.

To enable write forwarding using the AWS Management Console, choose the **Enable read replica write forwarding** option when you add a Region for a global database. For an existing secondary cluster, modify the cluster to use the **Enable read replica write forwarding** option. To turn off write forwarding, clear the **Enable read replica write forwarding** check box when adding the Region or modifying the secondary cluster.

To enable write forwarding using the AWS CLI, use the `--enable-global-write-forwarding` option. This option works when you create a new secondary cluster using the `create-db-cluster` command. It also works when you modify an existing secondary cluster using the `modify-db-cluster` command. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by using the `--no-enable-global-write-forwarding` option with these same CLI commands.
To enable write forwarding using the Amazon RDS API, set the `EnableGlobalWriteForwarding` parameter to `true`. This parameter works when you create a new secondary cluster using the `CreateDBCluster` operation. It also works when you modify an existing secondary cluster using the `ModifyDBCluster` operation. It requires that the global database uses an Aurora version that supports write forwarding. You can turn write forwarding off by setting the `EnableGlobalWriteForwarding` parameter to `false`.

**Note**
For a database session to use write forwarding, you also specify a setting for the `aurora_replica_read_consistency` configuration parameter. Do this in every session that uses the write forwarding feature. For information about this parameter, see [Isolation and consistency for write forwarding](p. 185).

The following CLI examples show how you can set up an Aurora global database with write forwarding enabled or disabled. The highlighted items represent the commands and options that are important to specify and keep consistent when setting up the infrastructure for an Aurora global database.

The following example creates an Aurora global database, a primary cluster, and a secondary cluster with write forwarding enabled. Substitute your own choices for the user name, password, and primary and secondary AWS Regions.

```bash
# Create overall global database.
aws rds create-global-cluster --global-cluster-identifier write-forwarding-test \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
    --region us-east-1

# Create primary cluster, in the same AWS Region as the global database.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
    --db-cluster-identifier write-forwarding-test-cluster-1 \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
    --master-username my_user_name --master-user-password my_password \
    --region us-east-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \
    --db-instance-identifier write-forwarding-test-cluster-1-instance-1 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
    --region us-east-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-1 \
    --db-instance-identifier write-forwarding-test-cluster-1-instance-2 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
    --region us-east-1

# Create secondary cluster, in a different AWS Region than the global database, 
# with write forwarding enabled.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
    --db-cluster-identifier write-forwarding-test-cluster-2 \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
    --region us-east-2 \
    --enable-global-write-forwarding

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-1 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
    --region us-east-2

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
    --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
    --db-instance-class db.r5.large \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
    --region us-east-2
```

182
The following example continues from the previous one. It creates a secondary cluster without write forwarding enabled, then enables write forwarding. After this example finishes, all secondary clusters in the global database have write forwarding enabled.

```bash
# Create secondary cluster, in a different AWS Region than the global database, # without write forwarding enabled.
aws rds create-db-cluster --global-cluster-identifier write-forwarding-test \
  --db-cluster-identifier write-forwarding-test-cluster-2 \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
  --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
  --db-instance-identifier write-forwarding-test-cluster-2-instance-1 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
  --region us-west-1

aws rds create-db-instance --db-cluster-identifier write-forwarding-test-cluster-2 \
  --db-instance-identifier write-forwarding-test-cluster-2-instance-2 \
  --db-instance-class db.r5.large \
  --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.08.1 \
  --region us-west-1

aws rds modify-db-cluster --db-cluster-identifier write-forwarding-test-cluster-2 \
  --region us-east-2 \
  --enable-global-write-forwarding

Checking if a secondary cluster has write forwarding enabled

To determine whether you can use write forwarding from a secondary cluster, you can check whether the cluster has the attribute "GlobalWriteForwardingStatus": "enabled".

In the AWS Management Console, you see Read replica write forwarding on the Configuration tab of the details page for the cluster. To see the status of the global write forwarding setting for all of your clusters, run the following AWS CLI command.

A secondary cluster shows the value "enabled" or "disabled" to indicate if write forwarding is turned on or off. A value of null indicates that write forwarding isn’t available for that cluster. Either the cluster isn’t part of a global database, or is the primary cluster instead of a secondary cluster. The value can also be "enabling" or "disabling" if write forwarding is in the process of being turned on or off.

Example

```bash
aws rds describe-db-clusters --query '.*'.
(DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus)' [ 
  { 
    "GlobalWriteForwardingStatus": "enabled", 
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
  }, 
  { 
    "GlobalWriteForwardingStatus": "disabled", 
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-2"
  }, 
  { 
    "GlobalWriteForwardingStatus": null, 
    "DBClusterIdentifier": "non-global-cluster"
  }
]
To find all secondary clusters that have global write forwarding enabled, run the following command. This command also returns the cluster's reader endpoint. You use the secondary cluster's reader endpoint to when you use write forwarding from the secondary to the primary in your Aurora global database.

Example

```bash
aws rds describe-db-clusters --query 'DBClusters[].
  {DBClusterIdentifier:DBClusterIdentifier,GlobalWriteForwardingStatus:GlobalWriteForwardingStatus,ReaderEndpoint:ReaderEndpoint}
  | [?GlobalWriteForwardingStatus == `enabled`]'
[
  {
    "GlobalWriteForwardingStatus": "enabled",
    "ReaderEndpoint": "aurora-write-forwarding-test-replica-1.cluster-ro-cnpexample.us-west-2.rds.amazonaws.com",
    "DBClusterIdentifier": "aurora-write-forwarding-test-replica-1"
  }
]
```

Application and SQL compatibility with write forwarding

Certain statements aren't allowed or can produce stale results when you use them in a global database with write forwarding. Thus, the EnableGlobalWriteForwarding setting is turned off by default for secondary clusters. Before turning it on, check to make sure that your application code isn't affected by any of these restrictions.

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as `INSERT`, `DELETE`, and `UPDATE`. There are some restrictions on the properties of these statements that you can use with write forwarding, as described following.
- `SELECT ... LOCK IN SHARE MODE` and `SELECT FOR UPDATE` statements.
- `PREPARE` and `EXECUTE` statements.

The following restrictions apply to the SQL statements you use with write forwarding. In some cases, you can use the statements on secondary clusters with write forwarding enabled at the cluster level. This approach works if write forwarding isn't turned on within the session by the `aurora_replica_read_consistency` configuration parameter. Trying to use a statement when it's not allowed because of write forwarding causes an error message with the following format.

```
ERROR 1235 (42000): This version of MySQL doesn't yet support 'operation with write forwarding'.
```

Data definition language (DDL)

Connect to the primary cluster to run DDL statements.

Updating a permanent table using data from a temporary table

You can use temporary tables on secondary clusters with write forwarding enabled. However, you can't use a DML statement to modify a permanent table if the statement refers to a temporary table. For example, you can't use an `INSERT ... SELECT` statement that takes the data from a temporary table. The temporary table exists on the secondary cluster and isn't available when the statement runs on the primary cluster.

XA transactions

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting
is empty. Before turning on write forwarding within a session, check if your code uses these statements.

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER [CONVERT XID]
```

**LOAD statements for permanent tables**

You can't use the following statements on a secondary cluster with write forwarding enabled.

```
LOAD DATA INFILE 'data.txt' INTO TABLE t1;
LOAD XML LOCAL INFILE 'test.xml' INTO TABLE t1;
```

You can load data into a temporary table on a secondary cluster. However, make sure that you run any LOAD statements that refer to permanent tables only on the primary cluster.

**Plugin statements**

You can't use the following statements on a secondary cluster with write forwarding enabled.

```
INSTALL PLUGIN example SONAME 'ha_example.so';
UNINSTALL PLUGIN example;
```

**SAVEPOINT statements**

You can't use the following statements on a secondary cluster when write forwarding is turned on within the session. You can use these statements on secondary clusters that don't have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is blank. Check if your code uses these statements before turning on write forwarding within a session.

```
SAVEPOINT t1_save;
ROLLBACK TO SAVEPOINT t1_save;
RELEASE SAVEPOINT t1_save;
```

**Isolation and consistency for write forwarding**

In sessions that use write forwarding, you can only use the REPEATABLE READ isolation level. Although you can also use the READ COMMITTED isolation level with read-only clusters in secondary AWS Regions, that isolation level doesn't work with write forwarding. For information about the REPEATABLE READ and READ COMMITTED isolation levels, see Aurora MySQL isolation levels (p. 979).

You can control the degree of read consistency on a secondary cluster. The read consistency level determines how much waiting the secondary cluster does before each read operation to ensure that some or all changes are replicated from the primary cluster. You can adjust the read consistency level to ensure that all forwarded write operations from your session are visible in the secondary cluster before any subsequent queries. You can also use this setting to ensure that queries on the secondary cluster always see the most current updates from the primary cluster. This is so even for those submitted by other sessions or other clusters. To specify this type of behavior for your application, you choose a value for the session-level parameter `aurora_replica_read_consistency`.

**Important**

Always set the `aurora_replica_read_consistency` parameter for any session for which you want to forward writes. If you don't, Aurora doesn't enable write forwarding for that session. This parameter has an empty value by default, so choose a specific value when you use
this parameter. The `aurora_replica_read_consistency` parameter has an effect only on secondary clusters that have write forwarding enabled.

For the `aurora_replica_read_consistency` parameter, you can specify the values `EVENTUAL`, `SESSION`, and `GLOBAL`.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between AWS Regions. You can choose the balance between fast response time and ensuring that changes made in other locations are fully available before your queries run.

With the read consistency set to `EVENTUAL`, queries in a secondary AWS Region that uses write forwarding might see data that is slightly stale due to replication lag. Results of write operations in the same session aren’t visible until the write operation is performed on the primary Region and replicated to the current Region. The query doesn’t wait for the updated results to be available. Thus, it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag.

With the read consistency set to `SESSION`, all queries in a secondary AWS Region that uses write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated to the current Region. It doesn’t wait for updated results from write operations performed in other Regions or in other sessions within the current Region.

With the read consistency set to `GLOBAL`, a session in a secondary AWS Region sees changes made by that session. It also sees all committed changes from both the primary AWS Region and other secondary AWS Regions. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the secondary cluster is up-to-date with all committed data from the primary cluster, as of the time that the query began.

For more information about all the parameters involved with write forwarding, see Configuration parameters for write forwarding (p. 188).

**Examples of using write forwarding**

In the following example, the primary cluster is in the US East (N. Virginia) Region. The secondary cluster is in the US East (Ohio) Region. The example shows the effects of running `INSERT` statements followed by `SELECT` statements. Depending on the value of the `aurora_replica_read_consistency` setting, the results might differ depending on the timing of the statements. To achieve higher consistency, you might wait briefly before issuing the `SELECT` statement. Or Aurora can automatically wait until the results finish replicating before proceeding with `SELECT`.

In this example, there is a read consistency setting of `eventual`. Running an `INSERT` statement immediately followed by a `SELECT` statement still returns the value of `COUNT(*)`. This value reflects the number of rows before the new row is inserted. Running the `SELECT` again a short time later does return the updated row count. The `SELECT` statements don’t do any waiting.

```
mysql> set aurora_replica_read_consistency = 'eventual';
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        5 |
+----------+
1 row in set (0.00 sec)
mysql> insert into t1 values (6); select count(*) from t1;
+----------+
| count(*) |
+----------+
|        5 |
+----------+
1 row in set (0.00 sec)
```
**Using write forwarding in an Aurora global database**

```
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        6 |
+----------+
1 row in set (0.00 sec)
```

With a read consistency setting of `session`, a `SELECT` statement immediately after an `INSERT` does not wait until the changes from the `INSERT` statement are visible. Subsequent `SELECT` statements don't do any waiting.

```
mysql> set aurora_replica_read_consistency = 'session';
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        6 |
+----------+
1 row in set (0.01 sec)
```

```
mysql> insert into t1 values (6); select count(*) from t1;
Query OK, 1 row affected (0.08 sec)
+----------+
| count(*) |
+----------+
|        7 |
+----------+
1 row in set (0.37 sec)
```

```
mysql> insert into t1 values (6); select sleep(2); select count(*) from t1;
Query OK, 1 row affected (0.07 sec)
+----------+
| sleep(2) |
+----------+
|        0 |
+----------+
1 row in set (2.01 sec)
```

```
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        8 |
+----------+
1 row in set (0.00 sec)
```

With the read consistency setting still set to `session`, introducing a brief wait after performing an `INSERT` statement makes the updated row count available by the time the next `SELECT` statement runs.

```
mysql> set aurora_replica_read_consistency = 'global';
```

With a read consistency setting of `global`, each `SELECT` statement waits to ensure that all data changes as of the start time of the statement are visible before performing the query. The amount of waiting for each `SELECT` statement varies, depending on the amount of replication lag between the primary and secondary clusters.

```
mysql> set aurora_replica_read_consistency = 'global';
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
```

187
Running multipart statements with write forwarding

A DML statement might consist of multiple parts, such as a `INSERT ... SELECT` statement or a `DELETE ... WHERE` statement. In this case, the entire statement is forwarded to the primary cluster and run there.

Transactions with write forwarding

Whether the transaction is forwarded to the primary cluster depends on the access mode of the transaction. You can specify the access mode for the transaction by using the `SET TRANSACTION` statement or the `START TRANSACTION` statement. You can also specify the transaction access mode by changing the value of the Aurora MySQL session variable `tx_read_only`. You can only change this session value while you’re connected to a secondary cluster that has write forwarding enabled.

If a long-running transaction doesn’t issue any statement for a substantial period of time, it might exceed the idle timeout period. This period has a default of one minute. You can increase it up to one day. A transaction that exceeds the idle timeout is canceled by the primary cluster. The next subsequent statement you submit receives a timeout error. Then Aurora rolls back the transaction.

This type of error can occur in other cases when write forwarding becomes unavailable. For example, Aurora cancels any transactions that use write forwarding if you restart the primary cluster or if you turn off the write forwarding configuration setting.

Configuration parameters for write forwarding

The Aurora cluster parameter groups include settings for the write forwarding feature. Because these are cluster parameters, all DB instances in each cluster have the same values for these variables. Details about these parameters are summarized in the following table, with usage notes after the table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Scope</th>
<th>Type</th>
<th>Default value</th>
<th>Valid values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aurora_fwd_master_idle_timeout</code> (Aurora MySQL version 2)</td>
<td>Global</td>
<td>unsigned integer</td>
<td>60</td>
<td>1–86,400</td>
</tr>
<tr>
<td><code>aurora_fwd_master_max_connections</code> (Aurora MySQL version 2)</td>
<td>Global</td>
<td>unsigned integer</td>
<td>10</td>
<td>0–90</td>
</tr>
<tr>
<td><code>aurora_fwd_writer_idle_timeout</code> (Aurora MySQL version 3)</td>
<td>Global</td>
<td>unsigned integer</td>
<td>60</td>
<td>1–86,400</td>
</tr>
</tbody>
</table>
To control incoming write requests from secondary clusters, use these settings on the primary cluster:

- **aurora_fwd_master_idle_timeout**, **aurora_fwd_writer_idle_timeout**: The number of seconds the primary cluster waits for activity on a connection that's forwarded from a secondary cluster before closing it. If the session remains idle beyond this period, Aurora cancels the session.

- **aurora_fwd_master_max_connections_pct**, **aurora_fwd_writer_max_connections_pct**: The upper limit on database connections that can be used on a writer DB instance to handle queries forwarded from readers. It's expressed as a percentage of the max_connections setting for the writer DB instance in the primary cluster. For example, if max_connections is 800 and aurora_fwd_master_max_connections_pct or aurora_fwd_writer_max_connections_pct is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the max_connections setting.

This setting applies only on the primary cluster, when one or more secondary clusters have write forwarding enabled. If you decrease the value, existing connections aren't affected. Aurora takes the new value of the setting into account when attempting to create a new connection from a secondary cluster. The default value is 10, representing 10% of the max_connections value. If you enable query forwarding on any of the secondary clusters, this setting must have a nonzero value for write operations from secondary clusters to succeed. If the value is zero, the write operations receive the error code **ER_CON_COUNT_ERROR** with the message Not enough connections on writer to handle your request.

The **aurora_replica_read_consistency** parameter is a session-level parameter that enables write forwarding. You use it in each session. You can specify **EVENTUAL**, **SESSION**, or **GLOBAL** for read consistency level. To learn more about consistency levels, see Isolation and consistency for write forwarding (p. 185). The following rules apply to this parameter:

- This is a session-level parameter. The default value is " (empty).
- Write forwarding is available in a session only if aurora_replica_read_consistency is set to EVENTUAL or SESSION or GLOBAL. This parameter is relevant only in reader instances of secondary clusters that have write forwarding enabled and that are in an Aurora global database.
- You can't set this variable (when empty) or unset (when already set) inside a multistatement transaction. However, you can change it from one valid value (EVENTUAL, SESSION, or GLOBAL) to another valid value (EVENTUAL, SESSION, or GLOBAL) during such a transaction.
- The variable can't be SET when write forwarding isn't enabled on the secondary cluster.
- Setting the session variable on a primary cluster doesn't have any effect. If you try to modify this variable on a primary cluster, you receive an error.

**Amazon CloudWatch metrics for write forwarding**

The following Amazon CloudWatch metrics apply to the primary cluster when you use write forwarding on one or more secondary clusters. These metrics are all measured on the writer DB instance in the primary cluster.
<table>
<thead>
<tr>
<th>CloudWatch Metric</th>
<th>Units and description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ForwardingMasterDMLLatency</td>
<td>Milliseconds. Average time to process each forwarded DML statement on the writer DB instance. It doesn't include the time for the secondary cluster to forward the write request. It also doesn't include the time to replicate changes back to the secondary cluster. For Aurora MySQL version 2.</td>
</tr>
<tr>
<td>ForwardingMasterOpenSessions</td>
<td>Count. Number of forwarded sessions on the writer DB instance. For Aurora MySQL version 2.</td>
</tr>
<tr>
<td>ForwardingMasterDMLThroughput</td>
<td>Count, per second. Number of forwarded DML statements processed each second by this writer DB instance. For Aurora MySQL version 2.</td>
</tr>
<tr>
<td></td>
<td>Microseconds. Total duration of DML statements forwarded to this writer DB instance. For Aurora MySQL version 2.</td>
</tr>
<tr>
<td></td>
<td>Count. Total number of DML statements forwarded to this writer DB instance. For Aurora MySQL version 2.</td>
</tr>
<tr>
<td></td>
<td>Microseconds. Total duration of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 2.</td>
</tr>
<tr>
<td></td>
<td>Count. Total number of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 2.</td>
</tr>
<tr>
<td>ForwardingWriterDMLLatency</td>
<td>Milliseconds. Average time to process each forwarded DML statement on the writer DB instance. It doesn't include the time for the secondary cluster to forward the write request. It also doesn't include the time to replicate changes back to the secondary cluster. For Aurora MySQL version 3 and higher.</td>
</tr>
<tr>
<td>ForwardingWriterOpenSessions</td>
<td>Count. Number of forwarded sessions on the writer DB instance. For Aurora MySQL version 3 and higher.</td>
</tr>
<tr>
<td>ForwardingWriterDMLThroughput</td>
<td>Count, per second. Number of forwarded DML statements processed each second by this writer DB instance. For Aurora MySQL version 3 and higher.</td>
</tr>
<tr>
<td></td>
<td>Microseconds. Total duration of DML statements forwarded to this writer DB instance.</td>
</tr>
<tr>
<td></td>
<td>Count. Total number of DML statements forwarded to this writer DB instance. For Aurora MySQL version 3 and higher.</td>
</tr>
</tbody>
</table>
CloudWatch Metric                              | Units and description                                                                 |
| (Aurora MySQL status variable)               |                                                                                      |
| – (Aurora_fwd_writer_select_stmt_duration)   | Microseconds. Total duration of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 3 and higher. |
| – (Aurora_fwd_writer_select_stmt_count)      | Count. Total number of SELECT statements forwarded to this writer DB instance. For Aurora MySQL version 3 and higher. |

The following CloudWatch metrics apply to each secondary cluster. These metrics are measured on each reader DB instance in a secondary cluster with write forwarding enabled.

CloudWatch Metric                              | Unit and description                                                                 |
| (Aurora MySQL status variable)               |                                                                                      |
| ForwardingReplicaDMLLatency (-)              | Milliseconds. Average response time in milliseconds of forwarded DMLs on replica.     |
| ForwardingReplicaReadWaitLatency (-)         | Milliseconds. Average wait time in milliseconds that a SELECT statement on a reader DB instance waits to catch up to the primary cluster. The degree to which the reader DB instance waits before processing a query depends on the aurora_replica_read_consistency setting. |
| ForwardingReplicaDMLThroughput (-)           | Count (per second). Number of forwarded DML statements processed each second.          |
| ForwardingReplicaReadWaitThroughput (-)      | Count (SELECT statements per second). Total number of SELECT statements processed each second in all sessions that are forwarding writes. |
| ForwardingReplicaOpenSessions                 | Count. The number of sessions that are using write forwarding on a reader DB instance. |
| (Aurora_fwd_replica_open_sessions)           |                                                                                      |
| ForwardingReplicaSelectLatency (-)           | Milliseconds. Forwarded SELECT latency, average over all forwarded SELECT statements within the monitoring period. |
| ForwardingReplicaSelectThroughput (-)        | Count per second. Forwarded SELECT throughput, per second average within the monitoring period. |
| – (Aurora_fwd_replica_dml_stmt_count)         | Count. Total number of DML statements forwarded from this reader DB instance.          |
| – (Aurora_fwd_replica_dml_stmt_duration)      | Microseconds. Total duration of all DML statements forwarded from this reader DB instance. |
Using failover in an Amazon Aurora global database

An Aurora global database provides more comprehensive failover capabilities than the failover provided by a default Aurora DB cluster (p. 71). By using an Aurora global database, you can plan for and recover from disaster fairly quickly. Recovery from disaster is typically measured using values for RTO and RPO.

- **Recovery time objective (RTO)** – The time it takes a system to return to a working state after a disaster. In other words, RTO measures downtime. For an Aurora global database, RTO can be in the order of minutes.

- **Recovery point objective (RPO)** – The amount of data that can be lost (measured in time). For an Aurora global database, RPO is typically measured in seconds. With an Aurora PostgreSQL–based global database, you can use the rds.global_db_rpo parameter to set and track the upper bound on RPO, but doing so might affect transaction processing on the primary cluster's writer node. For more information, see Managing RPOs for Aurora PostgreSQL–based global databases (p. 198).

With an Aurora global database, there are two different approaches to failover depending on the scenario.

- **Manual unplanned failover** ("detach and promote") – To recover from an unplanned outage or to do disaster recovery (DR) testing, perform a cross-Region failover to one of the secondaries in your Aurora global database. The RTO for this manual process depends on how quickly you can perform the tasks listed in Recovering an Amazon Aurora global database from an unplanned outage (p. 193). The RPO is typically measured in seconds, but this depends on the Aurora storage replication lag across the network at the time of the failure.

- **Managed planned failover** – This feature is intended for controlled environments, such as operational maintenance and other planned operational procedures. By using managed planned failover, you can relocate the primary DB cluster of your Aurora global database to one of the secondary Regions. Because this feature synchronizes secondary DB clusters with the primary before making any other changes, RPO is 0 (no data loss). To learn more, see Performing managed planned failovers for Amazon Aurora global databases (p. 194).
Recovering an Amazon Aurora global database from an unplanned outage

On very rare occasions, your Aurora global database might experience an unexpected outage in its primary AWS Region. If this happens, your primary Aurora DB cluster and its writer node aren't available, and the replication between the primary cluster and the secondaries ceases. To minimize both downtime (RTO) and data loss (RPO), you can work quickly to perform a cross-Region failover and reconstruct your Aurora global database.

**Tip**
We recommend that you understand this process before using it. Have a plan ready to quickly proceed at the first sign of a Region-wide issue. Be ready to identify the secondary Region with the least lag time. Use Amazon CloudWatch regularly to track lag times for the secondary clusters. Make sure to test your plan to check that your procedures are complete and accurate, and that staff are trained to perform a DR failover before it really happens.

To fail over to a secondary cluster after an unplanned outage in the primary Region

1. Stop issuing DML statements and other write operations to the primary Aurora DB cluster in the AWS Region with the outage.
2. Identify an Aurora DB cluster from a secondary AWS Region to use as a new primary DB cluster. If you have two or more secondary AWS Regions in your Aurora global database, choose the secondary cluster that has the least lag time.
3. Detach your chosen secondary DB cluster from the Aurora global database.

Removing a secondary DB cluster from an Aurora global database immediately stops the replication from the primary to this secondary and promotes it to a standalone provisioned Aurora DB cluster with full read/write capabilities. Any other secondary Aurora DB clusters associated with the primary cluster in the Region with the outage are still available and can accept calls from your application.

They also consume resources. Because you're recreating the Aurora global database, remove the other secondary DB clusters before creating the new Aurora global database in the following steps. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (split-brain issues).

For detailed steps for detaching, see Removing a cluster from an Amazon Aurora global database (p. 177).

4. Reconfigure your application to send all write operations to this now standalone Aurora DB cluster using its new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the -ro from the cluster's endpoint string in your application.

For example, the secondary cluster's endpoint my-global.cluster-ro-aaaaaabbffffff.us-west-1.rds.amazonaws.com becomes my-global.cluster-aaaaaabbffffff.us-west-1.rds.amazonaws.com when that cluster is detached from the Aurora global database.

This Aurora DB cluster becomes the primary cluster of a new Aurora global database when you start adding Regions to it in the next step.

5. Add an AWS Region to the DB cluster. When you do this, the replication process from primary to secondary begins. For detailed steps to add a Region, see Adding an AWS Region to an Amazon Aurora global database (p. 168).
6. Add more AWS Regions as needed to recreate the topology needed to support your application.

Make sure that application writes are sent to the correct Aurora DB cluster before, during, and after making these changes. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (split-brain issues).

If you reconfigured in response to an outage in an AWS Region, you might be able to return your Aurora global database to its original primary AWS Region after the outage is resolved. In this case, you use the managed planned failover process. Your Aurora global database must use a version of Aurora PostgreSQL or Aurora MySQL that supports managed planned failovers. For more information, see Performing managed planned failovers for Amazon Aurora global databases (p. 194).

Performing managed planned failovers for Amazon Aurora global databases

By using managed planned failovers, you can relocate the primary cluster of your Aurora global database to a different AWS Region on a routine basis. This approach is intended for controlled environments, such as operational maintenance and other planned operational procedures.

As an example, say a financial institution headquartered in New York has branch offices located in San Francisco, the UK, and Europe. The organization's core business applications use an Aurora global database. Its primary cluster runs in the US East (Ohio) Region. It has secondary clusters running in the US West (N. California) Region, Europe (London) Region, and the Europe (Frankfurt) Region. Every quarter, it relocates the primary cluster from the (current) primary AWS Region to the secondary Region designated for that rotation.

**Note**

Managed planned failover is designed to be used on a healthy Aurora global database. To recover from an unplanned outage or to do disaster recovery (DR) testing, follow the "detach and promote" process detailed in Recovering an Amazon Aurora global database from an unplanned outage (p. 193).

During a managed planned failover, your primary cluster is failed over to your choice of secondary Region while your Aurora global database's existing replication topology is maintained. Before the managed planned failover process begins, Aurora global database synchronizes all secondary clusters with its primary cluster. After ensuring that all clusters are synchronized, the managed planned failover begins. The DB cluster in the primary Region becomes read-only. The chosen secondary cluster promotes one of its read-only nodes to full writer status, thus allowing the cluster to assume the role of primary cluster. Because all secondary clusters were synchronized with the primary at the beginning of the process, the new primary continues operations for the Aurora global database without losing any data. Your database is unavailable for a short time while the primary and selected secondary clusters are assuming their new roles.

To optimize application availability, we recommend that you do the following before using this feature:

- Perform this operation during nonpeak hours or at another time when writes to the primary DB cluster are minimal.
- Take applications offline to prevent writes from being sent to the primary cluster of Aurora global database.
- Check lag times for all secondary Aurora DB clusters in the Aurora global database. Choose the secondary with the least overall lag time for the managed planned failover. Use Amazon CloudWatch to view the `AuroraGlobalDBReplicationLag` metric for all secondaries. This metric tells you how far behind (in milliseconds) a secondary is to the primary DB cluster. Its value is directly proportional to the time it’ll take for Aurora to complete failover. In other words, the larger the lag value, the longer the outage, so choose the Region with the least lag.
During a managed planned failover, the chosen secondary DB cluster is promoted to its new role as primary. However, it doesn't inherit the various configuration options of the primary DB cluster. A mismatch in configuration can lead to performance issues, workload incompatibilities, and other anomalous behavior. To avoid such issues, we recommend that you resolve differences between your Aurora global database clusters for the following:

- **Configure Aurora DB cluster parameter group for the new primary, if necessary** – You can configure your Aurora DB cluster parameter groups independently for each Aurora cluster in your Aurora global database. That means that when you promote a secondary DB cluster to take over the primary role, the parameter group from the secondary might be configured differently than for the primary. If so, modify the promoted secondary DB cluster's parameter group to conform to your primary cluster's settings. To learn how, see Modifying parameters for an Aurora global database (p. 176).

- **Configure monitoring tools and options, such as Amazon CloudWatch Events and alarms** – Configure the promoted DB cluster with the same logging ability, alarms, and so on as needed for the global database. As with parameter groups, configuration for these features isn't inherited from the primary during the failover process. For more information about Aurora DB clusters and monitoring, see Overview of monitoring Amazon Aurora.

- **Configure integrations with other AWS services** – If your Aurora global database integrates with AWS services, such as AWS Secrets Manager, AWS Identity and Access Management, Amazon S3, and AWS Lambda, you need to make sure these are configured as needed. For more information about integrating Aurora global databases with IAM, Amazon S3 and Lambda, see Using Amazon Aurora global databases with other AWS services (p. 205). To learn more about Secrets Manager, see How to automate replication of secrets in AWS Secrets Manager across AWS Regions.

When the failover process completes, the promoted Aurora DB cluster can handle write operations for the Aurora global database. Make sure to change the endpoint for your application to use the new endpoint. If you accepted the provided names when you created the Aurora global database, you can change the endpoint by removing the `-ro` from the promoted cluster's endpoint string in your application.

For example, the secondary cluster's endpoint `my-global.cluster-ro-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` becomes `my-global.cluster-aaaaaabbbbbb.us-west-1.rds.amazonaws.com` when that cluster is promoted to primary.

You can fail over your Aurora global database using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To start the failover process on your Aurora global database**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Databases** and find the Aurora global database you want to fail over.
3. Choose **Fail over global database** from Actions menu. The failover process doesn't begin until after you choose the failover target in the next step. At this point, the failover is pending.
a. Choose the secondary Aurora DB cluster that you want to promote to primary. The secondary DB cluster must be available. If you have more than one secondary DB cluster, you can compare the lag amount for all secondaries and choose the one with the smallest amount of lag.

b. Choose **Fail over global database** to confirm your choice of secondary DB cluster and begin the failover process.

**Tip**

The failover process can take some time to complete. You can cancel once the process is underway, but it can take some time to return your Aurora global database to its original configuration.
The **Status** column of the Databases list shows the state of each Aurora DB instance and Aurora DB cluster during the failover process.

![Image of Aurora Databases list showing failover status](image)

The status bar at the top of the Console displays progress and provides a **Cancel failover** option. If you choose **Cancel failover**, you’re given the option to proceed with the failover or to cancel the failover process.

Choose **Cancel failover** if you want to cancel the failover.

**c.** Choose **Close** to continue failing over and dismiss the prompt.

When the failover completes, you can see the Aurora DB clusters and their current state in the **Databases** list, as shown following.
AWS CLI

To fail over an Aurora global database

Use the `failover-global-cluster` CLI command to fail over your Aurora global database. With the command, pass values for the following parameters.

- `--region` – Specify the AWS Region where the primary DB cluster of the Aurora global database is running.
- `--global-cluster-identifier` – Specify the name of your Aurora global database.
- `--target-db-cluster-identifier` – Specify the Amazon Resource Name (ARN) of the Aurora DB cluster that you want to promote to be the primary for the Aurora global database.

For Linux, macOS, or Unix:

```bash
aws rds --region aws-Region \
  failover-global-cluster --global-cluster-identifier global_database_id \
  --target-db-cluster-identifier ARN-of-secondary-to-promote
```

For Windows:

```bash
aws rds --region aws-Region ^
  failover-global-cluster --global-cluster-identifier global_database_id ^
  --target-db-cluster-identifier ARN-of-secondary-to-promote
```

RDS API

To fail over an Aurora global database, run the `FailoverGlobalCluster` API operation.

Managing RPOs for Aurora PostgreSQL–based global databases

With an Aurora PostgreSQL–based global database, you can manage the recovery point objective (RPO) for your Aurora global database by using PostgreSQL's `rds.global_db_rpo` parameter. RPO represents maximum amount of data that can be lost in the event of an outage.

When you set an RPO for your Aurora PostgreSQL–based global database, Aurora monitors the `RPO lag time` of all secondary clusters to make sure that at least one secondary cluster stays within the target RPO window. RPO lag time is another time-based metric.

The RPO is used when your database resumes operations in a new AWS Region after a failover. Aurora evaluates RPO and RPO lag times to commit (or block) transactions on the primary as follows:

- Commits the transaction if at least one secondary DB cluster has an RPO lag time less than the RPO.
• Blocks the transaction if all secondary DB clusters have RPO lag times that are larger than the RPO. It also logs the event to the PostgreSQL log file and emits “wait” events that show the blocked sessions.

In other words, if all secondary clusters are behind the target RPO, Aurora pauses transactions on the primary cluster until at least one of the secondary clusters catches up. Paused transactions are resumed and committed as soon as the lag time of at least one secondary DB cluster becomes less than the RPO. The result is that no transactions can commit until the RPO is met.

If you set this parameter as outlined in the following, you can then also monitor the metrics that it generates. You can do so by using `psql` or another tool to query the Aurora global database’s primary DB cluster and obtain detailed information about your Aurora PostgreSQL-based global database’s operations. To learn how, see Monitoring Aurora PostgreSQL-based Aurora global databases (p. 203).

**Topics**

- Setting the recovery point objective (p. 199)
- Viewing the recovery point objective (p. 200)
- Disabling the recovery point objective (p. 201)

### Setting the recovery point objective

The `rds.global_db_rpo` parameter controls the RPO setting for a PostgreSQL database. This parameter is supported by Aurora PostgreSQL. Valid values for `rds.global_db_rpo` range from 20 seconds to 2,147,483,647 seconds (68 years). Choose a realistic value to meet your business need and use case. For example, you might want to allow up to 10 minutes for your RPO, in which case you set the value to 600.

You can set this value for your Aurora PostgreSQL-based global database by using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To set the RPO**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the primary cluster of your Aurora global database and open the Configuration tab to find its DB cluster parameter group. For example, the default parameter group for a primary DB cluster running Aurora PostgreSQL 11.7 is `default.aurora-postgresql11`.

   Parameter groups can't be edited directly. Instead, you do the following:

   - Create a custom DB cluster parameter group using the appropriate default parameter group as the starting point. For example, create a custom DB cluster parameter group based on the `default.aurora-postgresql11`.
   - On your custom DB parameter group, set the value of the `rds.global_db_rpo` parameter to meet your use case. Valid values range from 20 seconds up to the maximum integer value of 2,147,483,647 (68 years).
   - Apply the modified DB cluster parameter group to your Aurora DB cluster.

For more information, see Modifying parameters in a DB cluster parameter group (p. 221).

**AWS CLI**

To set the `rds.global_db_rpo` parameter, use the `modify-db-cluster-parameter-group` CLI command. In the command, specify the name of your primary cluster's parameter group and values for RPO parameter.
The following example sets the RPO to 600 seconds (10 minutes) for the primary DB cluster's parameter group named `my_custom_global_parameter_group`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group
    --db-cluster-parameter-group-name my_custom_global_parameter_group
    --parameters "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group
    --db-cluster-parameter-group-name my_custom_global_parameter_group
    --parameters "ParameterName=rds.global_db_rpo,ParameterValue=600,ApplyMethod=immediate"
```

**RDS API**

To modify the `rds.global_db_rpo` parameter, use the Amazon RDS `ModifyDBClusterParameterGroup` API operation.

**Viewing the recovery point objective**

The recovery point objective (RPO) of a global database is stored in the `rds.global_db_rpo` parameter for each DB cluster. You can connect to the endpoint for the secondary cluster you want to view and use `psql` to query the instance for this value.

```bash
db-name=>show rds.global_db_rpo;
```

If this parameter isn't set, the query returns the following:

```
rds.global_db_rpo
-------------------
    -1
(1 row)
```

This next response is from a secondary DB cluster that has 1 minute RPO setting.

```
rds.global_db_rpo
-------------------
      60
(1 row)
```

You can also use the CLI to get values for find out if `rds.global_db_rpo` is active on any of the Aurora DB clusters by using the CLI to get values of all `user` parameters for the cluster.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-cluster-parameters
    --db-cluster-parameter-group-name lab-test-apg-global
    --source user
```

For Windows:

```bash
aws rds describe-db-cluster-parameters
    --db-cluster-parameter-group-name lab-test-apg-global
```
The command returns output similar to the following for all user parameters that aren’t
default-engine or system DB cluster parameters.

```json
{
    "Parameters": [
        {
            "ParameterName": "rds.global_db_rpo",
            "ParameterValue": "60",
            "Description": "(s) Recovery point objective threshold, in seconds, that blocks user commits when it is violated.",
            "Source": "user",
            "ApplyType": "dynamic",
            "DataType": "integer",
            "AllowedValues": "20-2147483647",
            "IsModifiable": true,
            "ApplyMethod": "immediate",
            "SupportedEngineModes": [
                "provisioned"
            ]
        }
    ]
}
```

To learn more about viewing parameters of the cluster parameter group, see Viewing parameter values for a DB cluster parameter group (p. 226).

### Disabling the recovery point objective

To disable the RPO, reset the `rds.global_db_rpo` parameter. You can reset parameters using the AWS Management Console, the AWS CLI, or the RDS API.

#### Console

**To disable the RPO**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose your primary DB cluster parameter group.
4. Choose **Edit parameters**.
5. Choose the box next to the `rds.global_db_rpo` parameter.
6. Choose **Reset**.
7. When the screen shows **Reset parameters in DB parameter group**, choose **Reset parameters**.

For more information on how to reset a parameter with the console, see Modifying parameters in a DB cluster parameter group (p. 221).

#### AWS CLI

To reset the `rds.global_db_rpo` parameter, use the `reset-db-cluster-parameter-group` command.

For Linux, macOS, or Unix:

```bash
aws rds reset-db-cluster-parameter-group \
    --db-cluster-parameter-group-name global_db_cluster_parameter_group \
```
--parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"

For Windows:

```bash
aws rds reset-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name global_db_cluster_parameter_group ^
    --parameters "ParameterName=rds.global_db_rpo,ApplyMethod=immediate"
```

RDS API

To reset the `rds.global_db_rpo` parameter, use the Amazon RDS API `ResetDBClusterParameterGroup` operation.

Monitoring an Amazon Aurora global database

When you create the Aurora DB clusters that make up your Aurora global database, you can choose many options that let you monitor your DB cluster's performance. These options include the following:

- Amazon RDS Performance Insights – Enables performance schema in the underlying Aurora database engine. To learn more about Performance Insights and Aurora global databases, see Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights (p. 203).
- Enhanced monitoring – Generates metrics for process or thread utilization on the CPU.
- Amazon CloudWatch Logs – Publishes specified log types to CloudWatch Logs. Error logs are published by default, but you can choose other logs specific to your Aurora database engine.
  - For Aurora MySQL–based Aurora DB clusters, you can export the audit log, general log, and slow query log.
  - For Aurora PostgreSQL–based Aurora DB clusters, you can export the Postgresql log.
  - For Aurora PostgreSQL–based global databases, you can use certain functions to check status of your Aurora global database and its instances. To learn how, see Monitoring Aurora PostgreSQL-based Aurora global databases (p. 203).

The following screenshot shows some of the options available on the Monitoring tab of a primary Aurora DB cluster in an Aurora global database.
Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights

You can use Amazon RDS Performance Insights for your Aurora global databases. You enable this feature individually, for each Aurora DB cluster in your Aurora global database. To do so, you choose **Enable Performance Insights** in the **Additional configuration** section of the Create database page. Or you can modify your Aurora DB clusters to use this feature after they are up and running. You can enable or turn off Performance Insights for each cluster that's part of your Aurora global database.

The reports created by Performance Insights apply to each cluster in the global database. When you add a new secondary AWS Region to an Aurora global database that's already using Performance Insights, be sure that you enable Performance Insights in the newly added cluster. It doesn't inherit the Performance Insights setting from the existing global database.

You can switch AWS Regions while viewing the Performance Insights page for a DB instance that's attached to a global database. However, you might not see performance information immediately after switching AWS Regions. Although the DB instances might have identical names in each AWS Region, the associated Performance Insights URL is different for each DB instance. After switching AWS Regions, choose the name of the DB instance again in the Performance Insights navigation pane.

For DB instances associated with a global database, the factors affecting performance might be different in each AWS Region. For example, the DB instances in each AWS Region might have different capacity.

To learn more about using Performance Insights, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 461).

Monitoring Aurora PostgreSQL-based Aurora global databases

To view the status of a global database, use the `aurora_global_db_status` and `aurora_global_db_instance_status` functions.

**Note**

Only Aurora PostgreSQL supports the `aurora_global_db_status` and `aurora_global_db_instance_status` functions.

To monitor an Aurora PostgreSQL-based global database

1. Connect to the global database primary cluster endpoint using a PostgreSQL utility such as `psql`. For more information about how to connect, see Connecting to an Amazon Aurora global database (p. 180).
2. Use the `aurora_global_db_status` function in a `psql` command to list the primary and secondary volumes. This shows the lag times of the global database secondary DB clusters.

```sql
postgres=> select * from aurora_global_db_status();
```

<table>
<thead>
<tr>
<th>aws_region</th>
<th>highest_lsn_written</th>
<th>durability_lag_in_msec</th>
<th>rpo_lag_in_msec</th>
<th>last_lag_calculation_time</th>
<th>feedback_epoch</th>
<th>feedback_xmin</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-1</td>
<td>93763984222</td>
<td>-1</td>
<td>-1</td>
<td>1970-01-01 00:00:00+00</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>us-west-2</td>
<td>93763984222</td>
<td>900</td>
<td>1090</td>
<td>2020-05-12 22:19:14.328+00</td>
<td>3315479243</td>
<td></td>
</tr>
</tbody>
</table>

(2 rows)
The output includes a row for each DB cluster of the global database containing the following columns:

- **aws_region** – The AWS Region that this DB cluster is in. For tables listing AWS Regions by engine, see [Regions and Availability Zones](#).
- **highest_lsn_written** – The highest log sequence number (LSN) currently written on this DB cluster.

* A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.

- **durability_lag_in_msec** – The timestamp difference between the highest log sequence number written on a secondary DB cluster (highest_lsn_written) and the highest_lsn_written on the primary DB cluster.

- **rpo_lag_in_msec** – The recovery point objective (RPO) lag. This lag is the time difference between the most recent user transaction commit stored on a secondary DB cluster and the most recent user transaction commit stored on the primary DB cluster.

- **last_lag_calculation_time** – The timestamp when values were last calculated for durability_lag_in_msec and rpo_lag_in_msec.

- **feedback_epoch** – The epoch the secondary DB cluster uses when it generates hot standby information.

* Hot standby is when a DB cluster can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB cluster when it’s in hot standby. For more information, see [Hot standby](#) in the PostgreSQL documentation.

- **feedback_xmin** – The minimum (oldest) active transaction ID used by the secondary DB cluster.

3. Use the `aurora_global_db_instance_status` function to list all secondary DB instances for both the primary DB cluster and secondary DB clusters.

```sql
postgres=> select * from aurora_global_db_instance_status();
```

<table>
<thead>
<tr>
<th>server_id</th>
<th>session_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>apg-global-db-rpo-mammothrw-elephantro-1-n1</td>
<td>MASTER_SESSION_ID</td>
</tr>
<tr>
<td>us-east-1</td>
<td>93763985102</td>
</tr>
<tr>
<td></td>
<td>f38430cf-6576-479a-b296-dc06b1b1964a</td>
</tr>
<tr>
<td></td>
<td>93763985099</td>
</tr>
<tr>
<td></td>
<td>93763985102</td>
</tr>
<tr>
<td></td>
<td>93763985095</td>
</tr>
<tr>
<td>apg-global-db-rpo-mammothrw-elephantro-1-n2</td>
<td>0d9f1d98-04ad-4aa4-8f6d-e08674cbbbfe</td>
</tr>
<tr>
<td>us-west-2</td>
<td>93763985095</td>
</tr>
<tr>
<td></td>
<td>93763985099</td>
</tr>
<tr>
<td></td>
<td>1017</td>
</tr>
</tbody>
</table>

The output includes a row for each DB instance of the global database containing the following columns:

- **server_id** – The server identifier for the DB instance.

- **session_id** – A unique identifier for the current session.

- **aws_region** – The AWS Region that this DB instance is in. For tables listing AWS Regions by engine, see [Regions and Availability Zones](#).

- **durable_lsn** – The LSN made durable in storage.
• **highest_lsn_rcvd** – The highest LSN received by the DB Instance from the writer DB Instance.
• **feedback_epoch** – The epoch the DB instance uses when it generates hot standby information.

Hot standby is when a DB instance can connect and query while the server is in recovery or standby mode. Hot standby feedback is information about the DB instance when it’s in hot standby. For more information, see the PostgreSQL documentation on Hot standby.
• **feedback_xmin** – The minimum (oldest) active transaction ID used by the DB instance.
• **oldest_read_view_lsn** – The oldest LSN used by the DB instance to read from storage.
• **visibility_lag_in_msec** – How far this DB instance is lagging behind the writer DB instance.

To see how these values change over time, consider the following transaction block where a table insert takes an hour.

```
psql> BEGIN;
psql> INSERT INTO table1 SELECT Large_Data_That_Takes_1_Hr_To_Insert;
psql> COMMIT;
```

In some cases, there might be a network disconnect between the primary DB cluster and the secondary DB cluster after the `BEGIN` statement. If so, the secondary DB cluster's `replication_lag_in_msec` value starts increasing. At the end of the `INSERT` statement, the `replication_lag_in_msec` value is 1 hour. However, the `rpo_lag_in_msec` value is 0 because all the user data committed between the primary DB cluster and secondary DB cluster are still the same. As soon as the `COMMIT` statement completes, the `rpo_lag_in_msec` value increases.

### Using Amazon Aurora global databases with other AWS services

You can use your Aurora global databases with other AWS services, such as Amazon S3 and AWS Lambda. Doing so requires that all Aurora DB clusters in your global database have the same privileges, external functions, and so on in the respective AWS Regions. Because a read-only Aurora secondary DB cluster in an Aurora global database can be promoted to the role of primary, we recommend that you set up write privileges ahead of time, on all Aurora DB clusters for any services you plan to use with your Aurora global database.

The following procedures summarize the actions to take for each AWS service.

#### To invoke AWS Lambda functions from an Aurora global database

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster](p. 918).
2. For each cluster in the Aurora global database, set the (ARN) of the new IAM (IAM) role.
3. To permit database users in an Aurora global database to invoke Lambda functions, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services](p. 898) with each cluster in the Aurora global database.
4. Configure each cluster in the Aurora global database to allow outbound connections to Lambda. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services](p. 903).

#### To load data from Amazon S3

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](p. 904).
2. For each Aurora cluster in the global database, set either the `aurora_load_from_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_load_from_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

3. To permit database users in an Aurora global database to access S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898) with each Aurora cluster in the global database.

4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 903).

To save queried data to Amazon S3

1. For all the Aurora clusters that make up the Aurora global database, perform the procedures in Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 912).

2. For each Aurora cluster in the global database, set either the `aurora_select_into_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_select_into_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

3. To permit database users in an Aurora global database to access S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898) with each Aurora cluster in the global database.

4. Configure each Aurora cluster in the global database to allow outbound connections to S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 903).

Upgrading an Amazon Aurora global database

Upgrading an Aurora global database follows the same procedures as upgrading Aurora DB clusters. However, following are some important differences to take note of before you start the process.

Major version upgrades

When you perform a major version upgrade of an Amazon Aurora global database, you upgrade the global database cluster instead the individual clusters that it contains.

To learn how to upgrade an Aurora PostgreSQL global database to a higher major version, see Major upgrades for global databases (p. 1423). To learn how to upgrade an Aurora MySQL global database to a higher major version, see In-place major upgrades for global databases (p. 1010).

**Note**

With an Aurora global database based on Aurora PostgreSQL, you can't perform a major version upgrade of the Aurora DB engine if the recovery point objective (RPO) feature is turned on.

Minor version upgrades

For a minor upgrade on an Aurora global database, you upgrade all of the secondary clusters before you upgrade the primary cluster.

To learn how to upgrade an Aurora PostgreSQL global database to a higher minor version, see Upgrading the Aurora PostgreSQL engine to a new major version (p. 1421). To learn how to upgrade an Aurora MySQL global database to a higher minor version, see Upgrading Aurora MySQL by modifying the engine version (p. 997).
Connecting to an Amazon Aurora DB cluster

You can connect to an Aurora DB cluster using the same tools that you use to connect to a MySQL or PostgreSQL database. You specify a connection string with any script, utility, or application that connects to a MySQL or PostgreSQL DB instance. You use the same public key for Secure Sockets Layer (SSL) connections.

In the connection string, you typically use the host and port information from special endpoints associated with the DB cluster. With these endpoints, you can use the same connection parameters regardless of how many DB instances are in the cluster. You also use the host and port information from a specific DB instance in your Aurora DB cluster for specialized tasks, such as troubleshooting.

Note
For Aurora Serverless DB clusters, you connect to the database endpoint rather than to the DB instance. You can find the database endpoint for an Aurora Serverless DB cluster on the Connectivity & security tab of the AWS Management Console. For more information, see Using Amazon Aurora Serverless v1 (p. 1542).

Regardless of the Aurora DB engine and specific tools you use to work with the DB cluster or instance, the endpoint must be accessible. An Amazon Aurora DB cluster can be created only in a virtual private cloud (VPC) based on the Amazon VPC service. That means that you access the endpoint from either inside the VPC or outside the VPC using one of the following approaches.

• Access the Amazon Aurora DB cluster inside the VPC – Enable access to the Amazon Aurora DB cluster through the VPC. You do so by editing the Inbound rules on the Security group for the VPC to allow access to your specific Aurora DB cluster. To learn more, including how to configure your VPC for different Aurora DB cluster scenarios, see Amazon Virtual Private Cloud VPCs and Amazon Aurora.

• Access the Amazon Aurora DB cluster outside the VPC – To access an Amazon Aurora DB cluster from outside the VPC, use the public endpoint address of the Amazon Aurora DB cluster.

For more information, see Troubleshooting Aurora connection failures (p. 214).

Topics
• Connecting to an Amazon Aurora MySQL DB cluster (p. 207)
• Connecting to an Amazon Aurora PostgreSQL DB cluster (p. 212)
• Troubleshooting Aurora connection failures (p. 214)

Connecting to an Amazon Aurora MySQL DB cluster

To authenticate to your Aurora MySQL DB cluster, you can use either MySQL user name and password authentication or AWS Identity and Access Management (IAM) database authentication. For more information on using MySQL user name and password authentication, see Access control and account management in the MySQL documentation. For more information on using IAM database authentication, see IAM database authentication (p. 1682).

When you have a connection to your Amazon Aurora DB cluster with MySQL 8.0 compatibility, you can run SQL commands that are compatible with MySQL version 8.0. The minimum compatible version is MySQL 8.0.23. For more information about MySQL 8.0 SQL syntax, see the MySQL 8.0 reference manual. For information about limitations that apply to Aurora MySQL version 3, see Comparison of Aurora MySQL version 3 and MySQL 8.0 Community Edition (p. 663).

When you have a connection to your Amazon Aurora DB cluster with MySQL 5.7 compatibility, you can run SQL commands that are compatible with MySQL version 5.7. For more information about MySQL 5.7
SQL syntax, see the MySQL 5.7 reference manual. For information about limitations that apply to Aurora MySQL 5.7, see Aurora MySQL version 2 compatible with MySQL 5.7 (p. 680).

When you have a connection to your Amazon Aurora DB cluster with MySQL 5.6 compatibility, you can run SQL commands that are compatible with MySQL version 5.6. For more information about MySQL 5.6 SQL syntax, see the MySQL 5.6 reference manual.

**Note**

For a helpful and detailed guide on connecting to an Amazon Aurora MySQL DB cluster, you can see the Aurora connection management handbook.

In the details view for your DB cluster, you can find the cluster endpoint, which you can use in your MySQL connection string. The endpoint is made up of the domain name and port for your DB cluster. For example, if an endpoint value is `mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com:3306`, then you specify the following values in a MySQL connection string:

- For host or host name, specify `mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com`
- For port, specify `3306` or the port value you used when you created the DB cluster

The cluster endpoint connects you to the primary instance for the DB cluster. You can perform both read and write operations using the cluster endpoint. Your DB cluster can also have up to 15 Aurora Replicas that support read-only access to the data in your DB cluster. The primary instance and each Aurora Replica has a unique endpoint that is independent of the cluster endpoint and allows you to connect to a specific DB instance in the cluster directly. The cluster endpoint always points to the primary instance. If the primary instance fails and is replaced, then the cluster endpoint points to the new primary instance.

To view the cluster endpoint (writer endpoint), choose **Databases** on the Amazon RDS console and choose the name of the DB cluster to show the DB cluster details.
Topics

- Connection utilities for Aurora MySQL (p. 209)
- Connecting with Aurora MySQL using the MySQL utility (p. 210)
- Connecting with the Amazon Web Services JDBC Driver for MySQL (p. 211)
- Connecting with SSL for Aurora MySQL (p. 211)

Connection utilities for Aurora MySQL

Some connection utilities you can use are the following:

- **Command line** – You can connect to an Amazon Aurora DB cluster by using tools like the MySQL command line utility. For more information on using the MySQL utility, see `mysql - the MySQL command line tool` in the MySQL documentation.

- **GUI** – You can use the MySQL Workbench utility to connect by using a UI interface. For more information, see the `Download MySQL workbench` page.
Applications – You can use the AWS JDBC Driver for MySQL to connect your client applications to an Aurora MySQL DB cluster. For more information about the AWS JDBC Driver for MySQL and complete instructions for using it, see the AWS JDBC Driver for MySQL GitHub repository.

Note
Version 3.0.3 of the MariaDB Connector/J utility drops support for Aurora DB clusters, so we highly recommend moving to the AWS JDBC Driver for MySQL. The AWS JDBC Driver for MySQL offers improved failover speed for Aurora MySQL DB clusters by caching DNS connections for quick use.
If you are using an Aurora Serverless DB cluster, the failover benefits don’t apply, but you can disable the feature by setting the failureDetectionEnabled parameter to false. To review a complete list of configuration options, see the AWS JDBC Driver for MySQL GitHub repository.

Connecting with Aurora MySQL using the MySQL utility

Use the following procedure. It assumes that you configured your DB cluster in a private subnet in your VPC. You connect using an Amazon EC2 instance that you configured according to the tutorials in Tutorial: Create a web server and an Amazon Aurora DB cluster (p. 107).

Note
This procedure doesn't require installing the web server in the tutorial, but it does require installing MariaDB 10.5.

To connect to a DB cluster using the MySQL utility

1. Log in to the EC2 instance that you're using to connect to your DB cluster.

   You should see output similar to the following.

   Last login: Thu Jun 23 13:32:52 2022 from xxx.xxx.xxx.xxx
   __|  __|_  )  Amazon Linux 2 AMI
   ___
   [ec2-user@ip-10-0-xxx.xxx -]

2. Type the following command at the command prompt to connect to the primary DB instance of your DB cluster.

   For the -h parameter, substitute the endpoint DNS name for your primary instance. For the -u parameter, substitute the user ID of a database user account.

   mysql -h primary-instance-endpoint.AWS_account.AWS_Region.rds.amazonaws.com -P 3306 -u database_user -p

   For example:

   mysql -h my-aurora-cluster-instance.c1xy5example.123456789012.eu-central-1.rds.amazonaws.com -P 3306 -u admin -p

3. Enter the password for the database user.

   You should see output similar to the following.

   Welcome to the MariaDB monitor. Commands end with ; or \
g.
Connecting to Aurora MySQL

4. Enter your SQL commands.

Connecting with the Amazon Web Services JDBC Driver for MySQL

The AWS JDBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. The driver is drop-in compatible with the MySQL Connector/J driver. To install or upgrade your connector, replace the MySQL connector .jar file (located in the application CLASSPATH) with the AWS JDBC Driver for MySQL .jar file, and update the connection URL prefix from `jdbc:mysql://` to `jdbc:mysql:aws://`.

The AWS JDBC Driver for MySQL takes full advantage of the failover capabilities of Aurora MySQL. In the event of a failover, the driver queries the cluster directly for the new topology instead of using DNS resolution. By querying the cluster directly, the driver is able to connect to the new primary faster in a reliable and predictable manner, avoiding potential delays caused by DNS resolution.

The AWS JDBC Driver for MySQL supports IAM database authentication. For more information, see AWS IAM Database Authentication in the AWS JDBC Driver for MySQL GitHub repository. For more information about IAM database authentication, see IAM database authentication (p. 1682).

For more information about the AWS JDBC Driver for MySQL and complete instructions for using it, see the AWS JDBC Driver for MySQL GitHub repository.

Connecting with SSL for Aurora MySQL

You can use SSL encryption on connections to an Aurora MySQL DB instance. For information, see Using SSL/TLS with Aurora MySQL DB clusters (p. 683).

To connect using SSL, use the MySQL utility as described in the following procedure. If you are using IAM database authentication, you must use an SSL connection. For information, see IAM database authentication (p. 1682).

Note
To connect to the cluster endpoint using SSL, your client connection utility must support Subject Alternative Names (SAN). If your client connection utility doesn't support SAN, you can connect directly to the instances in your Aurora DB cluster. For more information on Aurora endpoints, see Amazon Aurora connection management (p. 35).

To connect to a DB cluster with SSL using the MySQL utility

1. Download the public key for the Amazon RDS signing certificate.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1642).

2. Type the following command at a command prompt to connect to the primary instance of a DB cluster with SSL using the MySQL utility. For the `-h` parameter, substitute the endpoint DNS name for your primary instance. For the `-u` parameter, substitute the user ID of a database user account. For the `--ssl-ca` parameter, substitute the SSL certificate file name as appropriate. Type the master user password when prompted.
Connecting to Aurora PostgreSQL

You can connect to a DB instance in your Amazon Aurora PostgreSQL DB cluster using the same tools that you use to connect to a PostgreSQL database. As part of this, you use the same public key for Secure Sockets Layer (SSL) connections. You can use the endpoint and port information from the primary instance or Aurora Replicas in your Aurora PostgreSQL DB cluster in the connection string of any script, utility, or application that connects to a PostgreSQL DB instance. In the connection string, specify the DNS address from the primary instance or Aurora Replica endpoint as the host parameter. Specify the port number from the endpoint as the port parameter.

When you have a connection to a DB instance in your Amazon Aurora PostgreSQL DB cluster, you can run any SQL command that is compatible with PostgreSQL.

In the details view for your Aurora PostgreSQL DB cluster you can find the cluster endpoint name, status, type, and port number. You use the endpoint and port number in your PostgreSQL connection string. For example, if an endpoint value is mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com, then you specify the following values in a PostgreSQL connection string:

- For host or host name, specify mycluster.cluster-123456789012.us-east-1.rds.amazonaws.com
- For port, specify 5432 or the port value you used when you created the DB cluster

The cluster endpoint connects you to the primary instance for the DB cluster. You can perform both read and write operations using the cluster endpoint. Your DB cluster can also have up to 15 Aurora Replicas that support read-only access to the data in your DB cluster. Each DB instance in the Aurora cluster (that is, the primary instance and each Aurora Replica) has a unique endpoint that is independent of the cluster endpoint. This unique endpoint allows you to connect to a specific DB instance in the cluster directly. The cluster endpoint always points to the primary instance. If the primary instance fails and is replaced, the cluster endpoint points to the new primary instance.

To view the cluster endpoint (writer endpoint), choose Databases on the Amazon RDS console and choose the name of the DB cluster to show the DB cluster details.
Connection utilities for Aurora PostgreSQL

Some connection utilities you can use are the following:

- **Command line** – You can connect to an Amazon Aurora PostgreSQL DB instance by using tools like psql, the PostgreSQL interactive terminal. For more information on using the PostgreSQL interactive terminal, see psql in the PostgreSQL documentation.
- **GUI** – You can use the pgAdmin utility to connect to a PostgreSQL DB instance by using a UI interface. For more information, see the Download page from the pgAdmin website.
- **Applications** – You can use the PostgreSQL JDBC driver to connect your applications to your PostgreSQL DB instance. For more information, see the Download page from the PostgreSQL JDBC driver website.
Connecting with the Amazon Web Services JDBC Driver for PostgreSQL (preview)

This is preview documentation for Amazon Web Services JDBC Driver for PostgreSQL. It is subject to change.

The AWS JDBC Driver for PostgreSQL (preview) is a client driver designed for the high availability of Aurora PostgreSQL. The AWS JDBC Driver for PostgreSQL is drop-in compatible with the PostgreSQL JDBC Driver.

The AWS JDBC Driver for PostgreSQL takes full advantage of the failover capabilities of Aurora PostgreSQL. The AWS JDBC Driver for PostgreSQL fully maintains a cache of the DB cluster topology and each DB instance's role, either primary DB instance or Aurora Replica. It uses this topology to bypass the delays caused by DNS resolution so that a connection to the new primary DB instance is established as fast as possible.

For more information about the AWS JDBC Driver for PostgreSQL and complete instructions for using it, see the AWS JDBC Driver for PostgreSQL GitHub repository.

Troubleshooting Aurora connection failures

Common causes of connection failures to a new Aurora DB cluster include the following:

- **Security group in the VPC doesn't allow access** – Your VPC needs to allow connections from your device or from an Amazon EC2 instance by proper configuration of the security group in the VPC. To resolve, modify your VPC's Security group Inbound rules to allow connections. For an example, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 1743).

- **Port blocked by firewall rules** – Check the value of the port configured for your Aurora DB cluster. If a firewall rule blocks that port, you can re-create the instance using a different port.

- **Incomplete or incorrect IAM configuration** – If you created your Aurora DB instance to use IAM-based authentication, make sure that it's properly configured. For more information, see IAM database authentication (p. 1682).

For more information about troubleshooting Aurora DB connection issues, see Can't connect to Amazon RDS DB instance (p. 1760).
Working with parameter groups

Database parameters specify how the database is configured. For example, database parameters can specify the amount of resources, such as memory, to allocate to a database.

You manage your database configuration by associating your DB instances and Aurora DB clusters with parameter groups. Aurora defines parameter groups with default settings.

**Important**
- You can define your own parameter groups with customized settings. Then you can modify your DB instances and Aurora DB clusters to use your own parameter groups.
- For information about modifying a DB cluster or DB instance, see Modifying an Amazon Aurora DB cluster (p. 248).

A **DB cluster parameter group** acts as a container for engine configuration values that are applied to every DB instance in an Aurora DB cluster. For example, the Aurora shared storage model requires that every DB instance in an Aurora cluster use the same setting for parameters such as `innodb_file_per_table`. Thus, parameters that affect the physical storage layout are part of the cluster parameter group. The DB cluster parameter group also includes default values for all the instance-level parameters.

A **DB parameter group** acts as a container for engine configuration values that are applied to one or more DB instances. DB parameter groups apply to DB instances in both Amazon RDS and Aurora. These configuration settings apply to properties that can vary among the DB instances within an Aurora cluster, such as the sizes for memory buffers.

If you create a DB instance without specifying a DB parameter group, the DB instance uses a default DB parameter group. Likewise, if you create an Aurora DB cluster without specifying a DB cluster parameter group, the DB cluster uses a default DB cluster parameter group. Each default parameter group contains database engine defaults and Amazon RDS system defaults based on the engine, compute class, and allocated storage of the instance. You can't modify the parameter settings of a default parameter group. Instead, you create your own parameter group where you choose your own parameter settings. Not all DB engine parameters can be changed in a parameter group that you create.

To use your own parameter group, you create a new parameter group and modify the parameters that you want to modify. You then modify your DB instance or DB cluster to use the new parameter group. If you update parameters within a DB parameter group, the changes apply to all DB instances that are associated with that parameter group. Likewise, if you update parameters within an Aurora DB cluster parameter group, the changes apply to all Aurora clusters that are associated with that DB cluster parameter group.

You can copy an existing DB parameter group with the AWS CLI `copy-db-parameter-group` command. You can copy an existing DB cluster parameter group with the AWS CLI `copy-db-cluster-parameter-group` command. Copying a parameter group can be convenient when you want to include most of an existing parameter group's custom parameters and values in a new parameter group.

Here are some important points about working with parameters in a parameter group:

- DB cluster parameters are either *static* or *dynamic*. When you change a static parameter and save the DB cluster parameter group, the parameter change takes effect after you manually reboot the DB instances in each associated DB cluster.

  When you change a dynamic parameter, by default the parameter change is applied to your DB cluster immediately, without requiring a reboot. To defer the parameter change until after the DB instances in an associated DB cluster are rebooted, use the AWS CLI or RDS API, and set the `ApplyMethod` to `pending-reboot` for the parameter change.
When you use the AWS Management Console to change DB cluster parameter values, it always uses immediate for the ApplyMethod for dynamic parameters. For static parameters, the AWS Management Console always uses pending-reboot for the ApplyMethod.

For more information about using the AWS CLI to change a parameter value, see modify-db-cluster-parameter-group. For more information about using the RDS API to change a parameter value, see ModifyDBClusterParameterGroup.

- DB instance parameters are either static or dynamic. When you change a static parameter and save the DB parameter group, the parameter change takes effect after you manually reboot the associated DB instances.

When you change a dynamic parameter, by default the parameter change is applied to your DB instance immediately, without requiring a reboot. To defer the parameter change until after an associated DB instance is rebooted, use the AWS CLI or RDS API, and set the ApplyMethod to pending-reboot for the parameter change.

When you use the AWS Management Console to change DB instance parameter values, it always uses immediate for the ApplyMethod for dynamic parameters. For static parameters, the AWS Management Console always uses pending-reboot for the ApplyMethod.

For more information about using the AWS CLI to change a parameter value, see modify-db-parameter-group. For more information about using the RDS API to change a parameter value, see ModifyDBParameterGroup.

- If a DB instance isn’t using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of pending-reboot. The pending-reboot parameter groups status doesn’t result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

- When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot. For more information about changing the DB parameter group, see Modifying an Amazon Aurora DB cluster (p. 248).

- After you change the DB cluster parameter group associated with a DB cluster, reboot the DB instances in the DB cluster to apply the changes to all of the DB instances in the DB cluster.

To determine whether the DB instances of a DB cluster must be rebooted to apply changes, run the following AWS CLI command.

```bash
aws rds describe-db-clusters --db-cluster-identifier db_cluster_identifier
```

Check the DBClusterParameterGroupStatus value for the primary DB instance in the output. If the value is pending-reboot, then reboot the DB instances of the DB cluster.

- In many cases, you can specify integer and Boolean parameter values using expressions, formulas, and functions. Functions can include a mathematical log expression. However, not all parameters support expressions, formulas, and functions for parameter values. For more information, see Specifying DB parameters (p. 238).

- Set any parameters that relate to the character set or collation of your database in your parameter group before creating the DB cluster and before you create a database in it. This ensures that the default database and new databases use the character set and collation values that you specify. If you change character set or collation parameters, the parameter changes aren’t applied to existing databases.

For some DB engines, you can change character set or collation values for an existing database using the ALTER DATABASE command, for example:
ALTER DATABASE *database_name* CHARACTER SET *character_set_name* COLLATE *collation*;

For more information about changing the character set or collation values for a database, check the documentation for your DB engine.

- Improperly setting parameters in a parameter group can have unintended adverse effects, including degraded performance and system instability. Always be cautious when modifying database parameters, and back up your data before modifying a parameter group. Try out parameter group setting changes on a test DB instance or DB cluster before applying those parameter group changes to a production DB instance or DB cluster.

- For an Aurora global database, you can specify different configuration settings for the individual Aurora clusters. Make sure that the settings are similar enough to produce consistent behavior if you promote a secondary cluster to be the primary cluster. For example, use the same settings for time zones and character sets across all the clusters of an Aurora global database.

- To determine the supported parameters for your DB engine, you can view the parameters in the DB parameter group and DB cluster parameter group used by the DB instance or DB cluster. For more information, see Viewing parameter values for a DB parameter group (p. 237) and Viewing parameter values for a DB cluster parameter group (p. 226).

Topics
- Working with DB cluster parameter groups (p. 217)
- Working with DB parameter groups (p. 228)
- Comparing parameter groups (p. 238)
- Specifying DB parameters (p. 238)

Working with DB cluster parameter groups

Amazon Aurora DB clusters use DB cluster parameter groups. The following sections describe configuring and managing DB cluster parameter groups.

Topics
- Amazon Aurora DB cluster and DB instance parameters (p. 217)
- Creating a DB cluster parameter group (p. 219)
- Associating a DB cluster parameter group with a DB cluster (p. 220)
- Modifying parameters in a DB cluster parameter group (p. 221)
- Resetting parameters in a DB cluster parameter group (p. 223)
- Copying a DB cluster parameter group (p. 224)
- Listing DB cluster parameter groups (p. 225)
- Viewing parameter values for a DB cluster parameter group (p. 226)

Amazon Aurora DB cluster and DB instance parameters

Aurora uses a two-level system of configuration settings:

- Parameters in a DB cluster parameter group apply to every DB instance in a DB cluster. Your data is stored in the Aurora shared storage subsystem. Because of this, all parameters related to physical layout of table data must be the same for all DB instances in an Aurora cluster. Likewise, because Aurora DB instances are connected by replication, all the parameters for replication settings must be identical throughout an Aurora cluster.
Parameters in a *DB parameter group* apply to a single DB instance in an Aurora DB cluster. These parameters are related to aspects such as memory usage that you can vary across DB instances in the same Aurora cluster. For example, a cluster often contains DB instances with different AWS instance classes.

Every Aurora cluster is associated with a DB cluster parameter group. This parameter group assigns default values for every configuration value for the corresponding DB engine. The cluster parameter group includes defaults for both the cluster-level and instance-level parameters. Each DB instance within a provisioned or Aurora Serverless v2 cluster inherits the settings from that DB cluster parameter group.

Each DB instance is also associated with a DB parameter group. The values in the DB parameter group can override default values from the cluster parameter group. For example, if one instance in a cluster experienced issues, you might assign a custom DB parameter group to that instance. The custom parameter group might have specific settings for parameters related to debugging or performance tuning.

Aurora assigns default parameter groups when you create a cluster or a new DB instance, based on the specified database engine and version. You can specify custom parameter groups instead. You create those parameter groups yourself, and you can edit the parameter values. You can specify these custom parameter groups at creation time. You can also modify a DB cluster or instance later to use a custom parameter group.

For provisioned and Aurora Serverless v2 instances, any configuration values that you modify in the DB cluster parameter group override default values in the DB parameter group. If you edit the corresponding values in the DB parameter group, those values override the settings from the DB cluster parameter group.

Any DB parameter settings that you modify take precedence over the DB cluster parameter group values, even if you change the configuration parameters back to their default values. You can see which parameters are overridden by using the describe-db-parameters AWS CLI command or the DescribeDBParameters RDS API operation. The *Source* field contains the value *user* if you modified that parameter. To reset one or more parameters so that the value from the DB cluster parameter group takes precedence, use the reset-db-parameter-group AWS CLI command or the ResetDBParameterGroup RDS API operation.

The DB cluster and DB instance parameters available to you in Aurora vary depending on database engine compatibility.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Note**

Aurora Serverless v1 clusters have only DB cluster parameter groups, not DB parameter groups. For Aurora Serverless v2 clusters, you make all your changes to custom parameters in the DB cluster parameter group.
Aurora Serverless v2 uses both DB cluster parameter groups and DB parameter groups. With Aurora Serverless v2, you can modify almost all of the configuration parameters. Aurora Serverless v2 overrides the settings of some capacity-related configuration parameters so that your workload isn't interrupted when Aurora Serverless v2 instances scale down. To learn more about Aurora Serverless configuration settings and which settings you can modify, see Working with parameter groups for Aurora Serverless v2 (p. 1534) and Parameter groups for Aurora Serverless v1 (p. 1553).

Creating a DB cluster parameter group

You can create a new DB cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

After you create a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully create the parameter group before it is used by the new DB cluster. You can use the Parameter groups page in the Amazon RDS console or the describe-db-cluster-parameters command to verify that your DB cluster parameter group is created.

Console

To create a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
   The Create parameter group window appears.
4. In the Parameter group family list, select a DB parameter group family
5. In the Type list, select DB Cluster Parameter Group.
6. In the Group name box, enter the name of the new DB cluster parameter group.
7. In the Description box, enter a description for the new DB cluster parameter group.
8. Choose Create.

AWS CLI

To create a DB cluster parameter group, use the AWS CLI create-db-cluster-parameter-group command.

The following example creates a DB cluster parameter group named mydbclusterparametergroup for Aurora MySQL version 5.7 with a description of "My new cluster parameter group."

Include the following required parameters:

- --db-cluster-parameter-group-name
- --db-parameter-group-family
- --description

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

Note
The output contains duplicates.
Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster-parameter-group \
  --db-cluster-parameter-group-name mydbclusterparametergroup \
  --db-parameter-group-family aurora-mysql5.7 \
  --description "My new cluster parameter group"
```

For Windows:

```bash
aws rds create-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name mydbclusterparametergroup ^
  --db-parameter-group-family aurora-mysql5.7 ^
  --description "My new cluster parameter group"
```

This command produces output similar to the following:

```json
{
    "DBClusterParameterGroup": {
        "DBClusterParameterGroupName": "mydbclusterparametergroup",
        "DBParameterGroupFamily": "aurora-mysql5.7",
        "Description": "My new cluster parameter group",
        "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-pg:mydbclusterparametergroup"
    }
}
```

RDS API

To create a DB cluster parameter group, use the RDS API `CreateDBClusterParameterGroup` action.

Include the following required parameters:

- `DBClusterParameterGroupName`
- `DBParameterGroupFamily`
- `Description`

Associating a DB cluster parameter group with a DB cluster

You can create your own DB cluster parameter groups with customized settings. You can associate a DB cluster parameter group with a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB cluster.

For information about creating a DB cluster parameter group, see Creating a DB cluster parameter group (p. 219). For information about creating a DB cluster, see Creating an Amazon Aurora DB cluster (p. 127). For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 248).

Note

After you change the DB cluster parameter group associated with a DB cluster, reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster.

To determine whether the primary DB instance of a DB cluster must be rebooted to apply changes, run the following AWS CLI command:

```bash
aws rds describe-db-clusters --db-cluster-identifier db_cluster_identifier
```

Check the `DBClusterParameterGroupStatus` value for the primary DB instance in the output. If the value is `pending-reboot`, then reboot the primary DB instance of the DB cluster.
**Console**

**To associate a DB cluster parameter group with a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB cluster that you want to modify.
4. Change the DB cluster parameter group setting.
5. Choose Continue and check the summary of modifications.
   The change is applied immediately regardless of the Scheduling of modifications setting.
6. On the confirmation page, review your changes. If they are correct, choose Modify cluster to save your changes.
   Alternatively, choose Back to edit your changes, or choose Cancel to cancel your changes.

**AWS CLI**

To associate a DB cluster parameter group with a DB cluster, use the AWS CLI `modify-db-cluster` command with the following options:

- `--db-cluster-name`
- `--db-cluster-parameter-group-name`

The following example associates the mydbclpg DB parameter group with the mydbcluster DB cluster.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --db-cluster-parameter-group-name mydbclpg
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --db-cluster-parameter-group-name mydbclpg
```

**RDS API**

To associate a DB cluster parameter group with a DB cluster, use the RDS API `ModifyDBCluster` operation with the following parameters:

- `DBClusterIdentifier`
- `DBClusterParameterGroupName`

**Modifying parameters in a DB cluster parameter group**

You can modify parameter values in a customer-created DB cluster parameter group. You can't change the parameter values in a default DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.
Console

To modify a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the parameter group that you want to modify.
4. For Parameter group actions, choose Edit.
5. Change the values of the parameters you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
   You can't change values in a default parameter group.
6. Choose Save changes.
7. Reboot the primary DB instance in the cluster to apply the changes to all of the DB instances in the cluster.

AWS CLI

To modify a DB cluster parameter group, use the AWS CLI `modify-db-cluster-parameter-group` command with the following required parameters:

- `--db-cluster-parameter-group-name`
- `--parameters`

The following example modifies the `server_audit_logging` and `server_audit_logs_upload` values in the DB cluster parameter group named `mydbclusterparametergroup`.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name mydbclusterparametergroup \
  --parameters
  "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" \
  "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name mydbclusterparametergroup ^
  --parameters
  "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
  "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBCLUSTERPARAMETERGROUP  mydbclusterparametergroup
```

RDS API

To modify a DB cluster parameter group, use the RDS API `ModifyDBClusterParameterGroup` command with the following required parameters:
• `DBClusterParameterGroupName`

• `Parameters`

### Resetting parameters in a DB cluster parameter group

You can reset parameters to their default values in a customer-created DB cluster parameter group. Changes to parameters in a customer-created DB cluster parameter group are applied to all DB clusters that are associated with the DB cluster parameter group.

**Note**

In a default DB cluster parameter group, parameters are always set to their default values.

#### Console

**To reset parameters in a DB cluster parameter group to their default values**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

   You can't reset values in a default parameter group.
6. Choose **Reset** and then confirm by choosing **Reset parameters**.
7. Reboot the primary DB instance in the DB cluster to apply the changes to all of the DB instances in the DB cluster.

#### AWS CLI

**To reset parameters in a DB cluster parameter group to their default values**, use the AWS CLI `reset-db-cluster-parameter-group` command with the following required option: `--db-cluster-parameter-group-name`.

To reset all of the parameters in the DB cluster parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named `mydbparametergroup` to their default values.

**Example**

**For Linux, macOS, or Unix:**

```bash
aws rds reset-db-cluster-parameter-group \
  --db-cluster-parameter-group-name mydbparametergroup \
  --reset-all-parameters
```

**For Windows:**

```bash
aws rds reset-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name mydbparametergroup ^
  --reset-all-parameters
```
The following example resets the `server_audit_logging` and `server_audit_logs_upload` to their default values in the DB cluster parameter group named `mydbclusterparametergroup`.

### Example

For Linux, macOS, or Unix:

```bash
aws rds reset-db-cluster-parameter-group \
  --db-cluster-parameter-group-name mydbclusterparametergroup \
  --parameters "ParameterName=server_audit_logging,ApplyMethod=immediate" \
  "ParameterName=server_audit_logs_upload,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds reset-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name mydbclusterparametergroup ^
  --parameters "ParameterName=server_audit_logging,ParameterValue=1,ApplyMethod=immediate" ^
  "ParameterName=server_audit_logs_upload,ParameterValue=1,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBClusterParameterGroupName  mydbclusterparametergroup
```

### RDS API

To reset parameters in a DB cluster parameter group to their default values, use the RDS API `ResetDBClusterParameterGroup` command with the following required parameter: `DBClusterParameterGroupName`.

To reset all of the parameters in the DB cluster parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

### Copying a DB cluster parameter group

You can copy custom DB cluster parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB cluster parameter group and you want to include most of the custom parameters and values from that group in a new DB cluster parameter group.

You can copy a DB cluster parameter group by using the AWS CLI `copy-db-cluster-parameter-group` command or the RDS API `CopyDBClusterParameterGroup` operation.

After you copy a DB cluster parameter group, wait at least 5 minutes before creating a DB cluster that uses that DB cluster parameter group. Doing this allows Amazon RDS to fully copy the parameter group before it is used by the new DB cluster. You can use the `Parameter groups` page in the Amazon RDS console or the `describe-db-cluster-parameters` command to verify that your DB cluster parameter group is created.

**Note**

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

### Console

#### To copy a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the custom parameter group that you want to copy.
4. For **Parameter group actions**, choose **Copy**.
5. In **New DB parameter group identifier**, enter a name for the new parameter group.
6. In **Description**, enter a description for the new parameter group.
7. Choose **Copy**.

**AWS CLI**

To copy a DB cluster parameter group, use the AWS CLI `copy-db-cluster-parameter-group` command with the following required parameters:

- `--source-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-identifier`
- `--target-db-cluster-parameter-group-description`

The following example creates a new DB cluster parameter group named `mygroup2` that is a copy of the DB cluster parameter group `mygroup1`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds copy-db-cluster-parameter-group
  --source-db-cluster-parameter-group-identifier mygroup1
  --target-db-cluster-parameter-group-identifier mygroup2
  --target-db-cluster-parameter-group-description "DB parameter group 2"
```

For Windows:

```bash
aws rds copy-db-cluster-parameter-group
  --source-db-cluster-parameter-group-identifier mygroup1
  --target-db-cluster-parameter-group-identifier mygroup2
  --target-db-cluster-parameter-group-description "DB parameter group 2"
```

**RDS API**

To copy a DB cluster parameter group, use the RDS API `CopyDBClusterParameterGroup` operation with the following required parameters:

- `SourceDBClusterParameterGroupIdentifier`
- `TargetDBClusterParameterGroupIdentifier`
- `TargetDBClusterParameterGroupDescription`

**Listing DB cluster parameter groups**

You can list the DB cluster parameter groups you've created for your AWS account.

**Note**

Default parameter groups are automatically created from a default parameter template when you create a DB cluster for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.
Console

To list all DB cluster parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.

   The DB cluster parameter groups appear in the list with DB cluster parameter group for Type.

AWS CLI

To list all DB cluster parameter groups for an AWS account, use the AWS CLI describe-db-cluster-parameter-groups command.

Example

The following example lists all available DB cluster parameter groups for an AWS account.

```bash
aws rds describe-db-cluster-parameter-groups
```

The following example describes the mydbclusterparametergroup parameter group.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-cluster-parameter-groups --db-cluster-parameter-group-name mydbclusterparametergroup
```

For Windows:

```bash
aws rds describe-db-cluster-parameter-groups --db-cluster-parameter-group-name mydbclusterparametergroup
```

The command returns a response like the following:

```json
{
   "DBClusterParameterGroups": [
      {
         "DBClusterParameterGroupName": "mydbclusterparametergroup",
         "DBParameterGroupFamily": "aurora-mysql5.7",
         "Description": "My new cluster parameter group",
         "DBClusterParameterGroupArn": "arn:aws:rds:us-east-1:123456789012:cluster-pg:mydbclusterparametergroup"
      }
   ]
}
```

RDS API

To list all DB cluster parameter groups for an AWS account, use the RDS API DescribeDBClusterParameterGroups action.

Viewing parameter values for a DB cluster parameter group

You can get a list of all parameters in a DB cluster parameter group and their values.
Console

To view the parameter values for a DB cluster parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
   The DB cluster parameter groups appear in the list with DB cluster parameter group for Type.
3. Choose the name of the DB cluster parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB cluster parameter group, use the AWS CLI describe-db-cluster-parameters command with the following required parameter.

• --db-cluster-parameter-group-name

Example

The following example lists the parameters and parameter values for a DB cluster parameter group named mydbclusterparametergroup, in JSON format.

The command returns a response like the following:

```
aws rds describe-db-cluster-parameters --db-cluster-parameter-group-name mydbclusterparametergroup
```

```
{
    "Parameters": [
        {
            "ParameterName": "allow-suspicious-udfs",
            "Description": "Controls whether user-defined functions that have only an xxx symbol for the main function can be loaded",
            "Source": "engine-default",
            "ApplyType": "static",
            "DataType": "boolean",
            "IsModifiable": false,
            "ApplyMethod": "pending-reboot",
            "SupportedEngineModes": ["provisioned"],
        },
        {
            "ParameterName": "aurora_binlog_read_buffer_size",
            "ParameterValue": "5242880",
            "Description": "Read buffer size used by master dump thread when the switch aurora_binlog_use_large_read_buffer is ON.",
            "Source": "engine-default",
            "ApplyType": "dynamic",
            "DataType": "integer",
            "IsModifiable": false,
            "ApplyMethod": "pending-reboot",
            "SupportedEngineModes": ["provisioned",
        }
    ],
}
```
To view the parameter values for a DB cluster parameter group, use the RDS API `DescribeDBClusterParameters` command with the following required parameter:

- `DBClusterParameterGroupName`

**Working with DB parameter groups**

DB instances use DB parameter groups. The following sections describe configuring and managing DB instance parameter groups.

**Topics**

- Creating a DB parameter group (p. 228)
- Associating a DB parameter group with a DB instance (p. 229)
- Modifying parameters in a DB parameter group (p. 231)
- Resetting parameters in a DB parameter group to their default values (p. 233)
- Copying a DB parameter group (p. 235)
- Listing DB parameter groups (p. 236)
- Viewing parameter values for a DB parameter group (p. 237)

**Creating a DB parameter group**

You can create a new DB parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

To create a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
   
   The **Create parameter group** window appears.
4. In the **Parameter group family** list, select a DB parameter group family.
5. In the **Type** list, select **DB Parameter Group**.
6. In the **Group name** box, enter the name of the new DB parameter group.
7. In the **Description** box, enter a description for the new DB parameter group.
8. Choose **Create**.

**AWS CLI**

To create a DB parameter group, use the AWS CLI `create-db-parameter-group` command. The following example creates a DB parameter group named `mydbparametergroup` for MySQL version 8.0 with a description of "My new parameter group."

Include the following required parameters:
To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

**Note**
The output contains duplicates.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
   --db-parameter-group-name mydbparametergroup \
   --db-parameter-group-family aurora5.6 \
   --description "My new parameter group"
```

For Windows:

```
aws rds create-db-parameter-group ^
   --db-parameter-group-name mydbparametergroup ^
   --db-parameter-group-family aurora5.6 ^
   --description "My new parameter group"
```

This command produces output similar to the following:

```
DBPARAMETERGROUP  mydbparametergroup  aurora5.6  My new parameter group
```

**RDS API**

To create a DB parameter group, use the RDS API `CreateDBParameterGroup` operation.

Include the following required parameters:

- `DBParameterGroupName`
- `DBParameterGroupFamily`
- `Description`

**Associating a DB parameter group with a DB instance**

You can create your own DB parameter groups with customized settings. You can associate a DB parameter group with a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB instance.

For information about creating a DB parameter group, see Creating a DB parameter group (p. 228). For information about modifying a DB instance, see Modify a DB instance in a DB cluster (p. 249).

**Note**
When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the newly associated DB parameter group, these changes are applied immediately without a reboot.
Console

To associate a DB parameter group with a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.
3. Choose Modify. The Modify DB Instance page appears.
4. Change the DB parameter group setting.
5. Choose Continue and check the summary of modifications.
6. (Optional) Choose Apply immediately to apply the changes immediately. Choosing this option can cause an outage in some cases.
7. On the confirmation page, review your changes. If they are correct, choose Modify DB instance to save your changes.

Or choose Back to edit your changes or Cancel to cancel your changes.

AWS CLI

To associate a DB parameter group with a DB instance, use the AWS CLI modify-db-instance command with the following options:

- `--db-instance-identifier`
- `--db-parameter-group-name`

The following example associates the mydbpg DB parameter group with the database-1 DB instance. The changes are applied immediately by using `--apply-immediately`. Use `--no-apply-immediately` to apply the changes during the next maintenance window.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance --db-instance-identifier database-1 --db-parameter-group-name mydbpg --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance --db-instance-identifier database-1 --db-parameter-group-name mydbpg --apply-immediately
```

RDS API

To associate a DB parameter group with a DB instance, use the RDS API ModifyDBInstance operation with the following parameters:

- DBInstanceName
- DBParameterGroupName
Modifying parameters in a DB parameter group

You can modify parameter values in a customer-created DB parameter group; you can't change the parameter values in a default DB parameter group. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the Configuration tab. For example, if the DB instance isn't using the latest changes to its associated DB parameter group, the RDS console shows the DB parameter group with a status of pending-reboot. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

Console

To modify a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters that you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

   You can't change values in a default parameter group.

6. Choose **Save changes**.

### AWS CLI

To modify a DB parameter group, use the AWS CLI `modify-db-parameter-group` command with the following required options:

- `--db-parameter-group-name`
- `--parameters`

The following example modifies the `max_connections` and `max_allowed_packet` values in the DB parameter group named `mydbparametergroup`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
   --db-parameter-group-name mydbparametergroup \
   --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" \
   "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
   --db-parameter-group-name mydbparametergroup ^
   --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" ^
   "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBPARAMETERGROUP  mydbparametergroup
```

### RDS API

To modify a DB parameter group, use the RDS API `ModifyDBParameterGroup` operation with the following required parameters:

- `DBParameterGroupName`
- `Parameters`
Resetting parameters in a DB parameter group to their default values

You can reset parameter values in a customer-created DB parameter group to their default values. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

When you use the console, you can reset specific parameters to their default values, but you can't easily reset all of the parameters in the DB parameter group at once. When you use the AWS CLI or RDS API, you can reset specific parameters to their default values, and you can reset all of the parameters in the DB parameter group at once.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the Configuration tab. For example, if the DB instance isn't using the latest changes to its associated DB parameter group, the RDS console shows the DB parameter group with a status of pending-reboot. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.
Note
In a default DB parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB parameter group to their default values

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the parameter group.
4. For Parameter group actions, choose Edit.
5. Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't reset values in a default parameter group.
6. Choose Reset and then confirm by choosing Reset parameters.

AWS CLI

To reset some or all of the parameters in a DB parameter group, use the AWS CLI `reset-db-parameter-group` command with the following required option: `--db-parameter-group-name`.

To reset all of the parameters in the DB parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named `mydbparametergroup` to their default values.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --reset-all-parameters
```

For Windows:

```
aws rds reset-db-parameter-group ^
    --db-parameter-group-name mydbparametergroup ^
    --reset-all-parameters
```

The following example resets the `max_connections` and `max_allowed_packet` options to their default values in the DB parameter group named `mydbparametergroup`.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --parameters "ParameterName=max_connections,ApplyMethod=immediate" \ 
        "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

For Windows:
aws rds reset-db-parameter-group ^
   --db-parameter-group-name mydbparametergroup ^
   --parameters "ParameterName=max_connections,ApplyMethod=immediate" ^
   "ParameterName=max_allowed_packet,ApplyMethod=immediate"

The command produces output like the following:

<table>
<thead>
<tr>
<th>DBParameterGroupName</th>
<th>mydbparametergroup</th>
</tr>
</thead>
</table>

RDS API

To reset parameters in a DB parameter group to their default values, use the RDS API `ResetDBParameterGroup` command with the following required parameter: `DBParameterGroupName`.

To reset all of the parameters in the DB parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

### Copying a DB parameter group

You can copy custom DB parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB parameter group and you want to include most of the custom parameters and values from that group in a new DB parameter group. You can copy a DB parameter group by using the AWS Management Console, the AWS CLI `copy-db-parameter-group` command, or the RDS API `CopyDBParameterGroup` operation.

After you copy a DB parameter group, wait at least 5 minutes before creating your first DB instance that uses that DB parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used. This is especially important for parameters that are critical when creating the default database for a DB instance. An example is the character set for the default database defined by the `character_set_database` parameter. Use the `Parameter Groups` option of the Amazon RDS console or the `describe-db-parameters` command to verify that your DB parameter group is created.

**Note**

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

Currently, you can't copy a parameter group to a different AWS Region.

#### Console

**To copy a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose `Parameter groups`.
3. In the list, choose the custom parameter group that you want to copy.
4. For `Parameter group actions`, choose `Copy`.
5. In `New DB parameter group identifier`, enter a name for the new parameter group.
6. In `Description`, enter a description for the new parameter group.
7. Choose `Copy`.

#### AWS CLI

To copy a DB parameter group, use the AWS CLI `copy-db-parameter-group` command with the following required options:
• --source-db-parameter-group-identifier
• --target-db-parameter-group-identifier
• --target-db-parameter-group-description

The following example creates a new DB parameter group named mygroup2 that is a copy of the DB parameter group mygroup1.

**Example**

For Linux, macOS, or Unix:

```
aws rds copy-db-parameter-group \
    --source-db-parameter-group-identifier mygroup1 \
    --target-db-parameter-group-identifier mygroup2 \
    --target-db-parameter-group-description "DB parameter group 2"
```

For Windows:

```
aws rds copy-db-parameter-group ^
    --source-db-parameter-group-identifier mygroup1 ^
    --target-db-parameter-group-identifier mygroup2 ^
    --target-db-parameter-group-description "DB parameter group 2"
```

**RDS API**

To copy a DB parameter group, use the RDS API CopyDBParameterGroup operation with the following required parameters:

- SourceDBParameterGroupIdentifier
- TargetDBParameterGroupIdentifier
- TargetDBParameterGroupDescription

**Listing DB parameter groups**

You can list the DB parameter groups you've created for your AWS account.

**Note**

Default parameter groups are automatically created from a default parameter template when you create a DB instance for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

**Console**

**To list all DB parameter groups for an AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
   The DB parameter groups appear in a list.

**AWS CLI**

To list all DB parameter groups for an AWS account, use the AWS CLI `describe-db-parameter-groups` command.
Example

The following example lists all available DB parameter groups for an AWS account.

```bash
aws rds describe-db-parameter-groups
```

The command returns a response like the following:

<table>
<thead>
<tr>
<th>DBPARAMETERGROUP</th>
<th>DBPARAMETERGROUP</th>
<th>DBPARAMETERGROUP</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default.mysql8.0</td>
<td>mysql8.0</td>
<td>Default parameter group for MySQL8.0</td>
<td></td>
</tr>
<tr>
<td>mydbparametergroup</td>
<td>mysql8.0</td>
<td>My new parameter group</td>
<td></td>
</tr>
</tbody>
</table>

The following example describes the `mydbparamgroup1` parameter group.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-parameter-groups --db-parameter-group-name mydbparamgroup1
```

For Windows:

```bash
aws rds describe-db-parameter-groups --db-parameter-group-name mydbparamgroup1
```

The command returns a response like the following:

<table>
<thead>
<tr>
<th>DBPARAMETERGROUP</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydbparametergroup1</td>
<td>mysql8.0 My new parameter group</td>
</tr>
</tbody>
</table>

**RDS API**

To list all DB parameter groups for an AWS account, use the RDS API `DescribeDBParameterGroups` operation.

**Viewing parameter values for a DB parameter group**

You can get a list of all parameters in a DB parameter group and their values.

**Console**

**To view the parameter values for a DB parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Parameter groups**.
   - The DB parameter groups appear in a list.
3. Choose the name of the parameter group to see its list of parameters.

**AWS CLI**

To view the parameter values for a DB parameter group, use the AWS CLI `describe-db-parameters` command with the following required parameter.

- `--db-parameter-group-name`
Example

The following example lists the parameters and parameter values for a DB parameter group named `mydbparametergroup`.

```
aws rds describe-db-parameters --db-parameter-group-name mydbparametergroup
```

The command returns a response like the following:

<table>
<thead>
<tr>
<th>DBPARAMETER</th>
<th>Parameter Name</th>
<th>Parameter Value</th>
<th>Source</th>
<th>Data Type</th>
<th>Apply</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>allow-suspicious-udfs</td>
<td></td>
<td>engine-default</td>
<td>boolean</td>
<td>static</td>
</tr>
<tr>
<td>true</td>
<td>auto_increment_increment</td>
<td></td>
<td>engine-default</td>
<td>integer</td>
<td>dynamic</td>
</tr>
<tr>
<td>true</td>
<td>auto_increment_offset</td>
<td></td>
<td>engine-default</td>
<td>integer</td>
<td>dynamic</td>
</tr>
<tr>
<td>true</td>
<td>binlog_cache_size</td>
<td>32768</td>
<td>system</td>
<td>integer</td>
<td>dynamic</td>
</tr>
<tr>
<td>false</td>
<td>socket</td>
<td>/tmp/mysql.sock</td>
<td>system</td>
<td>string</td>
<td>static</td>
</tr>
</tbody>
</table>

RDS API

To view the parameter values for a DB parameter group, use the RDS API `DescribeDBParameters` command with the following required parameter.

- `DBParameterGroupName`

Comparing parameter groups

You can use the AWS Management Console to view the differences between two parameter groups for the same DB engine and version.

To compare two parameter groups

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. In the navigation pane, choose `Parameter groups`.
3. In the list, choose the two parameter groups that you want to compare.
4. For `Parameter group actions`, choose `Compare`.

Note

The specified parameter groups must be for the same DB engine and version. If they aren't equivalent, you can't choose `Compare`. For example, you can't compare a MySQL 5.7 and a MySQL 8.0 parameter group because the DB engine version is different. In addition, they both must be DB parameter groups, or they both must be DB cluster parameter groups. For example, you can't compare an Aurora MySQL 8.0 DB parameter group and an Aurora MySQL 8.0 DB cluster parameter group, even though the DB engine and version are the same.

Specifying DB parameters

DB parameter types include the following:
• Integer
• Boolean
• String
• Long
• Double
• Timestamp
• Object of other defined data types
• Array of values of type integer, Boolean, string, long, double, timestamp, or object

You can also specify integer and Boolean parameters using expressions, formulas, and functions.

Contents
• DB parameter formulas (p. 239)
  • DB parameter formula variables (p. 239)
  • DB parameter formula operators (p. 240)
• DB parameter functions (p. 240)
• DB parameter log expressions (p. 241)
• DB parameter value examples (p. 241)

DB parameter formulas

A DB parameter formula is an expression that resolves to an integer value or a Boolean value. You enclose the expression in braces: {}. You can use a formula for either a DB parameter value or as an argument to a DB parameter function.

Syntax

```
{FormulaVariable}
{FormulaVariable*Integer}
{FormulaVariable*Integer/Integer}
{FormulaVariable/Integer}
```

DB parameter formula variables

Each formula variable returns an integer or a Boolean value. The names of the variables are case-sensitive.

AllocatedStorage

Returns an integer representing the size, in bytes, of the data volume.

DBInstanceClassMemory

Returns an integer for the number of bytes of memory available to the database process. This number is internally calculated by taking the total amount of memory for the DB instance class and subtracting memory reserved for the operating system and the RDS processes that manage the instance. Therefore, the number is always somewhat lower than the memory figures shown in the instance class tables in Aurora DB instance classes (p. 56). The exact value depends on a combination of instance class, DB engine, and whether it applies to an RDS instance or an instance that's part of an Aurora cluster.

EndPointPort

Returns an integer representing the port used when connecting to the DB instance.
DB parameter formula operators

DB parameter formulas support two operators: division and multiplication.

**Division operator:** `/`

Divides the dividend by the divisor, returning an integer quotient. Decimals in the quotient are truncated, not rounded.

**Syntax**

```
dividend / divisor
```

The dividend and divisor arguments must be integer expressions.

**Multiplication operator:** `*`

Multiplies the expressions, returning the product of the expressions. Decimals in the expressions are truncated, not rounded.

**Syntax**

```
expression * expression
```

Both expressions must be integers.

DB parameter functions

You specify the arguments of DB parameter functions as either integers or formulas. Each function must have at least one argument. Specify multiple arguments as a comma-separated list. The list can't have any empty members, such as `argument1,,argument3`. Function names are case-insensitive.

**IF**

Returns an argument.

**Syntax**

```
IF(argument1, argument2, argument3)
```

Returns the second argument if the first argument evaluates to true. Returns the third argument otherwise.

**GREATEST**

Returns the largest value from a list of integers or parameter formulas.

**Syntax**

```
GREATEST(argument1, argument2,...argumentn)
```

Returns an integer.

**LEAST**

Returns the smallest value from a list of integers or parameter formulas.

**Syntax**
### LEAST

\[
\text{LEAST}(\text{argument1}, \text{argument2},...\text{argumentn})
\]

Returns an integer.

### SUM

Adds the values of the specified integers or parameter formulas.

**Syntax**

\[
\text{SUM}(\text{argument1}, \text{argument2},...\text{argumentn})
\]

Returns an integer.

### DB parameter log expressions

You can set an integer DB parameter value to a log expression. You enclose the expression in braces: {}. For example:

\{\log(DBInstanceClassMemory/8187281418)*1000\}

The \log \text{ function represents log base 2. This example also uses the DBInstanceClassMemory formula variable. See DB parameter formula variables (p. 239).}

### DB parameter value examples

These examples show using formulas, functions, and expressions for the values of DB parameters.

**Note**

DB Parameter functions are currently supported only in the console and aren't supported in the AWS CLI.

**Warning**

Improperly setting parameters in a DB parameter group can have unintended adverse effects. These might include degraded performance and system instability. Use caution when modifying database parameters and back up your data before modifying your DB parameter group. Try out parameter group changes on a test DB instance, created using point-in-time-restores, before applying those parameter group changes to your production DB instances.

#### Example using the DB parameter function LEAST

You can specify the LEAST function in an Aurora MySQL table_definition_cache parameter value. Use it to set the number of table definitions that can be stored in the definition cache to the lesser of DBInstanceClassMemory/393040 or 20,000.

\[\text{LEAST}({\{\text{DBInstanceClassMemory}/393040\}}, 20000)\]
Migrating data to an Amazon Aurora DB cluster

You have several options for migrating data from your existing database to an Amazon Aurora DB cluster, depending on database engine compatibility. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating.

Migrating data to an Amazon Aurora MySQL DB cluster

You can migrate data from one of the following sources to an Amazon Aurora MySQL DB cluster.

- An RDS for MySQL DB instance
- A MySQL database external to Amazon RDS
- A database that is not MySQL-compatible

For more information, see Migrating data to an Amazon Aurora MySQL DB cluster (p. 690).

Migrating data to an Amazon Aurora PostgreSQL DB cluster

You can migrate data from one of the following sources to an Amazon Aurora PostgreSQL DB cluster.

- An Amazon RDS PostgreSQL DB instance
- A database that is not PostgreSQL-compatible

For more information, see Migrating data to Amazon Aurora with PostgreSQL compatibility (p. 1049).
Managing an Amazon Aurora DB cluster

This section shows how to manage and maintain your Aurora DB cluster. Aurora involves clusters of database servers that are connected in a replication topology. Thus, managing Aurora often involves deploying changes to multiple servers and making sure that all Aurora Replicas are keeping up with the master server. Because Aurora transparently scales the underlying storage as your data grows, managing Aurora requires relatively little management of disk storage. Likewise, because Aurora automatically performs continuous backups, an Aurora cluster does not require extensive planning or downtime for performing backups.

Topics

- Stopping and starting an Amazon Aurora DB cluster (p. 244)
- Modifying an Amazon Aurora DB cluster (p. 248)
- Adding Aurora Replicas to a DB cluster (p. 270)
- Managing performance and scaling for Aurora DB clusters (p. 274)
- Cloning a volume for an Amazon Aurora DB cluster (p. 280)
- Integrating Aurora with other AWS services (p. 304)
- Maintaining an Amazon Aurora DB cluster (p. 321)
- Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance (p. 329)
- Deleting Aurora DB clusters and DB instances (p. 345)
- Tagging Amazon RDS resources (p. 352)
- Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 360)
- Amazon Aurora updates (p. 367)
Stopping and starting an Amazon Aurora DB cluster

Stopping and starting Amazon Aurora clusters helps you manage costs for development and test environments. You can temporarily stop all the DB instances in your cluster, instead of setting up and tearing down all the DB instances each time that you use the cluster.

Topics
- Overview of stopping and starting an Aurora DB cluster (p. 244)
- Limitations for stopping and starting Aurora DB clusters (p. 244)
- Stopping an Aurora DB cluster (p. 245)
- Possible operations while an Aurora DB cluster is stopped (p. 246)
- Starting an Aurora DB cluster (p. 246)

Overview of stopping and starting an Aurora DB cluster

During periods where you don't need an Aurora cluster, you can stop all instances in that cluster at once. You can start the cluster again anytime you need to use it. Starting and stopping simplifies the setup and teardown processes for clusters used for development, testing, or similar activities that don't require continuous availability. You can perform all the AWS Management Console procedures involved with only a single action, regardless of how many instances are in the cluster.

While your DB cluster is stopped, you are charged only for cluster storage, manual snapshots, and automated backup storage within your specified retention window. You aren't charged for any DB instance hours.

Important
You can stop a DB cluster for up to seven days. If you don't manually start your DB cluster after seven days, your DB cluster is automatically started so that it doesn't fall behind any required maintenance updates.

To minimize charges for a lightly loaded Aurora cluster, you can stop the cluster instead of deleting all of its Aurora Replicas. For clusters with more than one or two instances, frequently deleting and recreating the DB instances is only practical using the AWS CLI or Amazon RDS API. Such a sequence of operations can also be difficult to perform in the right order, for example to delete all Aurora Replicas before deleting the primary instance to avoid activating the failover mechanism.

Don't use starting and stopping if you need to keep your DB cluster running but it has more capacity than you need. If your cluster is too costly or not very busy, delete one or more DB instances or change all your DB instances to a small instance class. You can't stop an individual Aurora DB instance.

Limitations for stopping and starting Aurora DB clusters

Some Aurora clusters can't be stopped and started:
- You can't stop and start a cluster that's part of an Aurora global database (p. 151).
- You can't stop and start a cluster that has a cross-Region read replica.
• For a cluster that uses the Aurora parallel query (p. 791) feature, the minimum Aurora MySQL versions are 1.23.0 and 2.09.0.
• You can't stop and start an Aurora Serverless v1 cluster (p. 1542). With Aurora Serverless v2 (p. 1481), you can stop and start the cluster.
• You can't stop and start an Aurora multi-master cluster (p. 868).

If an existing cluster can't be stopped and started, the Stop action isn't available from the Actions menu on the Databases page or the details page.

Stopping an Aurora DB cluster

To use an Aurora DB cluster or perform administration, you always begin with a running Aurora DB cluster, then stop the cluster, and then start the cluster again. While your cluster is stopped, you are charged for cluster storage, manual snapshots, and automated backup storage within your specified retention window, but not for DB instance hours.

The stop operation stops the Aurora Replica instances first, then the primary instance, to avoid activating the failover mechanism.

You can't stop a DB cluster that acts as the replication target for data from another DB cluster, or acts as the replication master and transmits data to another cluster.

You can't stop certain special kinds of clusters. Currently, you can't stop a cluster that's part of an Aurora global database, or a multi-master cluster.

**Console**

**To stop an Aurora cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose a cluster. You can perform the stop operation from this page, or navigate to the details page for the DB cluster that you want to stop.

   If an existing cluster can't be stopped and started, the Stop action isn't available from the Actions menu on the Databases page or the details page. For the kinds of clusters that you can't start and stop, see Limitations for stopping and starting Aurora DB clusters (p. 244).
3. For Actions, choose Stop.

**AWS CLI**

To stop a DB instance by using the AWS CLI, call the stop-db-cluster command with the following parameters:

• --db-cluster-identifier – the name of the Aurora cluster.

**Example**

```
aws rds stop-db-cluster --db-cluster-identifier mydbcluster
```

**RDS API**

To stop a DB instance by using the Amazon RDS API, call the StopDBCluster operation with the following parameter:
Possible operations while an Aurora DB cluster is stopped

While an Aurora cluster is stopped, you can do a point-in-time restore to any point within your specified automated backup retention window. For details about doing a point-in-time restore, see Restoring data (p. 371).

You can't modify the configuration of an Aurora DB cluster, or any of its DB instances, while the cluster is stopped. You also can't add or remove DB instances from the cluster, or delete the cluster if it still has any associated DB instances. You must start the cluster before performing any such administrative actions.

Stopping a DB cluster removes pending actions, except for the DB cluster parameter group or for the DB parameter groups of the DB cluster instances.

Aurora applies any scheduled maintenance to your stopped cluster after it's started again. Remember that after seven days, Aurora automatically starts any stopped clusters so that they don't fall too far behind in their maintenance status.

Aurora also doesn't perform any automated backups, because the underlying data can't change while the cluster is stopped. Aurora doesn't extend the backup retention period while the cluster is stopped.

Starting an Aurora DB cluster

You always start an Aurora DB cluster beginning with an Aurora cluster that is already in the stopped state. When you start the cluster, all its DB instances become available again. The cluster keeps its configuration settings such as endpoints, parameter groups, and VPC security groups.

Console

To start an Aurora cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose a cluster. You can perform the start operation from this page, or navigate to the details page for the DB cluster that you want to start.
3. For Actions, choose Start.

AWS CLI

To start a DB cluster by using the AWS CLI, call the start-db-cluster command with the following parameters:

- --db-cluster-identifier – the name of the Aurora cluster. This name is either a specific cluster identifier you chose when creating the cluster, or the DB instance identifier you chose with -cluster appended to the end.

Example

```
aws rds start-db-cluster --db-cluster-identifier mydbcluster
```
RDS API

To start an Aurora DB cluster by using the Amazon RDS API, call the `StartDBCluster` operation with the following parameter:

- `DBCluster` – the name of the Aurora cluster. This name is either a specific cluster identifier you chose when creating the cluster, or the DB instance identifier you chose with `-cluster` appended to the end.
Modifying an Amazon Aurora DB cluster

You can change the settings of a DB cluster to accomplish tasks such as changing its backup retention period or its database port. You can also modify DB instances in a DB cluster to accomplish tasks such as changing its DB instance class or enabling Performance Insights for it. This topic guides you through modifying an Aurora DB cluster and its DB instances, and describes the settings for each.

We recommend that you test any changes on a test DB cluster or DB instance before modifying a production DB cluster or DB instance, so that you fully understand the impact of each change. This is especially important when upgrading database versions.

Modifying the DB cluster by using the console, CLI, and API

You can modify a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

Note
For Aurora, when you modify a DB cluster, only changes to the DB cluster identifier, IAM DB authentication, and New master password settings are affected by the Apply immediately setting. All other modifications are applied immediately, regardless of the value of the Apply immediately setting.

Console

To modify a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB cluster that you want to modify.
4. Change any of the settings that you want. For information about each setting, see Settings for Amazon Aurora (p. 251).

Note
In the AWS Management Console, some instance level changes only apply to the current DB instance, while others apply to the entire DB cluster. For information about whether a setting applies to the DB instance or the DB cluster, see the scope for the setting in Settings for Amazon Aurora (p. 251). To change a setting that modifies the entire DB cluster at the instance level in the AWS Management Console, follow the instructions in Modify a DB instance in a DB cluster (p. 249).
5. When all the changes are as you want them, choose Continue and check the summary of modifications.
6. To apply the changes immediately, select Apply immediately.
7. On the confirmation page, review your changes. If they are correct, choose Modify cluster to save your changes.

Alternatively, choose Back to edit your changes, or choose Cancel to cancel your changes.

AWS CLI

To modify a DB cluster using the AWS CLI, call the modify-db-cluster command. Specify the DB cluster identifier, and the values for the settings that you want to modify. For information about each setting, see Settings for Amazon Aurora (p. 251).
Note
Some settings only apply to DB instances. To change those settings, follow the instructions in
Modify a DB instance in a DB cluster (p. 249).

Example
The following command modifies mydbcluster by setting the backup retention period to 1 week (7
days).

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \\
  --db-cluster-identifier mydbcluster \\
  --backup-retention-period 7
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --backup-retention-period 7
```

RDS API
To modify a DB cluster using the Amazon RDS API, call the ModifyDBCluster operation. Specify the DB
cluster identifier, and the values for the settings that you want to modify. For information about each
parameter, see Settings for Amazon Aurora (p. 251).

Note
Some settings only apply to DB instances. To change those settings, follow the instructions in
Modify a DB instance in a DB cluster (p. 249).

Modify a DB instance in a DB cluster
You can modify a DB instance in a DB cluster using the AWS Management Console, the AWS CLI, or the
RDS API.

When you modify a DB instance, you can apply the changes immediately. To apply changes immediately,
you select the Apply Immediately option in the AWS Management Console, you use the --apply-
immediately parameter when calling the AWS CLI, or you set the ApplyImmediately parameter to
true when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are deferred until the next maintenance
window. During the next maintenance window, any of these deferred changes are applied. If you choose
to apply changes immediately, your new changes and any previously deferred changes are applied.

Important
If any of the deferred modifications require downtime, choosing Apply immediately can cause
unexpected downtime for the DB instance. There is no downtime for the other DB instances in
the DB cluster.

Modifications that you defer aren't listed in the output of the describe-pending-
maintenance-actions CLI command. Maintenance actions only include system upgrades that
you schedule for the next maintenance window.

Console

To modify a DB instance in a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://
   console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then select the DB instance that you want to modify.

3. For **Actions**, choose **Modify**. The **Modify DB Instance** page appears.

4. Change any of the settings that you want. For information about each setting, see **Settings for Amazon Aurora (p. 251)**.

   **Note**
   Some settings apply to the entire DB cluster and must be changed at the cluster level. To change those settings, follow the instructions in **Modifying the DB cluster by using the console, CLI, and API (p. 248)**.
   In the AWS Management Console, some instance level changes only apply to the current DB instance, while others apply to the entire DB cluster. For information about whether a setting applies to the DB instance or the DB cluster, see the scope for the setting in **Settings for Amazon Aurora (p. 251)**.

5. When all the changes are as you want them, choose **Continue** and check the summary of modifications.

6. To apply the changes immediately, select **Apply immediately**.

7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

   Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

**AWS CLI**

To modify a DB instance in a DB cluster by using the AWS CLI, call the `modify-db-instance` command. Specify the DB instance identifier, and the values for the settings that you want to modify. For information about each parameter, see **Settings for Amazon Aurora (p. 251)**.

   **Note**
   Some settings apply to the entire DB cluster. To change those settings, follow the instructions in **Modifying the DB cluster by using the console, CLI, and API (p. 248)**.

**Example**

The following code modifies `mydbinstance` by setting the DB instance class to `db.r4.xlarge`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
   --db-instance-identifier mydbinstance \
   --db-instance-class db.r4.xlarge \
   --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --db-instance-class db.r4.xlarge ^
   --no-apply-immediately
```

**RDS API**

To modify a MySQL instance by using the Amazon RDS API, call the `ModifyDBInstance` operation. Specify the DB instance identifier, and the values for the settings that you want to modify. For information about each parameter, see **Settings for Amazon Aurora (p. 251)**.
Note
Some settings apply to the entire DB cluster. To change those settings, follow the instructions in Modifying the DB cluster by using the console, CLI, and API (p. 248).

Settings for Amazon Aurora

The following table contains details about which settings you can modify, the methods for modifying the setting, and the scope of the setting. The scope determines whether the setting applies to the entire DB cluster or if it can be set only for specific DB instances.

Note
Additional settings are available if you are modifying an Aurora Serverless v1 or Aurora Serverless v2 DB cluster. For information about these settings, see Modifying an Aurora Serverless v1 DB cluster (p. 1569) and Managing Aurora Serverless v2 (p. 1508). Some settings aren't available for Aurora Serverless v1 and Aurora Serverless v2 because of their limitations. For more information, see Limitations of Aurora Serverless v1 (p. 1543) and Requirements for Aurora Serverless v2 (p. 1489).

<table>
<thead>
<tr>
<th>Setting and description</th>
<th>Method</th>
<th>Scope</th>
<th>Downtime notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto minor version upgrade</td>
<td>Note</td>
<td>The entire DB cluster</td>
<td>An outage doesn't occur during this change. Outages do occur during future maintenance windows when Aurora applies automatic upgrades.</td>

### Settings that don't apply to Amazon Aurora DB instances

The following settings in the AWS CLI command `modify-db-instance` and the RDS API operation `ModifyDBInstance` don't apply to Amazon Aurora DB instances.

**Note**
You can't use the AWS Management Console to modify these settings for Aurora DB instances.

<table>

Adding Aurora Replicas to a DB cluster

An Aurora DB cluster with single-master replication has one primary DB instance and up to 15 Aurora Replicas. The primary DB instance supports read and write operations, and performs all data modifications to the cluster volume. Aurora Replicas connect to the same storage volume as the primary DB instance, but support read operations only. You use Aurora Replicas to offload read workloads from the primary DB instance. For more information, see Aurora Replicas (p. 73).

Amazon Aurora Replicas have the following limitations:

- You can't create an Aurora Replica for an Aurora Serverless v1 DB cluster. Aurora Serverless v1 has a single DB instance that scales up and down automatically to support all database read and write operations.

  However, you can add reader instances to Aurora Serverless v2 DB clusters. For more information, see Adding an Aurora Serverless v2 reader (p. 1516).

- You can't create Aurora Replicas for an Aurora multi-master cluster. By design, an Aurora multi-master cluster has read-write DB instances only.

We recommend that you distribute the primary instance and Aurora Replicas of your Aurora DB cluster over multiple Availability Zones to improve the availability of your DB cluster. For more information, see Region availability (p. 12).

To remove an Aurora Replica from an Aurora DB cluster, delete the Aurora Replica by following the instructions in Deleting a DB instance from an Aurora DB cluster (p. 350).

**Note**

Amazon Aurora also supports replication with an external database, such as an RDS DB instance. The RDS DB instance must be in the same AWS Region as Amazon Aurora. For more information, see Replication with Amazon Aurora (p. 73).

You can add Aurora Replicas to a DB cluster using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To add an Aurora replica to a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then select the DB cluster where you want to add the new DB instance.
3. Make sure that both the cluster and the primary instance are in the Available state. If the DB cluster or the primary instance are in a transitional state such as Creating, you can't add a replica.

   If the cluster doesn't have a primary instance, create one using the create-db-instance AWS CLI command. This situation can arise if you used the CLI to restore a DB cluster snapshot and then view the cluster in the AWS Management Console.
4. For Actions, choose Add reader.

   The Add reader page appears.
5. On the Add reader page, specify options for your Aurora Replica. The following table shows settings for an Aurora Replica.
<table>
<thead>
<tr>
<th>For this option</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Availability zone</strong></td>
<td>Determine if you want to specify a particular Availability Zone. The list includes only those Availability Zones that are mapped to the DB subnet group that you chose when you created the DB cluster. For more information about Availability Zones, see Regions and Availability Zones (p. 11).</td>
</tr>
<tr>
<td><strong>Publicly accessible</strong></td>
<td>Select Yes to give the Aurora Replica a public IP address; otherwise, select No. For more information about hiding Aurora Replicas from public access, see Hiding a DB cluster in a VPC from the internet (p. 1734).</td>
</tr>
<tr>
<td><strong>Encryption</strong></td>
<td>Select Enable encryption to enable encryption at rest for this Aurora Replica. For more information, see Encrypting Amazon Aurora resources (p. 1638).</td>
</tr>
<tr>
<td><strong>DB instance class</strong></td>
<td>Select a DB instance class that defines the processing and memory requirements for the Aurora Replica. For more information about DB instance class options, see Aurora DB instance classes (p. 56).</td>
</tr>
<tr>
<td><strong>Aurora replica source</strong></td>
<td>Select the identifier of the primary instance to create an Aurora Replica for.</td>
</tr>
<tr>
<td><strong>DB instance identifier</strong></td>
<td>Enter a name for the instance that is unique for your account in the AWS Region you selected. You might choose to add some intelligence to the name such as including the AWS Region and DB engine you selected, for example <strong>aurora-read-instance1</strong>.</td>
</tr>
<tr>
<td><strong>Priority</strong></td>
<td>Choose a failover priority for the instance. If you don't select a value, the default is tier-1. This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. For more information, see Fault tolerance for an Aurora DB cluster (p. 72).</td>
</tr>
<tr>
<td><strong>Database port</strong></td>
<td>The port for an Aurora Replica is the same as the port for the DB cluster.</td>
</tr>
<tr>
<td><strong>DB parameter group</strong></td>
<td>Select a parameter group. Aurora has a default parameter group you can use, or you can create your own parameter group. For more information about parameter groups, see Working with parameter groups (p. 215).</td>
</tr>
<tr>
<td><strong>Performance Insights</strong></td>
<td>The Turn on Performance Insights check box is selected by default. The value isn't inherited from the writer instance. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 461).</td>
</tr>
<tr>
<td><strong>Enhanced monitoring</strong></td>
<td>Choose Enable enhanced monitoring to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 518).</td>
</tr>
<tr>
<td>For this option</td>
<td>Do this</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Monitoring Role</td>
<td>Only available if Enhanced Monitoring is set to Enable enhanced monitoring. Choose the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose Default to have RDS create a role for you named rds-monitoring-role. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 518).</td>
</tr>
<tr>
<td>Granularity</td>
<td>Only available if Enhanced Monitoring is set to Enable enhanced monitoring. Set the interval, in seconds, between when metrics are collected for your DB cluster.</td>
</tr>
<tr>
<td>Auto minor version upgrade</td>
<td>Select Enable auto minor version upgrade if you want to enable your Aurora DB cluster to receive minor DB Engine version upgrades automatically when they become available.</td>
</tr>
</tbody>
</table>

The Auto minor version upgrade setting applies to both Aurora PostgreSQL and Aurora MySQL DB clusters. For Aurora MySQL 1.x and 2.x clusters, this setting upgrades the clusters to a maximum version of 1.22.2 and 2.07.2.

For more information about engine updates for Aurora PostgreSQL, see Amazon Aurora PostgreSQL updates (p. 1412).

For more information about engine updates for Aurora MySQL, see Database engine updates for Amazon Aurora MySQL (p. 991).

6. Choose Add reader to create the Aurora Replica.

**AWS CLI**

To create an Aurora Replica in your DB cluster, run the create-db-instance AWS CLI command. Include the name of the DB cluster as the --db-cluster-identifier option. You can optionally specify an Availability Zone for the Aurora Replica using the --availability-zone parameter, as shown in the following examples.

For example, the following command creates a new MySQL 5.7–compatible Aurora Replica named sample-instance-us-west-2a.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a \
  --db-cluster-identifier sample-cluster --engine aurora-mysql --db-instance-class db.r5.large \
  --availability-zone us-west-2a
```

For Windows:

```bash
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a ^
  --db-cluster-identifier sample-cluster --engine aurora-mysql --db-instance-class db.r5.large ^
  --availability-zone us-west-2a
```
The following command creates a new MySQL 5.6–compatible Aurora Replica named `sample-instance-us-west-2a`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a
    --db-cluster-identifier sample-cluster --engine aurora
    --db-instance-class db.r5.large
    --availability-zone us-west-2a
```

For Windows:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a
    --db-cluster-identifier sample-cluster --engine aurora
    --db-instance-class db.r5.large
    --availability-zone us-west-2a
```

The following command creates a new PostgreSQL-compatible Aurora Replica named `sample-instance-us-west-2a`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a
    --db-cluster-identifier sample-cluster --engine aurora-postgresql
    --db-instance-class db.r5.large
    --availability-zone us-west-2a
```

For Windows:

```
aws rds create-db-instance --db-instance-identifier sample-instance-us-west-2a
    --db-cluster-identifier sample-cluster --engine aurora-postgresql
    --db-instance-class db.r5.large
    --availability-zone us-west-2a
```

**RDS API**

To create an Aurora Replica in your DB cluster, call the `CreateDBInstance` operation. Include the name of the DB cluster as the `DBClusterIdentifier` parameter. You can optionally specify an `AvailabilityZone` for the Aurora Replica using the `AvailabilityZone` parameter.
Managing performance and scaling for Aurora DB clusters

You can use the following options to manage performance and scaling for Aurora DB clusters and DB instances:

**Topics**
- Storage scaling (p. 274)
- Instance scaling (p. 278)
- Read scaling (p. 278)
- Managing connections (p. 278)
- Managing query execution plans (p. 279)

**Storage scaling**

Aurora storage automatically scales with the data in your cluster volume. As your data grows, your cluster volume storage expands up to a maximum of 128 tebibytes (TiB) or 64 TiB. The maximum size depends on the DB engine version. To learn what kinds of data are included in the cluster volume, see Amazon Aurora storage and reliability (p. 67). For details about the maximum size for a specific version, see Amazon Aurora size limits (p. 1758).

The size of your cluster volume is evaluated on an hourly basis to determine your storage costs. For pricing information, see the Aurora pricing page.

Even though an Aurora cluster volume can scale up in size to many tebibytes, you are only charged for the space that you use in the volume. The mechanism for determining billed storage space depends on the version of your Aurora cluster.

- When Aurora data is removed from the cluster volume, the overall billed space decreases by a comparable amount. This dynamic resizing behavior happens when underlying database files are deleted or reorganized to require less space. Thus, you can reduce storage charges by deleting tables, indexes, databases, and so on that you no longer need. Dynamic resizing applies to certain Aurora versions. The following are the Aurora versions where the cluster volume dynamically resizes as you delete data:
  - Aurora MySQL 3 (compatible with MySQL 8.0), all minor versions
  - Aurora MySQL 2.09 (compatible with MySQL 5.7) and higher
  - Aurora MySQL version 1.23 (compatible with MySQL 5.6) and higher
  - All Aurora PostgreSQL 14 and 13 versions
  - Aurora PostgreSQL version 12.4 and higher
  - Aurora PostgreSQL version 11.8 and higher
  - Aurora PostgreSQL version 10.13 and higher
- In Aurora versions lower than those in the preceding list, the cluster volume can reuse space that was freed up when you deleted data, but the volume itself never decreases in size.
- This feature is being deployed in phases to the AWS Regions where Aurora is available. Depending on the Region where your cluster is, this feature might not be available yet.

Dynamic resizing applies to operations that physically remove or resize data files within the cluster volume. Thus, it applies to SQL statements such as DROP TABLE, DROP DATABASE, TRUNCATE TABLE, and ALTER TABLE . . . DROP PARTITION. It doesn't apply to deleting rows using the DELETE statement. If you delete a large number of rows from a table, you can run the Aurora MySQL OPTIMIZE
TABLE statement or use the Aurora PostgreSQL pg_repack extension afterward to reorganize the table and dynamically resize the cluster volume.

**Note**
For Aurora MySQL, the innodb_file_per_table affects how table storage is organized. When tables are part of the system tablespace, dropping the table doesn't reduce the size of the system tablespace. Thus, make sure to use the setting innodb_file_per_table=1 for Aurora MySQL clusters to take full advantage of dynamic resizing.

These Aurora versions also have a higher storage limit for the cluster volume than lower versions do. Thus, you can consider upgrading to one of these versions if you are close to exceeding the original 64 TiB volume size.

You can check how much storage space a cluster is using by monitoring the VolumeBytesUsed metric in CloudWatch.

- In the AWS Management Console, you can see this figure in a chart by viewing the Monitoring tab on the details page for the cluster.
- With the AWS CLI, you can run a command similar to the following Linux example. Substitute your own values for the start and end times and the name of the cluster.

```bash
aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" --start-time "$(date -d '6 hours ago')" --end-time "$(date -d 'now')" --period 60 --namespace "AWS/RDS" --statistics Average Maximum Minimum --dimensions Name=DBClusterIdentifier,Value=my_cluster_identifier
```

That command produces output similar to the following.

```json
{
  "Label": "VolumeBytesUsed",
  "Datapoints": [
    {
      "Timestamp": "2020-08-04T21:25:00+00:00",
      "Average": 182871982080.0,
      "Minimum": 182871982080.0,
      "Maximum": 182871982080.0,
      "Unit": "Bytes"
    }
  ]
}
```

The following examples show how you might track storage usage for an Aurora cluster over time using AWS CLI commands on a Linux system. The --start-time and --end-time parameters define the overall time interval as one day. The --period parameter requests the measurements at one hour intervals. It doesn't make sense to choose a --period value that's small, because the metrics are collected at intervals, not continuously. Also, Aurora storage operations sometimes continue for some time in the background after the relevant SQL statement finishes.

The first example returns output in the default JSON format. The data points are returned in arbitrary order, not sorted by timestamp. You might import this JSON data into a charting tool to do sorting and visualization.

```bash
$ aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" --start-time "$(date -d '1 day ago')" --end-time "$(date -d 'now')" --period 3600 --namespace "AWS/RDS" --statistics Maximum --dimensions Name=DBClusterIdentifier,Value=my_cluster_id
```

```json
{
  "Label": "VolumeBytesUsed",
}
```
This example returns the same data as the previous one. The --output parameter represents the data in compact plain text format. The `aws cloudwatch` command pipes its output to the `sort` command. The -k parameter of the `sort` command sorts the output by the third field, which is the timestamp in Universal Coordinated Time (UTC) format.

```bash
$ aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" \
  --start-time "$(date -d '1 day ago')" --end-time "$(date -d 'now')" --period 3600 \
  --namespace "AWS/RDS" --statistics Maximum --dimensions
  Name=DBClusterIdentifier,Value=my_cluster_id \
  --output text | sort -k 3
```

The sorted output shows how much storage was used at the start and end of the monitoring period. You can also find the points during that period when Aurora allocated more storage for the cluster. The following example uses Linux commands to reformat the starting and ending `VolumeBytesUsed` values as gigabytes (GB) and as gibibytes (GiB). Gigabytes represent units measured in powers of 10 and are
commonly used in discussions of storage for rotational hard drives. Gibibytes represent units measured in powers of 2. Aurora storage measurements and limits are typically stated in the power-of-2 units, such as gibibytes and tebibytes.

```bash
$ GiB=$((1024*1024*1024))
$ GB=$((1000*1000*1000))
$ echo "Start: $((182872522752/$GiB)) GiB, End: $((206833664000/$GiB)) GiB"
Start: 170 GiB, End: 192 GiB
$ echo "Start: $((182872522752/$GB)) GB, End: $((206833664000/$GB)) GB"
Start: 182 GB, End: 206 GB
```

The `VolumeBytesUsed` metric tells you how much storage in the cluster is incurring charges. Thus, it's best to minimize this number when practical. However, this metric doesn't include some storage that Aurora uses internally in the cluster and doesn't charge for. If your cluster is approaching the storage limit and might run out of space, it's more helpful to monitor the `AuroraVolumeBytesLeftTotal` metric and try to maximize that number. The following example runs a similar calculation as the previous one, but for `AuroraVolumeBytesLeftTotal` instead of `VolumeBytesUsed`. You can see that the free size for this cluster reflects the original 64 TiB limit, because the cluster is running Aurora MySQL version 1.22.

```bash
$ aws cloudwatch get-metric-statistics --metric-name "AuroraVolumeBytesLeftTotal" \   --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 3600 \   --namespace "AWS/RDS" --statistics Maximum --dimensions \   Name=DBClusterIdentifier,Value=my_old_cluster_id \   --output text | sort -k 3
AuroraVolumeBytesLeftTotal
DATAPOINTS 69797193744384.0 2020-08-05T17:52:00+00:00 Count
DATAPOINTS 69797193744384.0 2020-08-05T18:52:00+00:00 Count
$ TiB=$((1024*1024*1024*1024))
$ TB=$((1000*1000*1000*1000))
$ echo "$(69797067915264 / $TB) TB remaining for this cluster"
69 TB remaining for this cluster
$ echo "$(69797067915264 / $TB) TB remaining for this cluster"
63 TiB remaining for this cluster
```

For a cluster running Aurora MySQL version 1.23 or 2.09 and higher, or Aurora PostgreSQL 3.3.0 or 2.6.0 and higher, the free size reported by `VolumeBytesUsed` increases when data is added and decreases when data is removed. The following example shows how. This report shows the maximum and minimum storage size for a cluster at 15-minute intervals as tables with temporary data are created and dropped. The report lists the maximum value before the minimum value. Thus, to understand how storage usage changed within the 15-minute interval, interpret the numbers from right to left.

```bash
$ aws cloudwatch get-metric-statistics --metric-name "VolumeBytesUsed" \   --start-time "$(date -d '4 hours ago')" --end-time "$(date -d 'now')" --period 1800 \   --namespace "AWS/RDS" --statistics Maximum Minimum --dimensions \   Name=DBClusterIdentifier,Value=my_new_cluster_id \   --output text | sort -k 4
VolumeBytesUsed
DATAPOINTS 14545305600.0 14545305600.0 2020-08-05T20:49:00+00:00 Bytes

DATAPOINTS 22022176768.0 22022176768.0 2020-08-05T22:49:00+00:00 Bytes
DATAPOINTS 22022176768.0 15614263296.0 2020-08-05T23:19:00+00:00 Bytes
DATAPOINTS 15614263296.0 15614263296.0 2020-08-05T23:49:00+00:00 Bytes
DATAPOINTS 15614263296.0 15614263296.0 2020-08-06T00:19:00+00:00 Bytes
```

The following example shows how with a cluster running Aurora MySQL version 1.23 or 2.09 and higher, or Aurora PostgreSQL 3.3.0 or 2.6.0 and higher, the free size reported by `AuroraVolumeBytesLeftTotal` reflects the higher 128 TiB size limit.
Instance scaling

You can scale your Aurora DB cluster as needed by modifying the DB instance class for each DB instance in the DB cluster. Aurora supports several DB instance classes optimized for Aurora, depending on database engine compatibility.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instance scaling</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>See Scaling Aurora MySQL DB instances (p. 721)</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL</td>
<td>See Scaling Aurora PostgreSQL DB instances (p. 1144)</td>
</tr>
</tbody>
</table>

Read scaling

You can achieve read scaling for your Aurora DB cluster by creating up to 15 Aurora Replicas in a DB cluster that uses single-master replication. Each Aurora Replica returns the same data from the cluster volume with minimal replica lag—usually considerably less than 100 milliseconds after the primary instance has written an update. As your read traffic increases, you can create additional Aurora Replicas and connect to them directly to distribute the read load for your DB cluster. Aurora Replicas don't have to be of the same DB instance class as the primary instance.

For information about adding Aurora Replicas to a DB cluster, see Adding Aurora Replicas to a DB cluster (p. 270).

Managing connections

The maximum number of connections allowed to an Aurora DB instance is determined by the max_connections parameter in the instance-level parameter group for the DB instance. The default value of that parameter varies depends on the DB instance class used for the DB instance and database engine compatibility.
Managing query execution plans

If your applications frequently open and close connections, or have long-lived connections that approach or exceed the specified limits, we recommend using Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see Using Amazon RDS Proxy (p. 1429).

### Managing query execution plans

If you use query plan management for Aurora PostgreSQL, you gain control over which plans the optimizer runs. For more information, see Managing query execution plans for Aurora PostgreSQL (p. 1289).

<table>

</tr>
</tbody>
</table>
Cloning a volume for an Amazon Aurora DB cluster

By using Aurora cloning, you can create a new cluster that uses the same Aurora cluster volume and has the same data as the original. The process is designed to be fast and cost-effective. The new cluster with its associated data volume is known as a clone. Creating a clone is faster and more space-efficient than physically copying the data using other techniques, such as restoring a snapshot.

Aurora supports many different types of cloning:

- You can create an Aurora provisioned clone from a provisioned Aurora DB cluster.
- You can create an Aurora Serverless v1 clone from an Aurora Serverless v1 DB cluster.
- You can also create Aurora Serverless v1 clones from Aurora provisioned DB clusters, and you can create provisioned clones from Aurora Serverless v1 DB clusters.
- Clusters with Aurora Serverless v2 instances follow the same rules as provisioned clusters.

When you create a clone using a different deployment configuration than the source, the clone is created using the latest minor version of the source's Aurora DB engine.

A cloned Aurora Serverless DB cluster has the same behavior and limitations as any Aurora Serverless v1 DB cluster. For more information, see Using Amazon Aurora Serverless v1 (p. 1542).

When you create clones from your Aurora DB clusters, the clones are created in your AWS account—the same account that owns the source Aurora DB cluster. However, you can also share provisioned Aurora DB clusters and clones with other AWS accounts. For more information, see Cross-account cloning with AWS RAM and Amazon Aurora (p. 293).

Cross-account cloning currently doesn't support cloning Aurora Serverless v1 DB clusters. For more information, see Limitations of cross-account cloning (p. 293).

Topics

- Overview of Aurora cloning (p. 280)
- Limitations of Aurora cloning (p. 281)
- How Aurora cloning works (p. 281)
- Creating an Amazon Aurora clone (p. 284)
- Cross-account cloning with AWS RAM and Amazon Aurora (p. 293)

Overview of Aurora cloning

Aurora uses a copy-on-write protocol to create a clone. This mechanism uses minimal additional space to create an initial clone. When the clone is first created, Aurora keeps a single copy of the data that is used by the source Aurora DB cluster and the new (cloned) Aurora DB cluster. Additional storage is allocated only when changes are made to data (on the Aurora storage volume) by the source Aurora DB cluster or the Aurora DB cluster clone. To learn more about the copy-on-write protocol, see How Aurora cloning works (p. 281).

Aurora cloning is especially useful for quickly setting up test environments using your production data, without risking data corruption. You can use clones for many types of applications, such as the following:

- Experiment with potential changes (schema changes and parameter group changes, for example) to assess all impacts.
- Run workload-intensive operations, such as exporting data or running analytical queries on the clone.
- Create a copy of your production DB cluster for development, testing, or other purposes.
You can create more than one clone from the same Aurora DB cluster. You can also create multiple clones from another clone.

After creating an Aurora clone, you can configure the Aurora DB instances differently from the source Aurora DB cluster. For example, you might not need a clone for development purposes to meet the same high availability requirements as the source production Aurora DB cluster. In this case, you can configure the clone with a single Aurora DB instance rather than the multiple DB instances used by the Aurora DB cluster.

When you finish using the clone for your testing, development, or other purposes, you can delete it.

**Limitations of Aurora cloning**

Aurora cloning currently has the following limitations:

- You can create as many clones as you want, up to the maximum number of DB clusters allowed in the AWS Region. However, after you create 15 clones, the next clone is a full copy. The cloning operation acts like a point-in-time recovery.
- You can't create a clone in a different AWS Region from the source Aurora DB cluster.
- You can't create an Aurora Serverless v1 clone from a nonencrypted provisioned Aurora DB cluster.
- You can't create an Aurora Serverless v1 clone from a MySQL 5.6-compatible provisioned cluster, or a provisioned clone of a MySQL 5.6-compatible Aurora Serverless v1 cluster.
- You can't create a clone from an Aurora DB cluster without the parallel query feature to a cluster that uses parallel query. To bring data into a cluster that uses parallel query, create a snapshot of the original cluster and restore it to the cluster that's using the parallel query feature.
- You can't create a clone from an Aurora DB cluster that has no DB instances. You can only clone Aurora DB clusters that have at least one DB instance.
- You can create a clone in a different virtual private cloud (VPC) than that of the Aurora DB cluster. If you do, the subnets of the VPCs must map to the same Availability Zones.

**How Aurora cloning works**

Aurora cloning works at the storage layer of an Aurora DB cluster. It uses a *copy-on-write* protocol that's both fast and space-efficient in terms of the underlying durable media supporting the Aurora storage volume. You can learn more about Aurora cluster volumes in the *Overview of Aurora storage* (p. 67).

**Topics**

- Understanding the copy-on-write protocol (p. 281)
- Deleting a source cluster volume (p. 284)

**Understanding the copy-on-write protocol**

An Aurora DB cluster stores data in pages in the underlying Aurora storage volume.

For example, in the following diagram you can find an Aurora DB cluster (A) that has four data pages, 1, 2, 3, and 4. Imagine that a clone, B, is created from the Aurora DB cluster. When the clone is created, no data is copied. Rather, the clone points to the same set of pages as the source Aurora DB cluster.
When the clone is created, no additional storage is usually needed. The copy-on-write protocol uses the same segment on the physical storage media as the source segment. Additional storage is required only if the capacity of the source segment isn't sufficient for the entire clone segment. If that's the case, the source segment is copied to another physical device.

In the following diagrams, you can find an example of the copy-on-write protocol in action using the same cluster A and its clone, B, as shown preceding. Let's say that you make a change to your Aurora DB cluster (A) that results in a change to data held on page 1. Instead of writing to the original page 1, Aurora creates a new page 1[A]. The Aurora DB cluster volume for cluster (A) now points to page 1[A], 2, 3, and 4, while the clone (B) still references the original pages.
On the clone, a change is made to page 4 on the storage volume. Instead of writing to the original page 4, Aurora creates a new page, 4[B]. The clone now points to pages 1, 2, 3, and to page 4[B], while the cluster (A) continues pointing to 1[A], 2, 3, and 4.
As more changes occur over time in both the source Aurora DB cluster volume and the clone, more storage is needed to capture and store the changes.

**Deleting a source cluster volume**

When you delete a source cluster volume that has one or more clones associated with it, the clones aren't affected. The clones continue to point to the pages that were previously owned by the source cluster volume.

**Creating an Amazon Aurora clone**

You can create a clone in the same AWS account as the source Aurora DB cluster. To do so, you can use the AWS Management Console or the AWS CLI and the procedures following.

To allow another AWS account to create a clone or to share a clone with another AWS account, use the procedures in Cross-account cloning with AWS RAM and Amazon Aurora (p. 293).

By using Aurora cloning, you can do the following types of cloning operations:

- Create a provisioned Aurora DB cluster clone from a provisioned Aurora DB cluster.
- Create an Aurora Serverless v1 cluster clone from an Aurora Serverless v1 DB cluster.
- Create an Aurora Serverless v1 DB cluster clone from a provisioned Aurora DB cluster.
- Create an Aurora provisioned DB cluster clone from an Aurora Serverless v1 DB cluster.

Aurora Serverless v1 DB clusters are always encrypted. When you clone an Aurora Serverless v1 DB cluster into a provisioned Aurora DB cluster, the provisioned Aurora DB cluster is encrypted. You can
choose the encryption key, but you can't disable the encryption. To clone from a provisioned Aurora DB cluster to an Aurora Serverless v1 cluster, you need an encrypted provisioned Aurora DB cluster.

**Console**

The following procedure describes how to clone an Aurora DB cluster using the AWS Management Console.

Creating a clone using the AWS Management Console results in an Aurora DB cluster with one Aurora DB instance.

These instructions apply for DB clusters owned by the same AWS account that is creating the clone. If the DB cluster is owned by a different AWS account, see Cross-account cloning with AWS RAM and Amazon Aurora (p. 293) instead.

**To create a clone of a DB cluster owned by your AWS account using the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose your Aurora DB cluster from the list, and for Actions, choose Create clone.

![Create clone in AWS Management Console](image)

The Create clone page opens, where you can configure Instance specifications, Connectivity, and other options for the Aurora DB cluster clone.

4. In the Instance specifications section, do the following:
   a. For DB cluster identifier, enter the name that you want to give to your cloned Aurora DB cluster.
b. For **Capacity type**, choose **Provisioned** or **Serverless** as needed for your use case.

You can choose **Serverless** only if the source Aurora DB cluster is an Aurora Serverless v1 DB cluster or is a provisioned Aurora DB cluster that is encrypted.

- If you choose **Provisioned**, you see a **DB instance size** configuration card.

You can accept the provided setting, or you can use a different DB instance class for your clone.

- If you choose **Serverless**, you see a **Capacity settings** configuration card.
You can accept the provided settings, or you can change them for your use case.

c. **For Additional configuration**, choose settings as you usually do for your Aurora DB clusters.

Additional settings include your choice for the database name and whether you want to use many optional features. These features include backup, Enhanced Monitoring, exporting logs to Amazon CloudWatch, deletion protection, and so on.

Some of the choices displayed depend on the type of clone that you are creating. For example, Aurora Serverless doesn't support Amazon RDS Performance Insights, so that option isn't shown in this case.

Encryption is a standard option available in Additional configuration. Aurora Serverless DB clusters are always encrypted. You can create an Aurora Serverless clone only from an Aurora Serverless DB cluster or an encrypted provisioned Aurora DB cluster. However, you can choose a different key for the Aurora Serverless clone than that used for the encrypted provisioned cluster.

When you create an Aurora Serverless clone from an Aurora Serverless DB cluster, you can choose a different key for the clone.
d. Finish entering all settings for your Aurora DB cluster clone. To learn more about Aurora DB cluster and instance settings, see Creating an Amazon Aurora DB cluster (p. 127).

5. Choose Create clone to launch the Aurora clone of your chosen Aurora DB cluster.

When the clone is created, it’s listed with your other Aurora DB clusters in the console Databases section and displays its current state. Your clone is ready to use when its state is Available.

AWS CLI

Using the AWS CLI for cloning your Aurora DB cluster involves a couple of steps.

The restore-db-cluster-to-point-in-time AWS CLI command that you use results in an empty Aurora DB cluster with 0 Aurora DB instances. That is, the command restores only the Aurora DB cluster, not the DB instances for that cluster. You do that separately after the clone is available. The two steps in the process are as follows:

1. Create the clone by using the restore-db-cluster-to-point-in-time CLI command. The parameters that you use with this command control the capacity type and other details of the empty Aurora DB cluster (clone) being created.
2. Create the Aurora DB instance for the clone by using the create-db-instance CLI command to recreate the Aurora DB instance in the restored Aurora DB cluster.

The commands following assume that the AWS CLI is set up with your AWS Region as the default. This approach saves you from passing the --region name in each of the commands. For more information, see Configuring the AWS CLI. You can also specify the --region in each of the CLI commands that follow.

Topics

- Creating the clone (p. 288)
- Checking the status and getting clone details (p. 291)
- Creating the Aurora DB instance for your clone (p. 291)
- Parameters to use for cloning (p. 292)

Creating the clone

The specific parameters that you pass to the restore-db-cluster-to-point-in-time CLI command vary. What you pass depends on the engine-mode type of the source DB cluster—Serverless or Provisioned—and the type of clone that you want to create.

Use the following procedure to create an Aurora Serverless clone from an Aurora Serverless DB cluster, or to create a provisioned Aurora clone from a provisioned Aurora DB cluster.
To create a clone of the same engine mode as the source Aurora DB cluster

- Use the `restore-db-cluster-to-point-in-time` CLI command and specify values for the following parameters:
  - `--db-cluster-identifier` – Choose a meaningful name for your clone. You name the clone when you use the `restore-db-cluster-to-point-in-time` CLI command. You then pass the name of the clone in the `create-db-instance` CLI command.
  - `--restore-type` – Use `copy-on-write` to create a clone of the source DB cluster. Without this parameter, the `restore-db-cluster-to-point-in-time` restores the Aurora DB cluster rather than creating a clone.
  - `--source-db-cluster-identifier` – Use the name of the source Aurora DB cluster that you want to clone.
  - `--use-latest-restorable-time` – This value points to the latest restorable volume data for the clone.

The following example creates a clone named `my-clone` from a cluster named `my-source-cluster`.

For Linux, macOS, or Unix:
```
aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier my-source-cluster \
  --db-cluster-identifier my-clone \
  --restore-type copy-on-write \
  --use-latest-restorable-time
```

For Windows:
```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-identifier my-source-cluster ^
  --db-cluster-identifier my-clone ^
  --restore-type copy-on-write ^
  --use-latest-restorable-time
```

The command returns the JSON object containing details of the clone. Check to make sure that your cloned DB cluster is available before trying to create the DB instance for your clone. For more information, see Checking the status and getting clone details (p. 291).

To create a clone with a different engine mode than the source Aurora DB cluster

- Use the `restore-db-cluster-to-point-in-time` CLI command and specify values for the following parameters:
  - `--db-cluster-identifier` – Choose a meaningful name for your clone. You name the clone when you use the `restore-db-cluster-to-point-in-time` CLI command. You then pass the name of the clone in the `create-db-instance` CLI command.
  - `--engine-mode` – Use this parameter only to create clones that are of a different type than the source Aurora DB cluster. Choose the value to pass with `--engine-mode` as follows:
    - Use `provisioned` to create a provisioned Aurora DB cluster clone from an Aurora Serverless DB cluster.
    - Use `serverless` to create an Aurora Serverless DB cluster clone from a provisioned Aurora DB cluster. When you specify `serverless` engine mode, you can also choose `--scaling-configuration`.
  - `--restore-type` – Use `copy-on-write` to create a clone of the source DB cluster. Without this parameter, the `restore-db-cluster-to-point-in-time` restores the Aurora DB cluster rather than creating a clone.
Creating an Aurora clone

- `--scaling-configuration` – (Optional) Use only with `--engine-mode serverless` to configure the minimum and maximum capacity for the clone. If you don’t use this parameter, Aurora creates the clone using a minimum capacity of 1. It uses a maximum capacity that matches the capacity of the source provisioned Aurora DB cluster.

- `--source-db-cluster-identifier` – Use the name of the source Aurora DB cluster that you want to clone.

- `--use-latest-restorable-time` – This value points to the latest restorable volume data for the clone.

The following example creates an Aurora Serverless clone (`my-clone`) from a provisioned Aurora DB cluster named `my-source-cluster`. The provisioned Aurora DB cluster is encrypted.

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier my-source-cluster \
  --db-cluster-identifier my-clone \
  --engine-mode serverless \
  --scaling-configuration MinCapacity=8, MaxCapacity=64 \
  --restore-type copy-on-write \
  --use-latest-restorable-time
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-identifier my-source-cluster ^
  --db-cluster-identifier my-clone ^
  --engine-mode serverless ^
  --scaling-configuration MinCapacity=8, MaxCapacity=64 ^
  --restore-type copy-on-write ^
  --use-latest-restorable-time
```

These commands return the JSON object containing details of the clone that you need to create the DB instance. You can’t do that until the status of the clone (the empty Aurora DB cluster) has the status `Available`.

**Note**

The `restore-db-cluster-to-point-in-time` AWS CLI command only restores the DB cluster, not the DB instances for that DB cluster. You must invoke the `create-db-instance` command to create DB instances for the restored DB cluster, specifying the identifier of the restored DB cluster in `--db-cluster-identifier`. You can create DB instances only after the `restore-db-cluster-to-point-in-time` command has completed and the DB cluster is available.

For example, suppose you have a cluster named `tpch100g` that you want to clone. The following Linux example creates a cloned cluster named `tpch100g-clone` and a primary instance named `tpch100g-clone-instance` for the new cluster. You don’t need to supply some parameters, such as `--master-username reinvent` and `--master-user-password`. Aurora automatically determines those from the original cluster. You do need to specify the DB engine to use. Thus, the example tests the new cluster to determine the right value to use for the `--engine` parameter.

```
# aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier tpch100g \
  --db-cluster-identifier tpch100g-clone \
  --restore-type copy-on-write \
  --use-latest-restorable-time

# aws rds describe-db-clusters \
  --db-cluster-identifier tpch100g-clone \
  --query '[].[Engine]
```
Creating an Aurora clone

--output text
aurora

$ aws rds create-db-instance \
   --db-instance-identifier tpch100g-clone-instance \
   --db-cluster-identifier tpch100g-clone \
   --db-instance-class db.r5.4xlarge \
   --engine aurora

Checking the status and getting clone details

You can use the following command to check the status of your newly created empty DB cluster.

$ aws rds describe-db-clusters --db-cluster-identifier my-clone --query '*[].[Status]' --output text

Or you can obtain the status and the other values that you need to create the DB instance for your clone (p. 291) by using the following AWS CLI query.

For Linux, macOS, or Unix:

For Windows:

This query returns output similar to the following.

[  
  {  
    "Status": "available",  
    "Engine": "aurora-mysql",  
    "EngineVersion": "5.7.mysql_aurora.2.09.1",  
    "EngineMode": "provisioned"
  }
]

Creating the Aurora DB instance for your clone

Use the create-db-instance CLI command to create the DB instance for your clone.

The --db-instance-class parameter is used for provisioned Aurora DB clusters only.

For Linux, macOS, or Unix:

aws rds create-db-instance \   --db-instance-identifier my-new-db \   --db-cluster-identifier my-clone \   --db-instance-class db.r5.4xlarge \   --engine aurora-mysql

For Windows:

aws rds create-db-instance ^
Amazon Aurora User Guide for Aurora
Creating an Aurora clone

```
--db-instance-identifier my-new-db
--db-cluster-identifier my-clone
--db-instance-class db.r5.4xlarge
--engine aurora-mysql
```

For an Aurora Serverless clone created from an Aurora Serverless DB cluster, you specify only a few parameters. The DB instance inherits the `--engine-mode`, `--master-username`, and `--master-user-password` properties from the source DB cluster. You can change the `--scaling-configuration`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier my-new-db \
    --db-cluster-identifier my-clone \
    --engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance \
    --db-instance-identifier my-new-db \
    --db-cluster-identifier my-clone \
    --engine aurora-postgresql
```

Parameters to use for cloning

The following table summarizes the various parameters used with `restore-db-cluster-to-point-in-time` to clone Aurora DB clusters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--source-db-cluster-identifier</code></td>
<td>Use the name of the source Aurora DB cluster that you want to clone.</td>
</tr>
<tr>
<td><code>--db-cluster-identifier</code></td>
<td>Choose a meaningful name for your clone. You name your clone with the <code>restore-db-cluster-to-point-in-time</code> command. Then you pass this name to the <code>create-db-instance</code> command.</td>
</tr>
<tr>
<td><code>--engine-mode</code></td>
<td>Use this parameter to create clones that are of a different type than the source Aurora DB cluster. Choose the value to pass with <code>--engine-mode</code> as follows:</td>
</tr>
<tr>
<td></td>
<td>• Use <code>provisioned</code> to create a provisioned Aurora DB cluster clone from an Aurora Serverless DB cluster.</td>
</tr>
<tr>
<td></td>
<td>• Use <code>serverless</code> to create an Aurora Serverless DB cluster clone from a provisioned Aurora DB cluster. When you specify <code>serverless</code> engine mode, you can also choose <code>--scaling-configuration</code></td>
</tr>
<tr>
<td><code>--restore-type</code></td>
<td>Specify <code>copy-on-write</code> as the <code>--restore-type</code> to create a clone of the source DB cluster rather than restoring the source Aurora DB cluster.</td>
</tr>
<tr>
<td><code>--scaling-configuration</code></td>
<td>Use this parameter with <code>--engine-mode serverless</code> to configure the minimum and maximum capacity for the clone. If you don’t use this parameter, Aurora creates the Aurora Serverless clone using a minimum capacity of 1 and a maximum capacity of 16.</td>
</tr>
<tr>
<td><code>--use-latest-restorable-time</code></td>
<td>This value points to the latest restorable volume data for the clone.</td>
</tr>
</tbody>
</table>
Cross-account cloning with AWS RAM and Amazon Aurora

By using AWS Resource Access Manager (AWS RAM) with Amazon Aurora, you can share Aurora DB clusters and clones that belong to your AWS account with another AWS account or organization. Such cross-account cloning is much faster than creating and restoring a database snapshot. You can create a clone of one of your Aurora DB clusters and share the clone. Or you can share your Aurora DB cluster with another AWS account and let the account holder create the clone. The approach that you choose depends on your use case.

For example, you might need to regularly share a clone of your financial database with your organization’s internal auditing team. In this case, your auditing team has its own AWS account for the applications that it uses. You can give the auditing team’s AWS account the permission to access your Aurora DB cluster and clone it as needed.

On the other hand, if an outside vendor audits your financial data you might prefer to create the clone yourself. You then give the outside vendor access to the clone only.

You can also use cross-account cloning to support many of the same use cases for cloning within the same AWS account, such as development and testing. For example, your organization might use different AWS accounts for production, development, testing, and so on. For more information, see Overview of Aurora cloning (p. 280).

Thus, you might want to share a clone with another AWS account or allow another AWS account to create clones of your Aurora DB clusters. In either case, start by using AWS RAM to create a share object. For complete information about sharing AWS resources between AWS accounts, see the AWS RAM User Guide.

Creating a cross-account clone requires actions from the AWS account that owns the original cluster, and the AWS account that creates the clone. First, the original cluster owner modifies the cluster to allow one or more other accounts to clone it. If any of the accounts is in a different AWS organization, AWS generates a sharing invitation. The other account must accept the invitation before proceeding. Then each authorized account can clone the cluster. Throughout this process, the cluster is identified by its unique Amazon Resource Name (ARN).

As with cloning within the same AWS account, additional storage space is used only if changes are made to the data by the source or the clone. Charges for storage are then applied at that time. If the source cluster is deleted, storage costs are distributed equally among remaining cloned clusters.

Topics

- Limitations of cross-account cloning (p. 293)
- Allowing other AWS accounts to clone your cluster (p. 294)
- Cloning a cluster that is owned by another AWS account (p. 296)

Limitations of cross-account cloning

Aurora cross-account cloning has the following limitations:

- You can’t clone an Aurora Serverless cluster across AWS accounts.
- You can’t view or accept invitations to shared resources with the AWS Management Console. Use the AWS CLI, the Amazon RDS API, or the AWS RAM console to view and accept invitations to shared resources.
- You can’t create new clones from a clone that’s been shared with your AWS account.
• You can't share resources (clones or Aurora DB clusters) that have been shared with your AWS account.
• You can create a maximum of 15 cross-account clones from any single Aurora DB cluster.
• Each of the 15 cross-account clones must be owned by a different AWS account. That is, you can only create one cross-account clone of a cluster within any AWS account.
• After you clone a cluster, the original cluster and its clone are considered to be the same for purposes of enforcing limits on cross-account clones. You can't create cross-account clones of both the original cluster and the cloned cluster within the same AWS account. The total number of cross-account clones for the original cluster and any of its clones can't exceed 15.
• You can't share an Aurora DB cluster with other AWS accounts unless the cluster is in an ACTIVE state.
• You can't rename an Aurora DB cluster that's been shared with other AWS accounts.
• You can't create a cross-account clone of a cluster that is encrypted with the default RDS key.
• You can't create nonencrypted clones in one AWS account from encrypted Aurora DB clusters that have been shared by another AWS account. The cluster owner must grant permission to access the source cluster's AWS KMS key. However, you can use a different key when you create the clone.

Allowing other AWS accounts to clone your cluster

To allow other AWS accounts to clone a cluster that you own, use AWS RAM to set the sharing permission. Doing so also sends an invitation to each of the other accounts that's in a different AWS organization.

For the procedures to share resources owned by you in the AWS RAM console, see Sharing resources owned by you in the AWS RAM User Guide.

Topics
• Granting permission to other AWS accounts to clone your cluster (p. 294)
• Checking if a cluster that you own is shared with other AWS accounts (p. 296)

Granting permission to other AWS accounts to clone your cluster

If the cluster that you're sharing is encrypted, you also share the AWS KMS key for the cluster. You can allow AWS Identity and Access Management (IAM) users or roles in one AWS account to use a KMS key in a different account.

To do this, you first add the external account (root user) to the KMS key's key policy through AWS KMS. You don't add the individual IAM users or roles to the key policy, only the external account that owns them. You can only share a KMS key that you create, not the default RDS service key. For information about access control for KMS keys, see Authentication and access control for AWS KMS.

Console

To grant permission to clone your cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB cluster that you want to share to see its Details page, and choose the Connectivity & security tab.
4. In the Share DB cluster with other AWS accounts section, enter the numeric account ID for the AWS account that you want to allow to clone this cluster. For account IDs in the same organization, you can begin typing in the box and then choose from the menu.
Important
In some cases, you might want an account that is not in the same AWS organization as your account to clone a cluster. In these cases, for security reasons the console doesn't report who owns that account ID or whether the account exists. Be careful entering account numbers that are not in the same AWS organization as your AWS account. Immediately verify that you shared with the intended account.

5. On the confirmation page, verify that the account ID that you specified is correct. Enter `share` in the confirmation box to confirm.

On the Details page, an entry appears that shows the specified AWS account ID under Accounts that this DB cluster is shared with. The Status column initially shows a status of Pending.

6. Contact the owner of the other AWS account, or sign in to that account if you own both of them. Instruct the owner of the other account to accept the sharing invitation and clone the DB cluster, as described following.

AWS CLI

To grant permission to clone your cluster

1. Gather the information for the required parameters. You need the ARN for your cluster and the numeric ID for the other AWS account.

2. Run the AWS RAM CLI command `create-resource-share`.

For Linux, macOS, or Unix:

```bash
aws ram create-resource-share --name descriptive_name \
   --region region \n   --resource-arns cluster_arn \n   --principals other_account_ids
```

For Windows:

```bash
aws ram create-resource-share --name descriptive_name ^
   --region region ^
   --resource-arns cluster_arn ^
   --principals other_account_ids
```

To include multiple account IDs for the --principals parameter, separate IDs from each other with spaces. To specify whether the permitted account IDs can be outside your AWS organization, include the --allow-external-principals or --no-allow-external-principals parameter for create-resource-share.

AWS RAM API

To grant permission to clone your cluster

1. Gather the information for the required parameters. You need the ARN for your cluster and the numeric ID for the other AWS account.

2. Call the AWS RAM API operation CreateResourceShare, and specify the following values:

   - Specify the account ID for one or more AWS accounts as the principals parameter.
   - Specify the ARN for one or more Aurora DB clusters as the resourceArns parameter.
   - Specify whether the permitted account IDs can be outside your AWS organization by including a Boolean value for the allowExternalPrincipals parameter.
Recreating a cluster that uses the default RDS key

If the encrypted cluster that you plan to share uses the default RDS key, make sure to recreate the cluster. To do this, create a manual snapshot of your DB cluster, use an AWS KMS key, and then restore the cluster to a new cluster. Then share the new cluster. To perform this process, take the following steps.

To recreate an encrypted cluster that uses the default RDS key

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Snapshots from the navigation pane.
3. Choose your snapshot.
4. For Actions, choose Copy Snapshot, and then choose Enable encryption.
5. For AWS KMS key, choose the new encryption key that you want to use.
6. Restore the copied snapshot. To do so, follow the procedure in Restoring from a DB cluster snapshot (p. 375). The new DB instance uses your new encryption key.
7. (Optional) Delete the old DB cluster if you no longer need it. To do so, follow the procedure in Deleting a DB cluster snapshot (p. 417). Before you do, confirm that your new cluster has all necessary data and that your application can access it successfully.

Checking if a cluster that you own is shared with other AWS accounts

You can check if other users have permission to share a cluster. Doing so can help you understand whether the cluster is approaching the limit for the maximum number of cross-account clones.

For the procedures to share resources using the AWS RAM console, see Sharing resources owned by you in the AWS RAM User Guide.

AWS CLI

To find out if a cluster that you own is shared with other AWS accounts

- Call the AWS RAM CLI command list-principals, using your account ID as the resource owner and the ARN of your cluster as the resource ARN. You can see all shares with the following command. The results indicate which AWS accounts are allowed to clone the cluster.

```bash
aws ram list-principals \
  --resource-arns your_cluster_arn \
  --principals your_aws_id
```

AWS RAM API

To find out if a cluster that you own is shared with other AWS accounts

- Call the AWS RAM API operation ListPrincipals. Use your account ID as the resource owner and the ARN of your cluster as the resource ARN.

Cloning a cluster that is owned by another AWS account

To clone a cluster that's owned by another AWS account, use AWS RAM to get permission to make the clone. After you have the required permission, use the standard procedure for cloning an Aurora cluster.

You can also check whether a cluster that you own is a clone of a cluster owned by a different AWS account.
For the procedures to work with resources owned by others in the AWS RAM console, see Accessing resources shared with you in the AWS RAM User Guide.

Topics
- Viewing invitations to clone clusters that are owned by other AWS accounts (p. 297)
- Accepting invitations to share clusters owned by other AWS accounts (p. 297)
- Cloning an Aurora cluster that is owned by another AWS account (p. 298)
- Checking if a DB cluster is a cross-account clone (p. 301)

Viewing invitations to clone clusters that are owned by other AWS accounts

To work with invitations to clone clusters owned by AWS accounts in other AWS organizations, use the AWS CLI, the AWS RAM console, or the AWS RAM API. Currently, you can't perform this procedure using the Amazon RDS console.

For the procedures to work with invitations in the AWS RAM console, see Accessing resources shared with you in the AWS RAM User Guide.

AWS CLI

To see invitations to clone clusters that are owned by other AWS accounts

1. Run the AWS RAM CLI command get-resource-share-invitations.

   
   ```bash
   aws ram get-resource-share-invitations --region region_name
   ```

   The results from the preceding command show all invitations to clone clusters, including any that you already accepted or rejected.

2. (Optional) Filter the list so you see only the invitations that require action from you. To do so, add the parameter --query 'resourceShareInvitations[?status==`PENDING`]'.

AWS RAM API

To see invitations to clone clusters that are owned by other AWS accounts

1. Call the AWS RAM API operation GetResourceShareInvitations. This operation returns all such invitations, including any that you already accepted or rejected.

2. (Optional) Find only the invitations that require action from you by checking the resourceShareAssociations return field for a status value of PENDING.

Accepting invitations to share clusters owned by other AWS accounts

You can accept invitations to share clusters owned by other AWS accounts that are in different AWS organizations. To work with these invitations, use the AWS CLI, the AWS RAM and RDS APIs, or the AWS RAM console. Currently, you can't perform this procedure using the RDS console.

For the procedures to work with invitations in the AWS RAM console, see Accessing resources shared with you in the AWS RAM User Guide.

Console

To accept an invitation to share a cluster from another AWS account

1. Find the invitation ARN by running the AWS RAM CLI command get-resource-share-invitations, as shown preceding.
2. Accept the invitation by calling the AWS RAM CLI command `accept-resource-share-invitation`, as shown following.

For Linux, macOS, or Unix:

```
aws ram accept-resource-share-invitation
  --resource-share-invitation-arn invitation_arn
  --region region
```

For Windows:

```
aws ram accept-resource-share-invitation
  --resource-share-invitation-arn invitation_arn
  --region region
```

**AWS RAM and RDS API**

**To accept invitations to share somebody's cluster**

1. Find the invitation ARN by calling the AWS RAM API operation `GetResourceShareInvitations`, as shown preceding.
2. Pass that ARN as the `resourceShareInvitationArn` parameter to the RDS API operation `AcceptResourceShareInvitation`.

**Cloning an Aurora cluster that is owned by another AWS account**

After you accept the invitation from the AWS account that owns the DB cluster, as shown preceding, you can clone the cluster.

**Console**

**To clone an Aurora cluster that is owned by another AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
   
   At the top of the database list, you should see one or more items with a **Role** value of **Shared from account #account_id**. For security reasons, you can only see limited information about the original clusters. The properties that you can see are the ones such as database engine and version that must be the same in your cloned cluster.
3. Choose the cluster that you intend to clone.
4. For **Actions**, choose **Create clone**.
5. Follow the procedure in **Console (p. 285)** to finish setting up the cloned cluster.
6. As needed, enable encryption for the cloned cluster. If the cluster that you are cloning is encrypted, you must enable encryption for the cloned cluster. The AWS account that shared the cluster with you must also share the KMS key that was used to encrypt the cluster. You can use the same KMS key to encrypt the clone, or your own KMS key. You can’t create a cross-account clone for a cluster that is encrypted with the default KMS key.

The account that owns the encryption key must grant permission to use the key to the destination account by using a key policy. This process is similar to how encrypted snapshots are shared, by using a key policy that grants permission to the destination account to use the key.
AWS CLI

To clone an Aurora cluster owned by another AWS account

1. Accept the invitation from the AWS account that owns the DB cluster, as shown preceding.
2. Clone the cluster by specifying the full ARN of the source cluster in the `source-db-cluster-identifier` parameter of the RDS CLI command `restore-db-cluster-to-point-in-time`, as shown following.

   If the ARN passed as the `source-db-cluster-identifier` hasn’t been shared, the same error is returned as if the specified cluster doesn’t exist.

   For Linux, macOS, or Unix:

   ```bash
   aws rds restore-db-cluster-to-point-in-time \
   --source-db-cluster-identifier=arn:aws:rds:arn_details \
   --db-cluster-identifier=new_cluster_id \
   --restore-type=copy-on-write \ 
   --use-latest-restorable-time
   ```

   For Windows:

   ```bash
   aws rds restore-db-cluster-to-point-in-time ^ 
   --source-db-cluster-identifier=arn:aws:rds:arn_details ^ 
   --db-cluster-identifier=new_cluster_id ^ 
   --restore-type=copy-on-write ^ 
   --use-latest-restorable-time
   ```

3. If the cluster that you are cloning is encrypted, encrypt your cloned cluster by including a `kms-key-id` parameter. This `kms-key-id` value can be the same one used to encrypt the original DB cluster, or your own KMS key. Your account must have permission to use that encryption key.

   For Linux, macOS, or Unix:

   ```bash
   aws rds restore-db-cluster-to-point-in-time \
   --source-db-cluster-identifier=arn:aws:rds:arn_details \
   --db-cluster-identifier=new_cluster_id \
   --restore-type=copy-on-write \ 
   --use-latest-restorable-time \
   --kms-key-id=arn:aws:kms:arn_details
   ```

   For Windows:

   ```bash
   aws rds restore-db-cluster-to-point-in-time ^ 
   --source-db-cluster-identifier=arn:aws:rds:arn_details ^ 
   --db-cluster-identifier=new_cluster_id ^ 
   --restore-type=copy-on-write ^ 
   --use-latest-restorable-time ^ 
   --kms-key-id=arn:aws:kms:arn_details
   ```

The account that owns the encryption key must grant permission to use the key to the destination account by using a key policy. This process is similar to how encrypted snapshots are shared, by using a key policy that grants permission to the destination account to use the key. An example of a key policy follows.

```json
{
   "Id": "key-policy-1",
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowAnyServerToUseMyKey",
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::destination_account_id:root"
         },
         "Action": [
            "kms:UseKey"
         ],
      }
   ]
}
```
"Statement": [
  {
    "Sid": "Allow use of the key",
    "Effect": "Allow",
    "Principal": {
      "AWS": [
        "arn:aws:iam::account_id:user/KeyUser",
        "arn:aws:iam::account_id:root"
      ]},
    "Action": [
      "kms:CreateGrant",
      "kms:Encrypt",
      "kms:Decrypt",
      "kms:ReEncrypt*",
      "kms:GenerateDataKey*",
      "kms:DescribeKey"
    ],
    "Resource": "*"
  },
  {
    "Sid": "Allow attachment of persistent resources",
    "Effect": "Allow",
    "Principal": {
      "AWS": [
        "arn:aws:iam::account_id:user/KeyUser",
        "arn:aws:iam::account_id:root"
      ]},
    "Action": [
      "kms:CreateGrant",
      "kms:ListGrants",
      "kms:RevokeGrant"
    ],
    "Resource": "*",
    "Condition": {
      "Bool": {
        "kms:GrantIsForAWSResource": true
      }
    }
  }
]

Note
The restore-db-cluster-to-point-in-time AWS CLI command restores only the DB cluster, not
the DB instances for that DB cluster. To create DB instances for the restored DB cluster, invoke
the create-db-instance command. Specify the identifier of the restored DB cluster in --db-
cluster-identifier.
You can create DB instances only after the restore-db-cluster-to-point-in-time
command has completed and the DB cluster is available.

RDS API

To clone an Aurora cluster owned by another AWS account
1. Accept the invitation from the AWS account that owns the DB cluster, as shown preceding.
2. Clone the cluster by specifying the full ARN of the source cluster in the
   SourceDBClusterIdentifier parameter of the RDS API operation
   RestoreDBClusterToPointInTime.

   If the ARN passed as the SourceDBClusterIdentifier hasn't been shared, then the same error is
   returned as if the specified cluster doesn't exist.
3. If the cluster that you are cloning is encrypted, include a KmsKeyId parameter to encrypt your
   cloned cluster. This kms-key-id value can be the same one used to encrypt the original DB cluster,
   or your own KMS key. Your account must have permission to use that encryption key.

---

300
When you clone a volume, the destination account must have permission to use the encryption key used to encrypt the source cluster. Aurora encrypts the new cloned cluster with the encryption key specified in \texttt{KmsKeyId}.

The account that owns the encryption key must grant permission to use the key to the destination account by using a key policy. This process is similar to how encrypted snapshots are shared, by using a key policy that grants permission to the destination account to use the key. An example of a key policy follows.

```json
{
   "Id": "key-policy-1",
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Allow use of the key",
         "Effect": "Allow",
         "Principal": {"AWS": [
            "arn:aws:iam::account_id:user/KeyUser",
            "arn:aws:iam::account_id:root"
         ]},
         "Action": ["kms:CreateGrant", "kms:Encrypt", "kms:Decrypt", "kms:ReEncrypt", "kms:GenerateDataKey", "kms:DescribeKey"],
         "Resource": "*"
      },
      {
         "Sid": "Allow attachment of persistent resources",
         "Effect": "Allow",
         "Principal": {"AWS": [
            "arn:aws:iam::account_id:user/KeyUser",
            "arn:aws:iam::account_id:root"
         ]},
         "Action": ["kms:CreateGrant", "kms:ListGrants", "kms:RevokeGrant"],
         "Resource": "*",
         "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
      }
   ]
}
```

\textbf{Note}

The \texttt{RestoreDBClusterToPointInTime} RDS API operation restores only the DB cluster, not the DB instances for that DB cluster. To create DB instances for the restored DB cluster, invoke the \texttt{CreateDBInstance} RDS API operation. Specify the identifier of the restored DB cluster in \texttt{DBClusterIdentifier}. You can create DB instances only after the \texttt{RestoreDBClusterToPointInTime} operation has completed and the DB cluster is available.

\textbf{Checking if a DB cluster is a cross-account clone}

The \texttt{DBClusters} object identifies whether each cluster is a cross-account clone. You can see the clusters that you have permission to clone by using the \texttt{include-shared} option when you run the RDS CLI.
command `describe-db-clusters`. However, you can't see most of the configuration details for such clusters.

**AWS CLI**

**To check if a DB cluster is a cross-account clone**

- Call the RDS CLI command `describe-db-clusters`.

  The following example shows how actual or potential cross-account clone DB clusters appear in `describe-db-clusters` output. For existing clusters owned by your AWS account, the `CrossAccountClone` field indicates whether the cluster is a clone of a DB cluster that is owned by another AWS account.

  In some cases, an entry might have a different AWS account number than yours in the `DBClusterArn` field. In this case, that entry represents a cluster that is owned by a different AWS account and that you can clone. Such entries have few fields other than `DBClusterArn`. When creating the cloned cluster, specify the same `StorageEncrypted`, `Engine`, and `EngineVersion` values as in the original cluster.

```bash
# aws rds describe-db-clusters --include-shared --region us-east-1
{
  "DBClusters": [
    {
      "Engine": "aurora",
      "EngineVersion": "5.6.10a",
      "CrossAccountClone": false,
      ...
    },
    {
      "EarliestRestorableTime": "2019-04-09T16:01:07.398Z",
      "Engine": "aurora",
      "EngineVersion": "5.6.10a",
      "CrossAccountClone": true,
      ...
    },
    {
      "StorageEncrypted": false,
      "Engine": "aurora",
      "EngineVersion": "5.6.10a",
    }
  ]
}
```

**RDS API**

**To check if a DB cluster is a cross-account clone**

- Call the RDS API operation `DescribeDBClusters`.

  For existing clusters owned by your AWS account, the `CrossAccountClone` field indicates whether the cluster is a clone of a DB cluster owned by another AWS account. Entries with a different AWS account number in the `DBClusterArn` field represent clusters that you can clone and that are owned by other AWS accounts. These entries have few fields other than `DBClusterArn`. When creating the cloned cluster, specify the same `StorageEncrypted`, `Engine`, and `EngineVersion` values as in the original cluster.
The following example shows a return value that demonstrates both actual and potential cloned clusters.

```json
{
  "DBClusters": [
    {
      "Engine": "aurora",
      "EngineVersion": "5.6.10a",
      "CrossAccountClone": false,
      ...
    },
    {
      "EarliestRestorableTime": "2019-04-09T16:01:07.398Z",
      "Engine": "aurora",
      "EngineVersion": "5.6.10a",
      "CrossAccountClone": true,
      ...
    },
    {
      "StorageEncrypted": false,
      "Engine": "aurora",
      "EngineVersion": "5.6.10a"
    }
  ]
}
```
Integrating Aurora with other AWS services

Integrate Amazon Aurora with other AWS services so that you can extend your Aurora DB cluster to use additional capabilities in the AWS Cloud.

Topics

• Integrating AWS services with Amazon Aurora MySQL (p. 304)
• Integrating AWS services with Amazon Aurora PostgreSQL (p. 304)
• Using Amazon Aurora Auto Scaling with Aurora replicas (p. 305)
• Using machine learning (ML) capabilities with Amazon Aurora (p. 320)

Integrating AWS services with Amazon Aurora MySQL

Amazon Aurora MySQL integrates with other AWS services so that you can extend your Aurora MySQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora MySQL DB cluster can use AWS services to do the following:

• Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. Or, asynchronously invoke an AWS Lambda function using the `mysql.lambda_async` procedure.
• Load data from text or XML files stored in an Amazon S3 bucket into your DB cluster using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` command.
• Save data to text files stored in an Amazon S3 bucket from your DB cluster using the `SELECT INTO OUTFILE S3` command.
• Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora replicas (p. 305).

For more information about integrating Aurora MySQL with other AWS services, see Integrating Amazon Aurora MySQL with other AWS services (p. 891).

Integrating AWS services with Amazon Aurora PostgreSQL

Amazon Aurora PostgreSQL integrates with other AWS services so that you can extend your Aurora PostgreSQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora PostgreSQL DB cluster can use AWS services to do the following:

• Quickly collect, view, and assess performance on your relational database workloads with Performance Insights.
• Automatically add or remove Aurora Replicas with Aurora Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora replicas (p. 305).

For more information about integrating Aurora PostgreSQL with other AWS services, see Integrating Amazon Aurora PostgreSQL with other AWS services (p. 1231).
Using Amazon Aurora Auto Scaling with Aurora replicas

To meet your connectivity and workload requirements, Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas provisioned for an Aurora DB cluster using single-master replication. Aurora Auto Scaling is available for both Aurora MySQL and Aurora PostgreSQL. Aurora Auto Scaling enables your Aurora DB cluster to handle sudden increases in connectivity or workload. When the connectivity or workload decreases, Aurora Auto Scaling removes unnecessary Aurora Replicas so that you don't pay for unused provisioned DB instances.

You define and apply a scaling policy to an Aurora DB cluster. The scaling policy defines the minimum and maximum number of Aurora Replicas that Aurora Auto Scaling can manage. Based on the policy, Aurora Auto Scaling adjusts the number of Aurora Replicas up or down in response to actual workloads, determined by using Amazon CloudWatch metrics and target values.

You can use the AWS Management Console to apply a scaling policy based on a predefined metric. Alternatively, you can use either the AWS CLI or Aurora Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

**Topics**

- Before you begin (p. 305)
- Aurora Auto Scaling policies (p. 306)
- Adding a scaling policy (p. 307)
- Editing a scaling policy (p. 316)
- Deleting a scaling policy (p. 318)
- DB instance IDs and tagging (p. 319)

**Before you begin**

Before you can use Aurora Auto Scaling with an Aurora DB cluster, you must first create an Aurora DB cluster with a primary instance and at least one Aurora Replica. Although Aurora Auto Scaling manages Aurora Replicas, the Aurora DB cluster must start with at least one Aurora Replica. For more information about creating an Aurora DB cluster, see Creating an Amazon Aurora DB cluster (p. 127).

Aurora Auto Scaling only scales a DB cluster if all Aurora Replicas in a DB cluster are in the available state. If any of the Aurora Replicas are in a state other than available, Aurora Auto Scaling waits until the whole DB cluster becomes available for scaling.

When Aurora Auto Scaling adds a new Aurora Replica, the new Aurora Replica is the same DB instance class as the one used by the primary instance. For more information about DB instance classes, see Aurora DB instance classes (p. 56). Also, the promotion tier for new Aurora Replicas is set to the last priority, which is 15 by default. This means that during a failover, a replica with a better priority, such as one created manually, would be promoted first. For more information, see Fault tolerance for an Aurora DB cluster (p. 72).

Aurora Auto Scaling only removes Aurora Replicas that it created.

To benefit from Aurora Auto Scaling, your applications must support connections to new Aurora Replicas. To do so, we recommend using the Aurora reader endpoint. For Aurora MySQL you can use a driver such as the AWS JDBC Driver for MySQL. For more information, see Connecting to an Amazon Aurora DB cluster (p. 207).

**Note**

Aurora global databases currently don't support Aurora Auto Scaling for secondary DB clusters.
Aurora Auto Scaling policies

Aurora Auto Scaling uses a scaling policy to adjust the number of Aurora Replicas in an Aurora DB cluster. Aurora Auto Scaling has the following components:

- A service-linked role
- A target metric
- Minimum and maximum capacity
- A cooldown period

Service linked role

Aurora Auto Scaling uses the AWSServiceRoleForApplicationAutoScaling_RDSCluster service-linked role. For more information, see Service-linked roles for Application Auto Scaling in the Application Auto Scaling User Guide.

Target metric

In this type of policy, a predefined or custom metric and a target value for the metric is specified in a target-tracking scaling policy configuration. Aurora Auto Scaling creates and manages CloudWatch alarms that trigger the scaling policy and calculates the scaling adjustment based on the metric and target value. The scaling policy adds or removes Aurora Replicas as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target-tracking scaling policy also adjusts to fluctuations in the metric due to a changing workload. Such a policy also minimizes rapid fluctuations in the number of available Aurora Replicas for your DB cluster.

For example, take a scaling policy that uses the predefined average CPU utilization metric. Such a policy can keep CPU utilization at, or close to, a specified percentage of utilization, such as 40 percent.

Note
For each Aurora DB cluster, you can create only one Auto Scaling policy for each target metric.

Minimum and maximum capacity

You can specify the maximum number of Aurora Replicas to be managed by Application Auto Scaling. This value must be set to 0–15, and must be equal to or greater than the value specified for the minimum number of Aurora Replicas.

You can also specify the minimum number of Aurora Replicas to be managed by Application Auto Scaling. This value must be set to 0–15, and must be equal to or less than the value specified for the maximum number of Aurora Replicas.

Note
The minimum and maximum capacity are set for an Aurora DB cluster. The specified values apply to all of the policies associated with that Aurora DB cluster.

Cooldown period

You can tune the responsiveness of a target-tracking scaling policy by adding cooldown periods that affect scaling your Aurora DB cluster in and out. A cooldown period blocks subsequent scale-in or scale-out requests until the period expires. These blocks slow the deletions of Aurora Replicas in your Aurora DB cluster for scale-in requests, and the creation of Aurora Replicas for scale-out requests.

You can specify the following cooldown periods:

- A scale-in activity reduces the number of Aurora Replicas in your Aurora DB cluster. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.
• A scale-out activity increases the number of Aurora Replicas in your Aurora DB cluster. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

When a scale-in or a scale-out cooldown period is not specified, the default for each is 300 seconds.

Enable or disable scale-in activities

You can enable or disable scale-in activities for a policy. Enabling scale-in activities allows the scaling policy to delete Aurora Replicas. When scale-in activities are enabled, the scale-in cooldown period in the scaling policy applies to scale-in activities. Disabling scale-in activities prevents the scaling policy from deleting Aurora Replicas.

Note
Scale-out activities are always enabled so that the scaling policy can create Aurora Replicas as needed.

Adding a scaling policy

You can add a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Note
For an example that adds a scaling policy using AWS CloudFormation, see Declaring a scaling policy for an Aurora DB cluster in the AWS CloudFormation User Guide.

Topics

• Adding a scaling policy using the AWS Management Console (p. 307)
• Adding a scaling policy using the AWS CLI or the Application Auto Scaling API (p. 310)

Adding a scaling policy using the AWS Management Console

You can add a scaling policy to an Aurora DB cluster by using the AWS Management Console.

To add an auto scaling policy to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora DB cluster that you want to add a policy for.
4. Choose the Logs & events tab.
5. In the Auto scaling policies section, choose Add.
   The Add Auto Scaling policy dialog box appears.
6. For Policy Name, type the policy name.
7. For the target metric, choose one of the following:
   • Average CPU utilization of Aurora Replicas to create a policy based on the average CPU utilization.
   • Average connections of Aurora Replicas to create a policy based on the average number of connections to Aurora Replicas.
8. For the target value, type one of the following:
• If you chose **Average CPU utilization of Aurora Replicas** in the previous step, type the percentage of CPU utilization that you want to maintain on Aurora Replicas.

• If you chose **Average connections of Aurora Replicas** in the previous step, type the number of connections that you want to maintain.

Aurora Replicas are added or removed to keep the metric close to the specified value.

9. (Optional) Open **Additional Configuration** to create a scale-in or scale-out cooldown period.

10. For **Minimum capacity**, type the minimum number of Aurora Replicas that the Aurora Auto Scaling policy is required to maintain.

11. For **Maximum capacity**, type the maximum number of Aurora Replicas the Aurora Auto Scaling policy is required to maintain.

12. Choose **Add policy**.

The following dialog box creates an Auto Scaling policy based an average CPU utilization of 40 percent. The policy specifies a minimum of 5 Aurora Replicas and a maximum of 15 Aurora Replicas.
The following dialog box creates an auto scaling policy based on an average number of connections of 100. The policy specifies a minimum of two Aurora Replicas and a maximum of eight Aurora Replicas.
Adding a scaling policy using the AWS CLI or the Application Auto Scaling API

You can apply a scaling policy based on either a predefined or custom metric. To do so, you can use the AWS CLI or the Application Auto Scaling API. The first step is to register your Aurora DB cluster with Application Auto Scaling.

Registering an Aurora DB cluster

Before you can use Aurora Auto Scaling with an Aurora DB cluster, you register your Aurora DB cluster with Application Auto Scaling. You do so to define the scaling dimension and limits to be applied to that cluster. Application Auto Scaling dynamically scales the Aurora DB cluster along the
Using Auto Scaling with Aurora replicas

rds:cluster:ReadReplicaCount scalable dimension, which represents the number of Aurora Replicas.

To register your Aurora DB cluster, you can use either the AWS CLI or the Application Auto Scaling API.

**AWS CLI**

To register your Aurora DB cluster, use the `register-scalable-target` AWS CLI command with the following parameters:

- `--service-namespace` – Set this value to `rds`.
- `--resource-id` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is cluster and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
- `--scalable-dimension` – Set this value to `rds:cluster:ReadReplicaCount`.
- `--min-capacity` – The minimum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of DB instances in your cluster, see Minimum and maximum capacity (p. 306).
- `--max-capacity` – The maximum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between `--min-capacity`, `--max-capacity`, and the number of DB instances in your cluster, see Minimum and maximum capacity (p. 306).

**Example**

In the following example, you register an Aurora DB cluster named `myscalablecluster`. The registration indicates that the DB cluster should be dynamically scaled to have from one to eight Aurora Replicas.

For Linux, macOS, or Unix:

```bash
aws application-autoscaling register-scalable-target
--service-namespace rds
--resource-id cluster:myscalablecluster
--scalable-dimension rds:cluster:ReadReplicaCount
--min-capacity 1
--max-capacity 8
```

For Windows:

```bash
aws application-autoscaling register-scalable-target
--service-namespace rds
--resource-id cluster:myscalablecluster
--scalable-dimension rds:cluster:ReadReplicaCount
--min-capacity 1
--max-capacity 8
```

**RDS API**

To register your Aurora DB cluster with Application Auto Scaling, use the `RegisterScalableTarget` Application Auto Scaling API operation with the following parameters:

- `ServiceNamespace` – Set this value to `rds`.
- `ResourceID` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is cluster and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`. 
• **ScalableDimension** – Set this value to `rds:cluster:ReadReplicaCount`.
• **MinCapacity** – The minimum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between MinCapacity, MaxCapacity, and the number of DB instances in your cluster, see Minimum and maximum capacity (p. 306).
• **MaxCapacity** – The maximum number of reader DB instances to be managed by Application Auto Scaling. For information about the relationship between MinCapacity, MaxCapacity, and the number of DB instances in your cluster, see Minimum and maximum capacity (p. 306).

### Example

In the following example, you register an Aurora DB cluster named `myscalablecluster` with the Application Auto Scaling API. This registration indicates that the DB cluster should be dynamically scaled to have from one to eight Aurora Replicas.

```plaintext
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget

{
    "ServiceNamespace": "rds",
    "ResourceId": "cluster:myscalablecluster",
    "ScalableDimension": "rds:cluster:ReadReplicaCount",
    "MinCapacity": 1,
    "MaxCapacity": 8
}
```

### Defining a scaling policy for an Aurora DB cluster

A target-tracking scaling policy configuration is represented by a JSON block that the metrics and target values are defined in. You can save a scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see `TargetTrackingScalingPolicyConfiguration` in the *Application Auto Scaling API Reference*.

The following options are available for defining a target-tracking scaling policy configuration.

**Topics**

- [Using a predefined metric](#)
- [Using a custom metric](#)
- [Using cooldown periods](#)
- [Disabling scale-in activity](#)

#### Using a predefined metric

By using predefined metrics, you can quickly define a target-tracking scaling policy for an Aurora DB cluster that works well with both target tracking and dynamic scaling in Aurora Auto Scaling.

Currently, Aurora supports the following predefined metrics in Aurora Auto Scaling:

- **RDSReaderAverageCPUUtilization** – The average value of the CPUUtilization metric in CloudWatch across all Aurora Replicas in the Aurora DB cluster.
- **RDSReaderAverageDatabaseConnections** – The average value of the `DatabaseConnections` metric in CloudWatch across all Aurora Replicas in the Aurora DB cluster.

For more information about the `CPUUtilization` and `DatabaseConnections` metrics, see Amazon CloudWatch metrics for Amazon Aurora (p. 525).

To use a predefined metric in your scaling policy, you create a target tracking configuration for your scaling policy. This configuration must include a `PredefinedMetricSpecification` for the predefined metric and a `TargetValue` for the target value of that metric.

**Example**

The following example describes a typical policy configuration for target-tracking scaling for an Aurora DB cluster. In this configuration, the `RDSReaderAverageCPUUtilization` predefined metric is used to adjust the Aurora DB cluster based on an average CPU utilization of 40 percent across all Aurora Replicas.

```json
{
  "TargetValue": 40.0,
  "PredefinedMetricSpecification":
  {
    "PredefinedMetricType": "RDSReaderAverageCPUUtilization"
  }
}
```

**Using a custom metric**

By using custom metrics, you can define a target-tracking scaling policy that meets your custom requirements. You can define a custom metric based on any Aurora metric that changes in proportion to scaling.

Not all Aurora metrics work for target tracking. The metric must be a valid utilization metric and describe how busy an instance is. The value of the metric must increase or decrease in proportion to the number of Aurora Replicas in the Aurora DB cluster. This proportional increase or decrease is necessary to use the metric data to proportionally scale out or in the number of Aurora Replicas.

**Example**

The following example describes a target-tracking configuration for a scaling policy. In this configuration, a custom metric adjusts an Aurora DB cluster based on an average CPU utilization of 50 percent across all Aurora Replicas in an Aurora DB cluster named `my-db-cluster`.

```json
{
  "TargetValue": 50,
  "CustomizedMetricSpecification":
  {
    "MetricName": "CPUUtilization",
    "Namespace": "AWS/RDS",
    "Dimensions": [
      {"Name": "DBClusterIdentifier","Value": "my-db-cluster"},
      {"Name": "Role","Value": "READER"}
    ],
    "Statistic": "Average",
    "Unit": "Percent"
  }
}
```

**Using cooldown periods**

You can specify a value, in seconds, for `ScaleOutCooldown` to add a cooldown period for scaling out your Aurora DB cluster. Similarly, you can add a value, in seconds, for `ScaleInCooldown` to add a
cooldown period for scaling in your Aurora DB cluster. For more information about ScaleInCooldown and ScaleOutCooldown, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

Example

The following example describes a target-tracking configuration for a scaling policy. In this configuration, the RDSReaderAverageCPUUtilization predefined metric is used to adjust an Aurora DB cluster based on an average CPU utilization of 40 percent across all Aurora Replicas in that Aurora DB cluster. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```json
{
    "TargetValue": 40.0,
    "PredefinedMetricSpecification": {
        "PredefinedMetricType": "RDSReaderAverageCPUUtilization",
    },
    "ScaleInCooldown": 600,
    "ScaleOutCooldown": 300
}
```

Disabling scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your Aurora DB cluster by disabling scale-in activity. Disabling scale-in activity prevents the scaling policy from deleting Aurora Replicas, while still allowing the scaling policy to create them as needed.

You can specify a Boolean value for DisableScaleIn to enable or disable scale in activity for your Aurora DB cluster. For more information about DisableScaleIn, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

Example

The following example describes a target-tracking configuration for a scaling policy. In this configuration, the RDSReaderAverageCPUUtilization predefined metric adjusts an Aurora DB cluster based on an average CPU utilization of 40 percent across all Aurora Replicas in that Aurora DB cluster. The configuration disables scale-in activity for the scaling policy.

```json
{
    "TargetValue": 40.0,
    "PredefinedMetricSpecification": {
        "PredefinedMetricType": "RDSReaderAverageCPUUtilization",
    },
    "DisableScaleIn": true
}
```

Applying a scaling policy to an Aurora DB cluster

After registering your Aurora DB cluster with Application Auto Scaling and defining a scaling policy, you apply the scaling policy to the registered Aurora DB cluster. To apply a scaling policy to an Aurora DB cluster, you can use the AWS CLI or the Application Auto Scaling API.

AWS CLI

To apply a scaling policy to your Aurora DB cluster, use the `put-scaling-policy` AWS CLI command with the following parameters:

- `--policy-name` – The name of the scaling policy.
- `--policy-type` – Set this value to TargetTrackingScaling.
• `--resource-id` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
• `--service-namespace` – Set this value to `rds`.
• `--scalable-dimension` – Set this value to `rds:cluster:ReadReplicaCount`.
• `--target-tracking-scaling-policy-configuration` – The target-tracking scaling policy configuration to use for the Aurora DB cluster.

Example

In the following example, you apply a target-tracking scaling policy named `myscalablepolicy` to an Aurora DB cluster named `myscalablecluster` with Application Auto Scaling. To do so, you use a policy configuration saved in a file named `config.json`.

For Linux, macOS, or Unix:

```bash
aws application-autoscaling put-scaling-policy
  --policy-name myscalablepolicy
  --policy-type TargetTrackingScaling
  --resource-id cluster:myscalablecluster
  --service-namespace rds
  --scalable-dimension rds:cluster:ReadReplicaCount
  --target-tracking-scaling-policy-configuration file://config.json
```

For Windows:

```bash
aws application-autoscaling put-scaling-policy
  --policy-name myscalablepolicy
  --policy-type TargetTrackingScaling
  --resource-id cluster:myscalablecluster
  --service-namespace rds
  --scalable-dimension rds:cluster:ReadReplicaCount
  --target-tracking-scaling-policy-configuration file://config.json
```

RDS API

To apply a scaling policy to your Aurora DB cluster with the Application Auto Scaling API, use the `PutScalingPolicy` Application Auto Scaling API operation with the following parameters:

• `PolicyName` – The name of the scaling policy.
• `ServiceNamespace` – Set this value to `rds`.
• `ResourceId` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
• `ScalableDimension` – Set this value to `rds:cluster:ReadReplicaCount`.
• `PolicyType` – Set this value to `TargetTrackingScaling`.
• `TargetTrackingScalingPolicyConfiguration` – The target-tracking scaling policy configuration to use for the Aurora DB cluster.

Example

In the following example, you apply a target-tracking scaling policy named `myscalablepolicy` to an Aurora DB cluster named `myscalablecluster` with Application Auto Scaling. You use a policy configuration based on the `RDSReaderAverageCPUUtilization` predefined metric.
Editing a scaling policy

You can edit a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Editing a scaling policy using the AWS Management Console

You can edit a scaling policy by using the AWS Management Console.

To edit an auto scaling policy for an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora DB cluster whose auto scaling policy you want to edit.
4. Choose the Logs & events tab.
5. In the Auto scaling policies section, choose the auto scaling policy, and then choose Edit.
6. Make changes to the policy.
7. Choose Save.

The following is a sample Edit Auto Scaling policy dialog box.
Editing a scaling policy using the AWS CLI or the Application Auto Scaling API

You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:
• When using the AWS CLI, specify the name of the policy you want to edit in the `--policy-name` parameter. Specify new values for the parameters you want to change.
• When using the Application Auto Scaling API, specify the name of the policy you want to edit in the `PolicyName` parameter. Specify new values for the parameters you want to change.

For more information, see Applying a scaling policy to an Aurora DB cluster (p. 314).

Deleting a scaling policy

You can delete a scaling policy using the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Deleting a scaling policy using the AWS Management Console

You can delete a scaling policy by using the AWS Management Console.

To delete an auto scaling policy for an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora DB cluster whose auto scaling policy you want to delete.
4. Choose the Logs & events tab.
5. In the Auto scaling policies section, choose the auto scaling policy, and then choose Delete.

Deleting a scaling policy using the AWS CLI or the Application Auto Scaling API

You can use the AWS CLI or the Application Auto Scaling API to delete a scaling policy from an Aurora DB cluster.

AWS CLI

To delete a scaling policy from your Aurora DB cluster, use the `delete-scaling-policy` AWS CLI command with the following parameters:

• `--policy-name` – The name of the scaling policy.
• `--resource-id` – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
• `--service-namespace` – Set this value to `rds`.
• `--scalable-dimension` – Set this value to `rds:cluster:ReadReplicaCount`.

Example

In the following example, you delete a target-tracking scaling policy named `myscalablepolicy` from an Aurora DB cluster named `myscalablecluster`.

For Linux, macOS, or Unix:

```bash
aws application-autoscaling delete-scaling-policy
   --policy-name myscalablepolicy
   --resource-id cluster:myscalablecluster
   --service-namespace rds
```
Using Auto Scaling with Aurora replicas

RDS API

To delete a scaling policy from your Aurora DB cluster, use the DeleteScalingPolicy operation with the following parameters:

- **PolicyName** – The name of the scaling policy.
- **ServiceNamespace** – Set this value to `rds`.
- **ResourceId** – The resource identifier for the Aurora DB cluster. For this parameter, the resource type is `cluster` and the unique identifier is the name of the Aurora DB cluster, for example `cluster:myscalablecluster`.
- **ScalableDimension** – Set this value to `rds:cluster:ReadReplicaCount`.

Example

In the following example, you delete a target-tracking scaling policy named `myscalablepolicy` from an Aurora DB cluster named `myscalablecluster` with the Application Auto Scaling API.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
Content-Length: 219
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "rds",
    "ResourceId": "cluster:myscalablecluster",
    "ScalableDimension": "rds:cluster:ReadReplicaCount"
}
```

DB instance IDs and tagging

When a replica is added by Aurora Auto Scaling, its DB instance ID is prefixed by `application-autoscaling-`, for example, `application-autoscaling-61aabbcc-4e2f-4c65-b620-ab7421abc123`.

The following tag is automatically added to the DB instance. You can view it on the Tags tab of the DB instance detail page.
For more information on Amazon RDS resource tags, see Tagging Amazon RDS resources (p. 352).

**Using machine learning (ML) capabilities with Amazon Aurora**

Following, you can find a description of how to use machine learning (ML) capabilities in your Aurora database applications. This feature simplifies developing database applications that use the Amazon SageMaker and Amazon Comprehend services to perform predictions. In ML terminology, these predictions are known as *inferences*.

This feature is suitable for many kinds of quick predictions. Examples include low-latency, real-time use cases such as fraud detection, ad targeting, and product recommendations. The queries pass customer profile, shopping history, and product catalog data to an SageMaker model. Then your application gets product recommendations returned as query results.

To use this feature, it helps for your organization to already have the appropriate ML models, notebooks, and so on available in the Amazon machine learning services. You can divide the database knowledge and ML knowledge among the members of your team. The database developers can focus on the SQL and database side of your application. The Aurora Machine Learning feature enables the application to use ML processing through the familiar database interface of stored function calls.

**Topics**

- Using machine learning (ML) with Aurora MySQL (p. 928)
- Using machine learning (ML) with Aurora PostgreSQL (p. 1272)
Maintaining an Amazon Aurora DB cluster

Periodically, Amazon RDS performs maintenance on Amazon RDS resources. Maintenance most often involves updates to the DB cluster's underlying hardware, underlying operating system (OS), or database engine version. Updates to the operating system most often occur for security issues and should be done as soon as possible.

Some maintenance items require that Amazon RDS take your DB cluster offline for a short time. Maintenance items that require a resource to be offline include required operating system or database patching. Required patching is automatically scheduled only for patches that are related to security and instance reliability. Such patching occurs infrequently (typically once every few months) and seldom requires more than a fraction of your maintenance window.

Deferred DB cluster and instance modifications that you have chosen not to apply immediately are also applied during the maintenance window. For example, you might choose to change DB instance classes or cluster or DB parameter groups during the maintenance window. Such modifications that you specify using the pending reboot setting don't show up in the Pending maintenance list. For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 248).

Viewing pending maintenance

You can view whether a maintenance update is available for your DB cluster by using the RDS console, the AWS CLI, or the Amazon RDS API. If an update is available, it is indicated in the Maintenance column for the DB cluster on the Amazon RDS console, as shown following.

If no maintenance update is available for a DB cluster, the column value is none for it.

If a maintenance update is available for a DB cluster, the following column values are possible:

- **required** – The maintenance action will be applied to the resource and can't be deferred indefinitely.
- **available** – The maintenance action is available, but it will not be applied to the resource automatically. You can apply it manually.
- **next window** – The maintenance action will be applied to the resource during the next maintenance window.
- **In progress** – The maintenance action is in the process of being applied to the resource.
If an update is available, you can take one of the actions:

- If the maintenance value is **next window**, defer the maintenance items by choosing **Defer upgrade** from **Actions**. You can't defer a maintenance action if it has already started.
- Apply the maintenance items immediately.
- Schedule the maintenance items to start during your next maintenance window.
- Take no action.

**Note**

Certain OS updates are marked as **required**. If you defer a required update, you get a notice from Amazon RDS indicating when the update will be performed. Other updates are marked as **available**, and these you can defer indefinitely.

To take an action, choose the DB cluster to show its details, then choose **Maintenance & backups**. The pending maintenance items appear.

The maintenance window determines when pending operations start, but doesn't limit the total run time of these operations. Maintenance operations aren't guaranteed to finish before the maintenance window ends, and can continue beyond the specified end time. For more information, see **The Amazon RDS maintenance window (p. 324)**.

For information about updates to Amazon Aurora engines and instructions for upgrading and patching them, see **Database engine updates for Amazon Aurora MySQL (p. 991)** and **Amazon Aurora PostgreSQL updates (p. 1412)**.

You can also view whether a maintenance update is available for your DB cluster by running the `describe-pending-maintenance-actions` AWS CLI command.
Applying updates for a DB cluster

With Amazon RDS, you can choose when to apply maintenance operations. You can decide when Amazon RDS applies updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API.

**Console**

**To manage an update for a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that has a required update.
4. For **Actions**, choose one of the following:
   - **Upgrade now**
   - **Upgrade at next window**

   **Note**
   If you choose **Upgrade at next window** and later want to delay the update, you can choose **Defer upgrade**. You can't defer a maintenance action if it has already started. To cancel a maintenance action, modify the DB instance and disable **Auto minor version upgrade**.

**AWS CLI**

To apply a pending update to a DB cluster, use the `apply-pending-maintenance-action` AWS CLI command.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds apply-pending-maintenance-action \
  --apply-action system-update \
  --opt-in-type immediate
```

For Windows:

```bash
aws rds apply-pending-maintenance-action ^
  --apply-action system-update ^
  --opt-in-type immediate
```

**Note**

To defer a maintenance action, specify `undo-opt-in` for `--opt-in-type`. You can't specify `undo-opt-in` for `--opt-in-type` if the maintenance action has already started. To cancel a maintenance action, run the `modify-db-instance` AWS CLI command and specify `--no-auto-minor-version-upgrade`.

To return a list of resources that have at least one pending update, use the `describe-pending-maintenance-actions` AWS CLI command.
Example

For Linux, macOS, or Unix:

```bash
aws rds describe-pending-maintenance-actions \
```

For Windows:

```bash
aws rds describe-pending-maintenance-actions ^
```

You can also return a list of resources for a DB cluster by specifying the `--filters` parameter of the `describe-pending-maintenance-actions` AWS CLI command. The format for the `--filters` command is `Name=filter-name,Value=resource-id,...`.

The following are the accepted values for the `Name` parameter of a filter:

- `db-instance-id` – Accepts a list of DB instance identifiers or Amazon Resource Names (ARNs). The returned list only includes pending maintenance actions for the DB instances identified by these identifiers or ARNs.
- `db-cluster-id` – Accepts a list of DB cluster identifiers or ARNs for Amazon Aurora. The returned list only includes pending maintenance actions for the DB clusters identified by these identifiers or ARNs.

For example, the following example returns the pending maintenance actions for the `sample-cluster1` and `sample-cluster2` DB clusters.

Example

For Linux, macOS, or Unix:

```bash
aws rds describe-pending-maintenance-actions \
  --filters Name=db-cluster-id,Values=sample-cluster1,sample-cluster2
```

For Windows:

```bash
aws rds describe-pending-maintenance-actions ^
  --filters Name=db-cluster-id,Values=sample-cluster1,sample-cluster2
```

RDS API

To apply an update to a DB cluster, call the Amazon RDS API `ApplyPendingMaintenanceAction` operation.

To return a list of resources that have at least one pending update, call the Amazon RDS API `DescribePendingMaintenanceActions` operation.

The Amazon RDS maintenance window

Every DB cluster has a weekly maintenance window during which any system changes are applied. You can think of the maintenance window as an opportunity to control when modifications and software patching occur, in the event either are requested or required. If a maintenance event is scheduled for a given week, it is initiated during the 30-minute maintenance window you identify. Most maintenance events also complete during the 30-minute maintenance window, although larger maintenance events may take more than 30 minutes to complete.
The 30-minute maintenance window is selected at random from an 8-hour block of time per region. If you don’t specify a preferred maintenance window when you create the DB cluster, then Amazon RDS assigns a 30-minute maintenance window on a randomly selected day of the week.

RDS will consume some of the resources on your DB cluster while maintenance is being applied. You might observe a minimal effect on performance. For a DB instance, on rare occasions, a Multi-AZ failover might be required for a maintenance update to complete.

Following, you can find the time blocks for each region from which default maintenance windows are assigned.

### Adjusting the preferred DB cluster maintenance window

The Aurora DB cluster maintenance window should fall at the time of lowest usage and thus might need modification from time to time. Your DB cluster is unavailable during this time only if the updates that are being applied require an outage. The outage is for the minimum amount of time required to make the necessary updates.

**Console**

**To adjust the preferred DB cluster maintenance window**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster for which you want to change the maintenance window.
4. Choose **Modify**.
5. In the **Maintenance** section, update the maintenance window.
6. Choose **Continue**.

   On the confirmation page, review your changes.

7. To apply the changes to the maintenance window immediately, choose **Immediately** in the **Schedule of modifications** section.
8. Choose **Modify cluster** to save your changes.

   Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

**AWS CLI**

To adjust the preferred DB cluster maintenance window, use the AWS CLI `modify-db-cluster` command with the following parameters:

- `--db-cluster-identifier`
- `--preferred-maintenance-window`

**Example**

The following code example sets the maintenance window to Tuesdays from 4:00–4:30 AM UTC.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster
   --db-cluster-identifier my-cluster
   --preferred-maintenance-window
```

Automatic minor version upgrades for Aurora DB clusters

The **Auto minor version upgrade** setting specifies whether Aurora automatically applies upgrades to your cluster. These upgrades include patch levels containing bug fixes, and new minor versions containing additional features. They don't include any incompatible changes.

**Note**
This setting is enabled by default. For each new cluster, choose the appropriate value for this setting based on its importance, expected lifetime, and the amount of verification testing that you do after each upgrade.

For instructions about turning this setting on or off, see Settings for Amazon Aurora (p. 251). In particular, make sure to apply the same setting to all DB instances in the cluster. If any DB instance in your cluster has this setting turned off, the cluster isn't automatically upgraded.

For more information about engine updates for Aurora PostgreSQL, see Amazon Aurora PostgreSQL updates (p. 1412).

For more information about the **Auto minor version upgrade** setting for Aurora MySQL, see Enabling automatic upgrades between minor Aurora MySQL versions (p. 998). For general information about engine updates for Aurora MySQL, see Database engine updates for Amazon Aurora MySQL (p. 991).

Choosing the frequency of Aurora MySQL maintenance updates

You can control whether Aurora MySQL upgrades happen frequently or rarely for each DB cluster. The best choice depends on your usage of Aurora MySQL and the priorities for your applications that run on Aurora. For information about the Aurora MySQL long-term stability (LTS) releases that require less frequent upgrades, see Aurora MySQL long-term support (LTS) releases (p. 994).

You might choose to upgrade an Aurora MySQL cluster rarely if some or all of the following conditions apply:

- Your testing cycle for your application takes a long time for each update to the Aurora MySQL database engine.
- You have many DB clusters or many applications all running on the same Aurora MySQL version. You prefer to upgrade all of your DB clusters and associated applications at the same time.
• You use both Aurora MySQL and RDS for MySQL, and you prefer to keep the Aurora MySQL clusters and RDS for MySQL DB instances compatible with the same level of MySQL.
• Your Aurora MySQL application is in production or is otherwise business-critical. You can't afford downtime for upgrades outside of rare occurrences for critical patches.
• Your Aurora MySQL application isn't limited by performance issues or feature gaps that are addressed in subsequent Aurora MySQL versions.

If the preceding factors apply to your situation, you can limit the number of forced upgrades for an Aurora MySQL DB cluster. You do so by choosing a specific Aurora MySQL version known as the "Long-Term Support" (LTS) version when you create or upgrade that DB cluster. Doing so minimizes the number of upgrade cycles, testing cycles, and upgrade-related outages for that DB cluster.

You might choose to upgrade an Aurora MySQL cluster frequently if some or all of the following conditions apply:

• The testing cycle for your application is straightforward and brief.
• Your application is still in the development stage.
• Your database environment uses a variety of Aurora MySQL versions, or Aurora MySQL and RDS for MySQL versions. Each Aurora MySQL cluster has its own upgrade cycle.
• You are waiting for specific performance or feature improvements before you increase your usage of Aurora MySQL.

If the preceding factors apply to your situation, you can enable Aurora to apply important upgrades more frequently by upgrading an Aurora MySQL DB cluster to a more recent Aurora MySQL version than the LTS version. Doing so makes the latest performance enhancements, bug fixes, and features available to you more quickly.
Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance

You might need to reboot your DB cluster or some instances within the cluster, usually for maintenance reasons. For example, suppose that you modify the parameters within a parameter group or associate a different parameter group with your cluster. In these cases, you must reboot the cluster for the changes to take effect. Similarly, you might reboot one or more reader DB instances within the cluster. You can arrange the reboot operations for individual instances to minimize downtime for the entire cluster.

The time required to reboot each DB instance in your cluster depends on the database activity at the time of reboot. It also depends on the recovery process of your specific DB engine. If it's practical, reduce database activity on that particular instance before starting the reboot process. Doing so can reduce the time needed to restart the database.

You can only reboot each DB instance in your cluster when it's in the available state. A DB instance can be unavailable for several reasons. These include the cluster being stopped state, a modification being applied to the instance, and a maintenance-window action such as a version upgrade.

Rebooting a DB instance restarts the database engine process. Rebooting a DB instance results in a momentary outage, during which the DB instance status is set to **rebooting**.

**Note**

If a DB instance isn't using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance. For more information about parameter groups, see Working with parameter groups (p. 215).

**Topics**

- Rebooting a DB instance within an Aurora cluster (p. 329)
- Rebooting an Aurora cluster (Aurora PostgreSQL and Aurora MySQL before version 2.10) (p. 330)
- Rebooting an Aurora MySQL cluster (version 2.10 and higher) (p. 330)
- Checking uptime for Aurora clusters and instances (p. 331)
- Examples of Aurora reboot operations (p. 333)

Rebooting a DB instance within an Aurora cluster

This procedure is the most important operation that you take when performing reboots with Aurora. Many of the maintenance procedures involve rebooting one or more Aurora DB instances in a particular order.

**Console**

**To reboot a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to reboot.
3. For **Actions**, choose **Reboot**.
   - The **Reboot DB Instance** page appears.
4. Choose **Reboot** to reboot your DB instance.
Rebooting an Aurora cluster (Aurora PostgreSQL and Aurora MySQL before version 2.10)

Or choose Cancel.

AWS CLI

To reboot a DB instance by using the AWS CLI, call the reboot-db-instance command.

Example

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance \
   --db-instance-identifier mydbinstance
```

For Windows:

```
aws rds reboot-db-instance ^
   --db-instance-identifier mydbinstance
```

RDS API

To reboot a DB instance by using the Amazon RDS API, call the RebootDBInstance operation.

Rebooting an Aurora cluster (Aurora PostgreSQL and Aurora MySQL before version 2.10)

In Aurora PostgreSQL-Compatible Edition, in Aurora MySQL-Compatible Edition version 1, and in Aurora MySQL before version 2.10, you reboot an entire Aurora DB cluster by rebooting the writer DB instance of that cluster. To do so, follow the procedure in Rebooting a DB instance within an Aurora cluster (p. 329).

Rebooting the writer DB instance also initiates a reboot for each reader DB instance in the cluster. That way, any cluster-wide parameter changes are applied to all DB instances at the same time. However, the reboot of all DB instances causes a brief outage for the cluster. The reader DB instances remain unavailable until the writer DB instance finishes rebooting and becomes available.

In the RDS console, the writer DB instance has the value Writer under the Role column on the Databases page. In the RDS CLI, the output of the describe-db-clusters command includes a section DBClusterMembers. The DBClusterMembers element representing the writer DB instance has a value of true for the IsClusterWriter field.

Important

In Aurora MySQL 2.10 and higher, the reboot behavior is different: the reader DB instances typically remain available while you reboot the writer instance. Then you can reboot the reader instances at a convenient time. You can reboot the reader instances on a staggered schedule if you want some reader instances to always be available. For more information, see Rebooting an Aurora MySQL cluster (version 2.10 and higher) (p. 330).

Rebooting an Aurora MySQL cluster (version 2.10 and higher)

In Aurora MySQL version 2.10 and higher, you can reboot the writer instance of your Aurora MySQL cluster without rebooting the reader instances in the cluster. Doing so can help maintain high availability
of the cluster for read operations while you reboot the writer instance. You can reboot the reader instances later, on a schedule that's convenient for you. For example, for a production cluster, you might reboot the reader instances one at a time, starting only after the reboot of the primary instance is finished. For each DB instance that you reboot, follow the procedure in Rebooting a DB instance within an Aurora cluster (p. 329).

Before Aurora MySQL 2.10, rebooting the primary instance caused a reboot for each reader instance at the same time. If your Aurora MySQL cluster is running an older version, use the reboot procedure in Rebooting an Aurora cluster (Aurora PostgreSQL and Aurora MySQL before version 2.10) (p. 330) instead.

**Important**
The change to reboot behavior in Aurora MySQL 2.10 and higher is different for Aurora global databases. If you reboot the writer instance for the primary cluster in an Aurora global database, the reader instances in the primary cluster remain available. However, the DB instances in any secondary clusters reboot at the same time.

You frequently reboot the cluster after making changes to cluster parameter groups. You make parameter changes by following the procedures in Working with parameter groups (p. 215). Suppose that you reboot the writer DB instance in an Aurora MySQL cluster to apply changes to cluster parameters. Some or all of the reader DB instances might continue using the old parameter settings. However, the different parameter settings don't affect the data integrity of the cluster. Any cluster parameters that affect the organization of data files are only used by the writer DB instance. For example, you can update cluster parameters such as `binlog_format` and `innodb_purge_threads` on the writer instance before the reader instances. Only the writer instance is writing binary logs and purging undo records.

For parameters that change how queries interpret SQL statements or query output, you might need to take care to reboot the reader instances immediately. You do this to avoid unexpected application behavior during queries. For example, suppose that you change the `lower_case_table_names` parameter and reboot the writer instance. In this case, the reader instances might not be able to access a newly created table until they are all rebooted.

For a list of all the Aurora MySQL cluster parameters, see Cluster-level parameters (p. 951).

**Tip**
Aurora MySQL might still reboot some of the reader instances along with the writer instance if your cluster is processing a workload with high throughput.

The reduction in the number of reboots applies during failover operations also. Aurora MySQL only restarts the writer DB instance and the failover target during a failover. Other reader DB instances in the cluster remain available to continue processing queries through connections to the reader endpoint. Thus, you can improve availability during a failover by having more than one reader DB instance in a cluster.

### Checking uptime for Aurora clusters and instances

You can check and monitor the length of time since the last reboot for each DB instance in your Aurora cluster. The Amazon CloudWatch metric `EngineUptime` reports the number of seconds since the last time a DB instance was started. You can examine this metric at a point in time to find out the uptime for the DB instance. You can also monitor this metric over time to detect when the instance is rebooted.

You can also examine the `EngineUptime` metric at the cluster level. The `Minimum` and `Maximum` dimensions report the smallest and largest uptime values for all DB instances in the cluster. To check the most recent time when any reader instance in a cluster was rebooted, or restarted for another reason, monitor the cluster-level metric using the `Minimum` dimension. To check which instance in the cluster has gone the longest without a reboot, monitor the cluster-level metric using the `Maximum` dimension. For example, you might want to confirm that all DB instances in the cluster were rebooted after a configuration change.
Tip
For long-term monitoring, we recommend monitoring the EngineUptime metric for individual instances instead of at the cluster level. The cluster-level EngineUptime metric is set to zero when a new DB instance is added to the cluster. Such cluster changes can happen as part of maintenance and scaling operations such as those performed by Auto Scaling.

The following CLI examples show how to examine the EngineUptime metric for the writer and reader instances in a cluster. The examples use a cluster named tpch100g. This cluster has a writer DB instance instance-1234. It also has two reader DB instances, instance-7448 and instance-6305.

First, the reboot-db-instance command reboots one of the reader instances. The wait command waits until the instance is finished rebooting.

```bash
$ aws rds reboot-db-instance --db-instance-identifier instance-6305
{
  "DBInstance": {
    "DBInstanceIdentifier": "instance-6305",
    "DBInstanceStatus": "rebooting",
    ...
  }
$ aws rds wait db-instance-available --db-instance-id instance-6305
```

The CloudWatch get-metric-statistics command examines the EngineUptime metric over the last five minutes at one-minute intervals. The uptime for the instance-6305 instance is reset to zero and begins counting upwards again. This AWS CLI example for Linux uses $() variable substitution to insert the appropriate timestamps into the CLI commands. It also uses the Linux sort command to order the output by the time the metric was collected. That timestamp value is the third field in each line of output.

```bash
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
  --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
  --period 60 --namespace "AWS/RDS" --statistics Maximum \ 
  --dimensions Name=DBInstanceIdentifier,Value=instance-6305 --output text \ 
  | sort -k 3
EngineUptime
DATAPOINTS 231.0 2021-03-16T18:19:00+00:00 Seconds
DATAPOINTS 291.0 2021-03-16T18:20:00+00:00 Seconds
DATAPOINTS 351.0 2021-03-16T18:21:00+00:00 Seconds
DATAPOINTS 411.0 2021-03-16T18:22:00+00:00 Seconds
DATAPOINTS 471.0 2021-03-16T18:23:00+00:00 Seconds
```

The minimum uptime for the cluster is reset to zero because one of the instances in the cluster was rebooted. The maximum uptime for the cluster isn't reset because at least one of the DB instances in the cluster remained available.

```bash
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
  --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
  --period 60 --namespace "AWS/RDS" --statistics Minimum \ 
  --dimensions Name=DBClusterIdentifier,Value=tpch100g --output text \ 
  | sort -k 3
EngineUptime
DATAPOINTS 63099.0 2021-03-16T18:12:00+00:00 Seconds
DATAPOINTS 63159.0 2021-03-16T18:13:00+00:00 Seconds
DATAPOINTS 63219.0 2021-03-16T18:14:00+00:00 Seconds
DATAPOINTS 63279.0 2021-03-16T18:15:00+00:00 Seconds
DATAPOINTS 51.0 2021-03-16T18:16:00+00:00 Seconds
```

```bash
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
  --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" \
  --period 60 --namespace "AWS/RDS" --statistics Maximum \ 
  --dimensions Name=DBClusterIdentifier,Value=tpch100g --output text \ 
```
Examples of Aurora reboot operations

The following Aurora MySQL examples show different combinations of reboot operations for reader and writer DB instances in an Aurora DB cluster. After each reboot, SQL queries demonstrate the uptime for the instances in the cluster.

Topics

- Finding the writer and reader instances for an Aurora cluster (p. 334)
- Rebooting a single reader instance (p. 334)
- Rebooting the writer instance (p. 335)
- Rebooting the writer and readers independently (p. 336)
- Applying a cluster parameter change to an Aurora MySQL version 2.10 cluster (p. 339)
**Finding the writer and reader instances for an Aurora cluster**

In an Aurora MySQL cluster with multiple DB instances, it's important to know which one is the writer and which ones are the readers. The writer and reader instances also can switch roles when a failover operation happens. Thus, it's best to perform a check like the following before doing any operation that requires a writer or reader instance. In this case, the False values for `IsClusterWriter` identify the reader instances, `instance-6305` and `instance-7448`. The True value identifies the writer instance, `instance-1234`.

```bash
$ aws rds describe-db-clusters --db-cluster-id tpch100g
--query "*[/].['Cluster:',DBClusterIdentifier,DBClusterMembers[*].
['Instance:',DBInstanceIdentifier,IsClusterWriter]]" 
--output text
Cluster:     tpch100g
Instance:    instance-6305    False
Instance:    instance-7448    False
Instance:    instance-1234    True
```

Before we start the examples of rebooting, the writer instance has an uptime of approximately one week. The SQL query in this example shows a MySQL-specific way to check the uptime. You might use this technique in a database application. For another technique that uses the AWS CLI and works for both Aurora engines, see Checking uptime for Aurora clusters and instances (p. 331).

```sql
$ mysql -h instance-7448.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p ...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
       -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
       -> from performance_schema.global_status
       -> where variable_name='Uptime';
+----------------------------+---------+
<table>
<thead>
<tr>
<th>Last Startup</th>
<th>Uptime</th>
</tr>
</thead>
<tbody>
<tr>
<td>2021-03-08 17:49:06.000000</td>
<td>174h 42m</td>
</tr>
</tbody>
</table>
+----------------------------+---------+
```

**Rebooting a single reader instance**

This example reboots one of the reader DB instances. Perhaps this instance was overloaded by a huge query or many concurrent connections. Or perhaps it fell behind the writer instance because of a network issue. After starting the reboot operation, the example uses a `wait` command to pause until the instance becomes available. By that point, the instance has an uptime of a few minutes.

```bash
$ aws rds reboot-db-instance --db-instance-identifier instance-6305
| DBInstance: { |
|   "DBInstanceIdentifier": "instance-6305",
|   "DBInstanceStatus": "rebooting",
| ...
| } |
$ aws rds wait db-instance-available --db-instance-id instance-6305
$ mysql -h instance-6305.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user -p ...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
       -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
       -> from performance_schema.global_status
       -> where variable_name='Uptime';
+----------------------------+---------+
<table>
<thead>
<tr>
<th>Last Startup</th>
<th>Uptime</th>
</tr>
</thead>
<tbody>
<tr>
<td>2021-03-08 17:49:06.000000</td>
<td>174h 42m</td>
</tr>
</tbody>
</table>
+----------------------------+---------+
```
Rebooting the reader instance didn't affect the uptime of the writer instance. It still has an uptime of about one week.

```
$ mysql -h instance-7448.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
   -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
   -> from performance_schema.global_status where variable_name='Uptime';
+-------------------+----------+
| Last Startup      | Uptime   |
+-------------------+----------+
| 2021-03-08 17:49:06.000000 | 174h 49m |
+-------------------+----------+
```

Rebooting the writer instance

This example reboots the writer instance. This cluster is running Aurora MySQL version 2.09. Because the Aurora MySQL version is lower than 2.10, rebooting the writer instance also reboots any reader instances in the cluster.

A wait command pauses until the reboot is finished. Now the uptime for that instance is reset to zero. It's possible that a reboot operation might take substantially different times for writer and reader DB instances. The writer and reader DB instances perform different kinds of cleanup operations depending on their roles.

```
$ aws rds reboot-db-instance --db-instance-identifier instance-1234
{
   "DBInstance": {
      "DBInstanceIdentifier": "instance-1234",
      "DBInstanceStatus": "rebooting",
      ...
   }
}{
# aws rds wait db-instance-available --db-instance-id instance-1234
# mysql -h instance-1234.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
   -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
   -> from performance_schema.global_status where variable_name='Uptime';
+-------------------+----------+
| Last Startup      | Uptime   |
+-------------------+----------+
| 2021-03-16 00:40:27.000000 | 00h 00m |
+-------------------+----------+
```

After the reboot for the writer DB instance, both of the reader DB instances also have their uptime reset. Rebooting the writer instance caused the reader instances to reboot also. This behavior applies to Aurora PostgreSQL clusters and to Aurora MySQL clusters before version 2.10.

```
$ mysql -h instance-7448.a12345.us-east-1.rds.amazonaws.com -P 3306 -u my-user
...
mysql> select date_sub(now(), interval variable_value second) "Last Startup",
   -> time_format(sec_to_time(variable_value),'%Hh %im') as "Uptime"
   -> from performance_schema.global_status where variable_name='Uptime';
+-------------------+----------+
| Last Startup      | Uptime   |
+-------------------+----------+
```
Rebooting the writer and readers independently

These next examples show a cluster that runs Aurora MySQL version 2.10. In this Aurora MySQL version and higher, you can reboot the writer instance without causing reboots for all the reader instances. That way, your query-intensive applications don’t experience any outage when you reboot the writer instance. You can reboot the reader instances later. You might do those reboots at a time of low query traffic. You might also reboot the reader instances one at a time. That way, at least one reader instance is always available for the query traffic of your application.

The following example uses a cluster named cluster-2393, running Aurora MySQL version 5.7.mysql_aurora.2.10.0. This cluster has a writer instance named instance-9404 and three reader instances named instance-6772, instance-2470, and instance-5138.

```bash
$ aws rds describe-db-clusters --db-cluster-id cluster-2393 --query '[][*].['Cluster:',DBClusterIdentifier,DBClusterMembers[*].['Instance:',DBInstanceIdentifier,IsClusterWriter']]' --output text
Cluster:        cluster-2393
Instance:       instance-5138        False
Instance:       instance-2470        False
Instance:       instance-6772        False
Instance:       instance-9404        True
```

Checking the uptime value of each database instance through the `mysql` command shows that each one has roughly the same uptime. For example, here is the uptime for instance-5138.

```mysql
mysql> SHOW GLOBAL STATUS LIKE 'uptime';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Uptime        | 3866  |
+---------------+-------+
```

By using CloudWatch, we can get the corresponding uptime information without actually logging into the instances. That way, an administrator can monitor the database but can’t view or change any table data. In this case, we specify a time period spanning five minutes, and check the uptime value every minute. The increasing uptime values demonstrate that the instances weren’t restarted during that period.

```bash
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 --namespace "AWS/RDS" --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=instance-9404 --output text | sort -k 3
```

336
Examples of Aurora reboot operations

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 --namespace "AWS/RDS" --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=instance-6772 --output text | sort -k 3
EngineUptime
DATAPOINTS 4315.0 2021-03-17T23:42:00+00:00 Seconds
DATAPOINTS 4375.0 2021-03-17T23:43:00+00:00 Seconds
DATAPOINTS 4435.0 2021-03-17T23:44:00+00:00 Seconds
DATAPOINTS 4495.0 2021-03-17T23:45:00+00:00 Seconds
DATAPOINTS 4555.0 2021-03-17T23:46:00+00:00 Seconds
```

Now we reboot one of the reader instances, `instance-5138`. We wait for the instance to become available again after the reboot. Now monitoring the uptime over a five-minute period shows that the uptime was reset to zero during that time. The most recent uptime value was measured five seconds after the reboot finished.

```
# aws rds reboot-db-instance --db-instance-identifier instance-5138
{
  "DBInstanceIdentifier": "instance-5138",
  "DBInstanceStatus": "rebooting"
}
# aws rds wait db-instance-available --db-instance-id instance-5138
# aws cloudwatch get-metric-statistics --metric-name "EngineUptime" --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 --namespace "AWS/RDS" --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=instance-5138 --output text | sort -k 3
EngineUptime
DATAPOINTS 4500.0 2021-03-17T23:46:00+00:00 Seconds
DATAPOINTS 4560.0 2021-03-17T23:47:00+00:00 Seconds
DATAPOINTS 4620.0 2021-03-17T23:48:00+00:00 Seconds
DATAPOINTS 4680.0 2021-03-17T23:49:00+00:00 Seconds
DATAPOINTS 5.0 2021-03-17T23:50:00+00:00 Seconds
```

Next, we perform a reboot for the writer instance, `instance-9404`. We compare the uptime values for the writer instance and one of the reader instances. By doing so, we can see that rebooting the writer didn’t cause a reboot for the readers. In versions before Aurora MySQL 2.10, the uptime values for all the readers would be reset at the same time as the writer.

```
# aws rds reboot-db-instance --db-instance-identifier instance-9404
{
  "DBInstanceIdentifier": "instance-9404",
  "DBInstanceStatus": "rebooting"
}
# aws rds wait db-instance-available --db-instance-id instance-9404
# aws cloudwatch get-metric-statistics --metric-name "EngineUptime" --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 --namespace "AWS/RDS" --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=instance-9404 --output text | sort -k 3
EngineUptime
DATAPOINTS 371.0 2021-03-17T23:57:00+00:00 Seconds
DATAPOINTS 431.0 2021-03-17T23:58:00+00:00 Seconds
```

Now we reboot one of the reader instances, `instance-5138`. We wait for the instance to become available again after the reboot. Now monitoring the uptime over a five-minute period shows that the uptime was reset to zero during that time. The most recent uptime value was measured five seconds after the reboot finished.

```
# aws rds reboot-db-instance --db-instance-identifier instance-5138
{
  "DBInstanceIdentifier": "instance-5138",
  "DBInstanceStatus": "rebooting"
}
# aws rds wait db-instance-available --db-instance-id instance-5138
# aws cloudwatch get-metric-statistics --metric-name "EngineUptime" --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 --namespace "AWS/RDS" --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=instance-5138 --output text | sort -k 3
EngineUptime
DATAPOINTS 4500.0 2021-03-17T23:46:00+00:00 Seconds
DATAPOINTS 4560.0 2021-03-17T23:47:00+00:00 Seconds
DATAPOINTS 4620.0 2021-03-17T23:48:00+00:00 Seconds
DATAPOINTS 4680.0 2021-03-17T23:49:00+00:00 Seconds
DATAPOINTS 5.0 2021-03-17T23:50:00+00:00 Seconds
```

Next, we perform a reboot for the writer instance, `instance-9404`. We compare the uptime values for the writer instance and one of the reader instances. By doing so, we can see that rebooting the writer didn’t cause a reboot for the readers. In versions before Aurora MySQL 2.10, the uptime values for all the readers would be reset at the same time as the writer.

```
# aws rds reboot-db-instance --db-instance-identifier instance-9404
{
  "DBInstanceIdentifier": "instance-9404",
  "DBInstanceStatus": "rebooting"
}
# aws rds wait db-instance-available --db-instance-id instance-9404
# aws cloudwatch get-metric-statistics --metric-name "EngineUptime" --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 --namespace "AWS/RDS" --statistics Minimum --dimensions Name=DBInstanceIdentifier,Value=instance-9404 --output text | sort -k 3
EngineUptime
DATAPOINTS 371.0 2021-03-17T23:57:00+00:00 Seconds
DATAPOINTS 431.0 2021-03-17T23:58:00+00:00 Seconds
```
Examples of Aurora reboot operations

To make sure that all the reader instances have all the same changes to configuration parameters as the writer instance, reboot all the reader instances after the writer. This example reboots all the readers and then waits until all of them are available before proceeding.

```
$ aws rds reboot-db-instance --db-instance-identifier instance-6772
{
  "DBInstanceIdentifier": "instance-6772",
  "DBInstanceStatus": "rebooting"
}

$ aws rds reboot-db-instance --db-instance-identifier instance-2470
{
  "DBInstanceIdentifier": "instance-2470",
  "DBInstanceStatus": "rebooting"
}

$ aws rds reboot-db-instance --db-instance-identifier instance-5138
{
  "DBInstanceIdentifier": "instance-5138",
  "DBInstanceStatus": "rebooting"
}

$ aws rds wait db-instance-available --db-instance-id instance-6772
$ aws rds wait db-instance-available --db-instance-id instance-2470
$ aws rds wait db-instance-available --db-instance-id instance-5138
```

Now we can see that the writer DB instance has the highest uptime. This instance's uptime value increased steadily throughout the monitoring period. The reader DB instances were all rebooted after the reader. We can see the point within the monitoring period when each reader was rebooted and its uptime was reset to zero.

```
$ aws cloudwatch get-metric-statistics --metric-name "EngineUptime" \
   --start-time "$(date -d '5 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
   --namespace "AWS/RDS" --statistics Minimum --dimensions

```
Applying a cluster parameter change to an Aurora MySQL version 2.10 cluster

The following example demonstrates how to apply a parameter change to all DB instances in your Aurora MySQL 2.10 cluster. With this Aurora MySQL version, you reboot the writer instance and all the reader instances independently.

The example uses the MySQL configuration parameter `lower_case_table_names` for illustration. When this parameter setting is different between the writer and reader DB instances, a query might not be able to access a table declared with an uppercase or mixed-case name. Or if two table names differ only in terms of uppercase and lowercase letters, a query might access the wrong table.

This example shows how to determine the writer and reader instances in the cluster by examining the `IsClusterWriter` attribute of each instance. The cluster is named `cluster-2393`. The cluster has a writer instance named `instance-9404`. The reader instances in the cluster are named `instance-5138` and `instance-2470`.

To demonstrate the effects of changing the `lower_case_table_names` parameter, we set up two DB cluster parameter groups. The `lower_case_table_names-0` parameter group has this parameter set to 0. The `lower_case_table_names-1` parameter group has this parameter group set to 1.
$ aws rds create-db-cluster-parameter-group --description 'lower-case-table-names-1' \\ 
--db-parameter-group-family aurora-mysql5.7 \\ 
--db-cluster-parameter-group-name lower-case-table-names-1 
{
  "DBClusterParameterGroup": {
    "DBClusterParameterGroupName": "lower-case-table-names-1",
    "DBParameterGroupFamily": "aurora-mysql5.7",
    "Description": "lower-case-table-names-1"
  }
}
$ aws rds modify-db-cluster-parameter-group \\ 
--db-cluster-parameter-group-name lower-case-table-names-0 \\ 
--parameters ParameterName=lower_case_table_names,ParameterValue=0,ApplyMethod=pending-reboot 
{
  "DBClusterParameterGroupName": "lower-case-table-names-0"
}
$ aws rds modify-db-cluster-parameter-group \\ 
--db-cluster-parameter-group-name lower-case-table-names-1 \\ 
--parameters ParameterName=lower_case_table_names,ParameterValue=1,ApplyMethod=pending-reboot 
{
  "DBClusterParameterGroupName": "lower-case-table-names-1"
}

The default value of lower_case_table_names is 0. With this parameter setting, the table foo is distinct from the table FOO. This example verifies that the parameter is still at its default setting. Then the example creates three tables that differ only in uppercase and lowercase letters in their names.

mysql> create database lctn;
Query OK, 1 row affected (0.07 sec)

mysql> use lctn;
Database changed
mysql> select @@lower_case_table_names;
+--------------------------+
<table>
<thead>
<tr>
<th>@@lower_case_table_names</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+--------------------------+

mysql> create table foo (s varchar(128));

mysql> insert into foo values ('Lowercase table name foo');

mysql> create table Foo (s varchar(128));

mysql> insert into Foo values ('Mixed-case table name Foo');

mysql> create table FOO (s varchar(128));

mysql> insert into FOO values ('Uppercase table name FOO');

mysql> select * from foo;
+--------------------------+
<table>
<thead>
<tr>
<th>s</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lowercase table name foo</td>
</tr>
</tbody>
</table>
+--------------------------+

mysql> select * from Foo;
+---------------------------+
| s                         |
+---------------------------+

mysql> select * from FOO;
+---------------------------+
Examples of Aurora reboot operations

<table>
<thead>
<tr>
<th>Mixed-case table name Foo</th>
</tr>
</thead>
</table>

mysql> select * from FOO;
+--------------------------+
| s                        |
+--------------------------+

Uppercase table name FOO
+--------------------------+

Next, we associate the DB parameter group with the cluster to set the `lower_case_table_names` parameter to 1. This change only takes effect after each DB instance is rebooted.

```bash
$ aws rds modify-db-cluster --db-cluster-identifier cluster-2393 --db-cluster-parameter-group-name lower-case-table-names-1
{
  "DBClusterIdentifier": "cluster-2393",
  "DBClusterParameterGroup": "lower-case-table-names-1",
  "Engine": "aurora-mysql",
  "EngineVersion": "5.7.mysql_aurora.2.10.0"
}
```

The first reboot we do is for the writer DB instance. Then we wait for the instance to become available again. At that point, we connect to the writer endpoint and verify that the writer instance has the changed parameter value. The `SHOW TABLES` command confirms that the database contains the three different tables. However, queries that refer to tables named `foo`, `Foo`, or `FOO` all access the table whose name is all-lowercase, `foo`.

```bash
# Rebooting the writer instance
$ aws rds reboot-db-instance --db-instance-identifier instance-9404
$ aws rds wait db-instance-available --db-instance-id instance-9404
```

Now, queries using the cluster endpoint show the effects of the parameter change. Whether the table name in the query is uppercase, lowercase, or mixed case, the SQL statement accesses the table whose name is all-lowercase.

```bash
mysql> select @@lower_case_table_names;
+--------------------------+
| @@lower_case_table_names |
+--------------------------+
|                        1 |
+--------------------------+

mysql> use lctn;
mysql> show tables;
+----------------+
| Tables_in_lctn |
+----------------+
| FOO           |
| Foo           |
| foo           |
+----------------+

mysql> select * from foo;
+--------------------------+
| s                        |
+--------------------------+

mysql> select from FOO;
+--------------------------+
```

The first reboot we do is for the writer DB instance. Then we wait for the instance to become available again. At that point, we connect to the writer endpoint and verify that the writer instance has the changed parameter value. The `SHOW TABLES` command confirms that the database contains the three different tables. However, queries that refer to tables named `foo`, `Foo`, or `FOO` all access the table whose name is all-lowercase, `foo`.
<table>
<thead>
<tr>
<th>s</th>
<th>Lowercase table name foo</th>
</tr>
</thead>
</table>

mysql> select * from FOO;

The next example shows the same queries as the previous one. In this case, the queries use the reader endpoint and run on one of the reader DB instances. Those instances haven't been rebooted yet. Thus, they still have the original setting for the lower_case_table_names parameter. That means that queries can access each of the foo, Foo, and FOO tables.

mysql> select @@lower_case_table_names;

mysql> use lctn;

mysql> select * from foo;

mysql> select * from Foo;

mysql> select * from FOO;

Next, we reboot one of the reader instances and wait for it to become available again.

$ aws rds reboot-db-instance --db-instance-identifier instance-2470

While connected to the instance endpoint for instance-2470, a query shows that the new parameter is in effect.

mysql> select @@lower_case_table_names;

At this point, the two reader instances in the cluster are running with different `lower_case_table_names` settings. Thus, any connection to the reader endpoint of the cluster uses a value for this setting that’s unpredictable. It’s important to immediately reboot the other reader instance so that they both have consistent settings.

```bash
$ aws rds reboot-db-instance --db-instance-identifier instance-5138
{
    "DBInstanceIdentifier": "instance-5138",
    "DBInstanceStatus": "rebooting"
}
$ aws rds wait db-instance-available --db-instance-id instance-5138
```

The following example confirms that all the reader instances have the same setting for the `lower_case_table_names` parameter. The commands check the `lower_case_table_names` setting value on each reader instance. Then the same command using the reader endpoint demonstrates that each connection to the reader endpoint uses one of the reader instances, but which one isn’t predictable.

```bash
# Check lower_case_table_names setting on each reader instance.
$ mysql -h instance-5138.a12345.us-east-1.rds.amazonaws.com \
    -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'
+--------------------------+--------------------------+
| @@aurora_server_id       | @@lower_case_table_names |
+--------------------------+--------------------------+
| instance-5138            | 1                        |
+--------------------------+--------------------------+
$ mysql -h instance-2470.a12345.us-east-1.rds.amazonaws.com \
    -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'
+--------------------------+--------------------------+
| @@aurora_server_id       | @@lower_case_table_names |
+--------------------------+--------------------------+
| instance-2470            | 1                        |
+--------------------------+--------------------------+

# Check lower_case_table_names setting on the reader endpoint of the cluster.
$ mysql -h cluster-2393.cluster-ro-a12345.us-east-1.rds.amazonaws.com \
    -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'
+--------------------------+--------------------------+
| @@aurora_server_id       | @@lower_case_table_names |
+--------------------------+--------------------------+
| instance-5138            | 1                        |
+--------------------------+--------------------------+

# Run query on writer instance
$ mysql -h cluster-2393.cluster-a12345.us-east-1.rds.amazonaws.com \
    -u my-user -p -e 'select @@aurora_server_id, @@lower_case_table_names'
+--------------------------+--------------------------+
| @@aurora_server_id       | @@lower_case_table_names |
+--------------------------+--------------------------+
| instance-9404            | 1                        |
+--------------------------+--------------------------+
```

With the parameter change applied everywhere, we can see the effect of setting `lower_case_table_names=1`. Whether the table is referred to as `foo`, `Foo`, or `FOO` the query converts the name to `foo` and accesses the same table in each case.
```sql
mysql> use lctn;

mysql> select * from foo;
+--------------------------+
| s                        |
+--------------------------+
| Lowercase table name foo |
+--------------------------+

mysql> select * from Foo;
+--------------------------+
| s                        |
+--------------------------+
| Lowercase table name foo |
+--------------------------+

mysql> select * from FOO;
+--------------------------+
| s                        |
+--------------------------+
| Lowercase table name foo |
+--------------------------+
```
Deleting Aurora DB clusters and DB instances

You can delete an Aurora DB cluster when you don't need it any longer. Doing so removes the cluster volume containing all your data. Before deleting the cluster, you can save a snapshot of your data. You can restore the snapshot later create a new cluster containing the same data.

You can also delete DB instances from a cluster, while preserving the cluster itself and the data that it contains. Doing so can help you reduce charges if the cluster isn't busy and doesn't need the computation capacity of multiple DB instances.

Topics
- Deleting an Aurora DB cluster (p. 345)
- Deletion protection for Aurora clusters (p. 349)
- Deleting a stopped Aurora cluster (p. 350)
- Deleting Aurora MySQL clusters that are read replicas (p. 350)
- The final snapshot when deleting a cluster (p. 350)
- Deleting a DB instance from an Aurora DB cluster (p. 350)

Deleting an Aurora DB cluster

Aurora doesn't provide a single-step method to delete a DB cluster. This design choice is intended to prevent you from accidentally losing data or taking your application offline. Aurora applications are typically mission-critical and require high availability. Thus, Aurora makes it easy to scale the capacity of the cluster up and down by adding and removing DB instances. However, removing the cluster itself requires you to make a separate choice.

Use the following general procedure to remove all the DB instances from a cluster and then delete the cluster itself.

1. Delete any reader instances in the cluster. Use the procedure in Deleting a DB instance from an Aurora DB cluster (p. 350). If the cluster has any reader instances, deleting one of the instances just reduces the computation capacity of the cluster. Deleting the reader instances first ensures that the cluster remains available throughout the procedure and doesn't perform unnecessary failover operations.

2. Delete the writer instance from the cluster. Again, use the procedure in Deleting a DB instance from an Aurora DB cluster (p. 350).

   If you use the AWS Management Console, this is the final step. Deleting the final DB instance in a DB cluster through the console automatically deletes the DB cluster and the data in the cluster volume. At this point, Aurora prompts you to optionally create a snapshot before deleting the cluster. Aurora also requires you to confirm that you intend to delete the cluster.

3. CLI and API only: If you delete the DB instances using the AWS CLI or the RDS API, the cluster and its associated cluster volume remain even after you delete all the DB instances. To delete the cluster itself, you call the `delete-db-cluster` CLI command or `DeleteDBCluster` API operation when the cluster has zero associated DB instances. At this point, you choose whether to create a snapshot of the cluster volume. Doing so preserves the data from the cluster if you might need it later.

Topics
- Deleting an empty Aurora cluster (p. 346)
- Deleting an Aurora cluster with a single DB instance (p. 346)
- Deleting an Aurora cluster with multiple DB instances (p. 347)
Deleting an empty Aurora cluster

If you use the AWS Management Console, Aurora automatically deletes your cluster when you delete the last DB instance in that cluster. Thus, the procedures for deleting an empty cluster only apply when you use the AWS CLI or the RDS API.

**Tip**
You can keep a cluster with no DB instances to preserve your data without incurring CPU charges for the cluster. You can quickly start using the cluster again by creating one or more new DB instances for the cluster. You can perform Aurora-specific administrative operations on the cluster while it doesn’t have any associated DB instances. You just can’t access the data or perform any operations that require connecting to a DB instance.

To delete an empty Aurora DB cluster by using the AWS CLI, call the `delete-db-cluster` command.

To delete an empty Aurora DB cluster by using the Amazon RDS API, call the `DeleteDBInstance` operation.

Suppose that the empty cluster `deleteme-zero-instances` was only used for development and testing and doesn't contain any important data. In that case, you don't need to preserve a snapshot of the cluster volume when you delete the cluster. The following example demonstrates that a cluster doesn't contain any DB instances, and then deletes the empty cluster without creating a final snapshot.

```
$ aws rds describe-db-clusters --db-cluster-identifier deleteme-zero-instances --output text \  
--query '[].["Cluster":DBClusterIdentifier,DClusterMembers[*].["Instance":DBInstanceIdentifier,IsClusterWriter]]' 
Cluster: deleteme-zero-instances
$ aws rds delete-db-cluster --db-cluster-identifier deleteme-zero-instances --skip-final-snapshot 
{
  "DBClusterIdentifier": "deleteme-zero-instances",
  "Status": "available",
  "Engine": "aurora-mysql"
}
```

Deleting an Aurora cluster with a single DB instance

If you try to delete the last DB instance in your Aurora cluster, the behavior depends on the method you use. You can delete the last DB instance using the AWS Management Console. Doing so also deletes the DB cluster. You can also delete the last DB instance through the AWS CLI or API, even if the DB cluster has deletion protection enabled. In this case, the DB cluster itself still exists and your data is preserved. You can access the data again by attaching a new DB instance to the cluster.

The following example shows how the `delete-db-cluster` command doesn’t work when the cluster still has any associated DB instances. This cluster has a single writer DB instance. When we examine the DB instances in the cluster, we check the `IsClusterWriter` attribute of each one. The cluster could have zero or one writer DB instance. A value of `true` signifies a writer DB instance. A value of `false` signifies a reader DB instance. The cluster could have zero, one, or many reader DB instances. In this case, we delete the writer DB instance using the `delete-db-instance` command. As soon as the DB instance goes into `deleting` state, we can delete the cluster also. For this example also, suppose that the cluster doesn't contain any data worth preserving and so we don't create a snapshot of the cluster volume.

```
$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-only --skip-final-snapshot 
An error occurred (InvalidDBClusterStateFault) when calling the DeleteDBCluster operation: Cluster cannot be deleted, it still contains DB instances in non-deleting state.
$ aws rds describe-db-clusters --db-cluster-identifier deleteme-writer-only \
```
Deleting an Aurora DB cluster

```sql
--query '[].[DBClusterIdentifier,Status,DBClusterMembers[*].
[DBInstanceIdentifier,IsClusterWriter]]'
[
  "deleteme-writer-only",
  "available",
  [
    "instance-2130",
    true
  ]
]

$ aws rds delete-db-instance --db-instance-identifier instance-2130
{
  "DBInstanceIdentifier": "instance-2130",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}

$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-only --skip-final-snapshot
{
  "DBClusterIdentifier": "deleteme-writer-only",
  "Status": "available",
  "Engine": "aurora-mysql"
}
```

Deleting an Aurora cluster with multiple DB instances

If your cluster contains multiple DB instances, typically there is a single writer instance and one or more reader instances. The reader instances help with high availability, by being on standby to take over if the writer instance encounters a problem. You can also use reader instances to scale the cluster up to handle a read-intensive workload without adding overhead to the writer instance.

To delete a cluster with multiple reader DB instances, you delete the reader instances first and then the writer instance. If you use the AWS Management Console, deleting the writer instance automatically deletes the cluster afterwards. If you use the AWS CLI or RDS API, deleting the writer instance leaves the cluster and its data in place. In that case, you delete the cluster through a separate command or API operation.

- For the procedure to delete an Aurora DB instance, see Deleting a DB instance from an Aurora DB cluster (p. 350).
- For the procedure to delete the writer DB instance in an Aurora cluster, see Deleting an Aurora cluster with a single DB instance (p. 346).
- For the procedure to delete an empty Aurora cluster, see Deleting an empty Aurora cluster (p. 346).

This example shows how to delete a cluster containing both a writer DB instance and a single reader DB instance. The `describe-db-clusters` output shows that `instance-7384` is the writer instance and `instance-1039` is the reader instance. The example deletes the reader instance first, because deleting the writer instance while a reader instance still existed would cause a failover operation. It doesn't make sense to promote the reader instance to a writer if you plan to delete that instance also. Again, suppose that these `db.t2.small` instances are only used for development and testing, and so the delete operation skips the final snapshot.

```
$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-and-reader --skip-final-snapshot
```
An error occurred (InvalidDBClusterStateFault) when calling the DeleteDBCluster operation: Cluster cannot be deleted, it still contains DB instances in non-deleting state.

$ aws rds describe-db-clusters --db-cluster-identifier deleteme-writer-and-reader --output text \
  --query '*["Cluster":DBClusterIdentifier,DBClusterMembers[*].\n  ["Instance":DBInstanceIdentifier,IsClusterWriter]]
Cluster: deleteme-writer-and-reader
Instance: instance-1039 False
Instance: instance-7384 True

$ aws rds delete-db-instance --db-instance-identifier instance-1039
{
  "DBInstanceIdentifier": "instance-1039",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}

$ aws rds delete-db-instance --db-instance-identifier instance-7384
{
  "DBInstanceIdentifier": "instance-7384",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}

$ aws rds delete-db-cluster --db-cluster-identifier deleteme-writer-and-reader --skip-final-snapshot
{
  "DBClusterIdentifier": "deleteme-writer-and-reader",
  "Status": "available",
  "Engine": "aurora-mysql"
}

The following example shows how to delete a DB cluster containing a writer DB instance and multiple reader DB instances. It uses concise output from the describe-db-clusters command to get a report of the writer and reader instances. Again, we delete all reader DB instances before deleting the writer DB instance. It doesn’t matter what order we delete the reader DB instances in. Suppose that this cluster with several DB instances does contain data worth preserving. Thus, the delete-db-cluster command in this example includes the --no-skip-final-snapshot and --final-db-snapshot-identifier parameters to specify the details of the snapshot to create.

$ aws rds describe-db-clusters --db-cluster-identifier deleteme-multiple-readers --output text \
  --query '*["Cluster":DBClusterIdentifier,DBClusterMembers[*].\n  ["Instance":DBInstanceIdentifier,IsClusterWriter]]
Cluster: deleteme-multiple-readers
Instance: instance-1010 False
Instance: instance-5410 False
Instance: instance-9948 False
Instance: instance-8451 True

$ aws rds delete-db-instance --db-instance-identifier instance-1010
{
  "DBInstanceIdentifier": "instance-1010",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}

$ aws rds delete-db-instance --db-instance-identifier instance-5410
{
  "DBInstanceIdentifier": "instance-5410",
  "DBInstanceStatus": "deleting",
  "Engine": "aurora-mysql"
}
Deletion protection for Aurora clusters

You can't delete clusters that have deletion protection enabled. You can delete DB instances within the cluster, but not the cluster itself. That way, the cluster volume containing all your data is safe from accidental deletion. Aurora enforces deletion protection for a DB cluster whether you try to delete the cluster using the console, the AWS CLI, or the RDS API.

Deletion protection is enabled by default when you create a production DB cluster using the AWS Management Console. However, deletion protection is disabled by default if you create a cluster using...
Deleting a stopped Aurora cluster

You can't delete a cluster if it's in the stopped state. In this case, start the cluster before deleting it. For more information, see Starting an Aurora DB cluster (p. 246).

Deleting Aurora MySQL clusters that are read replicas

For Aurora MySQL, you can't delete a DB instance in a DB cluster if both of the following conditions are true:

- The DB cluster is a read replica of another Aurora DB cluster.
- The DB instance is the only instance in the DB cluster.

To delete a DB instance in this case, first promote the DB cluster so that it's no longer a read replica. After the promotion completes, you can delete the final DB instance in the DB cluster. For more information, see Replicating Amazon Aurora MySQL DB clusters across AWS Regions (p. 832).

The final snapshot when deleting a cluster

Throughout this section, the examples show how you can choose whether to take a final snapshot when you delete an Aurora cluster. If you choose to take a final snapshot but the name you specify matches an existing snapshot, the operation stops with an error. In this case, examine the snapshot details to confirm if it represents your current detail or if it is an older snapshot. If the existing snapshot doesn't have the latest data that you want to preserve, rename the snapshot and try again, or specify a different name for the final snapshot parameter.

Deleting a DB instance from an Aurora DB cluster

You can delete a DB instance from an Aurora DB cluster as part of the process of deleting the entire cluster. If your cluster contains a certain number of DB instances, then deleting the cluster requires deleting each of those DB instances. You can also delete one or more reader instances from a cluster while leaving the cluster running. You might do so to reduce compute capacity and associated charges if your cluster isn't busy.

To delete a DB instance, you specify the name of the instance.

You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

Note

When an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three-minute grace period. Existing statements can finish during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

For Aurora DB clusters, deleting a DB instance doesn't necessarily delete the entire cluster. You can delete a DB instance in an Aurora cluster to reduce compute capacity and associated charges when the
Deleting a DB instance from a cluster isn't busy. For information about the special circumstances for Aurora clusters that have one DB instance or zero DB instances, see Deleting an Aurora cluster with a single DB instance (p. 346) and Deleting an empty Aurora cluster (p. 346).

**Note**
- You can't delete a DB cluster when deletion protection is enabled for it. For more information, see Deletion protection for Aurora clusters (p. 349).
- You can disable deletion protection by modifying the DB cluster. For more information, see Modifying an Amazon Aurora DB cluster (p. 248).

**Console**

**To delete a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB instance that you want to delete.
3. For Actions, choose Delete.
4. Enter delete me in the box.
5. Choose Delete.

**AWS CLI**

To delete a DB instance by using the AWS CLI, call the `delete-db-instance` command and specify the `--db-instance-identifier` value.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds delete-db-instance \
   --db-instance-identifier mydbinstance
```

For Windows:

```bash
aws rds delete-db-instance ^
   --db-instance-identifier mydbinstance
```

**RDS API**

To delete a DB instance by using the Amazon RDS API, call the `DeleteDBInstance` operation and specify the `DBInstanceIdentifier` parameter.

**Note**
- When the status for a DB instance is deleting, its CA certificate value doesn't appear in the RDS console or in output for AWS CLI commands or RDS API operations. For more information about CA certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1642).
Tagging Amazon RDS resources

You can use Amazon RDS tags to add metadata to your Amazon RDS resources. You can use the tags to add your own notations about database instances, snapshots, Aurora clusters, and so on. Doing so can help you to document your Amazon RDS resources. You can also use the tags with automated maintenance procedures.

In particular, you can use these tags with IAM policies to manage access to Amazon RDS resources and to control what actions can be applied to the Amazon RDS resources. You can also use these tags to track costs by grouping expenses for similarly tagged resources.

You can tag the following Amazon RDS resources:

- DB instances
- DB clusters
- Read replicas
- DB snapshots
- DB cluster snapshots
- Reserved DB instances
- Event subscriptions
- DB option groups
- DB parameter groups
- DB cluster parameter groups
- DB subnet groups
- RDS Proxies
- RDS Proxy endpoints

**Note**
Currently, you can’t tag RDS Proxies and RDS Proxy endpoints by using the AWS Management Console.

**Topics**

- Overview of Amazon RDS resource tags (p. 352)
- Using tags for access control with IAM (p. 353)
- Using tags to produce detailed billing reports (p. 353)
- Adding, listing, and removing tags (p. 354)
- Using the AWS Tag Editor (p. 356)
- Copying tags to DB cluster snapshots (p. 356)
- Tutorial: Use tags to specify which Aurora DB clusters to stop (p. 357)

**Overview of Amazon RDS resource tags**

An Amazon RDS tag is a name-value pair that you define and associate with an Amazon RDS resource. The name is referred to as the key. Supplying a value for the key is optional. You can use tags to assign arbitrary information to an Amazon RDS resource. You can use a tag key, for example, to define a category, and the tag value might be an item in that category. For example, you might define a tag key of “project” and a tag value of “Salix”, indicating that the Amazon RDS resource is assigned to the Salix
You can use tags to designate Amazon RDS resources as being used for test or production by using a key such as `environment=test` or `environment=production`. We recommend that you use a consistent set of tag keys to make it easier to track metadata associated with Amazon RDS resources.

In addition, you can use conditions in your IAM policies to control access to AWS resources based on the tags on that resource. You can do this by using the global `aws:ResourceTag/tag-key` condition key. For more information, see Controlling access to AWS resources in the AWS Identity and Access Management User Guide.

Each Amazon RDS resource has a tag set, which contains all the tags that are assigned to that Amazon RDS resource. A tag set can contain as many as 50 tags, or it can be empty. If you add a tag to an Amazon RDS resource that has the same key as an existing tag on resource, the new value overwrites the old value.

AWS does not apply any semantic meaning to your tags; tags are interpreted strictly as character strings. Amazon RDS can set tags on a DB instance or other Amazon RDS resources, depending on the settings that you use when you create the resource. For example, Amazon RDS might add a tag indicating that a DB instance is for production or for testing.

- The tag key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with `aws:` or `rds:`. The string can contain only the set of Unicode letters, digits, white-space, `_' /` , `='` , `+` , and `@` (Java regex: `[^{\p{L}\p{Z}\p{N}_.:/=+\-@}]`).

- The tag value is an optional string value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with `aws:`. The string can contain only the set of Unicode letters, digits, white-space, `_' /` , `='` , `+` , and `@` (Java regex: `[^{\p{L}\p{Z}\p{N}_.:/=+\-@}]`).

Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of `project=Trinity` and `cost-center=Trinity`.

You can use the AWS Management Console, the command line interface, or the Amazon RDS API to add, list, and delete tags on Amazon RDS resources. When using the command line interface or the Amazon RDS API, you must provide the Amazon Resource Name (ARN) for the Amazon RDS resource you want to work with. For more information about constructing an ARN, see Constructing an ARN for Amazon RDS (p. 360).

Tags are cached for authorization purposes. Because of this, additions and updates to tags on Amazon RDS resources can take several minutes before they are available.

**Using tags for access control with IAM**

You can use tags with IAM policies to manage access to Amazon RDS resources and to control what actions can be applied to the Amazon RDS resources.

For information on managing access to tagged resources with IAM policies, see Identity and access management for Amazon Aurora (p. 1653).

**Using tags to produce detailed billing reports**

You can also use tags to track costs by grouping expenses for similarly tagged resources.

Use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of combined resources, organize your
billing information according to resources with the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using Cost Allocation Tags in the AWS Billing User Guide.

Note
You can add a tag to a snapshot, however, your bill will not reflect this grouping.

Adding, listing, and removing tags

The following procedures show how to perform typical tagging operations on resources related to DB instances and Aurora DB clusters.

Console

The process to tag an Amazon RDS resource is similar for all resources. The following procedure shows how to tag an Amazon RDS DB instance.

To add a tag to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.

   Note
   To filter the list of DB instances in the Databases pane, enter a text string for Filter databases. Only DB instances that contain the string appear.
3. Choose the name of the DB instance that you want to tag to show its details.
4. In the details section, scroll down to the Tags section.
5. Choose Add. The Add tags window appears.
6. Enter a value for Tag key and Value.
7. To add another tag, you can choose Add another Tag and enter a value for its Tag key and Value.
   Repeat this step as many times as necessary.
8. Choose Add.
To delete a tag from a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
   
   **Note**
   To filter the list of DB instances in the Databases pane, enter a text string in the Filter databases box. Only DB instances that contain the string appear.
3. Choose the name of the DB instance to show its details.
4. In the details section, scroll down to the Tags section.
5. Choose the tag you want to delete.
6. Choose Delete, and then choose Delete in the Delete tags window.

**AWS CLI**

You can add, list, or remove tags for a DB instance using the AWS CLI.

- To add one or more tags to an Amazon RDS resource, use the AWS CLI command `add-tags-to-resource`.
- To list the tags on an Amazon RDS resource, use the AWS CLI command `list-tags-for-resource`.
- To remove one or more tags from an Amazon RDS resource, use the AWS CLI command `remove-tags-from-resource`.

To learn more about how to construct the required ARN, see Constructing an ARN for Amazon RDS (p. 360).

**RDS API**

You can add, list, or remove tags for a DB instance using the Amazon RDS API.

- To add a tag to an Amazon RDS resource, use the `AddTagsToResource` operation.
- To list tags that are assigned to an Amazon RDS resource, use the `ListTagsForResource`.
- To remove tags from an Amazon RDS resource, use the `RemoveTagsFromResource` operation.

To learn more about how to construct the required ARN, see Constructing an ARN for Amazon RDS (p. 360).

When working with XML using the Amazon RDS API, tags use the following schema:

```xml
<Tagging>
  <TagSet>
    <Tag>
      <Key>Project</Key>
```
The following table provides a list of the allowed XML tags and their characteristics. Values for Key and Value are case-dependent. For example, project=Trinity and PROJECT=Trinity are two distinct tags.

<table>
<thead>
<tr>
<th>Tagging element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TagSet</td>
<td>A tag set is a container for all tags assigned to an Amazon RDS resource. There can be only one tag set per resource. You work with a TagSet only through the Amazon RDS API.</td>
</tr>
<tr>
<td>Tag</td>
<td>A tag is a user-defined key-value pair. There can be from 1 to 50 tags in a tag set.</td>
</tr>
<tr>
<td>Key</td>
<td>A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with <code>aws:</code> or <code>rds:</code>. The string can only contain only the set of Unicode letters, digits, white-space, <code>\</code> (Java regex: <code>&quot;^([\p{L}\p{Z}\p{N}_.:/=+\-]*)$&quot;</code>). Keys must be unique to a tag set. For example, you cannot have a key-pair in a tag set with the key the same but with different values, such as project/Trinity and project/Xanadu.</td>
</tr>
<tr>
<td>Value</td>
<td>A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with <code>aws:</code> or <code>rds:</code>. The string can only contain only the set of Unicode letters, digits, white-space, <code>\</code> (Java regex: <code>&quot;^([\p{L}\p{Z}\p{N}_.:/=+\-]*)$&quot;</code>). Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of project/Trinity and cost-center/Trinity.</td>
</tr>
</tbody>
</table>

**Using the AWS Tag Editor**

You can browse and edit the tags on your RDS resources in the AWS Management Console by using the AWS Tag editor. For more information, see Tag Editor in the AWS Resource Groups User Guide.

**Copying tags to DB cluster snapshots**

When you create or restore a DB cluster, you can specify that the tags from the DB cluster are copied to snapshots of the DB cluster. Copying tags ensures that the metadata for the DB snapshots matches that of the source DB cluster and any access policies for the DB snapshot also match those of the source DB cluster. Tags are not copied by default.

You can specify that tags are copied to DB snapshots for the following actions:

- Creating a DB cluster.
- Restoring a DB cluster.
- Creating a read replica.
Tutorial: Use tags to specify which Aurora DB clusters to stop

Suppose that you're creating a number of Aurora DB clusters in a development or test environment. You need to keep all of these clusters for several days. Some of the clusters run tests overnight. Other clusters can be stopped overnight and started again the next day. The following example shows how to assign a tag to those clusters that are suitable to stop overnight. Then the example shows how a script can detect which clusters have that tag and then stop those clusters. In this example, the value portion of the key-value pair doesn't matter. The presence of the \texttt{stoppable} tag signifies that the cluster has this user-defined property.

To specify which Aurora DB clusters to stop

1. Determine the ARN of a cluster that you want to designate as stoppable.

   The commands and APIs for tagging work with ARNs. That way, they can work seamlessly across AWS Regions, AWS accounts, and different types of resources that might have identical short names. You can specify the ARN instead of the cluster ID in CLI commands that operate on clusters. Substitute the name of your own cluster for \texttt{dev-test-cluster}. In subsequent commands that use ARN parameters, substitute the ARN of your own cluster. The ARN includes your own AWS account ID and the name of the AWS Region where your cluster is located.

   ```bash
   $ aws rds describe-db-clusters --db-cluster-identifier dev-test-cluster \
   --query "*[][].DBClusterArn" --output text
   arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster
   ```

2. Add the tag \texttt{stoppable} to this cluster.

   The name for this tag is chosen by you. Using a tag like this is an alternative to devising a naming convention that encodes all the relevant information in the name of the cluster, DB instance, and so on. Because this example treats the tag as an attribute that is either present or absent, it omits the \texttt{Value=} part of the \texttt{--tags} parameter.

   ```bash
   $ aws rds add-tags-to-resource \n   --resource-name arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster \n   --tags Key=stoppable
   ```

3. Confirm that the tag is present in the cluster.

   These commands retrieve the tag information for the cluster in JSON format and in plain tab-separated text.

   ```bash
   $ aws rds list-tags-for-resource \
   ```
Tutorial: Use tags to specify which Aurora DB clusters to stop

---

4. To stop all the clusters that are designated as stoppable, prepare a list of all your clusters. Loop through the list and check if each cluster is tagged with the relevant attribute.

This Linux example uses shell scripting to save the list of cluster ARNs to a temporary file and then perform CLI commands for each cluster.

```bash
$ aws rds list-tags-for-resource --resource-name arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster --output text
```

```
TAGLIST stoppable
```

You can run a script like this at the end of each day to make sure that nonessential clusters are stopped. You might also schedule a job using a utility such as `cron` to perform such a check each night, in case some clusters were left running by mistake. In that case, you might fine-tune the command that prepares the list of clusters to check. The following command produces a list of your clusters, but only the ones in available state. The script can ignore clusters that are already stopped, because they will have different status values such as stopped or stopping.

```bash
$ aws rds describe-db-clusters --query '*[].{DBClusterArn:DBClusterArn,Status:Status} | [?Status == `available`] | .
```

---

```

{ "DBCluster": {
    "AllocatedStorage": 1,
    "AvailabilityZones": [
        "us-east-1e",
        "us-east-1c",
        "us-east-1d"
    ],
    "BackupRetentionPeriod": 1,
    "DBClusterIdentifier": "dev-test-cluster",
    ...
```

You can run a script like this at the end of each day to make sure that nonessential clusters are stopped. You might also schedule a job using a utility such as `cron` to perform such a check each night, in case some clusters were left running by mistake. In that case, you might fine-tune the command that prepares the list of clusters to check. The following command produces a list of your clusters, but only the ones in available state. The script can ignore clusters that are already stopped, because they will have different status values such as stopped or stopping.

```bash
$ aws rds describe-db-clusters --query ' []*[.DBClusterArn,DBClusterArn,Status:Status)] | [?Status == `available`] | .
```

```

{ "DBCluster": {
    "AllocatedStorage": 1,
    "AvailabilityZones": [
        "us-east-1e",
        "us-east-1c",
        "us-east-1d"
    ],
    "BackupRetentionPeriod": 1,
    "DBClusterIdentifier": "dev-test-cluster",
    ...
```

---

358
Tutorial: Use tags to specify which Aurora DB clusters to stop

| arn:aws:rds:us-east-1:123456789:cluster:dev-test-cluster |
| arn:aws:rds:us-east-1:123456789:cluster:pg2-cluster |

**Tip**
After you're familiar with the general procedure of assigning tags and finding clusters that have those tags, you can use the same technique to reduce costs in other ways. For example, in this scenario with Aurora DB clusters used for development and testing, you might designate some clusters to be deleted at the end of each day, or to have only their reader DB instances deleted, or to have their DB instances changed to a small DB instance classes during times of expected low usage.
Working with Amazon Resource Names (ARNs) in Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). For certain Amazon RDS operations, you must uniquely identify an Amazon RDS resource by specifying its ARN. For example, when you create an RDS DB instance read replica, you must supply the ARN for the source DB instance.

Constructing an ARN for Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). You can construct an ARN for an Amazon RDS resource using the following syntax.

`arn:aws:rds:<region>:<account number>:<resourcetype>:<name>`

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>

Getting an existing ARN

You can get the ARN of an RDS resource by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or RDS API.

**Console**

To get an ARN from the AWS Management Console, navigate to the resource you want an ARN for, and view the details for that resource. For example, you can get the ARN for a DB instance from the *Configuration* tab of the DB instance details, as shown following.
AWS CLI

To get an ARN from the AWS CLI for a particular RDS resource, you use the `describe` command for that resource. The following table shows each AWS CLI command, and the ARN property used with the command to get an ARN.

<table>
<thead>
<tr>
<th>AWS CLI command</th>
<th>ARN property</th>
</tr>
</thead>
<tbody>
<tr>
<td>describe-event-subscriptions</td>
<td>EventSubscriptionArn</td>
</tr>
<tr>
<td>describe-certificates</td>
<td>CertificateArn</td>
</tr>
<tr>
<td>describe-db-parameter-groups</td>
<td>DBParameterGroupArn</td>
</tr>
<tr>
<td>describe-db-cluster-parameter-groups</td>
<td>DBClusterParameterGroupArn</td>
</tr>
<tr>
<td>describe-db-instances</td>
<td>DBInstanceArn</td>
</tr>
<tr>
<td>describe-db-security-groups</td>
<td>DBSecurityGroupArn</td>
</tr>
<tr>
<td>describe-db-snapshots</td>
<td>DBSnapshotArn</td>
</tr>
<tr>
<td>describe-events</td>
<td>SourceArn</td>
</tr>
<tr>
<td>describe-reserved-db-instances</td>
<td>ReservedDBInstanceArn</td>
</tr>
<tr>
<td>describe-db-subnet-groups</td>
<td>DBSubnetGroupArn</td>
</tr>
<tr>
<td>describe-db-clusters</td>
<td>DBClusterArn</td>
</tr>
<tr>
<td>describe-db-cluster-snapshots</td>
<td>DBClusterSnapshotArn</td>
</tr>
</tbody>
</table>

For example, the following AWS CLI command gets the ARN for a DB instance.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds describe-db-instances \
  --db-instance-identifier DBInstanceIdentifier \
  --region us-west-2 \
  --query "*[].{DBInstanceIdentifier:DBInstanceIdentifier, DBInstanceArn:DBInstanceArn}"
```

For Windows:

```bash
aws rds describe-db-instances ^
  --db-instance-identifier DBInstanceIdentifier ^
  --region us-west-2 ^
  --query "*[].{DBInstanceIdentifier:DBInstanceIdentifier, DBInstanceArn:DBInstanceArn}"
```

The output of that command is like the following:

```json
[{
  "DBInstanceIdentifier": "instance_id"
}
```
RDS API

To get an ARN for a particular RDS resource, you can call the following RDS API operations and use the ARN properties shown following.

<table>
<thead>
<tr>
<th>RDS API operation</th>
<th>ARN property</th>
</tr>
</thead>
<tbody>
<tr>
<td>DescribeEventSubscriptions</td>
<td>EventSubscriptionArn</td>
</tr>
<tr>
<td>DescribeCertificates</td>
<td>CertificateArn</td>
</tr>
<tr>
<td>DescribeDBParameterGroups</td>
<td>DBParameterGroupArn</td>
</tr>
<tr>
<td>DescribeDBClusterParameterGroups</td>
<td>DBClusterParameterGroupArn</td>
</tr>
<tr>
<td>DescribeDBInstances</td>
<td>DBInstanceArn</td>
</tr>
<tr>
<td>DescribeDBSecurityGroups</td>
<td>DBSecurityGroupArn</td>
</tr>
<tr>
<td>DescribeDBSnapshots</td>
<td>DBSnapshotArn</td>
</tr>
<tr>
<td>DescribeEvents</td>
<td>SourceArn</td>
</tr>
<tr>
<td>DescribeReservedDBInstances</td>
<td>ReservedDBInstanceArn</td>
</tr>
<tr>
<td>DescribeDBSubnetGroups</td>
<td>DBSubnetGroupArn</td>
</tr>
<tr>
<td>DescribeDBClusters</td>
<td>DBClusterArn</td>
</tr>
<tr>
<td>DescribeDBClusterSnapshots</td>
<td>DBClusterSnapshotArn</td>
</tr>
</tbody>
</table>
Amazon Aurora updates

Amazon Aurora releases updates regularly. Updates are applied to Amazon Aurora DB clusters during system maintenance windows. The timing when updates are applied depends on the region and maintenance window setting for the DB cluster, and also the type of update. Updates require a database restart, so you typically experience 20 to 30 seconds of downtime. After this downtime, you can resume using your DB cluster or clusters. You can view or change your maintenance window settings from the AWS Management Console.

**Note**

The time required to reboot your DB instance depends on the crash recovery process, database activity at the time of reboot, and the behavior of your specific DB engine. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

Following, you can find information on general updates to Amazon Aurora. Some of the updates applied to Amazon Aurora are specific to a database engine supported by Aurora. For more information about database engine updates for Aurora, see the following table.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Updates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>See Database engine updates for Amazon Aurora MySQL (p. 991)</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL</td>
<td>See Amazon Aurora PostgreSQL updates (p. 1412)</td>
</tr>
</tbody>
</table>

### Identifying your Amazon Aurora version

Amazon Aurora includes certain features that are general to Aurora and available to all Aurora DB clusters. Aurora includes other features that are specific to a particular database engine that Aurora supports. These features are available only to those Aurora DB clusters that use that database engine, such as Aurora PostgreSQL.

An Aurora DB instance provides two version numbers, the Aurora version number and the Aurora database engine version number. Aurora version numbers use the following format.

```
<major version>.<minor version>.<patch version>
```

To get the Aurora version number from an Aurora DB instance using a particular database engine, use one of the following queries.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Queries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td><code>SELECT AURORA_VERSION();</code></td>
</tr>
<tr>
<td></td>

Backing up and restoring an Amazon Aurora DB cluster

These topics provide information about backing up and restoring Amazon Aurora DB clusters.

Tip
The Aurora high availability features and automatic backup capabilities help to keep your data safe without requiring extensive setup from you. Before you implement a backup strategy, learn about the ways that Aurora maintains multiple copies of your data and helps you to access them across multiple DB instances and AWS Regions. For details, see High availability for Amazon Aurora (p. 71).

Overview of backing up and restoring an Aurora DB cluster

In the following sections, you can find information about Aurora backups and how to restore your Aurora DB cluster using the AWS Management Console.

Backups

Aurora backs up your cluster volume automatically and retains restore data for the length of the backup retention period. Aurora backups are continuous and incremental so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period, from 1 to 35 days, when you create or modify a DB cluster. Aurora backups are stored in Amazon S3.

If you want to retain a backup beyond the backup retention period, you can also take a snapshot of the data in your cluster volume. Because Aurora retains incremental restore data for the entire backup retention period, you only need to create a snapshot for data that you want to retain beyond the backup retention period. You can create a new DB cluster from the snapshot.

Note

- For Amazon Aurora DB clusters, the default backup retention period is one day regardless of how the DB cluster is created.
- You can't disable automated backups on Aurora. The backup retention period for Aurora is managed by the DB cluster.

Your costs for backup storage depend upon the amount of Aurora backup and snapshot data you keep and how long you keep it. For information about the storage associated with Aurora backups and snapshots, see Understanding Aurora backup storage usage (p. 372). For pricing information about Aurora backup storage, see Amazon RDS for Aurora pricing. After the Aurora cluster associated with a snapshot is deleted, storing that snapshot incurs the standard backup storage charges for Aurora.

Note

You can also use AWS Backup to manage backups of Amazon Aurora DB clusters. Backups managed by AWS Backup are considered manual DB cluster snapshots, but don’t count toward the DB cluster snapshot quota for Aurora. Backups that were created with AWS Backup have names ending in awsbackup: AWS-Backup-job-number. For information about AWS Backup, see the AWS Backup Developer Guide.

Backup window

Automated backups occur daily during the preferred backup window. If the backup requires more time than allotted to the backup window, the backup continues after the window ends, until it finishes. The backup window can't overlap with the weekly maintenance window for the DB cluster.

Aurora backups are continuous and incremental, but the backup window is used to create a daily system backup that is preserved within the backup retention period. You can copy it to preserve it outside of the retention period.

Note

When you create a DB cluster using the AWS Management Console, you can't specify a backup window. However, you can specify a backup window when you create a DB cluster using the AWS CLI or RDS API.
If you don’t specify a preferred backup window when you create the DB cluster, Aurora assigns a default 30-minute backup window. This window is selected at random from an 8-hour block of time for each AWS Region. The following table lists the time blocks for each AWS Region from which the default backup windows are assigned.

<table>

</table>
**Restoring data**

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, or from a DB cluster snapshot that you have saved. You can quickly restore a new copy of a DB cluster created from backup data to any point in time during your backup retention period. The continuous and incremental nature of Aurora backups during the backup retention period means you don't need to take frequent snapshots of your data to improve restore times.

To determine the latest or earliest restorable time for a DB cluster, look for the *Latest restore time* or *Earliest restorable time* values on the RDS console. For information about viewing these values, see Viewing an Amazon Aurora DB cluster (p. 433). The latest restorable time for a DB cluster is the most recent point at which you can restore your DB cluster, typically within 5 minutes of the current time. The earliest restorable time specifies how far back within the backup retention period that you can restore your cluster volume.

You can determine when the restore of a DB cluster is complete by checking the *Latest Restorable Time* and *Earliest Restorable Time* values. The *Latest Restorable Time* and *Earliest Restorable Time* values return NULL until the restore operation is complete. You can't request a backup or restore operation if *Latest Restorable Time* or *Earliest Restorable Time* returns NULL.

For information about restoring a DB cluster to a specified time, see Restoring a DB cluster to a specified time (p. 415).

**Database cloning for Aurora**

You can also use database cloning to clone the databases of your Aurora DB cluster to a new DB cluster, instead of restoring a DB cluster snapshot. The clone databases use only minimal additional space when first created. Data is copied only as data changes, either on the source databases or the clone databases. You can make multiple clones from the same DB cluster, or create additional clones even from other clones. For more information, see Cloning a volume for an Amazon Aurora DB cluster (p. 280).

**Backtrack**

Aurora MySQL now supports "rewinding" a DB cluster to a specific time, without restoring data from a backup. For more information, see Backtracking an Aurora DB cluster (p. 725).
Understanding Aurora backup storage usage

Aurora stores continuous backups (within the backup retention period) and snapshots in Aurora backup storage. To control your backup storage usage, you can reduce the backup retention interval, remove old manual snapshots when they are no longer needed, or both. For general information about Aurora backups, see Backups (p. 369). For pricing information about Aurora backup storage, see the Amazon Aurora pricing webpage.

To control your costs, you can monitor the amount of storage consumed by continuous backups and manual snapshots that persist beyond the retention period. Then you can reduce the backup retention interval and remove manual snapshots when they are no longer needed.

You can use the Amazon CloudWatch metrics `TotalBackupStorageBilled`, `SnapshotStorageUsed`, and `BackupRetentionPeriodStorageUsed` to review and monitor the amount of storage used by your Aurora backups, as follows:

- `BackupRetentionPeriodStorageUsed` represents the amount of backup storage used, in bytes, for storing continuous backups at the current time. This value depends on the size of the cluster volume and the amount of changes you make during the retention period. However, for billing purposes it doesn't exceed the cumulative cluster volume size during the retention period. For example, if your cluster's `VolumeBytesUsed` size is 107,374,182,400 bytes (100 GiB), and your retention period is two days, the maximum value for `BackupRetentionPeriodStorageUsed` is 214,748,364,800 bytes (100 GiB + 100 GiB).

- `SnapshotStorageUsed` represents the amount of backup storage used, in bytes, for storing manual snapshots beyond the backup retention period. Manual snapshots don't count against your snapshot backup storage while their creation timestamp is within the retention period. All automatic snapshots also don't count against your snapshot backup storage. The size of each snapshot is the size of the cluster volume at the time you take the snapshot. The `SnapshotStorageUsed` value depends on the number of snapshots you keep and the size of each snapshot. For example, suppose you have one manual snapshot outside the retention period, and the cluster's `VolumeBytesUsed` size was 100 GiB when that snapshot was taken. The amount of `SnapshotStorageUsed` is 107,374,182,400 bytes (100 GiB).

- `TotalBackupStorageBilled` represents the sum, in bytes, of `BackupRetentionPeriodStorageUsed` and `SnapshotStorageUsed`, minus an amount of free backup storage, which equals the size of the cluster volume for one day. The free backup storage is equal to the latest volume size. For example if your cluster's `VolumeBytesUsed` size is 100 GiB, your retention period is two days, and you have one manual snapshot outside the retention period, the `TotalBackupStorageBilled` is 214,748,364,800 bytes (200 GiB + 100 GiB - 100 GiB).

- These metrics are computed independently for each Aurora DB cluster.

You can monitor your Aurora clusters and build reports using CloudWatch metrics through the CloudWatch console. For more information about how to use CloudWatch metrics, see Availability of Aurora metrics in the Amazon RDS console (p. 542).

The backtrack setting for an Aurora DB cluster doesn't affect the volume of backup data for that cluster. Amazon bills the storage for backtrack data separately. You can also find the backtrack pricing information on the Amazon Aurora pricing web page.

If you share a snapshot with another user, you are still the owner of that snapshot. The storage costs apply to the snapshot owner. If you delete a shared snapshot that you own, nobody can access it. To keep access to a shared snapshot owned by someone else, you can copy that snapshot. Doing so makes you the owner of the new snapshot. Any storage costs for the copied snapshot apply to your account.
Creating a DB cluster snapshot

Amazon RDS creates a storage volume snapshot of your DB cluster, backing up the entire DB cluster and not just individual databases. When you create a DB cluster snapshot, you need to identify which DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later. The amount of time it takes to create a DB cluster snapshot varies with the size of your databases. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot.

Unlike automated backups, manual snapshots aren't subject to the backup retention period. Snapshots don't expire.

For very long-term backups, we recommend exporting snapshot data to Amazon S3. If the major version of your DB engine is no longer supported, you can't restore to that version from a snapshot. For more information, see Exporting DB cluster snapshot data to Amazon S3 (p. 396).

You can create a DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To create a DB cluster snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose *Databases*.
3. In the list of DB instances, choose a writer instance for the DB cluster.
4. Choose *Actions*, and then choose *Take snapshot*.
   
   The *Take DB Snapshot* window appears.
5. Enter the name of the DB cluster snapshot in the *Snapshot name* box.

6. Choose *Take Snapshot*.

**AWS CLI**

When you create a DB cluster snapshot using the AWS CLI, you need to identify which DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later.
You can do this by using the AWS CLI `create-db-cluster-snapshot` command with the following parameters:

- `--db-cluster-identifier`
- `--db-cluster-snapshot-identifier`

In this example, you create a DB cluster snapshot named `mydbclustersnapshot` for a DB cluster called `mydbcluster`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster-snapshot \
  --db-cluster-identifier mydbcluster \
  --db-cluster-snapshot-identifier mydbclustersnapshot
```

For Windows:

```bash
aws rds create-db-cluster-snapshot ^
  --db-cluster-identifier mydbcluster ^
  --db-cluster-snapshot-identifier mydbclustersnapshot
```

**RDS API**

When you create a DB cluster snapshot using the Amazon RDS API, you need to identify which DB cluster you are going to back up, and then give your DB cluster snapshot a name so you can restore from it later. You can do this by using the Amazon RDS API `CreateDBClusterSnapshot` command with the following parameters:

- `DBClusterIdentifier`
- `DBClusterSnapshotIdentifier`

**Determining whether the DB cluster snapshot is available**

You can check that the DB cluster snapshot is available by looking under `Snapshots` on the `Maintenance & backups` tab on the detail page for the cluster in the AWS Management Console, by using the `describe-db-cluster-snapshots` CLI command, or by using the `DescribeDBClusterSnapshots` API action.

You can also use the `wait db-cluster-snapshot-available` CLI command to poll the API every 30 seconds until the snapshot is available.
Restoring from a DB cluster snapshot

Amazon RDS creates a storage volume snapshot of your DB cluster, backing up the entire DB instance and not just individual databases. You can create a new DB cluster by restoring from a DB snapshot. You provide the name of the DB cluster snapshot to restore from, and then provide a name for the new DB cluster that is created from the restore. You can't restore from a DB cluster snapshot to an existing DB cluster; a new DB cluster is created when you restore.

You can use the restored DB cluster as soon as its status is available.

You can use AWS CloudFormation to restore a DB cluster from a DB cluster snapshot. For more information, see AWS::RDS::DBCluster in the AWS CloudFormation User Guide.

Note
Sharing a manual DB cluster snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to directly restore a DB cluster from the snapshot instead of taking a copy of it and restoring from that. For more information, see Sharing a DB cluster snapshot (p. 388).

Parameter group considerations

We recommend that you retain the DB parameter group and DB cluster parameter group for any DB cluster snapshots you create, so that you can associate your restored DB cluster with the correct parameter groups.

The default DB parameter group and DB cluster parameter group are associated with the restored cluster, unless you choose different ones. No custom parameter settings are available in the default parameter groups.

You can specify the parameter groups when you restore the DB cluster.

For more information about DB parameter groups and DB cluster parameter groups, see Working with parameter groups (p. 215).

Security group considerations

When you restore a DB cluster, the default virtual private cloud (VPC), DB subnet group, and VPC security group are associated with the restored instance, unless you choose different ones.

- If you're using the Amazon RDS console, you can specify a custom VPC security group to associate with the cluster or create a new VPC security group.
- If you're using the AWS CLI, you can specify a custom VPC security group to associate with the cluster by including the --vpc-security-group-ids option in the restore-db-cluster-from-snapshot command.
- If you're using the Amazon RDS API, you can include the VpcSecurityGroupIds.VpcSecurityGroupId.N parameter in the RestoreDBClusterFromSnapshot action.

As soon as the restore is complete and your new DB cluster is available, you can also change the VPC settings by modifying the DB cluster. For more information, see Modifying an Amazon Aurora DB cluster (p. 248).

Amazon Aurora considerations

With Aurora, you restore a DB cluster snapshot to a DB cluster.
With both Aurora MySQL and Aurora PostgreSQL, you can also restore a DB cluster snapshot to an Aurora Serverless DB cluster. For more information, see Restoring an Aurora Serverless v1 DB cluster (p. 1565).

With Aurora MySQL, you can restore a DB cluster snapshot from a cluster without parallel query to a cluster with parallel query. Because parallel query is typically used with very large tables, the snapshot mechanism is the fastest way to ingest large volumes of data to an Aurora MySQL parallel query-enabled cluster. For more information, see Working with parallel query for Amazon Aurora MySQL (p. 791).

## Restoring from a snapshot

You can restore a DB cluster from a DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

### Console

**To restore a DB cluster from a DB cluster snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB cluster snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore snapshot** page, for **DB instance identifier**, enter the name for your restored DB cluster.
6. Specify other settings. For information about each setting, see [Settings for Aurora DB clusters (p. 137)](#).
7. Choose **Restore DB instance**.

### AWS CLI

To restore a DB cluster from a DB cluster snapshot, use the AWS CLI command `restore-db-cluster-from-snapshot`.

In this example, you restore from a previously created DB cluster snapshot named `mydbclustersnapshot`. You restore to a new DB cluster named `mynewdbcluster`.

You can specify other settings. For information about each setting, see [Settings for Aurora DB clusters (p. 137)](#).

**Example**

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot
   --db-cluster-identifier mynewdbcluster
   --snapshot-identifier mydbclustersnapshot
   --engine aurora|aurora-mysql|aurora-postgresql
```

For Windows:

```bash
aws rds restore-db-cluster-from-snapshot ^
```
After the DB cluster has been restored, you must add the DB cluster to the security group used by the DB cluster used to create the DB cluster snapshot if you want the same functionality as that of the previous DB cluster.

**Important**

If you use the console to restore a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to restore a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster. Call the `create-db-instance` AWS CLI command to create the primary instance for your DB cluster. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

**RDS API**

To restore a DB cluster from a DB cluster snapshot, call the RDS API operation `RestoreDBClusterFromSnapshot` with the following parameters:

- `DBClusterIdentifier`
- `SnapshotIdentifier`

**Important**

If you use the console to restore a DB cluster, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the RDS API to restore a DB cluster, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster. Call the RDS API operation `CreateDBInstance` to create the primary instance for your DB cluster. Include the name of the DB cluster as the `DBClusterIdentifier` parameter value.
Copy a DB cluster snapshot

With Amazon Aurora, you can copy automated backups or manual DB cluster snapshots. After you copy a snapshot, the copy is a manual snapshot. You can make multiple copies of an automated backup or manual snapshot, but each copy must have a unique identifier.

You can copy a snapshot within the same AWS Region, you can copy a snapshot across AWS Regions, and you can copy shared snapshots.

You can't copy a DB cluster snapshot across Regions and accounts in a single step. Perform one step for each of these copy actions. As an alternative to copying, you can also share manual snapshots with other AWS accounts. For more information, see Sharing a DB cluster snapshot (p. 388).

Note
Amazon bills you based upon the amount of Amazon Aurora backup and snapshot data you keep and the period of time that you keep it. For information about the storage associated with Aurora backups and snapshots, see Understanding Aurora backup storage usage (p. 372). For pricing information about Aurora storage, see Amazon RDS for Aurora pricing.

Limitations

The following are some limitations when you copy snapshots:

• You can't copy a snapshot to or from the following AWS Regions:
  • China (Beijing)
  • China (Ningxia)
  • Asia Pacific (Jakarta)
• You can copy a snapshot between AWS GovCloud (US-East) and AWS GovCloud (US-West). However, you can't copy a snapshot between these AWS GovCloud (US) Regions and commercial AWS Regions.
• If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of AVAILABLE before you delete a source snapshot.
• You can have up to five snapshot copy requests in progress to a single destination Region per account.
• When you request multiple snapshot copies for the same source DB instance, they're queued internally. The copies requested later won't start until the previous snapshot copies are completed. For more information, see Why is my EC2 AMI or EBS snapshot creation slow? in the AWS Knowledge Center.
• Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete. In some cases, there might be a large number of cross-Region snapshot copy requests from a given source Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copy starts.

Snapshot retention

Amazon RDS deletes automated backups in several situations:

• At the end of their retention period.
• When you disable automated backups for a DB cluster.
• When you delete a DB cluster.
If you want to keep an automated backup for a longer period, copy it to create a manual snapshot, which is retained until you delete it. Amazon RDS storage costs might apply to manual snapshots if they exceed your default storage space.

For more information about backup storage costs, see Amazon RDS pricing.

Copying shared snapshots

You can copy snapshots shared to you by other AWS accounts. In some cases, you might copy an encrypted snapshot that has been shared from another AWS account. In these cases, you must have access to the AWS KMS key that was used to encrypt the snapshot.

You can only copy a shared DB cluster snapshot, whether encrypted or not, in the same AWS Region. For more information, see Sharing encrypted snapshots (p. 389).

Handling encryption

You can copy a snapshot that has been encrypted using a KMS key. If you copy an encrypted snapshot, the copy of the snapshot must also be encrypted. If you copy an encrypted snapshot within the same AWS Region, you can encrypt the copy with the same KMS key as the original snapshot. Or you can specify a different KMS key.

If you copy an encrypted snapshot across Regions, you must specify a KMS key valid in the destination AWS Region. It can be a Region-specific KMS key, or a multi-Region key. For more information on multi-Region KMS keys, see Using multi-Region keys in AWS KMS.

The source snapshot remains encrypted throughout the copy process. For more information, see Limitations of Amazon Aurora encrypted DB clusters (p. 1640).

Note

For Amazon Aurora DB cluster snapshots, you can't encrypt an unencrypted DB cluster snapshot when you copy the snapshot.

Incremental snapshot copying

Aurora doesn't support incremental snapshot copying. Aurora DB cluster snapshot copies are always full copies. A full snapshot copy contains all of the data and metadata required to restore the DB cluster.

Cross-Region snapshot copying

You can copy DB cluster snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

Cross-Region copying of DB cluster snapshots isn't supported in the following opt-in AWS Regions:

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Europe (Milan)
- Middle East (Bahrain)

Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete.

In some cases, there might be a large number of cross-Region snapshot copy requests from a given source AWS Region. In such cases, Amazon RDS might put new cross-Region copy requests from that
source AWS Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copying starts.

Parameter group considerations

When you copy a snapshot across Regions, the copy doesn't include the parameter group used by the original DB cluster. When you restore a snapshot to create a new DB cluster, that DB cluster gets the default parameter group for the AWS Region it is created in. To give the new DB cluster the same parameters as the original, do the following:

1. In the destination AWS Region, create a DB cluster parameter group with the same settings as the original DB cluster. If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB cluster and add the new or existing parameter group from the previous step.

Copying a DB cluster snapshot

Use the procedures in this topic to copy a DB cluster snapshot. If your source database engine is Aurora, then your snapshot is a DB cluster snapshot.

For each AWS account, you can copy up to five DB cluster snapshots at a time from one AWS Region to another. Copying both encrypted and unencrypted DB cluster snapshots is supported. If you copy a DB cluster snapshot to another AWS Region, you create a manual DB cluster snapshot that is retained in that AWS Region. Copying a DB cluster snapshot out of the source AWS Region incurs Amazon RDS data transfer charges.

For more information about data transfer pricing, see Amazon RDS pricing.

After the DB cluster snapshot copy has been created in the new AWS Region, the DB cluster snapshot copy behaves the same as all other DB cluster snapshots in that AWS Region.

Console

This procedure works for copying encrypted or unencrypted DB cluster snapshots, in the same AWS Region or across Regions.

To cancel a copy operation once it is in progress, delete the target DB cluster snapshot while that DB cluster snapshot is in copying status.

To copy a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Select the check box for the DB cluster snapshot you want to copy.
4. For Actions, choose Copy Snapshot. The Make Copy of DB Snapshot page appears.
5. (Optional) To copy the DB cluster snapshot to a different AWS Region, choose that AWS Region for Destination Region.

6. Type the name of the DB cluster snapshot copy in New DB Snapshot Identifier.

7. To copy tags and values from the snapshot to the copy of the snapshot, choose Copy Tags.

8. Choose Copy Snapshot.

Copying an unencrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API

Use the procedures in the following sections to copy an unencrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API.

To cancel a copy operation once it is in progress, delete the target DB cluster snapshot identified by --target-db-cluster-snapshot-identifier or TargetDBClusterSnapshotIdentifier while that DB cluster snapshot is in copying status.
AWS CLI

To copy a DB cluster snapshot, use the AWS CLI `copy-db-cluster-snapshot` command. If you are copying the snapshot to another AWS Region, run the command in the AWS Region to which the snapshot will be copied.

The following options are used to copy an unencrypted DB cluster snapshot:

- `--source-db-cluster-snapshot-identifier` – The identifier for the DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- `--target-db-cluster-snapshot-identifier` – The identifier for the new copy of the DB cluster snapshot.

The following code creates a copy of DB cluster snapshot `arn:aws:rds:us-east-1:123456789012:cluster-snapshot:aurora-cluster1-snapshot-20130805` named `myclustersnapshotcopy` in the AWS Region in which the command is run. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

**Example**

For Linux, macOS, or Unix:

```
aws rds copy-db-cluster-snapshot
  --target-db-cluster-snapshot-identifier myclustersnapshotcopy
  --copy-tags
```

For Windows:

```
aws rds copy-db-cluster-snapshot
  --target-db-cluster-snapshot-identifier myclustersnapshotcopy
  --copy-tags
```

RDS API

To copy a DB cluster snapshot, use the Amazon RDS API `CopyDBClusterSnapshot` operation. If you are copying the snapshot to another AWS Region, perform the action in the AWS Region to which the snapshot will be copied.

The following parameters are used to copy an unencrypted DB cluster snapshot:

- `SourceDBClusterSnapshotIdentifier` – The identifier for the DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- `TargetDBClusterSnapshotIdentifier` – The identifier for the new copy of the DB cluster snapshot.

The following code creates a copy of a snapshot `arn:aws:rds:us-east-1:123456789012:cluster-snapshot:aurora-cluster1-snapshot-20130805` named `myclustersnapshotcopy` in the US West (N. California) Region. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.
Copying an encrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API

Use the procedures in the following sections to copy an encrypted DB cluster snapshot by using the AWS CLI or Amazon RDS API.

To cancel a copy operation once it is in progress, delete the target DB cluster snapshot identified by --target-db-cluster-snapshot-identifier or TargetDBClusterSnapshotIdentifier while that DB cluster snapshot is in copying status.

AWS CLI

To copy a DB cluster snapshot, use the AWS CLI copy-db-cluster-snapshot command. If you are copying the snapshot to another AWS Region, run the command in the AWS Region to which the snapshot will be copied.

The following options are used to copy an encrypted DB cluster snapshot:

- --source-db-cluster-snapshot-identifier – The identifier for the encrypted DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- --target-db-cluster-snapshot-identifier – The identifier for the new copy of the encrypted DB cluster snapshot.
- --kms-key-id – The KMS key identifier for the key to use to encrypt the copy of the DB cluster snapshot.

You can optionally use this option if the DB cluster snapshot is encrypted, you copy the snapshot in the same AWS Region, and you want to specify a new KMS key to encrypt the copy. Otherwise, the copy of the DB cluster snapshot is encrypted with the same KMS key as the source DB cluster snapshot.

You must use this option if the DB cluster snapshot is encrypted and you are copying the snapshot to another AWS Region. In that case, you must specify a KMS key for the destination AWS Region.

The following code example copies the encrypted DB cluster snapshot from the US West (Oregon) Region to the US East (N. Virginia) Region. The command is called in the US East (N. Virginia) Region.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-cluster-snapshot \\
```
Copying a DB cluster snapshot

```bash
--target-db-cluster-snapshot-identifier myclustersnapshotcopy \
--kms-key-id my-us-east-1-key
```

For Windows:

```bash
aws rds copy-db-cluster-snapshot ^
--target-db-cluster-snapshot-identifier myclustersnapshotcopy ^
--kms-key-id my-us-east-1-key
```

The `--source-region` parameter is required when you're copying an encrypted DB cluster snapshot between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. For `--source-region`, specify the AWS Region of the source DB instance. The AWS Region specified in `source-db-cluster-snapshot-identifier` must match the AWS Region specified for `--source-region`.

If `--source-region` isn't specified, specify a `--pre-signed-url` value. A presigned URL is a URL that contains a Signature Version 4 signed request for the `copy-db-cluster-snapshot` command that's called in the source AWS Region. To learn more about the pre-signed-url option, see `copy-db-cluster-snapshot` in the AWS CLI Command Reference.

**RDS API**

To copy a DB cluster snapshot, use the Amazon RDS API `CopyDBClusterSnapshot` operation. If you are copying the snapshot to another AWS Region, perform the action in the AWS Region to which the snapshot will be copied.

The following parameters are used to copy an encrypted DB cluster snapshot:

- **SourceDBClusterSnapshotIdentifier** – The identifier for the encrypted DB cluster snapshot to be copied. If you are copying the snapshot to another AWS Region, this identifier must be in the ARN format for the source AWS Region.
- **TargetDBClusterSnapshotIdentifier** – The identifier for the new copy of the encrypted DB cluster snapshot.
- **KmsKeyId** – The KMS key identifier for the key to use to encrypt the copy of the DB cluster snapshot.

You can optionally use this parameter if the DB cluster snapshot is encrypted, you copy the snapshot in the same AWS Region, and you specify a new KMS key to use to encrypt the copy. Otherwise, the copy of the DB cluster snapshot is encrypted with the same KMS key as the source DB cluster snapshot.

You must use this parameter if the DB cluster snapshot is encrypted and you are copying the snapshot to another AWS Region. In that case, you must specify a KMS key for the destination AWS Region.

- **PreSignedUrl** – If you are copying the snapshot to another AWS Region, you must specify the PreSignedUrl parameter. The PreSignedUrl value must be a URL that contains a Signature Version 4 signed request for the `CopyDBClusterSnapshot` action to be called in the source AWS Region where the DB cluster snapshot is copied from. To learn more about using a presigned URL, see `CopyDBClusterSnapshot`.

The following code example copies the encrypted DB cluster snapshot from the US West (Oregon) Region to the US East (N. Virginia) Region. The action is called in the US East (N. Virginia) Region.

**Example**

https://rds.us-east-1.amazonaws.com/
The **PreSignedUrl** parameter is required when you are copying an encrypted DB cluster snapshot between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions. The **PreSignedUrl** value must be a URL that contains a Signature Version 4 signed request for the **CopyDBClusterSnapshot** operation to be called in the source AWS Region where the DB cluster snapshot is copied from. To learn more about using a presigned URL, see CopyDBClusterSnapshot in the Amazon RDS API Reference.

To automatically rather than manually generate a presigned URL, use the AWS CLI `copy-db-cluster-snapshot` command with the --source-region option instead.

### Copying a DB cluster snapshot across accounts

You can enable other AWS accounts to copy DB cluster snapshots that you specify by using the Amazon RDS API **ModifyDBClusterSnapshotAttribute** and **CopyDBClusterSnapshot** actions. You can only copy DB cluster snapshots across accounts in the same AWS Region. The cross-account copying process works as follows, where Account A is making the snapshot available to copy, and Account B is copying it.

1. Using Account A, call **ModifyDBClusterSnapshotAttribute**, specifying `restore` for the **AttributeName** parameter, and the ID for Account B for the **ValuesToAdd** parameter.
2. (If the snapshot is encrypted) Using Account A, update the key policy for the KMS key, first adding the ARN of Account B as a **Principal**, and then allow the `kms:CreateGrant` action.
3. (If the snapshot is encrypted) Using Account B, choose or create an IAM user and attach an IAM policy to that user that allows it to copy an encrypted DB cluster snapshot using your KMS key.
4. Using Account B, call **CopyDBClusterSnapshot** and use the **SourceDBClusterSnapshotIdentifier** parameter to specify the ARN of the DB cluster snapshot to be copied, which must include the ID for Account A.
To list all of the AWS accounts permitted to restore a DB cluster snapshot, use the `DescribeDBSnapshotAttributes` or `DescribeDBClusterSnapshotAttributes` API operation.

To remove sharing permission for an AWS account, use the `ModifyDBSnapshotAttribute` or `ModifyDBClusterSnapshotAttribute` action with `AttributeName` set to `restore` and the ID of the account to remove in the `ValuesToRemove` parameter.

### Copying an unencrypted DB cluster snapshot to another account

Use the following procedure to copy an unencrypted DB cluster snapshot to another account in the same AWS Region.

1. In the source account for the DB cluster snapshot, call `ModifyDBClusterSnapshotAttribute`, specifying `restore` for the `AttributeName` parameter, and the ID for the target account for the `ValuesToAdd` parameter.

   Running the following example using the account `987654321` permits two AWS account identifiers, `123451234512` and `123456789012`, to restore the DB cluster snapshot named `manual-snapshot1`.

   ```
   https://rds.us-west-2.amazonaws.com/
   ?Action=ModifyDBClusterSnapshotAttribute
   &AttributeName=restore
   &DBClusterSnapshotIdentifier=manual-snapshot1
   &SignatureMethod=HmacSHA256&SignatureVersion=4
   &ValuesToAdd.member.1=123451234512
   &ValuesToAdd.member.2=123456789012
   &Version=2014-10-31
   &X-Amz-Algorithm=AWS4-HMAC-SHA256
   &X-Amz-Credential=AKIADQKE4SARGYLE/20150922/us-west-2/rds/aws4_request
   &X-Amz-Date=20150922T220515Z
   &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
   &X-Amz-Signature=ef38f1ce3db4ed1bf113d8d2a65c67d17ece1999ff36be85714ed36ddbb3
   ```

2. In the target account, call `CopyDBClusterSnapshot` and use the `SourceDBClusterSnapshotIdentifier` parameter to specify the ARN of the DB cluster snapshot to be copied, which must include the ID for the source account.

   Running the following example using the account `123451234512` copies the DB cluster snapshot `aurora-cluster1-snapshot-20130805` from account `987654321` and creates a DB cluster snapshot named `dbclustersnapshot1`.

   ```
   https://rds.us-west-2.amazonaws.com/
   ?Action=CopyDBClusterSnapshot
   &CopyTags=true
   &SignatureMethod=HmacSHA256
   &SignatureVersion=4
   &TargetDBClusterSnapshotIdentifier=dbclustersnapshot1
   &Version=2013-09-09
   &X-Amz-Algorithm=AWS4-HMAC-SHA256
   &X-Amz-Credential=AKIADQKE4SARGYLE/20150922/us-west-2/rds/aws4_request
   &X-Amz-Date=20140429T175351Z
   &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
   &X-Amz-Signature=9164337efa99caf850e874a1cb7ef6f3cea29d0b448b9e07c53b2888ddfed2
   ```
Copying a DB cluster snapshot

Use the following procedure to copy an encrypted DB cluster snapshot to another account in the same AWS Region.

1. In the source account for the DB cluster snapshot, call `ModifyDBClusterSnapshotAttribute`, specifying `restore` for the `AttributeName` parameter, and the ID for the target account for the `ValuesToAdd` parameter.

   Running the following example using the account 987654321 permits two AWS account identifiers, 123451234512 and 123456789012, to restore the DB cluster snapshot named manual-snapshot1.

   ```
   https://rds.us-west-2.amazonaws.com/?Action=ModifyDBClusterSnapshotAttribute
   &AttributeName=restore
   &DBClusterSnapshotIdentifier=manual-snapshot1
   &SignatureMethod=HmacSHA256&SignatureVersion=4
   &ValuesToAdd.member.1=123451234512
   &ValuesToAdd.member.2=123456789012
   &Version=2014-10-31
   &X-Amz-Algorithm=AWS4-HMAC-SHA256
   &X-Amz-Credential=AKIADQKE4SARGYLE/20150922/us-west-2/rds/aws4_request
   &X-Amz-Date=20150922T220515Z
   &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
   &X-Amz-Signature=ef38f1ce3dab4e1dbf113d8d2a265c6d7d17ece1999ff3636e85714ed36ddbb3
   ```

2. In the source account for the DB cluster snapshot, update the key policy for the KMS key, first adding the ARN of the target account as a `Principal`, and then allow the `kms:CreateGrant` action. For more information, see Allowing access to an AWS KMS key (p. 389).

3. In the target account, choose or create an IAM user and attach an IAM policy to that user that allows it to copy an encrypted DB cluster snapshot using your KMS key. For more information, see Creating an IAM policy to enable copying of the encrypted snapshot (p. 390).

4. In the target account, call `CopyDBClusterSnapshot` and use the `SourceDBClusterSnapshotIdentifier` parameter to specify the ARN of the DB cluster snapshot to be copied, which must include the ID for the source account.

   Running the following example using the account 123451234512 copies the DB cluster snapshot aurora-cluster1-snapshot-20130805 from account 987654321 and creates a DB cluster snapshot named dbclustersnapshot1.

   ```
   https://rds.us-west-2.amazonaws.com/?Action=CopyDBClusterSnapshot
   &CopyTags=true
   &SignatureMethod=HmacSHA256
   &SignatureVersion=4
   &TargetDBClusterSnapshotIdentifier=dbclustersnapshot1
   &Version=2013-09-09
   &X-Amz-Algorithm=AWS4-HMAC-SHA256
   &X-Amz-Credential=AKIADQKE4SARGYLE/20150429/us-west-2/rds/aws4_request
   &X-Amz-Date=20140909T015351Z
   &X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
   &X-Amz-Signature=9164337efa99cacf580e87461cb7f62b3ce29d0b44b9e0e7c5b288d8dfe2d
   ```
Sharing a DB cluster snapshot

Using Amazon RDS, you can share a manual DB cluster snapshot in the following ways:

- Sharing a manual DB cluster snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to copy the snapshot.
- Sharing a manual DB cluster snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to directly restore a DB cluster from the snapshot instead of taking a copy of it and restoring from that.

**Note**
To share an automated DB cluster snapshot, create a manual DB cluster snapshot by copying the automated snapshot, and then share that copy. This process also applies to AWS Backup–generated resources.

For more information on copying a snapshot, see Copying a DB cluster snapshot (p. 378). For more information on restoring a DB instance from a DB cluster snapshot, see Restoring from a DB cluster snapshot (p. 375).

For more information on restoring a DB cluster from a DB cluster snapshot, see Overview of backing up and restoring an Aurora DB cluster (p. 369).

You can share a manual snapshot with up to 20 other AWS accounts.

The following limitation applies when sharing manual snapshots with other AWS accounts:

- When you restore a DB cluster from a shared snapshot using the AWS Command Line Interface (AWS CLI) or Amazon RDS API, you must specify the Amazon Resource Name (ARN) of the shared snapshot as the snapshot identifier.

Sharing public snapshots

You can also share an unencrypted manual snapshot as public, which makes the snapshot available to all AWS accounts. Make sure when sharing a snapshot as public that none of your private information is included in the public snapshot.

When a snapshot is shared publicly, it gives all AWS accounts permission both to copy the snapshot and to create DB clusters from it.

You aren't billed for the backup storage of public snapshots owned by other accounts. You're billed only for snapshots that you own.

If you copy a public snapshot, you own the copy. You're billed for the backup storage of your snapshot copy. If you create a DB cluster from a public snapshot, you're billed for that DB cluster. For Amazon Aurora pricing information, see the Aurora pricing page.

You can delete only the public snapshots that you own. To delete a shared or public snapshot, make sure to log into the AWS account that owns the snapshot.

Viewing public snapshots owned by other AWS accounts

You can view public snapshots owned by other accounts in a particular AWS Region on the Public tab of the Snapshots page in the Amazon RDS console. Your snapshots (those owned by your account) don't appear on this tab.
Sharing encrypted snapshots

You can share DB cluster snapshots that have been encrypted “at rest” using the AES-256 encryption algorithm, as described in Encrypting Amazon Aurora resources (p. 1638). To do this, take the following steps:

1. Share the AWS KMS key that was used to encrypt the snapshot with any accounts that you want to be able to access the snapshot.

   You can share KMS keys with another AWS account by adding the other account to the KMS key policy. For details on updating a key policy, see Key policies in the AWS KMS Developer Guide. For an example of creating a key policy, see Allowing access to an AWS KMS key (p. 389) later in this topic.

2. Use the AWS Management Console, AWS CLI, or Amazon RDS API to share the encrypted snapshot with the other accounts.

These restrictions apply to sharing encrypted snapshots:

- You can’t share encrypted snapshots as public.
- You can’t share a snapshot that has been encrypted using the default KMS key of the AWS account that shared the snapshot.

Allowing access to an AWS KMS key

For another AWS account to copy an encrypted DB cluster snapshot shared from your account, the account that you share your snapshot with must have access to the AWS KMS key that encrypted the snapshot.
To allow another AWS account access to a KMS key, update the key policy for the KMS key. You update it with the Amazon Resource Name (ARN) of the AWS account that you are sharing to as Principal in the KMS key policy. Then you allow the kms:CreateGrant action.

After you have given an AWS account access to your KMS key, to copy your encrypted snapshot that AWS account must create an AWS Identity and Access Management (IAM) role or user if it doesn't already have one. In addition, that AWS account must also attach an IAM policy to that IAM role or user that allows the role or user to copy an encrypted DB cluster snapshot using your KMS key. The account must be an IAM user and cannot be a root AWS account identity due to AWS KMS security restrictions.

In the following key policy example, user 111122223333 is the owner of the KMS key, and user 444455556666 is the account that the key is being shared with. This updated key policy gives the AWS account access to the KMS key by including the ARN for the root AWS account identity for user 444455556666 as a Principal for the policy, and by allowing the kms:CreateGrant action.

```json
{
"Id": "key-policy-1",
"Version": "2012-10-17",
"Statement": [
{
"Sid": "Allow use of the key",
"Effect": "Allow",
"Principal": {"AWS": [
"arn:aws:iam::111122223333:user/KeyUser",
"arn:aws:iam::444455556666:root"
]}
},
"Action": [
"kms:CreateGrant",
"kms:Encrypt",
"kms:Decrypt",
"kms:ReEncrypt*",
"kms:GenerateDataKey*",
"kms:DescribeKey"
],
"Resource": "*"
},
{
"Sid": "Allow attachment of persistent resources",
"Effect": "Allow",
"Principal": {"AWS": [
"arn:aws:iam::111122223333:user/KeyUser",
"arn:aws:iam::444455556666:root"
]}
},
"Action": [
"kms:CreateGrant",
"kms:ListGrants",
"kms:RevokeGrant"
],
"Resource": "*",
"Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
}
}
```

Creating an IAM policy to enable copying of the encrypted snapshot

Once the external AWS account has access to your KMS key, the owner of that AWS account can create a policy that allows an IAM user created for that account to copy an encrypted snapshot encrypted with that KMS key.

The following example shows a policy that can be attached to an IAM user for AWS account 444455556666 that enables the IAM user to copy a shared snapshot from AWS account 111122223333.
that has been encrypted with the KMS key c989c1dd-a3f2-4a5d-8d96-e793d082ab26 in the us-west-2 region.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowUseOfTheKey",
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey",
                "kms:CreateGrant",
                "kms:RetireGrant"
            ],
            "Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"]
        },
        {
            "Sid": "AllowAttachmentOfPersistentResources",
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:ListGrants",
                "kms:RevokeGrant"
            ],
            "Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"],
            "Condition": {
                "Bool": {
                    "kms:GrantIsForAWSResource": true
                }
            }
        }
    ]
}
```

For details on updating a key policy, see Key policies in the AWS KMS Developer Guide.

**Sharing a snapshot**

You can share a DB cluster snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

Using the Amazon RDS console, you can share a manual DB cluster snapshot with up to 20 AWS accounts. You can also use the console to stop sharing a manual snapshot with one or more accounts.

**To share a manual DB cluster snapshot by using the Amazon RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Select the manual snapshot that you want to share.
4. For Actions, choose Share Snapshot.
5. Choose one of the following options for **DB snapshot visibility**.

   - If the source is unencrypted, choose **Public** to permit all AWS accounts to restore a DB cluster from your manual DB cluster snapshot, or choose **Private** to permit only AWS accounts that you specify to restore a DB cluster from your manual DB cluster snapshot.

     **Warning**
     If you set **DB snapshot visibility** to **Public**, all AWS accounts can restore a DB cluster from your manual DB cluster snapshot and have access to your data. Do not share any manual DB cluster snapshots that contain private information as **Public**.

   - If the source is encrypted, **DB snapshot visibility** is set as **Private** because encrypted snapshots can’t be shared as public.

6. For **AWS Account ID**, type the AWS account identifier for an account that you want to permit to restore a DB cluster from your manual snapshot, and then choose **Add**. Repeat to include additional AWS account identifiers, up to 20 AWS accounts.

   If you make an error when adding an AWS account identifier to the list of permitted accounts, you can delete it from the list by choosing **Delete** at the right of the incorrect AWS account identifier.

7. After you have added identifiers for all of the AWS accounts that you want to permit to restore the manual snapshot, choose **Save** to save your changes.

**To stop sharing a manual DB cluster snapshot with an AWS account**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to stop sharing.
4. Choose **Actions**, and then choose **Share Snapshot**.
5. To remove permission for an AWS account, choose **Delete** for the AWS account identifier for that account from the list of authorized accounts.

![Snapshot permissions](image)

6. Choose **Save** to save your changes.

**AWS CLI**

To share a DB cluster snapshot, use the `aws rds modify-db-cluster-snapshot-attribute` command. Use the `--values-to-add` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

**Example of sharing a snapshot with a single account**

The following example enables AWS account identifier `123456789012` to restore the DB cluster snapshot named `cluster-3-snapshot`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-snapshot-attribute \
  --db-cluster-snapshot-identifier cluster-3-snapshot \
  --attribute-name restore \
  --values-to-add 123456789012
```

For Windows:

```cmd
aws rds modify-db-cluster-snapshot-attribute ^
  --db-cluster-snapshot-identifier cluster-3-snapshot ^
  --attribute-name restore ^
  --values-to-add 123456789012
```
Example of sharing a snapshot with multiple accounts

The following example enables two AWS account identifiers, 111122223333 and 444455556666, to restore the DB cluster snapshot named manual-cluster-snapshot1.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-snapshot-attribute \
--db-cluster-snapshot-identifier manual-cluster-snapshot1 \
--attribute-name restore \
--values-to-add "111122223333","444455556666"
```

For Windows:

```bash
aws rds modify-db-cluster-snapshot-attribute ^
--db-cluster-snapshot-identifier manual-cluster-snapshot1 ^
--attribute-name restore ^
--values-to-add "["111122223333"","444455556666"]"
```

**Note**

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

To remove an AWS account identifier from the list, use the `--values-to-remove` parameter.

Example of stopping snapshot sharing

The following example prevents AWS account ID 444455556666 from restoring the snapshot.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-snapshot-attribute \
--db-cluster-snapshot-identifier manual-cluster-snapshot1 \
--attribute-name restore \
--values-to-remove 444455556666
```

For Windows:

```bash
aws rds modify-db-cluster-snapshot-attribute ^
--db-cluster-snapshot-identifier manual-cluster-snapshot1 ^
--attribute-name restore ^
--values-to-remove 444455556666
```

To list the AWS accounts enabled to restore a snapshot, use the `describe-db-cluster-snapshot-attributes` AWS CLI command.

**RDS API**

You can also share a manual DB cluster snapshot with other AWS accounts by using the Amazon RDS API. To do so, call the `ModifyDBClusterSnapshotAttribute` operation. Specify `restore` for `AttributeName`, and use the `ValuesToAdd` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

To make a manual snapshot public and restorable by all AWS accounts, use the value `all`. However, take care not to add the `all` value for any manual snapshots that contain private information that you don't want to be available to all AWS accounts. Also, don't specify `all` for encrypted snapshots, because making such snapshots public isn't supported.
To remove sharing permission for an AWS account, use the `ModifyDBClusterSnapshotAttribute` operation with `AttributeName` set to `restore` and the `ValuesToRemove` parameter. To mark a manual snapshot as private, remove the value `all` from the values list for the `restore` attribute.

To list all of the AWS accounts permitted to restore a snapshot, use the `DescribeDBClusterSnapshotAttributes` API operation.
Exporting DB cluster snapshot data to Amazon S3

You can export DB cluster snapshot data to an Amazon S3 bucket. The export process runs in the background and doesn’t affect the performance of your active DB cluster.

When you export a DB cluster snapshot, Amazon Aurora extracts data from the snapshot and stores it in an Amazon S3 bucket. The data is stored in an Apache Parquet format that is compressed and consistent.

You can export manual snapshots and automated system snapshots. By default, all data in the snapshot is exported. However, you can choose to export specific sets of databases, schemas, or tables.

After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. For more information on using Athena to read Parquet data, see Parquet SerDe in the Amazon Athena User Guide. For more information on using Redshift Spectrum to read Parquet data, see COPY from columnar data formats in the Amazon Redshift Database Developer Guide.

Amazon RDS supports exporting snapshots in all AWS Regions except the following:

- Asia Pacific (Jakarta)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

The following table shows the Aurora MySQL engine versions that are supported for exporting snapshot data to Amazon S3. For more information about Aurora MySQL engine versions, see Database engine updates for Amazon Aurora MySQL (p. 991).

<table>
<thead>
<tr>
<th>Aurora MySQL version</th>
<th>MySQL-compatible version</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.01.0 and higher</td>
<td>8.0</td>
</tr>
<tr>
<td>2.04.4 and higher</td>
<td>5.7</td>
</tr>
<tr>
<td>1.19.2 and higher</td>
<td>5.6</td>
</tr>
</tbody>
</table>

All currently available Aurora PostgreSQL engine versions support exporting snapshot data to Amazon S3. Versions include Aurora PostgreSQL 14.3, 13.3, 12.4, 11.4, 10.6, 9.6.11 and all higher minor versions. For more information about versions, see the Release Notes for Aurora PostgreSQL.

Topics
- Limitations (p. 397)
- Overview of exporting snapshot data (p. 397)
- Setting up access to an Amazon S3 bucket (p. 398)
- Using a cross-account AWS KMS key for encrypting Amazon S3 exports (p. 401)
- Exporting a snapshot to an Amazon S3 bucket (p. 402)
- Monitoring snapshot exports (p. 404)
- Canceling a snapshot export task (p. 406)
- Failure messages for Amazon S3 export tasks (p. 406)
- Troubleshooting PostgreSQL permissions errors (p. 407)
- File naming convention (p. 408)
- Data conversion when exporting to an Amazon S3 bucket (p. 408)
Limitations

Exporting DB snapshot data to Amazon S3 has the following limitations:

- The following characters in the S3 file path are converted to underscores (_) during export:

  \ ` " (space)

- If a database, schema, or table has characters in its name other than the following, partial export isn't supported. However, you can export the entire DB snapshot.
  - Latin letters (A–Z)
  - Digits (0–9)
  - Dollar symbol ($)
  - Underscore (_)

- Spaces ( ) and certain characters aren't supported in database table column names. Tables with the following characters in column names are skipped during export:

  , ; { } ( ) \n \t = (space)

- Tables with slashes (/) in their names are skipped during export.
- If the data contains a large object such as a BLOB or CLOB, close to or greater than 500 MB, the export fails.
- If a table contains a large row close to or greater than 2 GB, the table is skipped during export.
- We strongly recommend that you use a unique name for each export task. If you don't use a unique task name, you might receive the following error message:

  ExportTaskAlreadyExistsFault: An error occurred (ExportTaskAlreadyExists) when calling the StartExportTask operation: The export task with the ID xxxxx already exists.

- You can delete a snapshot while you're exporting its data to S3, but you're still charged for the storage costs for that snapshot until the export task has completed.
- You can't restore exported snapshot data from S3 to a new DB cluster.

Overview of exporting snapshot data

You use the following process to export DB snapshot data to an Amazon S3 bucket. For more details, see the following sections.

1. Identify the snapshot to export.

   Use an existing automated or manual snapshot, or create a manual snapshot of a DB instance.

2. Set up access to the Amazon S3 bucket.

   A **bucket** is a container for Amazon S3 objects or files. To provide the information to access a bucket, take the following steps:

   a. Identify the S3 bucket where the snapshot is to be exported to. The S3 bucket must be in the same AWS Region as the snapshot. For more information, see Identifying the Amazon S3 bucket for export (p. 398).

   b. Create an AWS Identity and Access Management (IAM) role that grants the snapshot export task access to the S3 bucket. For more information, see Providing access to an Amazon S3 bucket using an IAM role (p. 398).
3. Create a symmetric encryption AWS KMS key for the server-side encryption. The KMS key is used by the snapshot export task to set up AWS KMS server-side encryption when writing the export data to S3. For more information, see Encrypting Amazon Aurora resources (p. 1638).

The KMS key is also used for local disk encryption at rest on Amazon EC2. In addition, if you have a deny statement in your KMS key policy, make sure to explicitly exclude the AWS service principal export.rds.amazonaws.com.

You can use a KMS key within your AWS account, or you can use a cross-account KMS key. For more information, see Using a cross-account AWS KMS key for encrypting Amazon S3 exports (p. 401).

4. Export the snapshot to Amazon S3 using the console or the start-export-task CLI command. For more information, see Exporting a snapshot to an Amazon S3 bucket (p. 402).

5. To access your exported data in the Amazon S3 bucket, see Uploading, downloading, and managing objects in the Amazon Simple Storage Service User Guide.

Setting up access to an Amazon S3 bucket

To export DB snapshot data to an Amazon S3 file, you first give the snapshot permission to access the Amazon S3 bucket. You then create an IAM role to allow the Amazon Aurora service to write to the Amazon S3 bucket.

Topics
- Identifying the Amazon S3 bucket for export (p. 398)
- Providing access to an Amazon S3 bucket using an IAM role (p. 398)
- Using a cross-account Amazon S3 bucket (p. 400)

Identifying the Amazon S3 bucket for export

Identify the Amazon S3 bucket to export the DB snapshot to. Use an existing S3 bucket or create a new S3 bucket.

Note
The S3 bucket to export to must be in the same AWS Region as the snapshot.

For more information about working with Amazon S3 buckets, see the following in the Amazon Simple Storage Service User Guide:
- How do I view the properties for an S3 bucket?
- How do I enable default encryption for an Amazon S3 bucket?
- How do I create an S3 bucket?

Providing access to an Amazon S3 bucket using an IAM role

Before you export DB snapshot data to Amazon S3, give the snapshot export tasks write-access permission to the Amazon S3 bucket.

To do this, create an IAM policy that provides access to the bucket. Then create an IAM role and attach the policy to the role. You later assign the IAM role to your snapshot export task.

Important
If you plan to use the AWS Management Console to export your snapshot, you can choose to create the IAM policy and the role automatically when you export the snapshot. For instructions, see Exporting a snapshot to an Amazon S3 bucket (p. 402).
To give DB snapshot tasks access to Amazon S3

1. Create an IAM policy. This policy provides the bucket and object permissions that allow your snapshot export task to access Amazon S3.

Include in the policy the following required actions to allow the transfer of files from Amazon Aurora to an S3 bucket:

- s3:PutObject*
- s3:GetObject*
- s3:ListBucket
- s3:DeleteObject*
- s3:GetBucketLocation

Include in the policy the following resources to identify the S3 bucket and objects in the bucket. The following list of resources shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- arn:aws:s3:::your-s3-bucket
- arn:aws:s3:::your-s3-bucket/*

For more information on creating an IAM policy for Amazon Aurora, see Creating and using an IAM policy for IAM database access (p. 1685). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

The following AWS CLI command creates an IAM policy named ExportPolicy with these options. It grants access to a bucket named your-s3-bucket.

Note
After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name ExportPolicy --policy-document '{
"Version": "2012-10-17",
"Statement": [

  {
    "Sid": "ExportPolicy",
    "Effect": "Allow",
    "Action": [
      "s3:PutObject*",
      "s3:GetObject*",
      "s3:ListBucket",
      "s3:DeleteObject*",
      "s3:GetBucketLocation"
    ],
    "Resource": [
      "arn:aws:s3:::your-s3-bucket",
      "arn:aws:s3:::your-s3-bucket/*"
    ]

  }
]
}
```

2. Create an IAM role. You do this so that Aurora can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

The following example shows using the AWS CLI command to create a role named rds-s3-export-role.
aws iam create-role --role-name rds-s3-export-role --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "export.rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}'

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace your-policy-arn with the policy ARN that you noted in an earlier step.

aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role

Using a cross-account Amazon S3 bucket

You can use Amazon S3 buckets across AWS accounts. To use a cross-account bucket, add a bucket policy to allow access to the IAM role that you're using for the S3 exports. For more information, see Example 2: Bucket owner granting cross-account bucket permissions.

- Attach a bucket policy to your bucket, as shown in the following example.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::123456789012:role/Admin"
            },
            "Action": [
                "s3:PutObject",
                "s3:ListBucket",
                "s3:GetObject",
                "s3:DeleteObject",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::mycrossaccountbucket",
                "arn:aws:s3:::mycrossaccountbucket/*"
            ]
        }
    ]
}
```
Using a cross-account AWS KMS key for encrypting Amazon S3 exports

You can use a cross-account AWS KMS key to encrypt Amazon S3 exports. First, you add a key policy to the local account, then you add IAM policies in the external account. For more information, see Allowing users in other accounts to use a KMS key.

To use a cross-account KMS key

1. Add a key policy to the local account.

The following example gives ExampleRole and ExampleUser in the external account 444455556666 permissions in the local account 123456789012.

```
{
    "Sid": "Allow an external account to use this KMS key",
    "Effect": "Allow",
    "Principal": {
        "AWS": [
            "arn:aws:iam::444455556666:role/ExampleRole",
            "arn:aws:iam::444455556666:user/ExampleUser"
        ]
    },
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:CreateGrant",
        "kms:DescribeKey",
        "kms:RetireGrant"
    ],
    "Resource": "*"
}
```

2. Add IAM policies to the external account.

The following example IAM policy allows the principal to use the KMS key in account 123456789012 for cryptographic operations. To give this permission to ExampleRole and ExampleUser in account 444455556666, attach the policy to them in that account.

```
{
    "Sid": "Allow use of KMS key in account 123456789012",
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:CreateGrant",
        "kms:DescribeKey",
        "kms:RetireGrant"
    ],
    "Resource": "arn:aws:kms:us-west-2:123456789012:key/1234abcd-12ab-34cd-56ef-1234567890ab"
}
```
Exporting a snapshot to an Amazon S3 bucket

You can have up to five concurrent DB snapshot export tasks in progress per account.

**Note**
Exporting RDS snapshots can take a while depending on your database type and size. The export task first restores and scales the entire database before extracting the data to Amazon S3. The task's progress during this phase displays as *Starting*. When the task switches to exporting data to S3, progress displays as *In progress*.

The time it takes for the export to complete depends on the data stored in the database. For example, tables with well-distributed numeric primary key or index columns export the fastest. Tables that don't contain a column suitable for partitioning and tables with only one index on a string-based column take longer. This longer export time occurs because the export uses a slower single-threaded process.

You can export a DB snapshot to Amazon S3 using the AWS Management Console, the AWS CLI, or the RDS API.

If you use a Lambda function to export a snapshot, add the `kms:DescribeKey` action to the Lambda function policy. For more information, see AWS Lambda permissions.

**Console**
The Export to Amazon S3 console option appears only for snapshots that can be exported to Amazon S3. A snapshot might not be available for export because of the following reasons:

- The DB engine isn't supported for S3 export.
- The DB instance version isn't supported for S3 export.
- S3 export isn't supported in the AWS Region where the snapshot was created.

**To export a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Snapshots.
3. From the tabs, choose the type of snapshot that you want to export.
4. In the list of snapshots, choose the snapshot that you want to export.
5. For Actions, choose Export to Amazon S3.

   The Export to Amazon S3 window appears.
6. For Export identifier, enter a name to identify the export task. This value is also used for the name of the file created in the S3 bucket.
7. Choose the data to be exported:
   - Choose All to export all data in the snapshot.
   - Choose Partial to export specific parts of the snapshot. To identify which parts of the snapshot to export, enter one or more databases, schemas, or tables for Identifiers, separated by spaces.

Use the following format:

```plaintext
database[.schema][.table] database2[.schema2][.table2] ... database[n][.schema][.table]
```

For example:
8. **For S3 bucket**, choose the bucket to export to.

   To assign the exported data to a folder path in the S3 bucket, enter the optional path for **S3 prefix**.

9. **For IAM role**, either choose a role that grants you write access to your chosen S3 bucket, or create a new role.

   - If you created a role by following the steps in Providing access to an Amazon S3 bucket using an IAM role (p. 398), choose that role.
   - If you didn't create a role that grants you write access to your chosen S3 bucket, choose **Create a new role** to create the role automatically. Next, enter a name for the role in **IAM role name**.

10. **For AWS KMS key**, enter the ARN for the key to use for encrypting the exported data.

11. Choose **Export to Amazon S3**.

**AWS CLI**

To export a DB snapshot to Amazon S3 using the AWS CLI, use the `start-export-task` command with the following required options:

- `--export-task-identifier`
- `--source-arn`
- `--s3-bucket-name`
- `--iam-role-arn`
- `--kms-key-id`

In the following examples, the snapshot export task is named **my-snapshot-export**, which exports a snapshot to an S3 bucket named **my-export-bucket**.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds start-export-task \
  --export-task-identifier my-snapshot-export \
  --source-arn arn:aws:rds:AWS_Region:123456789012:snapshot:.snapshot-name \
  --s3-bucket-name my-export-bucket \
  --iam-role-arn iam-role \
  --kms-key-id my-key
```

For Windows:

```bash
aws rds start-export-task ^
  --export-task-identifier my-snapshot-export ^
  --s3-bucket-name my-export-bucket ^
  --iam-role-arn iam-role ^
  --kms-key-id my-key ^
```

Sample output follows.

```json
{
```
To provide a folder path in the S3 bucket for the snapshot export, include the `--s3-prefix` option in the `start-export-task` command.

**RDS API**

To export a DB snapshot to Amazon S3 using the Amazon RDS API, use the `StartExportTask` operation with the following required parameters:

- ExportTaskIdentifier
- SourceArn
- S3BucketName
- IamRoleArn
- KmsKeyId

**Monitoring snapshot exports**

You can monitor DB snapshot exports using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To monitor DB snapshot exports**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Snapshots.
3. To view the list of snapshot exports, choose the **Exports in Amazon S3** tab.
4. To view information about a specific snapshot export, choose the export task.

**AWS CLI**

To monitor DB snapshot exports using the AWS CLI, use the `describe-export-tasks` command.

The following example shows how to display current information about all of your snapshot exports.

**Example**

```bash
aws rds describe-export-tasks
{
  "ExportTasks": [
    {
      "Status": "CANCELED",
      "TaskEndTime": "2019-11-01T17:36:46.961Z",
```
To display information about a specific snapshot export, include the `--export-task-identifier` option with the `describe-export-tasks` command. To filter the output, include the `--Filters` option. For more options, see the `describe-export-tasks` command.

### RDS API

To display information about DB snapshot exports using the Amazon RDS API, use the `DescribeExportTasks` operation.

To track completion of the export workflow or to trigger another workflow, you can subscribe to Amazon Simple Notification Service topics. For more information on Amazon SNS, see Working with Amazon RDS event notification (p. 572).
Canceling a snapshot export task

You can cancel a DB snapshot export task using the AWS Management Console, the AWS CLI, or the RDS API.

**Note**
Canceling a snapshot export task doesn't remove any data that was exported to Amazon S3. For information about how to delete the data using the console, see How do I delete objects from an S3 bucket? To delete the data using the CLI, use the `delete-object` command.

**Console**

To cancel a snapshot export task

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the Exports in Amazon S3 tab.
4. Choose the snapshot export task that you want to cancel.
5. Choose Cancel.
6. Choose Cancel export task on the confirmation page.

**AWS CLI**

To cancel a snapshot export task using the AWS CLI, use the `cancel-export-task` command. The command requires the --export-task-identifier option.

**Example**

```
aws rds cancel-export-task --export-task-identifier my_export
{
  "Status": "CANCELING",
  "S3Prefix": "",
  "ExportTime": "2019-08-12T01:23:53.109Z",
  "S3Bucket": "examplebucket",
  "PercentProgress": 0,
  "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxFrifiCYEXAMPLEKEY",
  "ExportTaskIdentifier": "my_export",
  "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
  "TotalExtractedDataInGB": 0,
  "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:export-example-1"
}
```

**RDS API**

To cancel a snapshot export task using the Amazon RDS API, use the `CancelExportTask` operation with the `ExportTaskIdentifier` parameter.

**Failure messages for Amazon S3 export tasks**

The following table describes the messages that are returned when Amazon S3 export tasks fail.
### Failure message | Description
--- | ---
An unknown internal error occurred. | The task has failed because of an unknown error, exception, or failure.
An unknown internal error occurred writing the export task's metadata to the S3 bucket [bucket name]. | The task has failed because of an unknown error, exception, or failure.
The RDS export failed to write the export task's metadata because it can't assume the IAM role [role ARN]. | The export task assumes your IAM role to validate whether it is allowed to write metadata to your S3 bucket. If the task can't assume your IAM role, it fails.
The RDS export failed to write the export task's metadata to the S3 bucket [bucket name] using the IAM role [role ARN] with the KMS key [key ID]. Error code: [error code] | One or more permissions are missing, so the export task can't access the S3 bucket. This failure message is raised when receiving one of the following:
- AWSSecurityTokenServiceException with the error code AccessDenied
- AmazonS3Exception with the error code NoSuchBucket, AccessDenied, KMS.KMSInvalidStateException, 403 Forbidden, or KMS.DisabledException

This means that there are settings misconfigured among the IAM role, S3 bucket, or KMS key.
The IAM role [role ARN] isn't authorized to call [S3 action] on the S3 bucket [bucket name]. Review your permissions and retry the export. | The IAM policy is misconfigured. Permission for the specific S3 action on the S3 bucket is missing. This causes the export task to fail.
KMS key check failed. Check the credentials on your KMS key and try again. | The KMS key credential check failed.
S3 credential check failed. Check the permissions on your S3 bucket and IAM policy. | The S3 credential check failed.
The S3 bucket [bucket name] isn't valid. Either it isn't located in the current AWS Region or it doesn't exist. Review your S3 bucket name and retry the export. | The S3 bucket is invalid.
The S3 bucket [bucket name] isn't located in the current AWS Region. Review your S3 bucket name and retry the export. | The S3 bucket is in the wrong AWS Region.

### Troubleshooting PostgreSQL permissions errors

When exporting PostgreSQL databases to Amazon S3, you might see a `PERMISSIONS_DO_NOT_EXIST` error stating that certain tables were skipped. This is usually caused by the superuser, which you specify when creating the DB instance, not having permissions to access those tables.

To fix this error, run the following command:
File naming convention

Exported data for specific tables is stored in the format `base_prefix/files`, where the base prefix is the following:

```
export_identifier/database_name/schema_name.table_name/
```

For example:

```
export-1234567890123-459/rdststdb/rdststdb.DataInsert_7ADB5D19965123A2/
```

There are two conventions for how files are named. The current convention is the following:

```
partition_index/part-00000-random_uuid.format-based_extension
```

For example:

```
1/part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
2/part-00000-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
3/part-00000-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

The older convention is the following:

```
part-partition_index-random_uuid.format-based_extension
```

For example:

```
part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
part-00001-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
part-00002-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

The file naming convention is subject to change. Therefore, when reading target tables we recommend that you read everything inside the base prefix for the table.

Data conversion when exporting to an Amazon S3 bucket

When you export a DB snapshot to an Amazon S3 bucket, Amazon Aurora converts data to, exports data in, and stores data in the Parquet format. For more information about Parquet, see the Apache Parquet website.

Parquet stores all data as one of the following primitive types:

- BOOLEAN
- INT32
- INT64
- INT96
• FLOAT
• DOUBLE
• BYTE_ARRAY – A variable-length byte array, also known as binary
• FIXED_LEN_BYTE_ARRAY – A fixed-length byte array used when the values have a constant size

The Parquet data types are few to reduce the complexity of reading and writing the format. Parquet provides logical types for extending primitive types. A logical type is implemented as an annotation with the data in a LogicalType metadata field. The logical type annotation explains how to interpret the primitive type.

When the STRING logical type annotates a BYTE_ARRAY type, it indicates that the byte array should be interpreted as a UTF-8 encoded character string. After an export task completes, Amazon Aurora notifies you if any string conversion occurred. The underlying data exported is always the same as the data from the source. However, due to the encoding difference in UTF-8, some characters might appear different from the source when read in tools such as Athena.

For more information, see Parquet logical type definitions in the Parquet documentation.

Topics
• MySQL data type mapping to Parquet (p. 409)
• PostgreSQL data type mapping to Parquet (p. 412)

MySQL data type mapping to Parquet

The following table shows the mapping from MySQL data types to Parquet data types when data is converted and exported to Amazon S3.

<table>
<thead>
<tr>
<th>Source data type</th>
<th>Parquet primitive type</th>
<th>Logical type annotation</th>
<th>Conversion notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric data types</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BIGINT</td>
<td>INT64</td>
<td></td>
<td></td>
</tr>
<tr>
<td>BIGINT UNSIGNED</td>
<td>FIXED_LEN_BYTE_ARRAY(9) DECIMAL(20,0)</td>
<td>Parquet supports only signed types, so the mapping requires an additional byte (8 plus 1) to store the BIGINT UNSIGNED type.</td>
<td></td>
</tr>
<tr>
<td>BIT</td>
<td>BYTE_ARRAY</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DECIMAL</td>
<td>INT32</td>
<td>DECIMAL(p,s)</td>
<td>If the source value is less than $2^{31}$, it's stored as INT32.</td>
</tr>
<tr>
<td></td>
<td>INT64</td>
<td>DECIMAL(p,s)</td>
<td>If the source value is $2^{31}$ or greater, but less than $2^{63}$, it's stored as INT64.</td>
</tr>
<tr>

Restoring a DB cluster to a specified time

You can restore a DB cluster to a specific point in time, creating a new DB cluster.

When you restore a DB cluster to a point in time, you can choose the default virtual private cloud (VPC) security group. Or you can apply a custom VPC security group to your DB cluster.

Restored DB clusters are automatically associated with the default DB cluster and DB parameter groups. However, you can apply custom parameter groups by specifying them during a restore.

Amazon Aurora uploads log records for DB clusters to Amazon S3 continuously. To see the latest restorable time for a DB cluster, use the AWS CLI `describe-db-clusters` command and look at the value returned in the `LatestRestorableTime` field for the DB cluster.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for a DB cluster, use the AWS CLI `describe-db-clusters` command and look at the value returned in the `EarliestRestorableTime` field for the DB cluster.

**Note**
Information in this topic applies to Amazon Aurora. For information on restoring an Amazon RDS DB instance, see [Restoring a DB instance to a specified time](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_RestoreDBInstance.html).
For more information about backing up and restoring an Aurora DB cluster, see [Overview of backing up and restoring an Aurora DB cluster](https://docs.aws.amazon.com/AmazonAurora/latest/AuroraUserGuide/aurora-backup-overview.html) (p. 369).
For Aurora MySQL, you can restore a provisioned DB cluster to an Aurora Serverless DB cluster. For more information, see [Restoring an Aurora Serverless v1 DB cluster](https://docs.aws.amazon.com/AmazonAuroraServerless/latest/ServerlessUserGuide/serverless-db-clusters-backup.html) (p. 1565).

You can restore a DB cluster to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To restore a DB cluster to a specified time**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

   The **Restore to point in time** window appears.
5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

   If you chose **Custom**, enter the date and time to which you want to restore the cluster.

   **Note**
   Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.
6. For **DB instance identifier**, enter the name of the target restored DB cluster. The name must be unique.
7. Choose other options as needed, such as DB instance class.
8. For information about each setting, see [Settings for Aurora DB clusters](https://docs.aws.amazon.com/AmazonAurora/latest/AuroraUserGuide/aurora-db-cluster-settings.html) (p. 137).
9. Choose **Restore to point in time**.
AWS CLI

To restore a DB cluster to a specified time, use the AWS CLI command `restore-db-cluster-to-point-in-time` to create a new DB cluster.

You can specify other settings. For information about each setting, see Settings for Aurora DB clusters (p. 137).

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-cluster-to-point-in-time \
  --source-db-cluster-identifier mysourcedbcluster \
  --db-cluster-identifier mytargetdbcluster \
  --restore-to-time 2017-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-cluster-to-point-in-time ^
  --source-db-cluster-identifier mysourcedbcluster ^
  --db-cluster-identifier mytargetdbcluster ^
  --restore-to-time 2017-10-14T23:45:00.000Z
```

Important

If you use the console to restore a DB cluster to a specified time, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the AWS CLI to restore a DB cluster to a specified time, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

To create the primary instance for your DB cluster, call the `create-db-instance` AWS CLI command. Include the name of the DB cluster as the `--db-cluster-identifier` option value.

RDS API

To restore a DB cluster to a specified time, call the Amazon RDS API `RestoreDBClusterToPointInTime` operation with the following parameters:

- `SourceDBClusterIdentifier`
- `DBClusterIdentifier`
- `RestoreToTime`

Important

If you use the console to restore a DB cluster to a specified time, then Amazon RDS automatically creates the primary instance (writer) for your DB cluster. If you use the RDS API to restore a DB cluster to a specified time, make sure to explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

To create the primary instance for your DB cluster, call the RDS API operation `CreateDBInstance`. Include the name of the DB cluster as the `DBClusterIdentifier` parameter value.
Deleting a DB cluster snapshot

You can delete DB cluster snapshots managed by Amazon RDS when you no longer need them.

Note
To delete backups managed by AWS Backup, use the AWS Backup console. For information about AWS Backup, see the AWS Backup Developer Guide.

Deleting a DB cluster snapshot

You can delete a DB cluster snapshot using the console, the AWS CLI, or the RDS API.

To delete a shared or public snapshot, you must sign in to the AWS account that owns the snapshot.

**Console**

**To delete a DB cluster snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB cluster snapshot that you want to delete.
4. For **Actions**, choose **Delete Snapshot**.
5. Choose **Delete** on the confirmation page.

**AWS CLI**

You can delete a DB cluster snapshot by using the AWS CLI command `delete-db-cluster-snapshot`.

The following options are used to delete a DB cluster snapshot.

- `--db-cluster-snapshot-identifier` – The identifier for the DB cluster snapshot.

**Example**

The following code deletes the `mydbclustersnapshot` DB cluster snapshot.

For Linux, macOS, or Unix:

```bash
aws rds delete-db-cluster-snapshot \    
    --db-cluster-snapshot-identifier mydbclustersnapshot
```

For Windows:

```bash
aws rds delete-db-cluster-snapshot ^    
    --db-cluster-snapshot-identifier mydbclustersnapshot
```

**RDS API**

You can delete a DB cluster snapshot by using the Amazon RDS API operation `DeleteDBClusterSnapshot`.

The following parameters are used to delete a DB cluster snapshot.
• **DBClusterSnapshotIdentifier** – The identifier for the DB cluster snapshot.
Tutorial: Restore an Amazon Aurora DB cluster from a DB cluster snapshot

A common scenario when working with Amazon Aurora is to have a DB instance that you work with occasionally but that you don’t need full time. For example, you might use a DB cluster to hold the data for a report that you run only quarterly. One way to save money on such a scenario is to take a DB cluster snapshot of the DB cluster after the report is completed. Then you delete the DB cluster, and restore it when you need to upload new data and run the report during the next quarter.

When you restore a DB cluster, you provide the name of the DB cluster snapshot to restore from. You then provide a name for the new DB cluster that’s created from the restore operation. For more detailed information on restoring DB clusters from snapshots, see Restoring from a DB cluster snapshot (p. 375).

In this tutorial, we also upgrade the restored DB cluster from Aurora MySQL version 2 (compatible with MySQL 5.7) to Aurora MySQL version 3 (compatible with MySQL 8.0).

Restoring a DB cluster from a DB cluster snapshot using the Amazon RDS console

When you restore a DB cluster from a snapshot using the AWS Management Console, the primary (reader) DB instance is also created.

To restore a DB cluster from a DB cluster snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the DB cluster snapshot that you want to restore from.
4. For Actions, choose Restore snapshot.

The Restore snapshot page appears.

5. Under DB instance settings, do the following:
   a. Use the default setting for DB engine.
   b. For Available versions, choose a MySQL–8.0 compatible version, such as Aurora MySQL 3.02.0 (compatible with MySQL 8.0.23).
6. Under **Settings**, for **DB cluster identifier** enter the unique name that you want to use for the restored DB cluster, for example *my-80-cluster*.

7. Under **Connectivity**, use the default settings for the following:
   - **Virtual private cloud (VPC)**
   - **Subnet group**
   - **Public access**
   - **VPC security group**

8. Choose the **DB instance class**.
   
   For this tutorial, choose **Burstable classes (includes t classes)**, and then choose **db.t3.medium**.
9. For **Database authentication**, use the default setting.

10. For **Encryption**, use the default settings.

   If the source DB cluster for the snapshot was encrypted, the restored DB cluster is also encrypted. You can't make it unencrypted.

11. Expand **Additional configuration** at the bottom of the page.

12. Make the following choices:

   a. For this tutorial, use the default value for **DB cluster parameter group**.

   b. For this tutorial, use the default value for **DB parameter group**.

   c. For **Log exports**, select all of the check boxes.
d. For **Deletion protection**, select the **Enable deletion protection** check box.

13. Choose **Restore DB instance**.

The **Databases** page displays the restored DB cluster, with a status of **Creating**.

While the primary DB instance is being created, it appears as a reader instance, but after creation it's a writer instance.

### Restoring a DB cluster from a DB cluster snapshot using the AWS CLI

Restoring a DB cluster from a snapshot using the AWS CLI has two steps:

1. Restore the DB cluster using the `restore-db-cluster-from-snapshot` command.
2. Create the primary (writer) DB instance using the `create-db-instance` command.

### Restoring the DB cluster

You use the `restore-db-cluster-from-snapshot` command. The following options are required:

- `--db-cluster-identifier` – The name of the restored DB cluster.
- `--snapshot-identifier` – The name of the DB snapshot to restore from.
- `--engine` – The database engine of the restored DB cluster. It must be compatible with the database engine of the source DB cluster.

The choices are the following:

- `aurora` – Aurora MySQL 5.6 compatible.
- `aurora-mysql` – Aurora MySQL 5.7 and 8.0 compatible.
- `aurora-postgresql` – Aurora PostgreSQL compatible.

In this example, we use `aurora-mysql`.

- `--engine-version` – The version of the restored DB cluster. In this example, we use a MySQL-8.0 compatible version.

The following example restores an Aurora MySQL 8.0–compatible DB cluster named `my-new-80-cluster` from a DB cluster snapshot named `my-57-cluster-snapshot`.

### To restore the DB cluster

- Use one of the following commands.

  For Linux, macOS, or Unix:
aws rds restore-db-cluster-from-snapshot \
--db-cluster-identifier my-new-80-cluster \
--snapshot-identifier my-57-cluster-snapshot \
--engine aurora-mysql \
--engine-version 8.0.mysql_aurora.3.02.0

For Windows:

aws rds restore-db-cluster-from-snapshot ^
--db-cluster-identifier my-new-80-cluster ^
--snapshot-identifier my-57-cluster-snapshot ^
--engine aurora-mysql ^
--engine-version 8.0.mysql_aurora.3.02.0

The output resembles the following.

```json
{
  "DBCluster": {
    "AllocatedStorage": 1,
    "AvailabilityZones": [
      "eu-central-1b",
      "eu-central-1c",
      "eu-central-1a"
    ],
    "BackupRetentionPeriod": 14,
    "DatabaseName": "",
    "DBClusterIdentifier": "my-new-80-cluster",
    "DBClusterParameterGroup": "default.aurora-mysql8.0",
    "DBSubnetGroup": "default",
    "Status": "creating",
    "Endpoint": "my-new-80-cluster.cluster-############.eu-central-1.rds.amazonaws.com",
    "ReaderEndpoint": "my-new-80-cluster.cluster-ro-############.eu-central-1.rds.amazonaws.com",
    "MultiAZ": false,
    "Engine": "aurora-mysql",
    "EngineVersion": "8.0.mysql_aurora.3.02.0",
    "Port": 3306,
    "MasterUsername": "admin",
    "PreferredBackupWindow": "01:55-02:25",
    "ReadReplicaIdentifiers": [],
    "DBClusterMembers": [],
    "VpcSecurityGroups": [
      {
        "VpcSecurityGroupId": "sg-########",
        "Status": "active"
      }
    ],
    "HostedZoneId": "Z1RLNU0EXAMPLE",
    "StorageEncrypted": true,
    "KmsKeyId": "arn:aws:kms:eu-central-1:123456789012:key/######-5ccc-49cc-8aa-#####",
    "DBClusterResourceId": "cluster-ZZ12345678ITSJUSTANEXAMPLE",
    "AssociatedRoles": [],
    "IAMDatabaseAuthenticationEnabled": false,
    "ClusterCreateTime": "2022-07-05T20:45:42.171000+00:00",
    "EngineMode": "provisioned",
    "DeletionProtection": false,
    "HttpEndpointEnabled": false,
  }
}
```
Creating the primary (writer) DB instance

To create the primary (writer) DB instance, you use the `create-db-instance` command. The following options are required:

- `--db-cluster-identifier` – The name of the restored DB cluster.
- `--db-instance-identifier` – The name of the primary DB instance.
- `--db-instance-class` – The instance class of the primary DB instance. In this example, we use `db.t3.medium`.
- `--engine` – The database engine of the primary DB instance. It must be the same database engine as the restored DB cluster uses.

The choices are the following:

- `aurora` – Aurora MySQL 5.6 compatible.
- `aurora-mysql` – Aurora MySQL 5.7 and 8.0 compatible.
- `aurora-postgresql` – Aurora PostgreSQL compatible.

In this example, we use `aurora-mysql`.

The following example creates a primary (writer) DB instance named `my-new-80-cluster-instance` in the restored Aurora MySQL 8.0–compatible DB cluster named `my-new-80-cluster`.

To create the primary DB instance

- Use one of the following commands.

  For Linux, macOS, or Unix:

  ```bash
  aws rds create-db-instance \
  --db-cluster-identifier my-new-80-cluster \
  --db-instance-identifier my-new-80-cluster-instance \
  --db-instance-class db.t3.medium \
  --engine aurora-mysql
  ```

  For Windows:

  ```bash
  aws rds create-db-instance ^
  --db-cluster-identifier my-new-80-cluster ^
  --db-instance-identifier my-new-80-cluster-instance ^
  --db-instance-class db.t3.medium ^
  --engine aurora-mysql
  ```

  The output resembles the following.

  ```json
  {
    "DBInstance": {
      "DBInstanceIdentifier": "my-new-80-cluster-instance",
      "DBInstanceClass": "db.t3.medium",
    }
  }
  ```
"Engine": "aurora-mysql",
"DBInstanceStatus": "creating",
"MasterUsername": "admin",
"AllocatedStorage": 1,
"PreferredBackupWindow": "01:55-02:25",
"BackupRetentionPeriod": 14,
"DBSecurityGroups": [],
"VpcSecurityGroups": [
  {
    "VpcSecurityGroupId": "sg-########",
    "Status": "active"
  }
],
"DBParameterGroups": [
  {
    "DBParameterGroupName": "default.aurora-mysql8.0",
    "ParameterApplyStatus": "in-sync"
  }
],
"DBSubnetGroup": {
  "DBSubnetGroupName": "default",
  "DBSubnetGroupDescription": "default",
  "VpcId": "vpc-2305ca49",
  "SubnetGroupStatus": "Complete",
  "Subnets": [
    {
      "SubnetIdentifier": "subnet-########",
      "SubnetAvailabilityZone": {
        "Name": "eu-central-1a"
      },

Monitoring metrics in an Amazon Aurora cluster

Amazon Aurora uses a cluster of replicated database servers. Typically, monitoring an Aurora cluster requires checking the health of multiple DB instances. The instances might have specialized roles, handling mostly write operations, only read operations, or a combination. You also monitor the overall health of the cluster by measuring the replication lag. This is the amount of time for changes made by one DB instance to be available to the other instances.

Topics
- Overview of monitoring metrics in Amazon Aurora (p. 428)
- Viewing cluster status and recommendations (p. 432)
- Viewing metrics in the Amazon RDS console (p. 449)
- Monitoring Amazon Aurora metrics with Amazon CloudWatch (p. 452)
- Monitoring DB load with Performance Insights on Amazon Aurora (p. 461)
- Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS (p. 512)
- Monitoring OS metrics with Enhanced Monitoring (p. 518)
- Metrics reference for Amazon Aurora (p. 525)
Overview of monitoring metrics in Amazon Aurora

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your AWS solutions. To more easily debug multi-point failures, we recommend that you collect monitoring data from all parts of your AWS solution.

Topics
- Monitoring plan (p. 428)
- Performance baseline (p. 428)
- Performance guidelines (p. 428)
- Monitoring tools (p. 429)

Monitoring plan

Before you start monitoring Amazon Aurora, create a monitoring plan. This plan should answer the following questions:

- What are your monitoring goals?
- Which resources will you monitor?
- How often will you monitor these resources?
- Which monitoring tools will you use?
- Who will perform the monitoring tasks?
- Whom should be notified when something goes wrong?

Performance baseline

To achieve your monitoring goals, you need to establish a baseline. To do this, measure performance under different load conditions at various times in your Amazon Aurora environment. You can monitor metrics such as the following:

- Network throughput
- Client connections
- I/O for read, write, or metadata operations
- Burst credit balances for your DB instances

We recommend that you store historical performance data for Amazon Aurora. Using the stored data, you can compare current performance against past trends. You can also distinguish normal performance patterns from anomalies, and devise techniques to address issues.

Performance guidelines

In general, acceptable values for performance metrics depend on what your application is doing relative to your baseline. Investigate consistent or trending variances from your baseline. The following metrics are often the source of performance issues:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate, if they're in keeping with your goals for your application (like throughput or concurrency) and are expected.
• **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.

• **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.

• **Database connections** – If you see high numbers of user connections and also decreases in instance performance and response time, consider constraining database connections. The best number of user connections for your DB instance varies based on your instance class and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group where the User Connections parameter is set to a value other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see Working with parameter groups (p. 215).

• **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure that your typical working set fits into memory to minimize read and write operations.

When performance falls outside your established baseline, you might need to make changes to optimize your database availability for your workload. For example, you might need to change the instance class of your DB instance. Or you might need to change the number of DB instances and read replicas that are available for clients.

### Monitoring tools

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your other AWS solutions. AWS provides various monitoring tools to watch Amazon Aurora, report when something is wrong, and take automatic actions when appropriate.

**Topics**

- Automated monitoring tools (p. 429)
- Manual monitoring tools (p. 430)

### Automated monitoring tools

We recommend that you automate monitoring tasks as much as possible.

**Topics**

- Amazon Aurora cluster status and recommendations (p. 429)
- Amazon CloudWatch metrics for Amazon Aurora (p. 430)
- Amazon RDS Performance Insights and operating-system monitoring (p. 430)
- Integrated services (p. 430)

### Amazon Aurora cluster status and recommendations

You can use the following automated tools to watch Amazon Aurora and report when something is wrong:

- **Amazon Aurora cluster status** — View details about the current status of your cluster by using the Amazon RDS console, the AWS CLI, or the RDS API.
• **Amazon Aurora recommendations** — Respond to automated recommendations for database resources, such as DB instances, DB clusters, and DB cluster parameter groups. For more information, see Viewing Amazon Aurora recommendations (p. 444).

### Amazon CloudWatch metrics for Amazon Aurora

Amazon Aurora integrates with Amazon CloudWatch for additional monitoring capabilities.

- **Amazon CloudWatch** – This service monitors your AWS resources and the applications you run on AWS in real time. You can use the following Amazon CloudWatch features with Amazon Aurora:
  - **Amazon CloudWatch metrics** – Amazon Aurora automatically sends metrics to CloudWatch every minute for each active database. You don’t get additional charges for Amazon RDS metrics in CloudWatch. For more information, see Amazon CloudWatch metrics for Amazon Aurora (p. 525).
  - **Amazon CloudWatch alarms** – You can watch a single Amazon Aurora metric over a specific time period. You can then perform one or more actions based on the value of the metric relative to a threshold that you set.

### Amazon RDS Performance Insights and operating-system monitoring

You can use the following automated tools to monitor Amazon Aurora performance:

- **Amazon RDS Performance Insights** – Assess the load on your database, and determine when and where to take action. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 461).
  - **Amazon RDS Enhanced Monitoring** – Look at metrics in real time for the operating system. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 518).

### Integrated services

The following AWS services are integrated with Amazon Aurora:

- **Amazon EventBridge** is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. For more information, see Monitoring Amazon Aurora events (p. 568).
- **Amazon CloudWatch Logs** lets you monitor, store, and access your log files from Amazon Aurora instances, CloudTrail, and other sources. For more information, see Monitoring Amazon Aurora log files (p. 597).
- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information, see Monitoring Amazon Aurora API calls in AWS CloudTrail (p. 615).
- **Database Activity Streams** is an Amazon Aurora feature that provides a near-real-time stream of the activity in your DB cluster. For more information, see Monitoring Amazon Aurora with Database Activity Streams (p. 619).
- **DevOps Guru for RDS** is a capability of Amazon DevOps Guru that applies machine learning to Performance Insights metrics for Amazon Aurora databases. For more information, see Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS (p. 512).

### Manual monitoring tools

You need to manually monitor those items that the CloudWatch alarms don't cover. The Amazon RDS, CloudWatch, AWS Trusted Advisor and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your DB instance.
• From the Amazon RDS console, you can monitor the following items for your resources:
  • The number of connections to a DB instance
  • The amount of read and write operations to a DB instance
  • The amount of storage that a DB instance is currently using
  • The amount of memory and CPU being used for a DB instance
  • The amount of network traffic to and from a DB instance
• From the Trusted Advisor dashboard, you can review the following cost optimization, security, fault
  tolerance, and performance improvement checks:
  • Amazon RDS Idle DB Instances
  • Amazon RDS Security Group Access Risk
  • Amazon RDS Backups
  • Amazon RDS Multi-AZ
  • Aurora DB Instance Accessibility

For more information on these checks, see Trusted Advisor best practices (checks).
• CloudWatch home page shows:
  • Current alarms and status
  • Graphs of alarms and resources
  • Service health status

In addition, you can use CloudWatch to do the following:
  • Create customized dashboards to monitor the services that you care about.
  • Graph metric data to troubleshoot issues and discover trends.
  • Search and browse all your AWS resource metrics.
  • Create and edit alarms to be notified of problems.
Viewing cluster status and recommendations

Using the Amazon RDS console, you can quickly access the status of your DB cluster and respond to Amazon Aurora recommendations.

Topics
- Viewing an Amazon Aurora DB cluster (p. 433)
- Viewing DB cluster status (p. 439)
- Viewing DB instance status in an Aurora cluster (p. 441)
- Viewing Amazon Aurora recommendations (p. 444)
Viewing an Amazon Aurora DB cluster

You have several options for viewing information about your Amazon Aurora DB clusters and the DB instances in your DB clusters.

- You can view DB clusters and DB instances in the Amazon RDS console by choosing **Databases** from the navigation pane.
- You can get DB cluster and DB instance information using the AWS Command Line Interface (AWS CLI).
- You can get DB cluster and DB instance information using the Amazon RDS API.

**Console**

In the Amazon RDS console, you can see details about a DB cluster by choosing **Databases** from the console's navigation pane. You can also see details about DB instances that are members of an Amazon Aurora DB cluster.

**To view or modify DB clusters in the Amazon RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the name of the Aurora DB cluster that you want to view from the list.

   For example, the following image shows the details page for the DB cluster named *aurora-test*. The DB cluster has four DB instances shown in the DB identifier list. The writer DB instance, *dbinstance4*, is the primary DB instance for the DB cluster.
4. To modify a DB cluster, select the DB cluster from the list and choose **Modify**.

**To view or modify DB instances of a DB cluster in the Amazon RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Do one of the following:
   - To view a DB instance, choose one from the list that is a member of the Aurora DB cluster.
     
     For example, if you choose the `dbinstance4` DB instance identifier, the console shows the details page for the `dbinstance4` DB instance, as shown in the following image.
To modify a DB instance, choose the DB instance from the list and choose **Modify**. For more information about modifying a DB cluster, see **Modifying an Amazon Aurora DB cluster** (p. 248).

**AWS CLI**

To view DB cluster information by using the AWS CLI, use the `describe-db-clusters` command. For example, the following AWS CLI command lists the DB cluster information for all of the DB clusters in the `us-east-1` region for the configured AWS account.

```bash
aws rds describe-db-clusters --region us-east-1
```

The command returns the following output if your AWS CLI is configured for JSON output.

```json
{
    "DBClusters": [
        {
            "Status": "available",

"PreferredMaintenanceWindow": "sun:03:53-sun:04:23"
}

RDS API

To view DB cluster information using the Amazon RDS API, use the DescribeDBClusters operation. For example, the following Amazon RDS API command lists the DB cluster information for all of the DB clusters in the us-east-1 region.

https://rds.us-east-1.amazonaws.com/
?Action=DescribeDBClusters
&MaxRecords=100
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIAIQKE4SARGYLE/20140722/us-east-1/rds/aws4_request
&X-Amz-Date=20140722T200807Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=2d4f2b9e8abc31122b546f94c0499bba47de813cb875f9b0c78e8e1959afe1b

The action returns the following output:

  <DescribeDBClustersResult>
    <DBClusters>
      <DBCluster>
        <Engine>aurora5.6</Engine>
        <Status>available</Status>
        <BackupRetentionPeriod>0</BackupRetentionPeriod>
        <DBSubnetGroup>my-subgroup</DBSubnetGroup>
        <EngineVersion>5.6.10a</EngineVersion>

</DescribeDBClustersResponse>
Viewing DB cluster status

The status of a DB cluster indicates its health. You can view the status of a DB cluster and the cluster instances by using the Amazon RDS console, the AWS CLI, or the API.

**Note**
Aurora also uses another status called *maintenance status*, which is shown in the *Maintenance* column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB cluster. Maintenance status is independent of DB cluster status. For more information about maintenance status, see *Applying updates for a DB cluster* (p. 323).

**To view the status of a DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.

The **Databases page** appears with the list of DB clusters. For each DB cluster, the status value is displayed.

Find the possible status values for DB clusters in the following table.

<table>
<thead>
<tr>
<th>DB cluster status</th>
<th>Billed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>available</td>
<td>Billed</td>
<td>The DB cluster is healthy and available. When an Aurora Serverless cluster is available and paused, you're billed for storage only.</td>
</tr>
<tr>
<td>backing-up</td>
<td>Billed</td>
<td>The DB cluster is currently being backed up.</td>
</tr>
<tr>
<td>backtracking</td>
<td>Billed</td>
<td>The DB cluster is currently being backtracked. This status only applies to Aurora MySQL.</td>
</tr>
<tr>
<td>cloning-failed</td>
<td>Not billed</td>
<td>Cloning a DB cluster failed.</td>
</tr>
<tr>
<td>creating</td>
<td>Not billed</td>
<td>The DB cluster is being created. The DB cluster is inaccessible while it is being created.</td>
</tr>
<tr>
<td>deleting</td>
<td>Not billed</td>
<td>The DB cluster is being deleted.</td>
</tr>
<tr>
<td>DB cluster status</td>
<td>Billed</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>failing-over</td>
<td>Billed</td>
<td>A failover from the primary instance to an Aurora Replica is being performed.</td>
</tr>
<tr>
<td>inaccessible-encryption-credentials</td>
<td>Not billed</td>
<td>The AWS KMS key used to encrypt or decrypt the DB cluster can't be accessed or recovered.</td>
</tr>
</tbody>
</table>
| inaccessible-encryption-credentials-recoverable | Billed for storage | The KMS key used to encrypt or decrypt the DB cluster can't be accessed. However, if the KMS key is active, restarting the DB cluster can recover it.  
For more information, see Encrypting an Amazon Aurora DB cluster (p. 1638). |
| maintenance               | Billed     | Amazon RDS is applying a maintenance update to the DB cluster. This status is used for DB cluster-level maintenance that RDS schedules well in advance. |
| migrating                 | Billed     | A DB cluster snapshot is being restored to a DB cluster.                                                                                     |
| migration-failed          | Not billed | A migration failed.                                                                                                                          |
| modifying                 | Billed     | The DB cluster is being modified because of a customer request to modify the DB cluster.                                                    |
| promoting                 | Billed     | A read replica is being promoted to a standalone DB cluster.                                                                                    |
| renaming                  | Billed     | The DB cluster is being renamed because of a customer request to rename it.                                                                  |
| resetting-master-credentials | Billed   | The master credentials for the DB cluster are being reset because of a customer request to reset them.                                        |
| starting                  | Billed for storage | The DB cluster is starting.                                                                                                               |
| stopped                   | Billed for storage | The DB cluster is stopped.                                                                                                                |
| stopping                  | Billed for storage | The DB cluster is being stopped.                                                                                                         |
| storage-optimization       | Billed     | Your DB instance is being modified to change the storage size or type. The DB instance is fully operational. However, while the status of your DB instance is storage-optimization, you can't request any changes to the storage of your DB instance. The storage optimization process is usually short, but can sometimes take up to and even beyond 24 hours. |
| update-iam-db-auth         | Billed     | IAM authorization for the DB cluster is being updated.                                                                                     |
| upgrading                 | Billed     | The DB cluster engine version is being upgraded.                                                                                           |
Viewing DB instance status in an Aurora cluster

The status of a DB instance in an Aurora cluster indicates the health of the DB instance. You can view the status of a DB instance in a cluster by using the Amazon RDS console, the AWS CLI command `describe-db-instances`, or the API operation `DescribeDBInstances`.

**Note**

Amazon RDS also uses another status called *maintenance status*, which is shown in the **Maintenance** column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB instance. Maintenance status is independent of DB instance status. For more information about maintenance status, see Applying updates for a DB cluster (p. 323).

**To view the status of a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

The **Databases page** appears with the list of DB instances. For each DB instance in a cluster, the status value is displayed.

Find the possible status values for DB instances in the following table. This table also shows whether you will be billed for the DB instance and storage, billed only for storage, or not billed. For all DB instance statuses, you are always billed for backup usage.

<table>
<thead>
<tr>
<th>DB instance status</th>
<th>Billed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>available</td>
<td>Billed</td>
<td>The DB instance is healthy and available.</td>
</tr>
<tr>
<td>backing-up</td>
<td>Billed</td>
<td>The DB instance is currently being backed up.</td>
</tr>
<tr>
<td>backtracking</td>
<td>Billed</td>
<td>The DB instance is currently being backtracked. This status only applies to Aurora MySQL.</td>
</tr>
<tr>
<td>configuring-enhanced-monitoring</td>
<td>Billed</td>
<td>Enhanced Monitoring is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>configuring-iam-database-auth</td>
<td>Billed</td>
<td>AWS Identity and Access Management (IAM) database authentication is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>configuring-log-exports</td>
<td>Billed</td>
<td>Publishing log files to Amazon CloudWatch Logs is being enabled or disabled for this DB instance.</td>
</tr>
<tr>
<td>DB instance status</td>
<td>Billed</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>converting-to-vpc</td>
<td>Billed</td>
<td>The DB instance is being converted from a DB instance that is not in an Amazon Virtual Private Cloud (Amazon VPC) to a DB instance that is in an Amazon VPC.</td>
</tr>
<tr>
<td>creating</td>
<td>Not billed</td>
<td>The DB instance is being created. The DB instance is inaccessible while it is being created.</td>
</tr>
<tr>
<td>deleting</td>
<td>Not billed</td>
<td>The DB instance is being deleted.</td>
</tr>
<tr>
<td>failed</td>
<td>Not billed</td>
<td>The DB instance has failed and Amazon RDS can't recover it. Perform a point-in-time restore to the latest restorable time of the DB instance to recover the data.</td>
</tr>
<tr>
<td>inaccessible-encryption-credentials</td>
<td>Not billed</td>
<td>The AWS KMS key used to encrypt or decrypt the DB instance can't be accessed or recovered.</td>
</tr>
<tr>
<td>incompatible-network</td>
<td>Not billed</td>
<td>Amazon RDS is attempting to perform a recovery action on a DB instance but can't do so because the VPC is in a state that prevents the action from being completed. This status can occur if, for example, all available IP addresses in a subnet are in use and Amazon RDS can't get an IP address for the DB instance.</td>
</tr>
<tr>
<td>incompatible-option-group</td>
<td>Billed</td>
<td>Amazon RDS attempted to apply an option group change but can't do so, and Amazon RDS can't roll back to the previous option group state. For more information, check the Recent Events list for the DB instance. This status can occur if, for example, the option group contains an option such as TDE and the DB instance doesn't contain encrypted information.</td>
</tr>
<tr>
<td>incompatible-parameters</td>
<td>Billed</td>
<td>Amazon RDS can't start the DB instance because the parameters specified in the DB instance's DB parameter group aren't compatible with the DB instance. Revert the parameter changes or make them compatible with the DB instance to regain access to your DB instance. For more information about the incompatible parameters, check the Recent Events list for the DB instance.</td>
</tr>
<tr>
<td>incompatible-restore</td>
<td>Not billed</td>
<td>Amazon RDS can't do a point-in-time restore. Common causes for this status include using temp tables or using MyISAM tables with MySQL.</td>
</tr>
<tr>
<td>insufficient-capacity</td>
<td>Not billed</td>
<td>Amazon RDS can’t create your instance because sufficient capacity isn’t currently available. To create your DB instance in the same AZ with the same instance type, delete your DB instance, wait a few hours, and try to create again. Alternatively, create a new instance using a different instance class or AZ.</td>
</tr>
<tr>
<td>maintenance</td>
<td>Billed</td>
<td>Amazon RDS is applying a maintenance update to the DB instance. This status is used for instance-level maintenance that RDS schedules well in advance.</td>
</tr>
<tr>
<td>DB instance status</td>
<td>Billed</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>modifying</td>
<td>Billed</td>
<td>The DB instance is being modified because of a customer request to modify the DB instance.</td>
</tr>
<tr>
<td>moving-to-vpc</td>
<td>Billed</td>
<td>The DB instance is being moved to a new Amazon Virtual Private Cloud (Amazon VPC).</td>
</tr>
<tr>
<td>rebooting</td>
<td>Billed</td>
<td>The DB instance is being rebooted because of a customer request or an Amazon RDS process that requires the rebooting of the DB instance.</td>
</tr>
<tr>
<td>resetting-master-credentials</td>
<td>Billed</td>
<td>The master credentials for the DB instance are being reset because of a customer request to reset them.</td>
</tr>
<tr>
<td>renaming</td>
<td>Billed</td>
<td>The DB instance is being renamed because of a customer request to rename it.</td>
</tr>
<tr>
<td>restore-error</td>
<td>Billed</td>
<td>The DB instance encountered an error attempting to restore to a point-in-time or from a snapshot.</td>
</tr>
<tr>
<td>starting</td>
<td>Billed</td>
<td>The DB instance is starting.</td>
</tr>
<tr>
<td>stopped</td>
<td>Billed</td>
<td>The DB instance is stopped.</td>
</tr>
<tr>
<td>stopping</td>
<td>Billed</td>
<td>The DB instance is being stopped.</td>
</tr>
<tr>
<td>storage-full</td>
<td>Billed</td>
<td>The DB instance has reached its storage capacity allocation. This is a critical status, and we recommend that you fix this issue immediately. To do so, scale up your storage by modifying the DB instance. To avoid this situation, set Amazon CloudWatch alarms to warn you when storage space is getting low.</td>
</tr>
<tr>
<td>storage-optimization</td>
<td>Billed</td>
<td>Amazon RDS is optimizing the storage of your DB instance. The DB instance is fully operational. The storage optimization process is usually short, but can sometimes take up to and even beyond 24 hours.</td>
</tr>
<tr>
<td>upgrading</td>
<td>Billed</td>
<td>The database engine version is being upgraded.</td>
</tr>
</tbody>
</table>
Viewing Amazon Aurora recommendations

Amazon Aurora provides automated recommendations for database resources, such as DB instances, DB clusters, and DB cluster parameter groups. These recommendations provide best practice guidance by analyzing DB cluster configuration, DB instance configuration, usage, and performance data.

You can find examples of these recommendations in the following table.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Recommendation</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nondefault custom memory parameters</td>
<td>Your DB parameter group sets memory parameters that diverge too much from the default values.</td>
<td>Settings that diverge too much from the default values can cause poor performance and errors. We recommend setting custom memory parameters to their default values in the DB parameter group used by the DB instance.</td>
<td>Working with parameter groups (p. 215)</td>
</tr>
<tr>
<td>Change buffering enabled for a MySQL DB instance</td>
<td>Your DB parameter group has change buffering enabled.</td>
<td>Change buffering allows a MySQL DB instance to defer some writes necessary to maintain secondary indexes. This configuration can improve performance slightly, but it can create a large delay in crash recovery. During crash recovery, the secondary index must be brought up to date. So, the benefits of change buffering are outweighed by the potentially very long crash recovery events. We recommend disabling change buffering.</td>
<td>Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog</td>
</tr>
<tr>
<td>Logging to table</td>
<td>Your DB parameter group sets logging output to TABLE.</td>
<td>Setting logging output to TABLE uses more storage than setting this parameter to FILE. To avoid reaching the storage limit, we recommend setting the logging output parameter to FILE.</td>
<td>Aurora MySQL database log files (p. 604)</td>
</tr>
<tr>
<td>DB cluster with one DB instance</td>
<td>Your DB cluster only contains one DB instance.</td>
<td>For improved performance and availability, we recommend adding another DB instance with the same DB instance class in a different Availability Zone.</td>
<td>High availability for Amazon Aurora (p. 71)</td>
</tr>
<tr>
<td>DB cluster in one Availability Zone</td>
<td>Your DB cluster has all of its DB instances in the same Availability Zone.</td>
<td>For improved availability, we recommend adding another DB instance with the same DB instance class in a different Availability Zone.</td>
<td>High availability for Amazon Aurora (p. 71)</td>
</tr>
<tr>
<td>DB cluster outdated</td>
<td>Your DB cluster is running an older engine version.</td>
<td>We recommend that you keep your DB cluster at the most current minor version because it includes the latest security and functionality fixes. Unlike major version upgrades, minor version upgrades include only changes</td>
<td>Maintaining an Amazon Aurora DB cluster (p. 321)</td>
</tr>
</tbody>
</table>
Amazon Aurora generates recommendations for a resource when the resource is created or modified. Amazon Aurora also periodically scans your resources and generates recommendations.

**To view Amazon Aurora recommendations**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Recommendations.
Viewing Amazon Aurora recommendations

3. On the **Recommendations** page, choose one of the following:

- **Active** – Shows the current recommendations that you can apply, dismiss, or schedule.
- **Dismissed** – Shows the recommendations that have been dismissed. When you choose **Dismissed**, you can apply these dismissed recommendations.
- **Scheduled** – Shows the recommendations that are scheduled but not yet applied. These recommendations will be applied in the next scheduled maintenance window.
- **Applied** – Shows the recommendations that are currently applied.
From any list of recommendations, you can open a section to view the recommendations in that section.

To configure preferences for displaying recommendations in each section, choose the Preferences icon.

From the Preferences window that appears, you can set display options. These options include the visible columns and the number of recommendations to display on the page.

4. (optional) Respond to your active recommendations as follows:
   a. Choose Active and open one or more sections to view the recommendations in them.
   b. Choose one or more recommendations and choose Apply now (to apply them immediately), Schedule (to apply them in next maintenance window), or Dismiss.

   If the Apply now button appears for a recommendation but is unavailable (grayed out), the DB instance is not available. You can apply recommendations immediately only if the DB instance status is available. For example, you can't apply recommendations immediately to the DB
instance if its status is **modifying**. In this case, wait for the DB instance to be available and then apply the recommendation.

If the **Apply now** button doesn't appear for a recommendation, you can't apply the recommendation using the **Recommendations** page. You can modify the DB instance to apply the recommendation manually.

For more information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](p. 248).

**Note**

When you choose **Apply now**, a brief DB instance outage might result.
Viewing metrics in the Amazon RDS console

Amazon RDS integrates with Amazon CloudWatch to display a variety of Aurora DB cluster metrics in the RDS console. Some metrics are apply at the cluster level, whereas others apply at the instance level. For descriptions of the instance-level and cluster-level metrics, see Metrics reference for Amazon Aurora (p. 525).

The Monitoring tab for your Aurora DB cluster shows the following categories of metrics:

- **CloudWatch** – Shows the Amazon CloudWatch metrics for Aurora that you can access in the RDS console. You can also access these metrics in the CloudWatch console. Each metric includes a graph that shows the metric monitored over a specific time span. For a list of CloudWatch metrics, see Amazon CloudWatch metrics for Amazon Aurora (p. 525).

- **Enhanced monitoring** – Shows a summary of operating-system metrics when your Aurora DB cluster has turned on Enhanced Monitoring. RDS delivers the metrics from Enhanced Monitoring to your Amazon CloudWatch Logs account. Each OS metric includes a graph showing the metric monitored over a specific time span. For an overview, see Monitoring OS metrics with Enhanced Monitoring (p. 518). For a list of Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 558).

- **OS Process list** – Shows details for each process running in your DB cluster.

- **Performance Insights** – Opens the Amazon RDS Performance Insights dashboard for a DB instance in your Aurora DB cluster. Performance Insights isn't supported at the cluster level. For an overview of Performance Insights, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 461). For a list of Performance Insights metrics, see Amazon CloudWatch metrics for Performance Insights (p. 544).

To view metrics for your Aurora DB cluster in the RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the name of the Aurora DB cluster that you want to monitor.

The database page appears. The following example shows an Amazon Aurora PostgreSQL database named apga.
4. Scroll down and choose **Monitoring**.

The monitoring section appears. By default, CloudWatch metrics are shown. For descriptions of these metrics, see *Amazon CloudWatch metrics for Amazon Aurora* (p. 525).

5. Choose **Monitoring** to see the metric categories.

6. Choose the category of metrics that you want to see.

The following example shows Enhanced Monitoring metrics. For descriptions of these metrics, see *OS metrics in Enhanced Monitoring* (p. 558).
Tip
To choose the time range of the metrics represented by the graphs, you can use the time range list.
To bring up a more detailed view, you can choose any graph. You can also apply metric-specific filters to the data.
Monitoring Amazon Aurora metrics with Amazon CloudWatch

Amazon CloudWatch is a metrics repository. The repository collects and processes raw data from Amazon Aurora into readable, near real-time metrics. For a complete list of Amazon Aurora metrics sent to CloudWatch, see Metrics reference for Amazon Aurora.

Topics
- Overview of Amazon Aurora and Amazon CloudWatch (p. 453)
- Viewing DB cluster metrics in the CloudWatch console and AWS CLI (p. 454)
- Creating CloudWatch alarms to monitor Amazon Aurora (p. 459)
Overview of Amazon Aurora and Amazon CloudWatch

By default, Amazon Aurora automatically sends metric data to CloudWatch in 1-minute periods. For example, the CPUUtilization metric records the percentage of CPU utilization for a DB instance over time. Data points with a period of 60 seconds (1 minute) are available for 15 days. This means that you can access historical information and see how your web application or service is performing.

As shown in the following diagram, you can set up alarms for your CloudWatch metrics. For example, you might create an alarm that signals when the CPU utilization for an instance is over 70%. You can configure Amazon Simple Notification Service to email you when the threshold is passed.

Amazon RDS publishes the following types of metrics to Amazon CloudWatch:

- Aurora metrics at both the cluster and instance level

  For a table of these metrics, see Amazon CloudWatch metrics for Amazon Aurora (p. 525).

- Performance Insights metrics
For a table of these metrics, see Amazon CloudWatch metrics for Performance Insights (p. 544) and Performance Insights counter metrics (p. 546).

- Enhanced Monitoring metrics (published to Amazon CloudWatch Logs)

  For a table of these metrics, see OS metrics in Enhanced Monitoring (p. 558).

- Usage metrics for the Amazon RDS service quotas in your AWS account

  For a table of these metrics, see Amazon CloudWatch usage metrics for Amazon Aurora (p. 541). For more information about Amazon RDS quotas, see Quotas and constraints for Amazon Aurora (p. 1755).

For more information about CloudWatch, see What is Amazon CloudWatch? in the Amazon CloudWatch User Guide. For more information about CloudWatch metrics retention, see Metrics retention.

**Viewing DB cluster metrics in the CloudWatch console and AWS CLI**

Following, you can find details about how to view metrics for your DB instance using CloudWatch. For information on monitoring metrics for your DB instance's operating system in real time using CloudWatch Logs, see Monitoring OS metrics with Enhanced Monitoring (p. 518).

When you use Amazon Aurora resources, Amazon Aurora sends metrics and dimensions to Amazon CloudWatch every minute. You can use the following procedures to view the metrics for Amazon Aurora in the CloudWatch console and CLI.

**Console**

**To view metrics using the Amazon CloudWatch console**

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

   The CloudWatch overview home page appears.
2. If necessary, change the AWS Region. From the navigation bar, choose the AWS Region where your AWS resources are. For more information, see Regions and endpoints.

3. In the navigation pane, choose Metrics and then All metrics.

4. Scroll down and choose the RDS metric namespace.

The page displays the Amazon Aurora dimensions. For descriptions of these dimensions, see Amazon CloudWatch dimensions for Aurora (p. 541).

5. Choose a metric dimension, for example By Database Class.
6. Do any of the following actions:

- To sort the metrics, use the column heading.
- To graph a metric, select the check box next to the metric.
- To filter by resource, choose the resource ID, and then choose Add to search.
- To filter by metric, choose the metric name, and then choose Add to search.

The following example filters on the `db.t3.medium` class and graphs the CPUUtilization metric.
**AWS CLI**

To obtain metric information by using the AWS CLI, use the CloudWatch command `list-metrics`. In the following example, you list all metrics in the `AWS/RDS` namespace.

```bash
aws cloudwatch list-metrics --namespace AWS/RDS
```

To obtain metric statistics, use the command `get-metric-statistics`. The following command gets `CPUUtilization` statistics for instance `my-instance` over the specific 24-hour period, with a 5-minute granularity.

**Example**

For Linux, macOS, or Unix:

```bash
aws cloudwatch get-metric-statistics --namespace AWS/RDS
   --metric-name CPUUtilization
   --start-time 2021-12-15T00:00:00Z
   --end-time 2021-12-16T00:00:00Z
   --period 360
   --statistics Minimum
   --dimensions Name=DBInstanceIdentifier,Value=my-instance
```

For Windows:

```bash
aws cloudwatch get-metric-statistics --namespace AWS/RDS
   --metric-name CPUUtilization
   --start-time 2021-12-15T00:00:00Z
   --end-time 2021-12-16T00:00:00Z
   --period 360
   --statistics Minimum
   --dimensions Name=DBInstanceIdentifier,Value=my-instance
```

Sample output appears as follows:

```json
{
   "Datapoints": [
      {
         "Timestamp": "2021-12-15T18:00:00Z",
         "Minimum": 8.7,
         "Unit": "Percent"
      },
      {
         "Timestamp": "2021-12-15T23:54:00Z",
         "Minimum": 8.12486458559024,
         "Unit": "Percent"
      },
      {
         "Timestamp": "2021-12-15T17:24:00Z",
         "Minimum": 8.84166666666667,
         "Unit": "Percent"
      },
      {
         "Timestamp": "2021-12-15T17:24:00Z",
         "Minimum": 8.84166666666667,
         "Unit": "Percent"
      },
      ...,
      {
         "Timestamp": "2021-12-15T22:48:00Z",
         "Minimum": 8.366248354248954,
         "Unit": "Percent"
      }
   ],
   "Label": "CPUUtilization"
}
```
Creating CloudWatch alarms to monitor Amazon Aurora

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify. The alarm can also perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state. The state must have changed and have been maintained for a specified number of time periods. The following procedures show how to create alarms for Amazon RDS.

**Note**
For Aurora, use `WRITER` or `READER` role metrics to set up alarms instead of relying on metrics for specific DB instances. Aurora DB instance roles can change roles over time. You can find these role-based metrics in the CloudWatch console.

Aurora Auto Scaling automatically sets alarms based on `READER` role metrics. For more information about Aurora Auto Scaling, see Using Amazon Aurora Auto Scaling with Aurora replicas (p. 305).

To set alarms using the CloudWatch console

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose Alarms, All alarms.
   
   Choose Create an alarm.
   
   This action launches a wizard.
3. Choose Select metric.
4. In Browse, choose RDS.
5. Search for the metric that you want to place an alarm on. For example, search for `CPUUtilization`. To display only Amazon RDS metrics, search for the identifier of your resource.
6. Choose the metric to create an alarm on. Then choose Select metric.
7. In Conditions, define the alarm condition. Then choose Next.
   
   For example, you can specify that the alarm should be set when CPU utilization is over 75%.
8. Choose your notification method. Then choose Next.
   
   For example, to configure CloudWatch to send you an email when the alarm state is reached, do the following:
   
   1. Choose Create new topic (if one doesn't exist).
   2. Enter a topic name.
   3. Enter the email endpoints.

   The email addresses must be verified before they receive notifications. Emails are only sent when the alarm enters an alarm state. If this alarm state change happens before the email addresses are verified, the addresses don't receive a notification.
9. Enter a name and description for the alarm. The name must contain only ASCII characters. Then choose Next.
10. Preview the alarm that you’re about to create. Then choose **Create alarm**.

**To set an alarm using the AWS CLI**

- Call `put-metric-alarm`. For more information, see *AWS CLI Command Reference*.

**To set an alarm using the CloudWatch API**

- Call `PutMetricAlarm`. For more information, see *Amazon CloudWatch API Reference*

For more information about setting up Amazon SNS topics and creating alarms, see *Using Amazon CloudWatch alarms*. 
Monitoring DB load with Performance Insights on Amazon Aurora

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate and help you analyze your cluster performance. With the Performance Insights dashboard, you can visualize the database load on your Amazon Aurora cluster load and filter the load by waits, SQL statements, hosts, or users. For information about using Performance Insights with Amazon DocumentDB, see Amazon DocumentDB Developer Guide.

Topics
- Overview of Performance Insights on Amazon Aurora (p. 461)
- Turning Performance Insights on and off (p. 466)
- Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 469)
- Configuring access policies for Performance Insights (p. 473)
- Analyzing metrics with the Performance Insights dashboard (p. 476)
- Retrieving metrics with the Performance Insights API (p. 496)
- Logging Performance Insights calls using AWS CloudTrail (p. 510)

Overview of Performance Insights on Amazon Aurora

By default, Performance Insights is turned on in the console create wizard for all Amazon RDS engines. If you turn on Performance Insights at the DB cluster level, Performance Insights is turned on for every DB instance in the cluster. If you have more than one database on a DB instance, Performance Insights aggregates performance data.

You can find an overview of Performance Insights for Amazon Aurora in the following video.

Using Performance Insights to Analyze Performance of Amazon Aurora PostgreSQL

Topics
- Database load (p. 461)
- Maximum CPU (p. 464)
- Amazon Aurora DB engine and instance class support for Performance Insights (p. 464)
- AWS Region support for Performance Insights (p. 465)
- Pricing and data retention for Performance Insights (p. 465)

Database load

Database load (DB load) measures the level of activity in your database. The key metric in Performance Insights is DBLoad, which is collected every second.

Topics
- Active sessions (p. 462)
- Average active sessions (p. 462)
- Average active executions (p. 462)
- Dimensions (p. 463)
Active sessions

A *database session* represents an application's dialogue with a relational database. An *active session* is a connection that has submitted work to the DB engine and is waiting for a response.

A session is active when it's either running on CPU or waiting for a resource to become available so that it can proceed. For example, an active session might wait for a page to be read into memory, and then consume CPU while it reads data from the page.

Average active sessions

The *average active sessions (AAS)* is the unit for the *DBLoad* metric in Performance Insights. To get the average active sessions, Performance Insights samples the number of sessions concurrently running a query. The AAS is the total number of sessions divided by the total number of samples for a specific time period. The following table shows 5 consecutive samples of a running query.

<table>
<thead>
<tr>
<th>Sample</th>
<th>Number of sessions running query</th>
<th>AAS</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>2</td>
<td>2 sessions / 1 sample</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>1</td>
<td>2 sessions / 2 samples</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>2</td>
<td>6 sessions / 3 samples</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>1.5</td>
<td>6 sessions / 4 samples</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
<td>2</td>
<td>10 sessions / 5 samples</td>
</tr>
</tbody>
</table>

In the preceding example, the DB load for the time interval was 2 AAS. This measurement means that, on average, 2 sessions were active at a time during the time period when the 5 samples were taken.

An analogy for DB load is activity in a warehouse. Suppose that the warehouse employs 100 workers. If 1 order comes in, 1 worker fulfills the order while the other workers are idle. If 100 orders come in, all 100 workers fulfill orders simultaneously. If you periodically sample how many workers are active over a given time period, you can calculate the average number of active workers. The calculation shows that, on average, $N$ workers are busy fulfilling orders at any given time. If the average was 50 workers yesterday and 75 workers today, the activity level in the warehouse increased. In the same way, DB load increases as session activity increases.

Average active executions

The *average active executions (AAE)* per second is related to AAS. To calculate the AAE, Performance Insights divides the total execution time of a query by the time interval. The following table shows the AAE calculation for the same query in the preceding table.

<table>
<thead>
<tr>
<th>Elapsed time (sec)</th>
<th>Total execution time (sec)</th>
<th>AAE</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>60</td>
<td>120</td>
<td>2</td>
<td>120 execution seconds / 60 elapsed seconds</td>
</tr>
<tr>
<td>120</td>
<td>120</td>
<td>1</td>
<td>120 execution seconds / 120 elapsed seconds</td>
</tr>
</tbody>
</table>
### Elapsed time and Total execution time

<table>
<thead>
<tr>
<th>Elapsed time (sec)</th>
<th>Total execution time (sec)</th>
<th>AAE</th>
<th>Calculation</th>
</tr>
</thead>
<tbody>
<tr>
<td>180</td>
<td>380</td>
<td>2.11</td>
<td>380 execution seconds / 180 elapsed seconds</td>
</tr>
<tr>
<td>240</td>
<td>380</td>
<td>1.58</td>
<td>380 execution seconds / 240 elapsed seconds</td>
</tr>
<tr>
<td>300</td>
<td>600</td>
<td>2</td>
<td>600 execution seconds / 300 elapsed seconds</td>
</tr>
</tbody>
</table>

In most cases, the AAS and AAE for a query are approximately the same. However, because the inputs to the calculations are different data sources, the calculations often vary slightly.

### Dimensions

The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called dimensions. You can think of dimensions as "slice by" categories for the different characteristics of the DBLoad metric.

When you are diagnosing performance issues, the following dimensions are often the most useful:

#### Topics

- Wait events (p. 463)
- Top SQL (p. 464)

For a complete list of dimensions for the Aurora engines, see DB load sliced by dimensions (p. 479).

### Wait events

A *wait event* causes a SQL statement to wait for a specific event to happen before it can continue running. Wait events are an important dimension, or category, for DB load because they indicate where work is impeded.

Every active session is either running on the CPU or waiting. For example, sessions consume CPU when they search memory for a buffer, perform a calculation, or run procedural code. When sessions aren't consuming CPU, they might be waiting for a memory buffer to become free, a data file to be read, or a log to be written to. The more time that a session waits for resources, the less time it runs on the CPU.

When you tune a database, you often try to find out the resources that sessions are waiting for. For example, two or three wait events might account for 90 percent of DB load. This measure means that, on average, active sessions are spending most of their time waiting for a small number of resources. If you can find out the cause of these waits, you can attempt a solution.

Consider the analogy of a warehouse worker. An order comes in for a book. The worker might be delayed in fulfilling the order. For example, a different worker might be currently restocking the shelves, a trolley might not be available. Or the system used to enter the order status might be slow. The longer the worker waits, the longer it takes to fulfill the order. Waiting is a natural part of the warehouse workflow, but if wait time becomes excessive, productivity decreases. In the same way, repeated or lengthy session waits can degrade database performance. For more information, see Tuning with wait events for Aurora PostgreSQL and Tuning with wait events for Aurora MySQL in the *Amazon Aurora User Guide*.

Wait events vary by DB engine:
Overview of Performance Insights

- For a list of the common wait events for Aurora MySQL, see Aurora MySQL wait events (p. 972). To learn how to tune using these wait events, see Tuning Aurora MySQL with wait events and thread states (p. 747).
- For information about all MySQL wait events, see Wait Event Summary Tables in the MySQL documentation.
- For a list of common wait events for Aurora PostgreSQL, see Amazon Aurora PostgreSQL wait events (p. 1394). To learn how to tune using these wait events, see Tuning with wait events for Aurora PostgreSQL (p. 1153).
- For information about all PostgreSQL wait events, see The Statistics Collector > Wait Event tables in the PostgreSQL documentation.

Top SQL

Where wait events show bottlenecks, top SQL shows which queries are contributing the most to DB load. For example, many queries might be currently running on the database, but a single query might consume 99 percent of the DB load. In this case, the high load might indicate a problem with the query.

By default, the Performance Insights console displays top SQL queries that are contributing to the database load. The console also shows relevant statistics for each statement. To diagnose performance problems for a specific statement, you can examine its execution plan.

Maximum CPU

In the dashboard, the Database load chart collects, aggregates, and displays session information. To see whether active sessions are exceeding the maximum CPU, look at their relationship to the Max vCPU line. The Max vCPU value is determined by the number of vCPU (virtual CPU) cores for your DB instance. For Aurora Serverless v2, Max vCPU represents the estimated number of vCPUs.

If the DB load is often above the Max vCPU line, and the primary wait state is CPU, the CPU is overloaded. In this case, you might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve. This can be true even if the DB load doesn't cross the Max vCPU line.

Amazon Aurora DB engine and instance class support for Performance Insights

Following, you can find the Amazon Aurora DB engines that support Performance Insights.

<table>
<thead>
<tr>
<th>Amazon Aurora DB engine</th>
<th>Supported engine versions when parallel query isn’t turned on</th>
<th>Supported engine versions when parallel query is turned on</th>
<th>Instance class restrictions</th>
</tr>
</thead>
</table>
| Amazon Aurora MySQL- Compatible Edition | Performance Insights is supported for the following engine versions:  
- 3.0 and higher 3 versions (compatible with MySQL 8.0)  
- 2.04.2 and higher 2 versions (compatible with MySQL 5.7) | Performance Insights with parallel query enabled is supported for the following engine versions:  
- 2.09.0 and higher 2 versions (compatible with MySQL 5.7)  
- 1.23.0 and higher 1 versions (compatible with MySQL 5.6) | Performance Insights has the following engine class restrictions:  
- db.t2 – Not supported  
- db.t3 – Not supported  
- db.t4g – Supported only for 3 versions (compatible with MySQL 8.0) and 2.10.1 and higher 2 versions |

<td>(compatible with MySQL 5.7).</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**
Aurora Serverless v2 supports Performance Insights for all MySQL-compatible and PostgreSQL-compatible versions. We recommend that you set the minimum capacity to at least 2 Aurora capacity units (ACUs).
Aurora Serverless v1 doesn't support Performance Insights.

**AWS Region support for Performance Insights**

Performance Insights for Amazon Aurora is supported for all AWS Regions except the following:

- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

**Pricing and data retention for Performance Insights**

By default, Performance Insights offers a free tier that includes 7 days of performance data history and 1 million API requests per month. You can also purchase longer retention periods. For complete pricing information, see Performance Insights Pricing.

In the RDS console, you can choose any of the following retention periods for your Performance Insights data:

- **Default (7 days)**
- **n months**, where n is a number from 1–24
Turning Performance Insights on and off

You can turn on Performance Insights for your DB cluster when you create it. If needed, you can turn it off later at the instance level for any instance in your DB cluster. Turning Performance Insights on and off doesn't cause downtime, a reboot, or a failover.

**Note**
Performance Schema is an optional performance tool used by Aurora MySQL. If you turn Performance Schema on or off, you need to reboot. If you turn Performance Insights on or off, however, you don't need to reboot. For more information, see Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 469).

To learn how to set a retention period using the AWS CLI, see AWS CLI (p. 468).

### Performance Insights

- **Turn on Performance Insights**
  - Retention period
    - 7 days (free tier)
    - 1 month
    - 2 months
    - 3 months
    - 4 months
    - 5 months
    - 6 months
    - 7 months
    - 8 months
    - 9 months
    - 10 months
    - 11 months
    - 12 months
    - 13 months
    - 14 months
If you use Performance Insights with Aurora global databases, turn on Performance Insights individually for the DB instances in each AWS Region. For details, see Monitoring an Amazon Aurora global database with Amazon RDS Performance Insights (p. 203).

The Performance Insights agent consumes limited CPU and memory on the DB host. When the DB load is high, the agent limits the performance impact by collecting data less frequently.

**Console**

In the console, you can turn Performance Insights on or off when you create or modify a DB cluster.

**Turning Performance Insights on or off when creating a DB cluster**

When you create a new DB cluster, turn on Performance Insights by choosing **Enable Performance Insights** in the **Performance Insights** section. Or choose **Disable Performance Insights**. To create a DB cluster, follow the instructions for your DB engine in Creating an Amazon Aurora DB cluster (p. 127).

The following screenshot shows the **Performance Insights** section.

If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 465).
- **AWS KMS key** – Specify your AWS KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see Configuring an AWS KMS policy for Performance Insights (p. 475).

**Turning Performance Insights on or off when modifying a DB instance in your DB cluster**

In the console, you can modify a DB instance in your DB cluster to turn Performance Insights on or off. You can't turn Performance Insights on or off at the cluster level: you must do it for each instance in the cluster.

**To turn Performance Insights on or off for a DB instance in your DB cluster using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose **Databases**.
3. Choose a DB instance, and choose **Modify**.
4. In the **Performance Insights** section, choose either **Enable Performance Insights** or **Disable Performance Insights**.
   
   If you choose **Enable Performance Insights**, you have the following options:
• **Retention** – The amount of time to retain Performance Insights data. The retention setting in the free tier is **Default (7 days)**. To retain your performance data for longer, specify 1–24 months. For more information about retention periods, see Pricing and data retention for Performance Insights (p. 465).

• **AWS KMS key** – Specify your KMS key. Performance Insights encrypts all potentially sensitive data using your KMS key. Data is encrypted in flight and at rest. For more information, see Encrypting Amazon Aurora resources (p. 1638).

5. Choose **Continue**.

6. For **Scheduling of Modifications**, choose **Apply immediately**. If you choose **Apply** during the next scheduled maintenance window, your instance ignores this setting and turns on Performance Insights immediately.

7. Choose **Modify instance**.

**AWS CLI**

You can also specify these values using the following AWS CLI commands:

- `create-db-instance-read-replica`
- `modify-db-instance`
- `restore-db-instance-from-s3`

The following procedure describes how to turn Performance Insights on or off for an existing DB instance in your DB cluster using the AWS CLI.

**To turn Performance Insights on or off for a DB instance in your DB cluster using the AWS CLI**

- Call the `modify-db-instance` AWS CLI command and supply the following values:
  
  - `--db-instance-identifier` – The name of the DB instance in your DB cluster.
  - `--enable-performance-insights` to turn on or `--no-enable-performance-insights` to turn off

The following example turns on Performance Insights for `sample-db-instance`.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier sample-db-instance \
  --enable-performance-insights
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier sample-db-instance ^
  --enable-performance-insights
```

When you turn on Performance Insights in the CLI, you can optionally specify the number of days to retain Performance Insights data with the `--performance-insights-retention-period` option.
You can specify $7, \text{month} \times 31$ (where \text{month} is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is $3 \times 31$. The default is 7 days. For more information about retention periods, see \textit{Pricing and data retention for Performance Insights (p. 465)}.

The following example turns on Performance Insights for \texttt{sample-db-instance} and specifies that Performance Insights data is retained for 93 days (3 months).

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier sample-db-instance \
  --enable-performance-insights \
  --performance-insights-retention-period 93
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier sample-db-instance ^
  --enable-performance-insights ^
  --performance-insights-retention-period 93
```

If you specify a retention period such as 94 days, which isn't a valid value, RDS issues an error.

```
An error occurred (InvalidParameterValue) when calling the CreateDBInstance operation: Invalid Performance Insights retention period. Valid values are: [7, 31, 62, 93, 124, 155, 186, 217, 248, 279, 310, 341, 372, 403, 434, 465, 496, 527, 558, 589, 620, 651, 682, 713, 731]
```

\textbf{RDS API}

When you create a new DB instance in your DB cluster using the \texttt{CreateDBInstance} operation Amazon RDS API operation, turn on Performance Insights by setting \texttt{EnablePerformanceInsights} to \texttt{True}. To turn off Performance Insights, set \texttt{EnablePerformanceInsights} to \texttt{False}.

You can also specify the \texttt{EnablePerformanceInsights} value using the following API operations:

- \texttt{ModifyDBInstance}
- \texttt{CreateDBInstanceReadReplica}
- \texttt{RestoreDBInstanceFromS3}

When you turn on Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the \texttt{PerformanceInsightsRetentionPeriod} parameter. You can specify $7, \text{month} \times 31$ (where \text{month} is a number from 1–23), or 731. For example, if you want to retain your performance data for 3 months, specify 93, which is $3 \times 31$. The default is 7 days. For more information about retention periods, see \textit{Pricing and data retention for Performance Insights (p. 465)}.

\textbf{Turning on the Performance Schema for Performance Insights on Aurora MySQL}

The Performance Schema is an optional feature for monitoring Aurora MySQL runtime performance at a low level of detail. The Performance Schema is designed to have minimal impact on database performance. Performance Insights is a separate feature that you can use with or without the Performance Schema.

\textbf{Topics}
Overview of the Performance Schema

The Performance Schema monitors events in Aurora MySQL databases. An event is a database server action that consumes time and has been instrumented so that timing information can be collected. Examples of events include the following:

- Function calls
- Waits for the operating system
- Stages of SQL execution
- Groups of SQL statements

The `PERFORMANCE_SCHEMA` storage engine is a mechanism for implementing the Performance Schema feature. This engine collects event data using instrumentation in the database source code. The engine stores events in memory-only tables in the `performance_schema` database. You can query `performance_schema` just as you can query any other tables. For more information, see MySQL Performance Schema in the MySQL Reference Manual.

Performance Insights and the Performance Schema

Performance Insights and the Performance Schema are separate features, but they are connected. The behavior of Performance Insights for Aurora MySQL depends on whether the Performance Schema is turned on, and if so, whether Performance Insights manages the Performance Schema automatically. The following table describes the behavior.

<table>
<thead>
<tr>
<th>Performance Schema turned on</th>
<th>Performance Insights management mode</th>
<th>Performance Insights behavior</th>
</tr>
</thead>
</table>
| Yes                          | Automatic                           | • Collects detailed, low-level monitoring information  
                                  |                                    | • Collects active session metrics every second  
                                  |                                    | • Displays DB load categorized by detailed wait events, which you can use to identify bottlenecks |
| Yes                          | Manual                              | • Doesn't collect wait events, per-SQL metrics, or other detailed, low-level monitoring information  
                                  |                                    | • Collects active session metrics every five seconds instead of every second  
                                  |                                    | • Reports user states such as inserting and sending, which don't help you identify bottlenecks |
| No                           | N/A                                 | • Doesn't collect wait events, per-SQL metrics, or other detailed, low-level monitoring information  
                                  |                                    | • Collects active session metrics every five seconds instead of every second |
Performance Schema turned on | Performance Insights management mode | Performance Insights behavior
--- | --- | ---
| | | • Reports user states such as inserting and sending, which don't help you identify bottlenecks

### Automatic management of the Performance Schema by Performance Insights

When you create an Aurora MySQL DB instance with Performance Insights turned on, the Performance Schema is also turned on. In this case, Performance Insights automatically manages your Performance Schema parameters. This is the recommended configuration.

For Performance Insights to manage the Performance Schema automatically, the performance_schema must be set to 0. By default, the value of Source is system.

You can also manage the Performance Schema manually. If you choose this option, set the parameters according to the values in the following table.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter value</th>
</tr>
</thead>
<tbody>
<tr>
<td>performance_schema</td>
<td>1 (Source column has the value system)</td>
</tr>
<tr>
<td>performance-schema-consumer-events-waits-current</td>
<td>ON</td>
</tr>
<tr>
<td>performance-schema-instrument</td>
<td>wait/%=ON</td>
</tr>
<tr>
<td>performance_schema_consumer_global_instrumentation</td>
<td></td>
</tr>
<tr>
<td>performance_schema_consumer_thread_instrumentation</td>
<td></td>
</tr>
</tbody>
</table>

If you change the performance_schema parameter value manually, and then later want to change to automatic management, see Configuring the Performance Schema for automatic management (p. 472).

**Important**

When Performance Insights turns on the Performance Schema, it doesn't change the parameter group values. However, the values are changed on the DB instances that are running. The only way to see the changed values is to run the SHOW GLOBAL VARIABLES command.

### Effect of a reboot on the Performance Schema

Performance Insights and the Performance Schema differ in their requirements for DB instance reboots:

**Performance Schema**

To turn this feature on or off, you must reboot the DB instance.

**Performance Insights**

To turn this feature on or off, you don't need to reboot the DB instance.

If the Performance Schema isn't currently turned on, and you turn on Performance Insights without rebooting the DB instance, the Performance Schema won't be turned on.
Determining whether Performance Insights is managing the Performance Schema

To find out whether Performance Insights is currently managing the Performance Schema for major engine versions 5.6, 5.7, and 8.0, review the following table.

| Setting of performance_schema parameter | Setting of the Source column | Performance Insights is managing the Performance Schema?
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>system</td>
<td>Yes</td>
</tr>
<tr>
<td>0 or 1</td>
<td>user</td>
<td>No</td>
</tr>
</tbody>
</table>

To determine whether Performance Insights is managing the Performance Schema automatically

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups.
3. Select the name of the parameter group for your DB instance.
4. Enter performance_schema in the search bar.
5. Check whether Source is the system default and Values is 0. If so, Performance Insights is managing the Performance Schema automatically. If not, Performance Insights isn't managing the Performance Schema automatically.

Configuring the Performance Schema for automatic management

Assume that Performance Insights is turned on for your DB instance but isn't currently managing the Performance Schema. If you want to allow Performance Insights to manage the Performance Schema automatically, complete the following steps.

To configure the Performance Schema for automatic management

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups.
3. Select the name of the parameter group for your DB instance.
4. Enter performance_schema in the search bar.
5. Select the performance_schema parameter.
6. Choose Edit parameters.
7. Select the performance_schema parameter.
8. In **Values**, choose **0**.
9. Choose **Reset** and then **Reset parameters**.
10. Reboot the DB instance.

**Important**
Whenever you turn the Performance Schema on or off, make sure to reboot the DB instance.

For more information about modifying instance parameters, see Modifying parameters in a DB parameter group (p. 231). For more information about the dashboard, see Analyzing metrics with the Performance Insights dashboard (p. 476). For more information about the MySQL performance schema, see MySQL 8.0 Reference Manual.

### Configuring access policies for Performance Insights

To access Performance Insights, a principal must have the appropriate permissions from AWS Identity and Access Management (IAM). You can grant access in the following ways:

- Attach the **AmazonRDSPerformanceInsightsReadOnly** managed policy to an IAM user or role.
- Create a custom IAM policy and attach it to an IAM user or role.

If you specified a customer managed key when you turned on Performance Insights, make sure that users in your account have the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key.

#### Attaching the AmazonRDSPerformanceInsightsReadOnly policy to an IAM principal

AmazonRDSPerformanceInsightsReadOnly is an AWS-managed policy that grants access to all read-only operations of the Amazon RDS Performance Insights API. Currently, all operations in this API are read-only.

If you attach **AmazonRDSPerformanceInsightsReadOnly** to an IAM user or role, the recipient can use Performance Insights with other console features.

#### Creating a custom IAM policy for Performance Insights

For users who don't have the **AmazonRDSPerformanceInsightsReadOnly** policy, you can grant access to Performance Insights by creating or modifying a user-managed IAM policy. When you attach the policy to an IAM user or role, the recipient can use Performance Insights.

**To create a custom policy**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create Policy** page, choose the **JSON** tab.
5. Copy and paste the following text, replacing `us-east-1` with the name of your AWS Region and `111122223333` with your customer account number.

```json
{
   "Version": "2012-10-17",
   "Statement": [
   { "Effect": "Allow",
```
"Action": "rds:DescribeDBInstances",
"Resource": "*"
},
{
"Effect": "Allow",
"Action": "rds:DescribeDBClusters",
"Resource": "*"
},
{
"Effect": "Allow",
"Action": "pi:DescribeDimensionKeys",
},
{
"Effect": "Allow",
"Action": "pi:GetDimensionKeyDetails",
},
{
"Effect": "Allow",
"Action": "pi:GetResourceMetadata",
},
{
"Effect": "Allow",
"Action": "pi:GetResourceMetrics",
},
{
"Effect": "Allow",
"Action": "pi:ListAvailableResourceDimensions",
},
{
"Effect": "Allow",
"Action": "pi:ListAvailableResourceMetrics",
}

7. Provide a name for the policy and optionally a description, and then choose Create policy.

You can now attach the policy to an IAM user or role. The following procedure assumes that you already have an IAM user available for this purpose.

To attach the policy to an IAM user

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Users.
3. Choose an existing user from the list.

   **Important**

   To use Performance Insights, make sure that you have access to Amazon RDS in addition to the custom policy. For example, the AmazonRDSPerformanceInsightsReadOnly predefined policy provides read-only access to Amazon RDS. For more information, see Managing access using policies (p. 1655).

4. On the Summary page, choose Add permissions.
5. Choose Attach existing policies directly. For Search, type the first few characters of your policy name, as shown following.
6. Choose your policy, and then choose **Next: Review**.

7. Choose **Add permissions**.

### Configuring an AWS KMS policy for Performance Insights

Performance Insights uses an AWS KMS key to encrypt sensitive data. When you enable Performance Insights through the API or the console, you can do either of the following:

- Choose the default AWS managed key.
  - Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.
- Choose a customer managed key.
  - If you specify a customer managed key, users in your account that call the Performance Insights API need the `kms:Decrypt` and `kms:GenerateDataKey` permissions on the KMS key. You can configure these permissions through IAM policies. However, we recommend that you manage these permissions through your KMS key policy. For more information, see [Using key policies in AWS KMS](https://docs.aws.amazon.com/kms/latest/userguide/using-policies-reference.html).

#### Example

The following example shows how to add statements to your KMS key policy. These statements allow access to Performance Insights. Depending on how you use the KMS key, you might want to change some restrictions. Before adding statements to your policy, remove all comments.

```json
{
   "Version": "2012-10-17",
   "Id": "your-policy",
   "Statement": [
      //This represents a statement that currently exists in your policy.
      
      //Starting here, add new statement to your policy for Performance Insights.
      //We recommend that you add one new statement for every RDS instance
      
      "Sid": "Allow viewing RDS Performance Insights",
      "Effect": "Allow",
```
Analyzing metrics with the Performance Insights dashboard

The Performance Insights dashboard contains database performance information to help you analyze and troubleshoot performance issues. On the main dashboard page, you can view information about the database load. You can "slice" DB load by dimensions such as wait events or SQL.

Performance Insights dashboard

- Overview of the Performance Insights dashboard (p. 476)
- Accessing the Performance Insights dashboard (p. 482)
- Analyzing DB load by wait events (p. 484)
- Analyzing queries in the Performance Insights dashboard (p. 485)

Overview of the Performance Insights dashboard

The dashboard is the easiest way to interact with Performance Insights. The following example shows the dashboard for a MySQL DB instance.
Time range filter

By default, the Performance Insights dashboard shows DB load for the last hour. You can adjust this range to be as short as 5 minutes or as long as 2 years. You can also select a custom relative range.

You can select an absolute range with a beginning and ending date and time. The following example shows the time range beginning at midnight on 4/11/22 and ending at 11:59 PM on 4/14/22.

Counter metrics chart

With counter metrics, you can customize the Performance Insights dashboard to include up to 10 additional graphs. These graphs show a selection of dozens of operating system and database performance metrics. You can correlate this information with DB load to help identify and analyze performance problems.

The Counter metrics chart displays data for performance counters. The default metrics depend on the DB engine:

- Aurora MySQL – `db.SQL.Innodb_rows_read.avg`
- Aurora PostgreSQL – `db.Transactions.xact_commit(avg)`
To change the performance counters, choose **Manage Metrics**. You can select multiple **OS metrics** or **Database metrics**, as shown in the following screenshot. To see details for any metric, hover over the metric name.

For descriptions of the counter metrics that you can add for each DB engine, see *Performance Insights counter metrics* (p. 546).
Database load chart

The **Database load** chart shows how the database activity compares to DB instance capacity as represented by the **Max vCPU** line. By default, the stacked line chart represents DB load as average active sessions per unit of time. The DB load is sliced (grouped) by wait states.

![Database Load Chart](image)

**DB load sliced by dimensions**

You can choose to display load as active sessions grouped by any supported dimensions. The following table shows which dimensions are supported for the different engines.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Aurora PostgreSQL</th>
<th>Aurora MySQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>SQL</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>User</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Waits</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Application</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Database</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Session type</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

The following image shows the dimensions for a PostgreSQL DB instance.
DB load details for a dimension item

To see details about a DB load item within a dimension, hover over the item name. The following image shows details for a SQL statement.

To see details for any item for the selected time period in the legend, hover over that item.
### Top dimensions table

The Top dimensions table slices DB load by different dimensions. A dimension is a category or "slice by" for different characteristics of DB load. If the dimension is SQL, Top SQL shows the SQL statements that contribute the most to DB load.

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
<th>Supported engines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top SQL</td>
<td>The SQL statements that are currently running</td>
<td>All</td>
</tr>
<tr>
<td>Top waits</td>
<td>The event for which the database backend is waiting</td>
<td>All</td>
</tr>
</tbody>
</table>

Choose any of the following dimension tabs.
### Analyzing metrics with the Performance Insights dashboard

<table>

To learn how to analyze queries by using the **Top SQL** tab, see [Overview of the Top SQL tab](p. 486).

### Accessing the Performance Insights dashboard

To access the Performance Insights dashboard, use the following procedure.

**To view the Performance Insights dashboard in the AWS Management Console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the left navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

   The Performance Insights dashboard is shown for that DB instance.

   For DB instances with Performance Insights turned on, you can also reach the dashboard by choosing the **Sessions** item in the list of DB instances. Under **Current activity**, the **Sessions** item shows the database load in average active sessions over the last five minutes. The bar graphically shows the load. When the bar is empty, the DB instance is idle. As the load increases, the bar fills with blue. When the load passes the number of virtual CPUs (vCPUs) on the DB instance class, the bar turns red, indicating a potential bottleneck.

4. **(Optional)** Choose **View past** in the upper right and specify a different relative or absolute time interval.

   In the following example, the DB load is shown for the last 5 hours.

   In the following screenshot, the DB load interval is 5 hours.
5. (Optional) To zoom in on a portion of the DB load chart, choose the start time and drag to the end of the time period you want.

The selected area is highlighted in the DB load chart.

When you release the mouse, the DB load chart zooms in on the selected AWS Region, and the Top dimensions table is recalculated.
Analyzing metrics with the Performance Insights dashboard

6. (Optional) To refresh your data automatically, enable Auto refresh.

The Performance Insight dashboard automatically refreshes with new data. The refresh rate depends on the amount of data displayed:

- 5 minutes refreshes every 5 seconds.
- 1 hour refreshes every minute.
- 5 hours refreshes every minute.
- 24 hours refreshes every 5 minutes.
- 1 week refreshes every hour.

Analyzing DB load by wait events

If the Database load chart shows a bottleneck, you can find out where the load is coming from. To do so, look at the top load items table below the Database load chart. Choose a particular item, like a SQL query or a user, to drill down into that item and see details about it.

DB load grouped by waits and top SQL queries is the default Performance Insights dashboard view. This combination typically provides the most insight into performance issues. DB load grouped by waits
shows if there are any resource or concurrency bottlenecks in the database. In this case, the SQL tab of the top load items table shows which queries are driving that load.

Your typical workflow for diagnosing performance issues is as follows:

1. Review the Database load chart and see if there are any incidents of database load exceeding the Max CPU line.
2. If there is, look at the Database load chart and identify which wait state or states are primarily responsible.
3. Identify the digest queries causing the load by seeing which of the queries the SQL tab on the top load items table are contributing most to those wait states. You can identify these by the DB Load by Wait column.
4. Choose one of these digest queries in the SQL tab to expand it and see the child queries that it is composed of.

For example, in the dashboard following, log file sync waits account for most of the DB load. The LGWR all worker groups wait is also high. The Top SQL chart shows what is causing the log file sync waits: frequent COMMIT statements. In this case, committing less frequently will reduce DB load.

Analyzing queries in the Performance Insights dashboard

In the Amazon RDS Performance Insights dashboard, you can find information about running and recent queries in the Top SQL tab in the Top dimensions table. You can use this information to tune your queries.

Topics

- Overview of the Top SQL tab (p. 486)
- Accessing more SQL text in the Performance Insights dashboard (p. 491)
Overview of the Top SQL tab

By default, the Top SQL tab shows the SQL queries that are contributing the most to DB load. To help tune your queries, you can analyze information such as the query text, statistics, and Support SQL ID. You can also choose the statistics that you want to appear in the Top SQL tab.

Topics

- SQL text (p. 486)
- SQL statistics (p. 487)
- Load by waits (AAS) (p. 488)
- SQL information (p. 488)
- Preferences (p. 489)

SQL text

By default, each row in the Top SQL table shows 500 bytes of SQL text for each SQL statement.

A SQL digest is a composite of multiple actual queries that are structurally similar but might have different literal values. The digest replaces hardcoded values with a question mark. For example, a digest might be `SELECT * FROM emp WHERE lname= ?`. This digest might include the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

To see the literal SQL statements in a digest, select the query, and then choose the plus symbol (+). In the following example, the selected query is a digest.
Note
A SQL digest groups similar SQL statements, but doesn't redact sensitive information.

SQL statistics

SQL statistics are performance-related metrics about SQL queries. For example, Performance Insights might show executions per second or rows processed per second. Performance Insights collects statistics for only the most common queries. Typically, these match the top queries by load shown in the Performance Insights dashboard.

Every line in the Top SQL table shows relevant statistics for the SQL statement or digest, as shown in the following example.

Performance Insights can report 0.00 and – (unknown) for SQL statistics. This situation occurs under the following conditions:

- Only one sample exists. For example, Performance Insights calculates rates of change for Aurora PostgreSQL queries based on multiple samples from the pg_stats_statements view. When a workload runs for a short time, Performance Insights might collect only one sample, which means that it can't calculate a rate of change. The unknown value is represented with a dash (–).
- Two samples have the same values. Performance Insights can't calculate a rate of change because no change has occurred, so it reports the rate as 0.00.
- An Aurora PostgreSQL statement lacks a valid identifier. PostgreSQL creates a identifier for a statement only after parsing and analysis. Thus, a statement can exist in the PostgreSQL internal in-memory structures with no identifier. Because Performance Insights samples internal in-memory structures once per second, low-latency queries might appear for only a single sample. If the query identifier isn't available for this sample, Performance Insights can't associate this statement with its statistics. The unknown value is represented with a dash (–).

For a description of the SQL statistics for the Aurora engines, see SQL statistics for Performance Insights (p. 554).
Load by waits (AAS)

In **Top SQL**, the **Load by waits (AAS)** column illustrates the percentage of the database load associated with each top load item. This column reflects the load for that item by whatever grouping is currently selected in the **DB Load Chart**.

For example, you might group the **DB load** chart by wait states. You examine SQL queries in the top load items table. In this case, the **DB Load by Waits** bar is sized, segmented, and color-coded to show how much of a given wait state that query is contributing to. It also shows which wait states are affecting the selected query.

![DB Load Chart and Top SQL Table]

**SQL information**

In the **Top SQL** table, you can open a statement to view its information. The information appears in the bottom pane.
The following types of identifiers (IDs) that are associated with SQL statements:

- **Support SQL ID** – A hash value of the SQL ID. This value is only for referencing a SQL ID when you are working with AWS Support. AWS Support doesn't have access to your actual SQL IDs and SQL text.

- **Support Digest ID** – A hash value of the digest ID. This value is only for referencing a digest ID when you are working with AWS Support. AWS Support doesn't have access to your actual digest IDs and SQL text.

**Preferences**

You can control the statistics displayed in the Top SQL tab by choosing the Preferences icon.
When you choose the **Preferences** icon, the **Preferences** window opens.

To enable the statistics that you want to appear in the **Top SQL** tab, use your mouse to scroll to the bottom of the window, and then choose **Continue**.
Accessing more SQL text in the Performance Insights dashboard

By default, each row in the Top SQL table shows 500 bytes of SQL text for each SQL statement. When a SQL statement exceeds 500 bytes, you can view more text in the SQL text section below the Top SQL table. In this case, the maximum length for the text displayed in SQL text is 4 KB. This limit is introduced by the console and is subject to the limits set by the database engine. To save the text shown in SQL text, choose Download.

Topics
- Text size limits for Aurora MySQL (p. 491)
- Setting the SQL text limit for Aurora PostgreSQL DB instances (p. 491)
- Viewing and downloading SQL text in the Performance Insights dashboard (p. 492)

Text size limits for Aurora MySQL

When you download SQL text, the database engine determines its maximum length. You can download SQL text up to the following per-engine limits.

<table>
<thead>
<tr>
<th>DB engine</th>
<th>Maximum length of downloaded text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL 5.7</td>
<td>4,096 bytes</td>
</tr>
<tr>
<td>Aurora MySQL 5.6</td>
<td>1,024 bytes</td>
</tr>
</tbody>
</table>

The SQL text section of the Performance Insights console displays up to the maximum that the engine returns. For example, if Aurora MySQL returns at most 1 KB to Performance Insights, it can only collect and show 1 KB, even if the original query is larger. Thus, when you view the query in SQL text or download it, Performance Insights returns the same number of bytes.

If you use the AWS CLI or API, Performance Insights doesn't have the 4 KB limit enforced by the console. DescribeDimensionKeys and GetResourceMetrics return at most 500 bytes. GetDimensionKeyDetails returns the full query, but the size is subject to the engine limit.

Setting the SQL text limit for Aurora PostgreSQL DB instances

Aurora PostgreSQL handles text differently. You can set the text size limit with the DB instance parameter track_activity_query_size. This parameter has the following characteristics:

Default text size

On Aurora PostgreSQL version 9.6, the default setting for the track_activity_query_size parameter is 1,024 bytes. On Aurora PostgreSQL version 10 or higher, the default is 4,096 bytes.

Maximum text size

The limit for track_activity_query_size is 102,400 bytes for Aurora PostgreSQL version 12 and lower. The maximum is 1 MB for version 13 and higher.

If the engine returns 1 MB to Performance Insights, the console displays only the first 4 KB. If you download the query, you get the full 1 MB. In this case, viewing and downloading return different numbers of bytes. For more information about the track_activity_query_size DB instance parameter, see Run-time Statistics in the PostgreSQL documentation.
To increase the SQL text size, increase the `track_activity_query_size` limit. To modify the parameter, change the parameter setting in the parameter group that is associated with the Aurora PostgreSQL DB instance.

**To change the setting when the instance uses the default parameter group**

1. Create a new DB instance parameter group for the appropriate DB engine and DB engine version.
2. Set the parameter in the new parameter group.
3. Associate the new parameter group with the DB instance.

For information about setting a DB instance parameter, see [Modifying parameters in a DB parameter group](p. 231).

**Viewing and downloading SQL text in the Performance Insights dashboard**

In the Performance Insights dashboard, you can view or download SQL text.

**To view more SQL text in the Performance Insights dashboard**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance.

   The Performance Insights dashboard is displayed for your DB instance.
4. Scroll down to the **Top SQL** tab.
5. Choose a SQL statement.

   SQL statements with text larger than 500 bytes look similar to the following image.

   6. Scroll down to the **SQL text** tab.
Analyzing metrics with the Performance Insights dashboard

The Performance Insights dashboard can display up to 4,096 bytes for each SQL statement.

7. (Optional) Choose Copy to copy the displayed SQL statement, or choose Download to download the SQL statement to view the SQL text up to the DB engine limit.

   **Note**
   To copy or download the SQL statement, disable pop-up blockers.

**Viewing SQL statistics in the Performance Insights dashboard**

In the Performance Insights dashboard, SQL statistics are available in the Top SQL tab of the Database load chart.

**To view SQL statistics**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the left navigation pane, choose Performance Insights.
3. At the top of the page, choose the database whose SQL statistics you want to see.
4. Scroll to the bottom of the page and choose the Top SQL tab.
5. Choose an individual statement (Aurora MySQL only) or digest query.
6. Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart. For descriptions of the SQL statistics for the Amazon RDASaurora engines, see SQL statistics for Performance Insights (p. 554).

The following example shows the preferences for Aurora PostgreSQL.
The following example shows the preferences for Aurora MySQL DB instances.
7. Choose Save to save your preferences.

The Top SQL table refreshes.

Retrieving metrics with the Performance Insights API

When Performance Insights is enabled, the API provides visibility into instance performance. Amazon CloudWatch Logs provides the authoritative source for vended monitoring metrics for AWS services.

Performance Insights offers a domain-specific view of database load measured as average active sessions (AAS). This metric appears to API consumers as a two-dimensional time-series dataset. The time dimension of the data provides DB load data for each time point in the queried time range. Each time point decomposes overall load in relation to the requested dimensions, such as SQL, Wait-event, User, or Host, measured at that time point.

Amazon RDS Performance Insights monitors your Amazon Aurora cluster so that you can analyze and troubleshoot database performance. One way to view Performance Insights data is in the AWS Management Console. Performance Insights also provides a public API so that you can query your own data. You can use the API to do the following:

- Offload data into a database
- Add Performance Insights data to existing monitoring dashboards
- Build monitoring tools

To use the Performance Insights API, enable Performance Insights on one of your Amazon RDS DB instances. For information about enabling Performance Insights, see Turning Performance Insights on and off (p. 466). For more information about the Performance Insights API, see the Amazon RDS Performance Insights API Reference.
The Performance Insights API provides the following operations.

<table>
<thead>
<tr>
<th>Performance Insights action</th>
<th>AWS CLI command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DescribeDimensionKeys</td>
<td><code>aws pi describe-dimension-keys</code></td>
<td>Retrieves the top N dimension keys for a metric for a specific time period.</td>
</tr>
<tr>
<td>GetDimensionKeyDetails</td>
<td><code>aws pi get-dimension-key-details</code></td>
<td>Retrieves the attributes of the specified dimension group for a DB instance or data source. For example, if you specify a SQL ID, and if the dimension details are available, GetDimensionKeyDetails retrieves the full text of the dimension <code>db.sql.statement</code> associated with this ID. This operation is useful because GetResourceMetrics and DescribeDimensionKeys don't support retrieval of large SQL statement text.</td>
</tr>
<tr>
<td>GetResourceMetadata</td>
<td><code>aws pi get-resource-metadata</code></td>
<td>Retrieve the metadata for different features. For example, the metadata might indicate that a feature is turned on or off on a specific DB instance.</td>
</tr>
<tr>
<td>GetResourceMetrics</td>
<td><code>aws pi get-resource-metrics</code></td>
<td>Retrieves Performance Insights metrics for a set of data sources over a time period. You can provide specific dimension groups and dimensions, and provide aggregation and filtering criteria for each group.</td>
</tr>
<tr>
<td>ListAvailableResourceDimensions</td>
<td><code>aws pi list-available-resource-dimensions</code></td>
<td>Retrieve the dimensions that can be queried for each specified metric type on a specified instance.</td>
</tr>
<tr>
<td>ListAvailableResourceMetrics</td>
<td><code>aws pi list-available-resource-metrics</code></td>
<td>Retrieve all available metrics of the specified metric types that can be queried for a specified DB instance.</td>
</tr>
</tbody>
</table>

Topics
- AWS CLI for Performance Insights (p. 497)
- Retrieving time-series metrics (p. 498)
- AWS CLI examples for Performance Insights (p. 499)

AWS CLI for Performance Insights

You can view Performance Insights data using the AWS CLI. You can view help for the AWS CLI commands for Performance Insights by entering the following on the command line.
If you don’t have the AWS CLI installed, see Installing the AWS Command Line Interface in the AWS CLI User Guide for information about installing it.

### Retrieving time-series metrics

The `GetResourceMetrics` operation retrieves one or more time-series metrics from the Performance Insights data. `GetResourceMetrics` requires a metric and time period, and returns a response with a list of data points.

For example, the AWS Management Console uses `GetResourceMetrics` to populate the **Counter Metrics** chart and the **Database Load** chart, as seen in the following image.

![Counter Metrics and Database Load Charts](image)

All metrics returned by `GetResourceMetrics` are standard time-series metrics, with the exception of `db.load`. This metric is displayed in the **Database Load** chart. The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called **dimensions**. In the previous image, `db.load` is broken down and grouped by the waits states that make up the `db.load`.

**Note**

`GetResourceMetrics` can also return the `db.sampleload` metric, but the `db.load` metric is appropriate in most cases.

For information about the counter metrics returned by `GetResourceMetrics`, see Performance Insights counter metrics (p. 546).

The following calculations are supported for the metrics:

- **Average** – The average value for the metric over a period of time. Append `.avg` to the metric name.
- **Minimum** – The minimum value for the metric over a period of time. Append `.min` to the metric name.
- **Maximum** – The maximum value for the metric over a period of time. Append `.max` to the metric name.
- **Sum** – The sum of the metric values over a period of time. Append `.sum` to the metric name.
- **Sample count** – The number of times the metric was collected over a period of time. Append `.sample_count` to the metric name.
For example, assume that a metric is collected for 300 seconds (5 minutes), and that the metric is collected one time each minute. The values for each minute are 1, 2, 3, 4, and 5. In this case, the following calculations are returned:

- Average – 3
- Minimum – 1
- Maximum – 5
- Sum – 15
- Sample count – 5

For information about using the `get-resource-metrics` AWS CLI command, see [get-resource-metrics](#).

For the `--metric-queries` option, specify one or more queries that you want to get results for. Each query consists of a mandatory `Metric` and optional `GroupBy` and `Filter` parameters. The following is an example of a `--metric-queries` option specification.

```json
{
  "Metric": "string",
  "GroupBy": {
    "Group": "string",
    "Dimensions": ["string", ...],
    "Limit": integer
  },
  "Filter": {"string": "string" ...

AWS CLI examples for Performance Insights

The following examples show how to use the AWS CLI for Performance Insights.

Topics

- Retrieving counter metrics (p. 499)
- Retrieving the DB load average for top wait events (p. 502)
- Retrieving the DB load average for top SQL (p. 504)
- Retrieving the DB load average filtered by SQL (p. 506)
- Retrieving the full text of a SQL statement (p. 509)

Retrieving counter metrics

The following screenshot shows two counter metrics charts in the AWS Management Console.
The following example shows how to gather the same data that the AWS Management Console uses to generate the two counter metric charts.

**For Linux, macOS, or Unix:**

```bash
aws pi get-resource-metrics 
   --service-type RDS 
   --identifier db-ID 
   --start-time 2018-10-30T00:00:00Z 
   --end-time 2018-10-30T01:00:00Z 
   --period-in-seconds 60 
   --metric-queries '[["Metric": "os.cpuUtilization.user.avg" ],
   {"Metric": "os.cpuUtilization.idle.avg"}]]'
```

**For Windows:**

```bash
aws pi get-resource-metrics ^
   --service-type RDS ^
   --identifier db-ID ^
   --start-time 2018-10-30T00:00:00Z ^
   --end-time 2018-10-30T01:00:00Z ^
   --period-in-seconds 60 ^
   --metric-queries '[["Metric": "os.cpuUtilization.user.avg" ],
   {"Metric": "os.cpuUtilization.idle.avg"}]]'
```

You can also make a command easier to read by specifying a file for the `--metrics-query` option. The following example uses a file called `query.json` for the option. The file has the following contents.

```json
[  
   {  
      "Metric": "os.cpuUtilization.user.avg"
   },
   {  
      "Metric": "os.cpuUtilization.idle.avg"
   }
]
```

Run the following command to use the file.

**For Linux, macOS, or Unix:**

```bash
aws pi get-resource-metrics 
   --service-type RDS 
   --identifier db-ID 
   --start-time 2018-10-30T00:00:00Z 
   --end-time 2018-10-30T01:00:00Z 
   --period-in-seconds 60 
   --metrics-query file:query.json
```
Retrieving metrics with the Performance Insights API

```bash
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-30T00:00:00Z \
  --end-time 2018-10-30T01:00:00Z \
  --period-in-seconds 60 \
  --metric-queries file://query.json
```

For Windows:

```bash
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
  --start-time 2018-10-30T00:00:00Z ^
  --end-time 2018-10-30T01:00:00Z ^
  --period-in-seconds 60 ^
  --metric-queries file://query.json
```

The preceding example specifies the following values for the options:

- `--service-type` – RDS for Amazon RDS
- `--identifier` – The resource ID for the DB instance
- `--start-time` and `--end-time` – The ISO 8601 DateTime values for the period to query, with multiple supported formats

It queries for a one-hour time range:

- `--period-in-seconds` – 60 for a per-minute query
- `--metric-queries` – An array of two queries, each just for one metric.

The metric name uses dots to classify the metric in a useful category, with the final element being a function. In the example, the function is `avg` for each query. As with Amazon CloudWatch, the supported functions are `min`, `max`, `total`, and `avg`.

The response looks similar to the following.

```json
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1540857600.0,
  "AlignedEndTime": 1540861200.0,
  "MetricList": [
    //A list of key/datapoints
    "Key": {
      "Metric": "os.cpuUtilization.user.avg" //Metric1
    },
    "DataPoints": [
      //Each list of datapoints has the same timestamps and same number of items
      {
        "Timestamp": 1540857660.0, //Minute1
        "Value": 4.0
      },
      {
        "Timestamp": 1540857720.0, //Minute2
        "Value": 4.0
      },
      {
        "Timestamp": 1540857780.0, //Minute 3
        "Value": 10.0
      }
  ]
}
```
Retrieving the DB load average for top wait events

The following example is the same query that the AWS Management Console uses to generate a stacked area line graph. This example retrieves the `db.load.avg` for the last hour with load divided according to the top seven wait events. The command is the same as the command in Retrieving counter metrics (p. 499). However, the `query.json` file has the following contents.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.wait_event", "Limit": 7 }
  }
]
```

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
  --service-type RDS \ 
  --identifier db-ID \ 
  --start-time 2018-10-30T00:00:00Z \ 
  --end-time 2018-10-30T01:00:00Z \ 
  --period-in-seconds 60 \ 
  --metric-queries file://query.json
```
For Windows:

```bash
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
  --start-time 2018-10-30T00:00:00Z ^
  --end-time 2018-10-30T01:00:00Z ^
  --period-in-seconds 60 ^
  --metric-queries file://query.json
```

The example specifies the metric of `db.load.avg` and a `GroupBy` of the top seven wait events. For details about valid values for this example, see `DimensionGroup` in the Performance Insights API Reference.

The response looks similar to the following.

```json
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1540857600.0,
  "AlignedEndTime": 1540861200.0,
  "MetricList": [
    {
      "Key": {
        "Metric": "db.load.avg"
      },
      "DataPoints": [
        {
          "Timestamp": 1540857660.0, //Minute1
          "Value": 0.5166666666666667
        },
        {
          "Timestamp": 1540857720.0, //Minute2
          "Value": 0.38333333333333336
        },
        {
          "Timestamp": 1540857780.0, //Minute 3
          "Value": 0.26666666666666666
        },
        //... 60 datapoints for the total db.load.avg key
      ]
    },
    {
      "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
          "db.wait_event.name": "CPU",
          "db.wait_event.type": "CPU"
        }
      },
      "DataPoints": [
        {
          "Timestamp": 1540857660.0, //Minute1
          "Value": 0.35
        },
        {
          "Timestamp": 1540857720.0, //Minute2
          "Value": 0.15
        },
        //... 60 datapoints for the CPU key
      ]
    }
  ]
}
```
In this response, there are eight entries in the MetricList. There is one entry for the total db.load.avg, and seven entries each for the db.load.avg divided according to one of the top seven wait events. Unlike in the first example, because there was a grouping dimension, there must be one key for each grouping of the metric. There can’t be only one key for each metric, as in the basic counter metric use case.

### Retrieving the DB load average for top SQL

The following example groups db.wait_events by the top 10 SQL statements. There are two different groups for SQL statements:

- db.sql – The full SQL statement, such as `select * from customers where customer_id = 123`
- db.sql_tokenized – The tokenized SQL statement, such as `select * from customers where customer_id = ?`

When analyzing database performance, it can be useful to consider SQL statements that only differ by their parameters as one logic item. So, you can use db.sql_tokenized when querying. However, especially when you're interested in explain plans, sometimes it’s more useful to examine full SQL statements with parameters, and query grouping by db.sql. There is a parent-child relationship between tokenized and full SQL, with multiple full SQL (children) grouped under the same tokenized SQL (parent).

The command in this example is the similar to the command in **Retrieving the DB load average for top wait events** (p. 502). However, the query.json file has the following contents.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": {
      "Group": "db.sql_tokenized",
      "Limit": 10
    }
  }
]
```

The following example uses db.sql_tokenized.

For Linux, macOS, or Unix:

```bash
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-29T00:00:00Z \
  --end-time 2018-10-30T00:00:00Z \
  --period-in-seconds 3600 \
  --metric-queries file://query.json
```

For Windows:

```bash
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
  --start-time 2018-10-29T00:00:00Z ^
  --end-time 2018-10-30T00:00:00Z ^
```
This example queries over 24 hours, with a one hour period-in-seconds.

The example specifies the metric of \texttt{db.load.avg} and a \texttt{GroupBy} of the top seven wait events.
For details about valid values for this example, see \texttt{DimensionGroup} in the \textit{Performance Insights API Reference}.

The response looks similar to the following.

```json
{
  "AlignedStartTime": 1540771200.0,
  "AlignedEndTime": 1540857600.0,
  "Identifier": "db-XXX",
  "MetricList": [{ //11 entries in the MetricList
    "Key": { //First key is total
      "Metric": "db.load.avg"
    }
    "DataPoints": [{ //Each DataPoints list has 24 per-hour Timestamps and a value
      "Value": 1.6964980544747081,
      "Timestamp": 1540774800.0
    }, //... 24 datapoints
    },
    "Key": { //Next key is the top tokenized SQL
      "Dimensions": {
        "db.sql_tokenized.statement": "INSERT INTO authors (id,name,email)
VALUES\n( nextval(?),?,?)",
        "db.sql_tokenized.db_id": "pi-2372568224",
        "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE"
      }
    },
    "Metric": "db.load.avg"
    },
    "DataPoints": [ //... 24 datapoints
    ]
  }, // In total 11 entries, 10 Keys of top tokenized SQL, 1 total key
} //End of response
```

This response has 11 entries in the \texttt{MetricList} (1 total, 10 top tokenized SQL), with each entry having 24 per-hour \texttt{DataPoints}.

For tokenized SQL, there are three entries in each dimensions list:

- \texttt{db.sql_tokenized.statement} – The tokenized SQL statement.
- \texttt{db.sql_tokenized.db_id} – Either the native database ID used to refer to the SQL, or a synthetic ID that Performance Insights generates for you if the native database ID isn’t available. This example returns the \texttt{pi-2372568224} synthetic ID.
- \texttt{db.sql_tokenized.id} – The ID of the query inside Performance Insights.

In the AWS Management Console, this ID is called the Support ID. It’s named this because the ID is data that AWS Support can examine to help you troubleshoot an issue with your database. AWS takes the security and privacy of your data extremely seriously, and almost all data is stored encrypted with your AWS KMS customer master key (CMK). Therefore, nobody inside AWS can look at this data. In
the example preceding, both the `tokenized.statement` and the `tokenized.db_id` are stored encrypted. If you have an issue with your database, AWS Support can help you by referencing the Support ID.

When querying, it might be convenient to specify a `Group` in `GroupBy`. However, for finer-grained control over the data that's returned, specify the list of dimensions. For example, if all that is needed is the `db.sql_tokenized.statement`, then a `Dimensions` attribute can be added to the `query.json` file.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": {
      "Group": "db.sql_tokenized",
      "Dimensions": ["db.sql_tokenized.statement"],
      "Limit": 10
    }
  }
]
```

Retrieving the DB load average filtered by SQL

The preceding image shows that a particular query is selected, and the top average active sessions stacked area line graph is scoped to that query. Although the query is still for the top seven overall wait events, the value of the response is filtered. The filter causes it to take into account only sessions that are a match for the particular filter.

The corresponding API query in this example is similar to the command in Retrieving the DB load average for top SQL (p. 504). However, the `query.json` file has the following contents.

```json
[
  {
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.wait_event", "Limit": 5 },
    "Filter": { "db.sql_tokenized.id": "ARIAIOSFODNN7EXAMPLE" }
  }
]"
For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
  --service-type RDS \
  --identifier db-ID \
  --start-time 2018-10-30T00:00:00Z \
  --end-time 2018-10-30T01:00:00Z \
  --period-in-seconds 60 \
  --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
  --service-type RDS ^
  --identifier db-ID ^
  --start-time 2018-10-30T00:00:00Z ^
  --end-time 2018-10-30T01:00:00Z ^
  --period-in-seconds 60 ^
  --metric-queries file://query.json
```

The response looks similar to the following.

```
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1556215200.0,
  "MetricList": [
    {
      "Key": {
        "Metric": "db.load.avg"
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 1.4878117913832196
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 1.192823803967328
        }
      ]
    },
    {
      "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
          "db.wait_event.type": "io",
          "db.wait_event.name": "wait/io/aurora_redo_log_flush"
        }
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 1.1360544217687074
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 1.058051341890315
        }
      ]
    }
  ]
}
```
{ "Key": { "Metric": "db.load.avg", "Dimensions": { "db.wait_event.type": "io", "db.wait_event.name": "wait/io/table/sql/handler" } }, "DataPoints": [ { "Timestamp": 1556218800.0, "Value": 0.16241496598639457 }, { "Timestamp": 1556222400.0, "Value": 0.05163360560093349 } ] }, { "Key": { "Metric": "db.load.avg", "Dimensions": { "db.wait_event.type": "synch", "db.wait_event.name": "wait/synch/mutex/innodb/aurora_lock_thread_slot_futex" } }, "DataPoints": [ { "Timestamp": 1556218800.0, "Value": 0.11479591836734694 }, { "Timestamp": 1556222400.0, "Value": 0.013127187864644107 } ] }, { "Key": { "Metric": "db.load.avg", "Dimensions": { "db.wait_event.type": "CPU", "db.wait_event.name": "CPU" } }, "DataPoints": [ { "Timestamp": 1556218800.0, "Value": 0.05215419501133787 }, { "Timestamp": 1556222400.0, "Value": 0.05805134189031505 } ] }, { "Key": { "Metric": "db.load.avg", "Dimensions": { "db.wait_event.type": "synch", "db.wait_event.name": "wait/synch/mutex/innodb/lock_wait_mutex" } }, 508
"DataPoints": [
  {
    "Timestamp": 1556218800.0,
    "Value": 0.017573696145124718
  },
  {
    "Timestamp": 1556222400.0,
    "Value": 0.002333722287047841
  }
],
"AlignedEndTime": 1556222400.0
} //end of response

In this response, all values are filtered according to the contribution of tokenized SQL 
AKIAIOSFODNN7EXAMPLE specified in the query.json file. The keys also might follow a different order 
than a query without a filter, because it's the top five wait events that affected the filtered SQL.

Retrieving the full text of a SQL statement

The following example retrieves the full text of a SQL statement for DB instance 
db-10BCD2EFGH1J3KL4M5NO6PQRS5. The --group is db.sql, and the --group-identifier is 
db.sql.id. In this example, my-sql-id represents a SQL ID retrieved by invoking pi get-resource- 
metrics or pi describe-dimension-keys.

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-dimension-key-details --service-type RDS --identifier db-10BCD2EFGH1J3KL4M5NO6PQRS5 --group db.sql --group-identifier my-sql-id --requested-dimensions statement
```

For Windows:

```
aws pi get-dimension-key-details --service-type RDS --identifier db-10BCD2EFGH1J3KL4M5NO6PQRS5 --group db.sql --group-identifier my-sql-id --requested-dimensions statement
```

In this example, the dimensions details are available. Thus, Performance Insights retrieves the full text of 
the SQL statement, without truncating it.

```json
{
  "Dimensions": [
    {
      "Value": "SELECT e.last_name, d.department_name FROM employees e, departments d
WHERE e.department_id=d.department_id",
      "Dimension": "db.sql.statement",
      "Status": "AVAILABLE"
    },
    ...
  ]
}
```
Logging Performance Insights calls using AWS CloudTrail

Performance Insights runs with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Performance Insights. CloudTrail captures all API calls for Performance Insights as events. This capture includes calls from the Amazon RDS console and from code calls to the Performance Insights API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Performance Insights. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the data collected by CloudTrail, you can determine certain information. This information includes the request that was made to Performance Insights, the IP address the request was made from, who made the request, and when it was made. It also includes additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Working with Performance Insights information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Performance Insights, that activity is recorded in a CloudTrail event along with other AWS service events in the CloudTrail console in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History in AWS CloudTrail User Guide.

For an ongoing record of events in your AWS account, including events for Performance Insights, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in AWS CloudTrail User Guide:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Performance Insights operations are logged by CloudTrail and are documented in the Performance Insights API Reference. For example, calls to the DescribeDimensionKeys and GetResourceMetrics operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.
Performance Insights log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source. Each event includes information about the requested operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the GetResourceMetrics operation.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws:iam::123456789012:user/johndoe",
    "accountId": "123456789012",
    "accessKeyId": "AKIAI44QH8DHEEXAMPLE",
    "userName": "johndoe"
  },
  "eventTime": "2019-12-18T19:28:46Z",
  "eventSource": "pi.amazonaws.com",
  "eventName": "GetResourceMetrics",
  "awsRegion": "us-east-1",

Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS

Amazon DevOps Guru is a fully managed operations service that helps developers and operators improve the performance and availability of their applications. DevOps Guru offloads the tasks associated with identifying operational issues so that you can quickly implement recommendations to improve your application. To learn more, see What is Amazon DevOps Guru? in the Amazon DevOps Guru User Guide.

DevOps Guru detects, analyzes, and makes recommendations for operational issues for all Amazon RDS DB engines. DevOps Guru for RDS extends this capability by applying machine learning to Performance Insights metrics for Amazon Aurora databases. These monitoring features allow DevOps Guru for RDS to detect and diagnose performance bottlenecks and recommend specific corrective actions. To learn more, see Overview of DevOps Guru for RDS in the Amazon DevOps Guru User Guide.

The following video is an overview of DevOps Guru for RDS.

For a deep dive on this subject, see Amazon DevOps Guru for RDS under the hood.

Topics
- Benefits of DevOps Guru for RDS (p. 512)
- How DevOps Guru for RDS works (p. 513)
- Setting up DevOps Guru for RDS (p. 513)

Benefits of DevOps Guru for RDS

If you're responsible for an Amazon Aurora database, you might not know that an event or regression that is affecting that database is occurring. When you learn about the issue, you might not know why it's occurring or what to do about it. Rather than turning to a database administrator (DBA) for help or relying on third-party tools, you can follow recommendations from DevOps Guru for RDS.

You gain the following advantages from the detailed analysis of DevOps Guru for RDS:

Fast diagnosis

DevOps Guru for RDS continuously monitors and analyzes database telemetry. Performance Insights, Enhanced Monitoring, and Amazon CloudWatch collect telemetry data for your database cluster. DevOps Guru for RDS uses statistical and machine learning techniques to mine this data and detect anomalies. To learn more about telemetry data, see Monitoring DB load with Performance Insights on Amazon Aurora and Monitoring the OS by using Enhanced Monitoring in the Amazon Aurora User Guide.

Fast resolution

Each anomaly identifies the performance issue and suggests avenues of investigation or corrective actions. For example, DevOps Guru for RDS might recommend that you investigate specific wait events. Or it might recommend that you tune your application pool settings to limit the number of database connections. Based on these recommendations, you can resolve performance issues more quickly than by troubleshooting manually.

Deep knowledge of Amazon engineers

To detect performance issues and help you resolve bottlenecks, DevOps Guru for RDS relies on machine learning (ML). Amazon database engineers contributed to the development of the DevOps Guru for RDS findings, which encapsulate many years of managing hundreds of thousands
of databases. By drawing on this collective knowledge, DevOps Guru for RDS can teach you best practices.

**How DevOps Guru for RDS works**

DevOps Guru for RDS collects data about your Aurora databases from Amazon RDS Performance Insights. The most important metric is `DBLoad`. DevOps Guru for RDS consumes the Performance Insights metrics, analyzes them with machine learning, and publishes insights to the dashboard.

**Insights**

An insight is a collection of related anomalies that were detected by DevOps Guru. If DevOps Guru for RDS finds performance issues in your Amazon Aurora DB instances, it publishes an insight in the DevOps Guru dashboard. To learn more about insights, see Working with insights in DevOps Guru in the Amazon DevOps Guru User Guide.

**Anomalies**

In DevOps Guru for RDS, an anomaly is a pattern that deviates from what is considered normal performance for your Amazon Aurora database.

**Causal anomalies**

A causal anomaly is a top-level anomaly within an insight. Database load (DB load) is the causal anomaly for DevOps Guru for RDS.

An anomaly measures performance impact by assigning a severity level of High, Medium, or Low. To learn more, see Key concepts for DevOps Guru for RDS in the Amazon DevOps Guru User Guide.

If DevOps Guru detects an anomaly on your DB instance, you're alerted in the Databases page of the RDS console. To go to the anomaly page from the RDS console, choose the link in the alert message. The RDS console also alerts you in the page for your Amazon Aurora cluster.

**Contextual anomalies**

A contextual anomaly is a finding within Database load (DB load). Each contextual anomaly describes a specific Amazon Aurora performance issue that requires investigation. For example, DevOps Guru for RDS might recommend that you consider increasing CPU capacity or investigate wait events that are contributing to DB load.

**Important**

We recommend that you test any changes on a test instance before modifying a production instance. In this way, you understand the impact of the change.

To learn more, see Analyzing anomalies in Amazon Aurora clusters in the Amazon DevOps Guru User Guide.

**Setting up DevOps Guru for RDS**

To allow DevOps Guru for Amazon RDS to publish insights for an Amazon Aurora database, complete the following tasks.

**Topics**

- Configuring IAM access policies for DevOps Guru for RDS (p. 514)
- Turning on Performance Insights for your Aurora DB instances (p. 514)
• Turning on DevOps Guru and specifying resource coverage (p. 514)

Configuring IAM access policies for DevOps Guru for RDS

To view alerts from DevOps Guru in the RDS console, your AWS Identity and Access Management (IAM) user or role must have either of the following policies:

• The AWS managed policy AmazonDevOpsGuruConsoleFullAccess
• The AWS managed policy AmazonDevOpsGuruConsoleReadOnlyAccess and either of the following policies:
  • The AWS managed policy AmazonRDSFullAccess
  • A customer managed policy that includes pi:GetResourceMetrics and pi:DescribeDimensionKeys

For more information, see Configuring access policies for Performance Insights (p. 473).

Turning on Performance Insights for your Aurora DB instances

DevOps Guru for RDS relies on Performance Insights for its data. Without Performance Insights, DevOps Guru publishes anomalies, but doesn't include the detailed analysis and recommendations.

When you create an Aurora DB cluster or modify a cluster instance, you can turn on Performance Insights. For more information, see Turning Performance Insights on and off (p. 466).

Turning on DevOps Guru and specifying resource coverage

You can turn on DevOps Guru to have it monitor your Aurora databases in either of the following ways.

Topics
• Turning on DevOps Guru in the RDS console (p. 514)
• Adding Aurora resources on the DevOps Guru console (p. 517)

Turning on DevOps Guru in the RDS console

You can take multiple paths in the Amazon RDS console to turn on DevOps Guru.

Topics
• Turning on DevOps Guru when you create an Aurora database (p. 514)
• Turning on DevOps Guru from the notification banner (p. 515)
• Responding to a permissions error when you turn on DevOps Guru (p. 516)

Turning on DevOps Guru when you create an Aurora database

The creation workflow includes a setting that turns on DevOps Guru coverage for your database. This setting is turned on by default when you choose the Production template.

To turn on DevOps Guru when you create an Aurora database

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Follow the steps in Creating a DB cluster (p. 131), up to but not including the step where you choose monitoring settings.
3. In **Monitoring**, choose **Turn on Performance Insights**. For DevOps Guru for RDS to provide detailed analysis of performance anomalies, Performance Insights must be turned on.

4. Choose **Turn on DevOps Guru**.

![Turn on Performance Insights](image)

5. Create a tag for your database so that DevOps Guru can monitor it. Do the following:

   - In the text field for **Tag key**, enter a name that begins with `Devops-Guru-`.
   - In the text field for **Tag value**, enter any value. For example, if you enter `rds-database-1` for the name of your Aurora database, you can also enter `rds-database-1` as the tag value.

   For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the *Amazon DevOps Guru User Guide*.

6. Complete the remaining steps in **Creating a DB cluster** (p. 131).

**Turning on DevOps Guru from the notification banner**

If your resources aren't covered by DevOps Guru, Amazon RDS notifies you with a banner in the following locations:

- The **Monitoring** tab of a DB cluster instance
- The Performance Insights dashboard
To turn on DevOps Guru for your Aurora database

1. In the banner, choose Turn on DevOps Guru for RDS.
2. Enter a tag key name and value. For more information about tags, see "Use tags to identify resources in your DevOps Guru applications" in the Amazon DevOps Guru User Guide.

3. Choose Turn on DevOps Guru.

In the Performance Insights dashboard, you can also turn off DevOps Guru.

Responding to a permissions error when you turn on DevOps Guru

If you turn on DevOps Guru from the RDS console when you create a database, RDS might display the following banner about missing permissions.

To respond to a permissions error

1. Grant your IAM user or role the user managed role AmazonDevOpsGuruConsoleFullAccess. For more information, see Configuring IAM access policies for DevOps Guru for RDS (p. 514).
2. Open the RDS console.
3. In the navigation pane, choose Performance Insights.
4. Choose a DB instance in the cluster that you just created.
5. Turn on DevOps Guru for RDS.
6. Choose a tag value. For more information, see "Use tags to identify resources in your DevOps Guru applications" in the Amazon DevOps Guru User Guide.

```
Turn on DevOps Guru for database-1-instance-1
DevOps Guru for RDS automatically detects performance anomalies for Aurora databases and provides recommendations.

To allow DevOps Guru for RDS to monitor a resource, specify a tag. The tag key must begin with "DevOps-Guru". Learn more

Tag key  Tag value
devops-guru-default  database-1-instance-1

Cost per resource per hour
$0.0042  Amazon DevOps Guru pricing

By choosing Turn on DevOps Guru, you agree to the terms related to use of DevOps Guru in the AWS Service Terms.
```

7. Choose Turn on DevOps Guru.

**Adding Aurora resources on the DevOps Guru console**

You can specify your DevOps Guru resource coverage on the DevOps Guru console. Follow the step described in Specify your DevOps Guru resource coverage in the Amazon DevOps Guru User Guide. When you edit your analyzed resources, choose one of the following options:

- Choose **All account resources** to analyze all supported resources, including the Aurora databases, in your AWS account and Region.
- Choose **CloudFormation stacks** to analyze the Aurora databases that are in stacks you choose. For more information, see Use AWS CloudFormation stacks to identify resources in your DevOps Guru applications in the Amazon DevOps Guru User Guide.
- Choose **Tags** to analyze the Aurora databases that you have tagged. For more information, see Use tags to identify resources in your DevOps Guru applications in the Amazon DevOps Guru User Guide.

For more information, see Enable DevOps Guru in the Amazon DevOps Guru User Guide.
Monitoring OS metrics with Enhanced Monitoring

With Enhanced Monitoring, you can monitor the operating system of your DB instance in real time. When you want to see how different processes or threads use the CPU, Enhanced Monitoring metrics are useful.

Topics

• Overview of Enhanced Monitoring (p. 518)
• Setting up and enabling Enhanced Monitoring (p. 519)
• Viewing OS metrics in the RDS console (p. 523)
• Viewing OS metrics using CloudWatch Logs (p. 524)

Overview of Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view all the system metrics and process information for your RDS DB instances on the console. You can manage which metrics you want to monitor for each instance and customize the dashboard according to your requirements. For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 558).

RDS delivers the metrics from Enhanced Monitoring into your Amazon CloudWatch Logs account. You can create metrics filters in CloudWatch from CloudWatch Logs and display the graphs on the CloudWatch dashboard. You can consume the Enhanced Monitoring JSON output from CloudWatch Logs in a monitoring system of your choice. For more information, see Enhanced Monitoring in the Amazon RDS FAQs.

Topics

• Differences between CloudWatch and Enhanced Monitoring metrics (p. 518)
• Retention of Enhanced Monitoring metrics (p. 518)
• Cost of Enhanced Monitoring (p. 519)

Differences between CloudWatch and Enhanced Monitoring metrics

A hypervisor creates and runs virtual machines (VMs). Using a hypervisor, an instance can support multiple guest VMs by virtually sharing memory and CPU. CloudWatch gathers metrics about CPU utilization from the hypervisor for a DB instance. In contrast, Enhanced Monitoring gathers its metrics from an agent on the DB instance.

You might find differences between the CloudWatch and Enhanced Monitoring measurements, because the hypervisor layer performs a small amount of work. The differences can be greater if your DB instances use smaller instance classes. In this scenario, more virtual machines (VMs) are probably managed by the hypervisor layer on a single physical instance.

For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 558). For more information about CloudWatch metrics, see the Amazon CloudWatch User Guide.

Retention of Enhanced Monitoring metrics

By default, Enhanced Monitoring metrics are stored for 30 days in the CloudWatch Logs. This retention period is different from typical CloudWatch metrics.
To modify the amount of time the metrics are stored in the CloudWatch Logs, change the retention for the **RDSOSMetrics** log group in the CloudWatch console. For more information, see Change log data retention in CloudWatch logs in the *Amazon CloudWatch Logs User Guide*.

**Cost of Enhanced Monitoring**

Enhanced Monitoring metrics are stored in the CloudWatch Logs instead of in CloudWatch metrics. The cost of Enhanced Monitoring depends on the following factors:

- You are charged for Enhanced Monitoring only if you exceed the free tier provided by Amazon CloudWatch Logs. Charges are based on CloudWatch Logs data transfer and storage rates.
- The amount of information transferred for an RDS instance is directly proportional to the defined granularity for the Enhanced Monitoring feature. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your accounts.
- Usage costs for Enhanced Monitoring are applied for each DB instance that Enhanced Monitoring is enabled for. Monitoring a large number of DB instances is more expensive than monitoring only a few.
- DB instances that support a more compute-intensive workload have more OS process activity to report and higher costs for Enhanced Monitoring.

For more information about pricing, see *Amazon CloudWatch pricing*.

**Setting up and enabling Enhanced Monitoring**

To use Enhanced Monitoring, you must create an IAM role, and then enable Enhanced Monitoring.

**Topics**

- Creating an IAM role for Enhanced Monitoring (p. 519)
- Turning Enhanced Monitoring on and off (p. 520)
- Protecting against the confused deputy problem (p. 522)

**Creating an IAM role for Enhanced Monitoring**

Enhanced Monitoring requires permission to act on your behalf to send OS metric information to CloudWatch Logs. You grant Enhanced Monitoring permissions using an AWS Identity and Access Management (IAM) role. You can either create this role when you enable Enhanced Monitoring or create it beforehand.

**Topics**

- Creating the IAM role when you enable Enhanced Monitoring (p. 519)
- Creating the IAM role before you enable Enhanced Monitoring (p. 520)

**Creating the IAM role when you enable Enhanced Monitoring**

When you enable Enhanced Monitoring in the RDS console, Amazon RDS can create the required IAM role for you. The role is named **rds-monitoring-role**. RDS uses this role for the specified DB instance, read replica, or Multi-AZ DB cluster.

**To create the IAM role when enabling Enhanced Monitoring**

1. Follow the steps in Turning Enhanced Monitoring on and off (p. 520).
2. Set **Monitoring Role** to **Default** in the step where you choose a role.
Creating the IAM role before you enable Enhanced Monitoring

You can create the required role before you enable Enhanced Monitoring. When you enable Enhanced Monitoring, specify your new role's name. You must create this required role if you enable Enhanced Monitoring using the AWS CLI or the RDS API.

The user that enables Enhanced Monitoring must be granted the PassRole permission. For more information, see Example 2 in Granting a user permissions to pass a role to an AWS service in the IAM User Guide.

To create an IAM role for Amazon RDS enhanced monitoring

2. In the navigation pane, choose Roles.
3. Choose Create role.
4. Choose the AWS service tab, and then choose RDS from the list of services.
5. Choose RDS - Enhanced Monitoring, and then choose Next.
6. Ensure that the Permissions policies shows AmazonRDSEnhancedMonitoringRole, and then choose Next.
7. For Role name, enter a name for your role. For example, enter emaccess.
   The trusted entity for your role is the AWS service monitoring.rds.amazonaws.com.
8. Choose Create role.

Turning Enhanced Monitoring on and off

You can turn Enhanced Monitoring on and off using the AWS Management Console, AWS CLI, or RDS API. You choose the RDS DB instances on which you want to turn on Enhanced Monitoring. You can set different granularities for metric collection on each DB instance.

Console

You can turn on Enhanced Monitoring when you create a DB cluster or read replica, or when you modify a DB cluster. If you modify a DB instance to turn on Enhanced Monitoring, you don't need to reboot your DB instance for the change to take effect.

You can turn on Enhanced Monitoring in the RDS console when you do one of the following actions in the Databases page:

- Create a DB cluster – Choose Create database.
- Create a read replica – Choose Actions, then Create read replica.
- Modify a DB instance – Choose Modify.

To turn Enhanced Monitoring on or off in the RDS console

1. Scroll to Additional configuration.
2. In Monitoring, choose Enable Enhanced Monitoring for your DB instance or read replica. To turn Enhanced Monitoring off, choose Disable Enhanced Monitoring.
3. Set the Monitoring Role property to the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose Default to have RDS create a role for you named rds-monitoring-role.
4. Set the Granularity property to the interval, in seconds, between points when metrics are collected for your DB instance or read replica. The Granularity property can be set to one of the following values: 1, 5, 10, 15, 30, or 60.
The fastest that the RDS console refreshes is every 5 seconds. If you set the granularity to 1 second in the RDS console, you still see updated metrics only every 5 seconds. You can retrieve 1-second metric updates by using CloudWatch Logs.

**AWS CLI**

To turn on Enhanced Monitoring using the AWS CLI, in the following commands, set the `--monitoring-interval` option to a value other than 0 and set the `--monitoring-role-arn` option to the role you created in Creating an IAM role for Enhanced Monitoring (p. 519).

- `create-db-instance`
- `create-db-instance-read-replica`
- `modify-db-instance`

The `--monitoring-interval` option specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values for the option are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the AWS CLI, set the `--monitoring-interval` option to 0 in these commands.

**Example**

The following example turns on Enhanced Monitoring for a DB instance:

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --monitoring-interval 30 \
  --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```bash
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --monitoring-interval 30 ^
  --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

**Example**

The following example turns on Enhanced Monitoring for a Multi-AZ DB cluster:

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --monitoring-interval 30 \
  --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --monitoring-interval 30 ^
  --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```
RDS API

To turn on Enhanced Monitoring using the RDS API, set the MonitoringInterval parameter to a value other than 0 and set the MonitoringRoleArn parameter to the role you created in Creating an IAM role for Enhanced Monitoring (p. 519). Set these parameters in the following actions:

- CreateDBInstance
- CreateDBInstanceReadReplica
- ModifyDBInstance

The MonitoringInterval parameter specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values are 0, 1, 5, 10, 15, 30, and 60.

To turn off Enhanced Monitoring using the RDS API, set MonitoringInterval to 0.

Protecting against the confused deputy problem

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem.

To limit the permissions to the resource that Amazon RDS can give another service, we recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in a trust policy for your Enhanced Monitoring role. If you use both global condition context keys, they must use the same account ID.

The most effective way to protect against the confused deputy problem is to use the aws:SourceArn global condition context key with the full ARN of the resource. For Amazon RDS, set aws:SourceArn to `arn:aws:rds:Region:my-account-id:db:dbname`.

The following example uses the aws:SourceArn and aws:SourceAccount global condition context keys in a trust policy to prevent the confused deputy problem.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringLike": {
                    "aws:SourceArn": "arn:aws:rds:Region:my-account-id:db:dbname"
                },
                "StringEquals": {
                    "aws:SourceAccount": "my-account-id"
                }
            }
        }
    ]
}
```
Viewing OS metrics in the RDS console

You can view OS metrics reported by Enhanced Monitoring in the RDS console by choosing Enhanced monitoring for Monitoring.

The following example shows the Enhanced Monitoring page. For descriptions of the Enhanced Monitoring metrics, see OS metrics in Enhanced Monitoring (p. 558).

If you want to see details for the processes running on your DB instance, choose OS process list for Monitoring.

The Process List view is shown following.

The Enhanced Monitoring metrics shown in the Process list view are organized as follows:

- **RDS child processes** – Shows a summary of the RDS processes that support the DB instance, for example `aurora` for Amazon Aurora DB clusters. Process threads appear nested beneath the parent
process. Process threads show CPU utilization only as other metrics are the same for all threads for the
process. The console displays a maximum of 100 processes and threads. The results are a combination
of the top CPU consuming and memory consuming processes and threads. If there are more than 50
processes and more than 50 threads, the console displays the top 50 consumers in each category. This
display helps you identify which processes are having the greatest impact on performance.

- **RDS processes** – Shows a summary of the resources used by the RDS management agent, diagnostics
  monitoring processes, and other AWS processes that are required to support RDS DB instances.

- **OS processes** – Shows a summary of the kernel and system processes, which generally have minimal
  impact on performance.

The items listed for each process are:

- **VIRT** – Displays the virtual size of the process.
- **RES** – Displays the actual physical memory being used by the process.
- **CPU%** – Displays the percentage of the total CPU bandwidth being used by the process.
- **MEM%** – Displays the percentage of the total memory being used by the process.

The monitoring data that is shown in the RDS console is retrieved from Amazon CloudWatch Logs.
You can also retrieve the metrics for a DB instance as a log stream from CloudWatch Logs. For more
information, see Viewing OS metrics using CloudWatch Logs (p. 524).

Enhanced Monitoring metrics are not returned during the following:

- A failover of the DB instance.
- Changing the instance class of the DB instance (scale compute).

Enhanced Monitoring metrics are returned during a reboot of a DB instance because only the database
engine is rebooted. Metrics for the operating system are still reported.

**Viewing OS metrics using CloudWatch Logs**

After you have enabled Enhanced Monitoring for your DB cluster, you can view the metrics for it using
CloudWatch Logs, with each log stream representing a single DB instance or DB cluster being monitored.
The log stream identifier is the resource identifier (DbiResourceId) for the DB instance or DB cluster.

**To view Enhanced Monitoring log data**

2. If necessary, choose the AWS Region that your DB cluster is in. For more information, see Regions
   and endpoints in the Amazon Web Services General Reference.
3. Choose Logs in the navigation pane.
4. Choose **RDSOSMetrics** from the list of log groups.
5. Choose the log stream that you want to view from the list of log streams.
Metrics reference for Amazon Aurora

In this reference, you can find descriptions of Amazon Aurora metrics for Amazon CloudWatch, Performance Insights, and Enhanced Monitoring.

Topics
- Amazon CloudWatch metrics for Amazon Aurora (p. 525)
- Amazon CloudWatch dimensions for Aurora (p. 541)
- Availability of Aurora metrics in the Amazon RDS console (p. 542)
- Amazon CloudWatch metrics for Performance Insights (p. 544)
- Performance Insights counter metrics (p. 546)
- SQL statistics for Performance Insights (p. 554)
- OS metrics in Enhanced Monitoring (p. 558)

Amazon CloudWatch metrics for Amazon Aurora

The AWS/RDS namespace includes the following metrics that apply to database entities running on Amazon Aurora. Some metrics apply to either Aurora MySQL, Aurora PostgreSQL, or both. Furthermore, some metrics are specific to a DB cluster, primary DB instance, replica DB instance, or all DB instances.

For Aurora global database metrics, see Amazon CloudWatch metrics for write forwarding (p. 189). For Aurora parallel query metrics, see Monitoring parallel query (p. 807).

Topics
- Cluster-level metrics for Amazon Aurora (p. 525)
- Instance-level metrics for Amazon Aurora (p. 531)
- Amazon CloudWatch usage metrics for Amazon Aurora (p. 541)

Cluster-level metrics for Amazon Aurora

The following table describes metrics that are specific to Aurora clusters.

Amazon Aurora cluster-level metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Console name</th>
<th>Description</th>
<th>Applies to</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuroraGlobalDBDataTransferBytes</td>
<td><strong>Aurora Global DB Data Transfer Bytes (Bytes)</strong></td>
<td>In an Aurora Global Database, the amount of redo log data transferred from the master AWS Region to a secondary AWS Region.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Bytes</td>
</tr>
<tr>
<td>AuroraGlobalDBProgressLag</td>
<td><strong>Aurora Global DB Progress Lag</strong></td>
<td>In an Aurora Global Database, the measure of how far the secondary cluster is behind the primary cluster for both user transactions and system transactions.</td>
<td>Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>AuroraGlobalDBReplicatedWriteIO</td>
<td><strong>Aurora Global DB Replicated Write IO</strong></td>
<td>In an Aurora Global Database, the number of replicated write IO operations.</td>
<td>Aurora MySQL</td>
<td>Count</td>
</tr>
<tr>
<td>Metric</td>
<td>Console name</td>
<td>Description</td>
<td>Applies to</td>
<td>Units</td>
</tr>
<tr>
<td>--------</td>
<td>--------------</td>
<td>-------------</td>
<td>------------</td>
<td>-------</td>
</tr>
<tr>
<td>of write I/O operations replicated from the primary AWS Region to the cluster volume in a secondary AWS Region. The billing calculations for the secondary AWS Regions in a global database use VolumeWriteIOPS to account for writes performed within the cluster. The billing calculations for the primary AWS Region in a global database use VolumeWriteIOPS to account for the write activity within that cluster, and AuroraGlobalDBReplicatedWriteIO to account for cross-Region replication within the global database.</td>
<td>AuroraGlobalDBReplicationLag</td>
<td>For an Aurora Global Database, the amount of lag when replicating updates from the primary AWS Region.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>In an Aurora Global Database, the recovery point objective (RPO) lag time. This metric measures how far the secondary cluster is behind the primary cluster for user transactions.</td>
<td>AuroraGlobalDBRPO Lag</td>
<td></td>
<td>Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>

<td>Units</td>
</tr>
<tr>
<td>----------------</td>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>VolumeReadIOPs</td>
<td>Volume Read IOPS (Count)</td>
<td>The number of billed read I/O operations from a cluster volume within a 5-minute interval. Billed read operations are calculated at the cluster volume level, aggregated from all instances in the Aurora DB cluster, and then reported at 5-minute intervals. The value is calculated by taking the value of the Read operations metric over a 5-minute period. You can determine the amount of billed read operations per second by taking the value of the Billed read operations metric and dividing by 300 seconds. For example, if the Billed read operations returns 13,686, then the billed read operations per second is 45 (13,686 / 300 = 45.62). You accrue billed read operations for queries that request database pages that aren’t in the buffer cache and must be loaded from storage. You might see spikes in billed read operations as query results are read from storage and then loaded into the buffer cache. <strong>Tip</strong> If your Aurora MySQL cluster uses parallel query, you might see an increase in VolumeReadIOPS values. Parallel queries don’t use the buffer pool. Thus, although the queries are fast, this optimized processing</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Count per 5 minutes</td>
</tr>

<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>VolumeWriteIOPs</td>
<td>Volume Write IOPS</td>
<td>The number of write disk I/O operations to the cluster volume, reported at 5-minute intervals. For a detailed description of how billed write operations are calculated, see VolumeReadIOPs.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Count per 5 minutes</td>
</tr>
</tbody>
</table>

### Instance-level metrics for Amazon Aurora

The following instance-specific CloudWatch metrics apply to all Aurora MySQL and Aurora PostgreSQL instances unless noted otherwise.

#### Amazon Aurora instance-level metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Console Name</th>
<th>Description</th>
<th>Applies to</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>AbortedClients</td>
<td></td>
<td>The number of client connections that have not been closed properly.</td>
<td>Aurora MySQL</td>
<td>Count</td>
</tr>
<tr>
<td>ActiveTransactions</td>
<td>Active Transactions (Count)</td>
<td>The average number of current transactions executing on an Aurora database instance per second. By default, Aurora doesn’t enable this metric. To begin measuring this value, set <code>innodb_monitor_enable='all'</code> in the DB parameter group for a specific DB instance.</td>
<td>Aurora MySQL</td>
<td>Count per second</td>
</tr>
<tr>
<td>AuroraBinlogReplicaLag</td>
<td>Aurora Binlog Replica Lag (Seconds)</td>
<td>The amount of time that a binary log replica DB cluster running on Aurora MySQL-Compatible Edition lags behind the binary log replication source. A lag means that the source is generating records faster than the replica can apply them.</td>
<td>Primary for Aurora MySQL</td>
<td>Seconds</td>
</tr>
<tr>
<td>Metric</td>

<td>-------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>AuroraReplicaLag</td>
<td>Aurora Replica Lag (Milliseconds)</td>
<td>For an Aurora replica, the amount of lag when replicating updates from the primary instance.</td>
<td>Replica for Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>AuroraReplicaLagMaximum</td>
<td>Replica Lag Maximum (Milliseconds)</td>
<td>The maximum amount of lag between the primary instance and each Aurora DB instance in the DB cluster.</td>
<td>Primary for Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>AuroraReplicaLagMinimum</td>
<td>Replica Lag Minimum (Milliseconds)</td>
<td>The minimum amount of lag between the primary instance and each Aurora DB instance in the DB cluster.</td>
<td>Primary for Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>BacktrackWindowActual</td>
<td>Backtrack Window Actual (Minutes)</td>
<td>The difference between the target backtrack window and the actual backtrack window.</td>
<td>Primary for Aurora MySQL</td>
<td>Minutes</td>
</tr>
<tr>
<td>BacktrackWindowAlert</td>
<td>Backtrack Window Alert (Count)</td>
<td>The number of times that the actual backtrack window is smaller than the target backtrack window for a given period of time.</td>
<td>Primary for Aurora MySQL</td>
<td>Count</td>
</tr>
<tr>
<td>BlockedTransactions</td>
<td>Blocked Transactions (Count)</td>
<td>The average number of transactions in the database that are blocked per second.</td>
<td>Aurora MySQL</td>
<td>Count per second</td>
</tr>
<tr>
<td>BufferCacheHitRatio</td>
<td>Buffer Cache Hit Ratio (Percent)</td>
<td>The percentage of requests that are served by the buffer cache.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Percentage</td>
</tr>
<tr>
<td>CommitLatency</td>
<td>Commit Latency (Milliseconds)</td>
<td>The average duration of commit operations.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Milliseconds</td>
</tr>
<tr>
<td>CommitThroughput</td>
<td>Commit Throughput (Count/Second)</td>
<td>The average number of commit operations per second.</td>
<td>Aurora MySQL and Aurora PostgreSQL</td>
<td>Count per second</td>

### Amazon CloudWatch usage metrics for Amazon Aurora

The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. CloudWatch collects usage metrics automatically for all AWS Regions except Asia Pacific (Jakarta).

For more information, see CloudWatch usage metrics in the Amazon CloudWatch User Guide. For more information about quotas, see Quotas and constraints for Amazon Aurora (p. 1755) and Requesting a quota increase in the Service Quotas User Guide.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Units*</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBClusterParameterGroups</td>
<td>The number of DB cluster parameter groups in your AWS account. The count excludes default parameter groups.</td>
<td>Count</td>
</tr>
<tr>
<td>DBClusters</td>
<td>The number of Amazon Aurora DB clusters in your AWS account.</td>
<td>Count</td>
</tr>
<tr>
<td>DBInstances</td>
<td>The number of DB instances in your AWS account.</td>
<td>Count</td>
</tr>
<tr>
<td>DBParameterGroups</td>
<td>The number of DB parameter groups in your AWS account. The count excludes the default DB parameter groups.</td>
<td>Count</td>
</tr>
<tr>
<td>DBSubnetGroups</td>
<td>The number of DB subnet groups in your AWS account. The count excludes the default subnet group.</td>
<td>Count</td>
</tr>
<tr>
<td>ManualClusterSnapshots</td>
<td>The number of manually created DB cluster snapshots in your AWS account. The count excludes invalid snapshots.</td>
<td>Count</td>
</tr>
<tr>
<td>OptionGroups</td>
<td>The number of option groups in your AWS account. The count excludes the default option groups.</td>
<td>Count</td>
</tr>
<tr>
<td>ReservedDBInstances</td>
<td>The number of reserved DB instances in your AWS account. The count excludes retired or declined instances.</td>
<td>Count</td>
</tr>
</tbody>
</table>

*Amazon RDS doesn't publish units for usage metrics to CloudWatch. The units only appear in the documentation.*

### Amazon CloudWatch dimensions for Aurora

You can filter Aurora metrics data by using any dimension in the following table.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Filters the requested data for . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBInstanceIdentifier</td>
<td>A specific DB instance.</td>
</tr>
<tr>
<td>DBClusterIdentifier</td>
<td>A specific Aurora DB cluster.</td>
</tr>
</tbody>
</table>
Availability of Aurora metrics in the Amazon RDS console

Not all metrics provided by Amazon Aurora are available in the Amazon RDS console. You can view these metrics using tools such as the AWS CLI and CloudWatch API. Also, some metrics in the Amazon RDS console are either shown only for specific instance classes, or with different names and units of measurement.

Topics

- Aurora metrics available in the Last Hour view (p. 542)
- Aurora metrics available in specific cases (p. 543)
- Aurora metrics that aren't available in the console (p. 544)

Aurora metrics available in the Last Hour view

You can view a subset of categorized Aurora metrics in the default Last Hour view in the Amazon RDS console. The following table lists the categories and associated metrics displayed in the Amazon RDS console for an Aurora instance.

<table>
<thead>
<tr>
<th>Category</th>
<th>Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL</td>
<td>ActiveTransactions</td>
</tr>
<tr>
<td></td>
<td>BlockedTransactions</td>
</tr>
<tr>
<td></td>
<td>BufferCacheHitRatio</td>
</tr>
<tr>
<td></td>
<td>CommitLatency</td>
</tr>
<tr>
<td></td>
<td>CommitThroughput</td>
</tr>
<tr>
<td></td>
<td>DatabaseConnections</td>
</tr>
</tbody>
</table>

Amazon Aurora User Guide for Aurora
Availability of Aurora metrics in the Amazon RDS console
### Aurora metrics available in specific cases

In addition, some Aurora metrics are either shown only for specific instance classes, or only for DB instances, or with different names and different units of measurement:

- The `CPUCreditBalance` and `CPUCreditUsage` metrics are displayed only for Aurora MySQL `db.t2` instance classes and for Aurora PostgreSQL `db.t3` instance classes.
- The following metrics that are displayed with different names, as listed:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Display name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora Replication Lag Maximum</td>
<td>Replica lag maximum</td>
</tr>
</tbody>
</table>
The following metrics apply to an entire Aurora DB cluster, but are displayed only when viewing DB instances for an Aurora DB cluster in the Amazon RDS console:

- VolumeBytesUsed
- VolumeReadIOPs
- VolumeWriteIOPs

The following metrics are displayed in megabytes, instead of bytes, in the Amazon RDS console:

- FreeableMemory
- FreeLocalStorage
- NetworkReceiveThroughput
- NetworkTransmitThroughput

**Aurora metrics that aren't available in the console**

The following Aurora metrics aren't available in the Amazon RDS console:

- AuroraBinlogReplicaLag
- DeleteLatency
- DeleteThroughput
- EngineUptime
- InsertLatency
- InsertThroughput
- NetworkThroughput
- Queries
- UpdateLatency
- UpdateThroughput

**Amazon CloudWatch metrics for Performance Insights**

Performance Insights automatically publishes metrics to Amazon CloudWatch. The same data can be queried from Performance Insights, but having the metrics in CloudWatch makes it easy to add CloudWatch alarms. It also makes it easy to add the metrics to existing CloudWatch Dashboards.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Display name</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuroraReplicaLagMinimum</td>
<td>Replica lag minimum</td>
</tr>
<tr>
<td>DDLThroughput</td>
<td>DDL</td>
</tr>
<tr>
<td>NetworkReceiveThroughput</td>
<td>Network throughput</td>
</tr>
<tr>
<td>VolumeBytesUsed</td>
<td>[Billed] Volume bytes used</td>
</tr>
<tr>
<td>VolumeReadIOPs</td>
<td>[Billed] Volume read IOPS</td>
</tr>
<tr>
<td>VolumeWriteIOPs</td>
<td>[Billed] Volume write IOPS</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBLoad</td>
<td>The number of active sessions for the DB engine. Typically, you want the data for the average</td>
</tr>
</tbody>
</table>
CloudWatch metrics for Performance Insights

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of active sessions. In Performance Insights, this data is queried as <code>db.load.avg</code>.</td>
<td></td>
</tr>
<tr>
<td>DBLoadCPU</td>
<td>The number of active sessions where the wait event type is CPU. In Performance Insights, this data is queried as <code>db.load.avg</code>, filtered by the wait event type CPU.</td>
</tr>
<tr>
<td>DBLoadNonCPU</td>
<td>The number of active sessions where the wait event type is not CPU.</td>
</tr>
</tbody>
</table>

**Note**

These metrics are published to CloudWatch only if there is load on the DB instance.

You can examine these metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API.

For example, you can get the statistics for the `DBLoad` metric by running the `get-metric-statistics` command.

```
aws cloudwatch get-metric-statistics \   
--region us-west-2 \   
--namespace AWS/RDS \   
--metric-name DBLoad \   
--period 60 \   
--statistics Average \   
--start-time 1532035185 \   
--end-time 1532036185 \   
--dimensions Name=DBInstanceIdentifier,Value=db-loadtest-0
```

This example generates output similar to the following.

```json
{
    "Datapoints": [
        {
            "Timestamp": "2021-07-19T21:30:00Z",
            "Unit": "None",
            "Average": 2.1
        },
        {
            "Timestamp": "2021-07-19T21:34:00Z",
            "Unit": "None",
            "Average": 1.7
        },
        {
            "Timestamp": "2021-07-19T21:35:00Z",
            "Unit": "None",
            "Average": 2.8
        },
        {
            "Timestamp": "2021-07-19T21:31:00Z",
            "Unit": "None",
            "Average": 1.5
        },
        {
            "Timestamp": "2021-07-19T21:32:00Z",
            "Unit": "None",
            "Average": 1.8
        }
    ]
}
```
For more information about CloudWatch, see What is Amazon CloudWatch? in the Amazon CloudWatch User Guide.

Performance Insights counter metrics

Counter metrics are operating system and database performance metrics in the Performance Insights dashboard. To help identify and analyze performance problems, you can correlate counter metrics with DB load.

Topics
- Performance Insights operating system counters (p. 546)
- Performance Insights counters for Aurora MySQL (p. 548)
- Performance Insights counters for Aurora PostgreSQL (p. 552)

Performance Insights operating system counters

The following operating system counters, which are prefixed with os, are available with Performance Insights for Aurora PostgreSQL. You can find definitions for these metrics in Viewing OS metrics using CloudWatch Logs (p. 524).

<table>
<thead>

**Performance Insights counters for Aurora MySQL**

The following database counters are available with Performance Insights for Aurora MySQL.

**Topics**
- Native counters for Aurora MySQL (p. 549)
- Non-native counters for Aurora MySQL (p. 550)
Native counters for Aurora MySQL

Native metrics are defined by the database engine and not by Amazon Aurora. You can find definitions for these native metrics in Server Status Variables in the MySQL documentation.

<table>

**Non-native counters for Aurora MySQL**

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.
<table>

Performance Insights counters for Aurora PostgreSQL

The following database counters are available with Performance Insights for Aurora PostgreSQL.

Topics
• Native Counters for Aurora PostgreSQL (p. 552)
• Non-native counters for Aurora PostgreSQL (p. 553)

Native Counters for Aurora PostgreSQL

Native metrics are defined by the database engine and not by Amazon Aurora. You can find definitions for these native metrics in Viewing Statistics in the PostgreSQL documentation.

<th>Metric</th>
<th>Description</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>logical_reads</td>
<td>SQL</td>
<td>db.SQL.logical_reads</td>
<td>The total number of blocks hit and read.</td>
<td>blks_hit + blks_read</td>
</tr>
<tr>
<td>checkpoint_sync_latency</td>
<td>Checkpoint</td>
<td>db.Checkpoint.checkpoint_sync_latency</td>
<td>The checkpoint sync latency that has been spent in the portion of checkpoint</td>
<td>checkpoint_sync_time / (checkpoints_timed + checkpoints_reg)</td>
</tr>
</tbody>
</table>
### SQL statistics for Performance Insights

*SQL statistics* are performance-related metrics about SQL queries that are collected by Performance Insights. Performance Insights gathers statistics for each second that a query is running and for each SQL call. All engines support statistics for digest queries. All engines support statement-level statistics except for Aurora PostgreSQL.

#### Topics
- SQL statistics for Aurora MySQL (p. 554)
- SQL statistics for Aurora PostgreSQL (p. 556)

### SQL statistics for Aurora MySQL

Aurora MySQL collect SQL statistics only at the digest level. No statistics are shown at the statement level.

#### Topics
- Digest statistics for Aurora MySQL (p. 554)
- Per-second statistics for Aurora MySQL (p. 555)
- Per-call statistics for Aurora MySQL (p. 555)

#### Digest statistics for Aurora MySQL

Performance Insights collects SQL digest statistics from the `events_statements_summary_by_digest` table. The `events_statements_summary_by_digest` table is managed by your database.

The digest table doesn't have an eviction policy. When the table is full, the AWS Management Console shows the following message:

Performance Insights is unable to collect SQL Digest statistics on new queries because the table `events_statements_summary_by_digest` is full. Please truncate `events_statements_summary_by_digest` table to clear the issue. Check the User Guide for more details.
In this situation, Aurora MySQL doesn't track SQL queries. To address this issue, Performance Insights automatically truncates the digest table when both of the following conditions are met:

- The table is full.
- Performance Insights manages the Performance Schema automatically.

For automatic management, the `performance_schema` parameter must be set to 0 and the `Source` must not be set to `user`. If Performance Insights isn't managing the Performance Schema automatically, see Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 469).

In the AWS CLI, check the source of a parameter value by running the `describe-db-parameters` command.

**Per-second statistics for Aurora MySQL**

The following SQL statistics are available for Aurora MySQL DB clusters.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.count_star_per_sec</code></td>
<td>Calls per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_timer_wait_per_sec</code></td>
<td>Average active executions per second (AAE)</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_full_join_per_sec</code></td>
<td>Select full join per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_range_check_per_select</code></td>
<td>range check per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_scan_per_sec</code></td>
<td>Select scan per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_merge_passes_per_sort</code></td>
<td>merge passes per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_scan_per_sec</code></td>
<td>Sort scans per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_range_per_sec</code></td>
<td>Sort ranges per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_rows_per_sec</code></td>
<td>Sort rows per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_affected_per_sec</code></td>
<td>Rows affected per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_examined_per_sec</code></td>
<td>Rows examined per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_sent_per_sec</code></td>
<td>Rows sent per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_sec</code></td>
<td>Created temporary disk tables per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_created_tmp_tables_per_created</code></td>
<td>Created temporary tables per second</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_lock_time_per_sec</code></td>
<td>Lock time per second (in ms)</td>
</tr>
</tbody>
</table>

**Per-call statistics for Aurora MySQL**

The following metrics provide per call statistics for a SQL statement.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.sum_timer_wait_per_call</code></td>
<td>Average latency per call (in ms)</td>
</tr>
<tr>
<td>Metric</td>
<td>Unit</td>
</tr>
<tr>
<td>--------</td>
<td>------</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_full_join_per_call</code></td>
<td>Select full joins per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_range_check_per_call</code></td>
<td>Select range check per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_select_scan_per_call</code></td>
<td>Select scans per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_merge_passes_per_call</code></td>
<td>Merge passes per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_scan_per_call</code></td>
<td>Sort scans per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_sort_rows_per_call</code></td>
<td>Sort rows per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_affected_per_call</code></td>
<td>Rows affected per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_examined_per_call</code></td>
<td>Rows examined per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_rows_sent_per_call</code></td>
<td>Rows sent per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_created_tmp_disk_tables_per_call</code></td>
<td>Created temporary disk tables per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_created_tmp_tables_per_call</code></td>
<td>Created temporary tables per call</td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.sum_lock_time_per_call</code></td>
<td>Lock time per call (in ms)</td>
</tr>
</tbody>
</table>

**SQL statistics for Aurora PostgreSQL**

For each SQL call and for each second that a query runs, Performance Insights collects SQL statistics. For other Aurora engines, statistics are collected at the statement-level and the digest-level. However, for Aurora PostgreSQL, Performance Insights collects SQL statistics at the digest-level only.

A SQL *digest* is a composite of all queries having a given pattern but not necessarily having the same literal values. The digest replaces literal values with a question mark. For example, `SELECT * FROM emp WHERE lname= ?` is an example digest. This digest might consist of the following child queries:

```
SELECT * FROM emp WHERE lname = 'Sanchez'
SELECT * FROM emp WHERE lname = 'Olagappan'
SELECT * FROM emp WHERE lname = 'Wu'
```

Following, you can find information about digest-level statistics for Aurora PostgreSQL.

**Topics**

- Digest statistics for Aurora PostgreSQL (p. 556)
- Per-second digest statistics for Aurora PostgreSQL (p. 557)
- Per-call digest statistics for Aurora PostgreSQL (p. 557)

**Digest statistics for Aurora PostgreSQL**

To view SQL digest statistics, the `pg_stat_statements` library must be loaded. For Aurora PostgreSQL DB clusters that are compatible with PostgreSQL 10, this library is loaded by default. For Aurora PostgreSQL DB clusters that are compatible with PostgreSQL 9.6, you enable this library manually. To enable it manually, add `pg_stat_statements` to `shared_preload_libraries` in the DB parameter group associated with the DB instance. Then reboot your DB instance. For more information, see Working with parameter groups (p. 215).
**Note**
Performance Insights can only collect statistics for queries in `pg_stat_activity` that aren't truncated. By default, PostgreSQL databases truncate queries longer than 1,024 bytes. To increase the query size, change the `track_activity_query_size` parameter in the DB parameter group associated with your DB instance. When you change this parameter, a DB instance reboot is required.

**Per-second digest statistics for Aurora PostgreSQL**

The following SQL digest statistics are available for Aurora PostgreSQL DB instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Unit</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>db.sql_tokenized.stats.calls_per_sec</code></td>
<td>Calls per second</td>
<td></td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.rows_per_sec</code></td>
<td>Rows per second</td>
<td></td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.total_time_per_sec</code></td>
<td>Average active executions per second (AAE)</td>
<td></td>
</tr>
<tr>
<td><code>db.sql_tokenized.stats.shared_blks_hit_per_sec</code></td>
<td>Block hits per second</td>

Monitoring events, logs, and streams in an Amazon Aurora DB cluster

When you monitor your Amazon Aurora databases and your other AWS solutions, your goal is to maintain the following:

- Reliability
- Availability
- Performance

Monitoring metrics in an Amazon Aurora cluster (p. 427) explains how to monitor your cluster using metrics. A complete solution must also monitor database events, log files, and activity streams. AWS provides you with the following monitoring tools:

- **Amazon EventBridge** is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, Software-as-a-Service (SaaS) applications, and AWS services and routes that data to targets such as AWS Lambda. This enables you to monitor events that happen in services, and build event-driven architectures. For more information, see the Amazon EventBridge User Guide.

- **Amazon CloudWatch Logs** lets you monitor, store, and access your log files from Amazon Aurora instances, AWS CloudTrail, and other sources. Amazon CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the Amazon CloudWatch Logs User Guide.

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.

- **Database Activity Streams** is an Amazon Aurora feature that provides a near-real-time stream of the activity in your DB cluster. Amazon Aurora pushes activities to an Amazon Kinesis data stream. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Topics
- Viewing logs, events, and streams in the Amazon RDS console (p. 563)
- Monitoring Amazon Aurora events (p. 568)
- Monitoring Amazon Aurora log files (p. 597)
- Monitoring Amazon Aurora API calls in AWS CloudTrail (p. 615)
- Monitoring Amazon Aurora with Database Activity Streams (p. 619)

Viewing logs, events, and streams in the Amazon RDS console

Amazon RDS integrates with AWS services to show information about logs, events, and database activity streams in the RDS console.
The Logs & events tab for your Aurora DB cluster shows the following information:

- **Auto scaling policies and activities** – Shows policies and activities relating to the Aurora Auto Scaling feature. This information only appears in the Logs & events tab at the cluster level.

- **Amazon CloudWatch alarms** – Shows any metric alarms that you have configured for the DB instance in your Aurora cluster. If you haven't configured alarms, you can create them in the RDS console.

- **Recent events** – Shows a summary of events (environment changes) for your Aurora DB instance or cluster. For more information, see Viewing Amazon RDS events (p. 569).

- **Logs** – Shows database log files generated by a DB instance in your Aurora cluster. For more information, see Monitoring Amazon Aurora log files (p. 597).

The Configuration tab displays information about database activity streams.

**To view logs, events, and streams for your Aurora DB cluster in the RDS console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose Databases.

3. Choose the name of the Aurora DB cluster that you want to monitor.

   The database page appears. The following example shows an Amazon Aurora PostgreSQL DB cluster named apga.

   ![Database Page Example](image)

   4. Scroll down and choose Configuration.

      The following example shows the status of the database activity streams for your cluster.
5. Choose **Logs & events**.

The Logs & events section appears.
6. Choose a DB instance in your Aurora cluster, and then choose **Logs & events** for the instance.

The following example shows that the contents are different between the DB instance page and the DB cluster page. The DB instance page shows logs and alarms.

Monitoring Amazon Aurora events

An event indicates a change in an environment. This can be an AWS environment, an SaaS partner service or application, or a custom application or service. For descriptions of the Aurora events, see Amazon RDS event categories and event messages (p. 590).

Topics

• Overview of events for Aurora (p. 568)
• Viewing Amazon RDS events (p. 569)
• Working with Amazon RDS event notification (p. 572)
• Creating a rule that triggers on an Amazon Aurora event (p. 587)
• Amazon RDS event categories and event messages (p. 590)

Overview of events for Aurora

An RDS event indicates a change in the Aurora environment. For example, Amazon Aurora generates an event when a DB cluster is patched. Amazon Aurora delivers events to CloudWatch Events and EventBridge in near-real time.

Note
Amazon RDS emits events on a best effort basis. We recommend that you avoid writing programs that depend on the order or existence of notification events, because they might be out of sequence or missing.

Amazon RDS records events that relate to the following resources:

• DB clusters
  For a list of cluster events, see DB cluster events (p. 590).
• DB instances
  For a list of DB instance events, see DB instance events (p. 592).
• DB parameter groups
  For a list of DB parameter group events, see DB parameter group events (p. 595).
• DB security groups
  For a list of DB security group events, see DB security group events (p. 595).
• DB cluster snapshots
  For a list of DB cluster snapshot events, see DB cluster snapshot events (p. 595).
• RDS Proxy events
  For a list of RDS Proxy events, see RDS Proxy events (p. 596).

This information includes the following:

• The date and time of the event
• The source name and source type of the event
• A message associated with the event
Viewing Amazon RDS events

You can retrieve the following event information for your Amazon Aurora resources:

- Resource name
- Resource type
- Time of the event
- Message summary of the event

Access the events through the AWS Management Console, which shows events from the past 24 hours. You can also retrieve events by using the `describe-events` AWS CLI command, or the `DescribeEvents` RDS API operation. If you use the AWS CLI or the RDS API to view events, you can retrieve events for up to the past 14 days.

**Note**

If you need to store events for longer periods of time, you can send Amazon RDS events to CloudWatch Events. For more information, see Creating a rule that triggers on an Amazon Aurora event (p. 587)

For descriptions of the Amazon Aurora events, see Amazon RDS event categories and event messages (p. 590).

To access detailed information about events using AWS CloudTrail, including request parameters, see CloudTrail captures API calls for Amazon Aurora as events. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations.

Amazon Aurora activity is recorded in a CloudTrail event in Event history. You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see Viewing events with CloudTrail event history.

**Console**

**To view all Amazon RDS events for the past 24 hours**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Events**.

   The available events appear in a list.
3. (Optional) Enter a search term to filter your results.

   The following example shows a list of events filtered by the characters apg.
To view all events generated in the last hour, call `describe-events` with no parameters.

```bash
aws rds describe-events
```

The following sample output shows that a DB cluster instance has started recovery.

```json
{
    "Events": [
        {
            "EventCategories": [
                "recovery"
            ],
            "SourceType": "db-instance",
            "Date": "2022-04-20T15:02:38.416Z",
            "Message": "Recovery of the DB instance has started. Recovery time will vary with the amount of data to be recovered.",
            "SourceIdentifier": "mycluster-instance-1"
        }, ...
    ]
}
```

To view all Amazon RDS events for the past 10080 minutes (7 days), call the `describe-events` AWS CLI command and set the `--duration` parameter to 10080.

```bash
aws rds describe-events --duration 10080
```
The following example shows the events in the specified time range for DB instance `test-instance`.

```bash
aws rds describe-events \
  --source-identifier test-instance \
  --source-type db-instance \
  --start-time 2022-03-13T22:00Z \
  --end-time 2022-03-13T23:59Z
```

The following sample output shows the status of a backup.

```
{
  "Events": [
    {
      "SourceType": "db-instance",
      "SourceIdentifier": "test-instance",
      "EventCategories": [
        "backup"
      ],
      "Message": "Backing up DB instance",
      "Date": "2022-03-13T23:09:23.983Z",
      "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
    },
    {
      "SourceType": "db-instance",
      "SourceIdentifier": "test-instance",
      "EventCategories": [
        "backup"
      ],
      "Message": "Finished DB Instance backup",
      "Date": "2022-03-13T23:15:13.049Z",
      "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:test-instance"
    }
  ]
}
```

**API**

You can view all Amazon RDS instance events for the past 14 days by calling the `DescribeEvents` RDS API operation and setting the `Duration` parameter to 20160.
Working with Amazon RDS event notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint.

Topics
- Overview of Amazon RDS event notification (p. 572)
- Granting permissions to publish notifications to an Amazon SNS topic (p. 577)
- Subscribing to Amazon RDS event notification (p. 578)
- Listing Amazon RDS event notification subscriptions (p. 581)
- Modifying an Amazon RDS event notification subscription (p. 582)
- Adding a source identifier to an Amazon RDS event notification subscription (p. 583)
- Removing a source identifier from an Amazon RDS event notification subscription (p. 584)
- Listing the Amazon RDS event notification categories (p. 585)
- Deleting an Amazon RDS event notification subscription (p. 586)

Overview of Amazon RDS event notification

Amazon RDS groups events into categories that you can subscribe to so that you can be notified when an event in that category occurs.

Topics
- RDS resources eligible for event subscription (p. 572)
- Basic process for subscribing to Amazon RDS event notifications (p. 573)
- Delivery of RDS event notifications (p. 573)
- Billing for Amazon RDS event notifications (p. 573)
- Examples of Aurora events (p. 573)

RDS resources eligible for event subscription

For Amazon Aurora, events occur at both the DB cluster and the DB instance level. You can subscribe to an event category for the following resources:

- DB instance
- DB cluster
- DB cluster snapshot
- DB parameter group
- DB security group
- RDS Proxy
- Custom engine version

For example, if you subscribe to the backup category for a given DB instance, you're notified whenever a backup-related event occurs that affects the DB instance. If you subscribe to a configuration change category for a DB security group, you're notified when the DB security group is changed. You also receive notification when an event notification subscription changes.

You might want to create several different subscriptions. For example, you might create one subscription that receives all event notifications for all DB instances and another subscription that includes only
critical events for a subset of the DB instances. For the second subscription, specify one or more DB instances in the filter.

**Basic process for subscribing to Amazon RDS event notifications**

The process for subscribing to Amazon RDS event notification is as follows:

1. You create an Amazon RDS event notification subscription by using the Amazon RDS console, AWS CLI, or API.

   Amazon RDS uses the ARN of an Amazon SNS topic to identify each subscription. The Amazon RDS console creates the ARN for you when you create the subscription. Create the ARN by using the Amazon SNS console, the AWS CLI, or the Amazon SNS API.

2. Amazon RDS sends an approval email or SMS message to the addresses you submitted with your subscription.

3. You confirm your subscription by choosing the link in the notification you received.

4. The Amazon RDS console updates the **My Event Subscriptions** section with the status of your subscription.

5. Amazon RDS begins sending the notifications to the addresses that you provided when you created the subscription.

To learn about identity and access management when using Amazon SNS, see [Identity and access management in Amazon SNS](https://docs.aws.amazon.com/sns/latest/dg/snsiantmgmt.html) in the *Amazon Simple Notification Service Developer Guide*.

You can use AWS Lambda to process event notifications from a DB instance. For more information, see [Using AWS Lambda with Amazon RDS](https://docs.aws.amazon.com/lambda/latest/dg/rds-event-notifications.html) in the *AWS Lambda Developer Guide*.

**Delivery of RDS event notifications**

Amazon RDS sends notifications to the addresses that you provide when you create the subscription. Event notifications might take up to five minutes to be delivered.

*Important*

Amazon RDS doesn't guarantee the order of events sent in an event stream. The event order is subject to change.

When Amazon SNS sends a notification to a subscribed HTTP or HTTPS endpoint, the POST message sent to the endpoint has a message body that contains a JSON document. For more information, see [Amazon SNS message and JSON formats](https://docs.aws.amazon.com/sns/latest/dg/sns-messjson.html) in the *Amazon Simple Notification Service Developer Guide*.

You can configure SNS to notify you with text messages. For more information, see [Mobile text messaging (SMS)](https://docs.aws.amazon.com/sns/latest/dg/sns-mess-sms.html) in the *Amazon Simple Notification Service Developer Guide*.

To turn off notifications without deleting a subscription, choose **No** for **Enabled** in the Amazon RDS console. Or you can set the **Enabled** parameter to `false` using the AWS CLI or Amazon RDS API.

**Billing for Amazon RDS event notifications**

Billing for Amazon RDS event notification is through Amazon SNS. Amazon SNS fees apply when using event notification. For more information about Amazon SNS billing, see [Amazon Simple Notification Service pricing](https://aws.amazon.com/sns/pricing/).

**Examples of Aurora events**

The following examples illustrate different types of Aurora events in JSON format. For a tutorial that shows you how to capture and view events in JSON format, see [Tutorial: Log DB instance state changes using Amazon EventBridge](https://docs.aws.amazon.com/aurora/latest/userguide/Aurora-EventBridge-Configure.html) (p. 587).
Example of a DB cluster event

The following is an example of a DB cluster event in JSON format. The event shows that the cluster named `my-db-cluster` was patched. The event ID is `RDS-EVENT-0173`.

```json
{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dcb42",
    "detail-type": "RDS DB Cluster Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:cluster:my-db-cluster"
    ],
    "detail": {
        "EventCategories": [
            "notification"
        ],
        "SourceType": "CLUSTER",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:my-db-cluster",
        "Date": "2018-10-06T12:26:13.882Z",
        "Message": "Database cluster has been patched",
        "SourceIdentifier": "rds:my-db-cluster",
        "EventID": "RDS-EVENT-0173"
    }
}
```

Example of a DB instance event

The following is an example of a DB instance event in JSON format. The event shows that RDS performed a multi-AZ failover for the instance named `my-db-instance`. The event ID is `RDS-EVENT-0049`.

```json
{
    "version": "0",
    "id": "68f6e973-1a0c-d37b-f2f2-94a7f62ff09e",
    "detail-type": "RDS DB Instance Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-09-27T22:36:43Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:db:my-db-instance"
    ],
    "detail": {
        "EventCategories": [
            "failover"
        ],
        "SourceType": "DB_INSTANCE",
        "Date": "2018-09-27T22:36:43.88Z",
        "Message": "A Multi-AZ failover has completed."
    }
}
```
Example of a DB parameter group event

The following is an example of a DB parameter group event in JSON format. The event shows that the parameter `time_zone` was updated in parameter group `my-db-param-group`. The event ID is RDS-EVENT-0037.

```
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "RDS DB Parameter Group Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"
  ],
  "detail": {
    "EventCategories": [
      "configuration change"
    ],
    "SourceType": "DB_PARAM",
    "Date": "2018-10-06T12:26:13.882Z",
    "Message": "Updated parameter time_zone to UTC with apply method immediate",
    "SourceIdentifier": "rds:my-db-param-group",
    "EventID": "RDS-EVENT-0037"
  }
}
```

Example of a DB cluster snapshot event

The following is an example of a DB cluster snapshot event in JSON format. The event shows the creation of the snapshot named `my-db-cluster-snapshot`. The event ID is RDS-EVENT-0074.

```
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "RDS DB Cluster Snapshot Event",
  "source": "aws.rds",
  "account": "123456789012",
  "time": "2018-10-06T12:26:13Z",
  "region": "us-east-1",
  "resources": [
  ],
  "detail": {
    "EventCategories": [
      "backup"
    ],
    "SourceType": "CLUSTER_SNAPSHOT",
    "Date": "2018-10-06T12:26:13.882Z",
    "SourceIdentifier": "rds:my-db-cluster-snapshot",
    "Message": "Creating manual cluster snapshot",
    "EventID": "RDS-EVENT-0074"
  }
}
```
}
Granting permissions to publish notifications to an Amazon SNS topic

To grant Amazon RDS permissions to publish notifications to an Amazon Simple Notification Service (Amazon SNS) topic, attach an AWS Identity and Access Management (IAM) policy to the destination topic. For more information about permissions, see Example cases for Amazon Simple Notification Service access control in the Amazon Simple Notification Service Developer Guide.

By default, an Amazon SNS topic has a policy allowing all Amazon RDS resources within the same account to publish notifications to it. You can attach a custom policy to allow cross-account notifications, or to restrict access to certain resources.

The following is an example of an IAM policy that you attach to the destination Amazon SNS topic. It restricts the topic to DB instances with names that match the specified prefix. To use this policy, specify the following values:

- **Resource** – The Amazon Resource Name (ARN) for your Amazon SNS topic
- **SourceARN** – Your RDS resource ARN
- **SourceAccount** – Your AWS account ID

To see a list of resource types and their ARNs, see Resources Defined by Amazon RDS in the Service Authorization Reference.

```
{
    "Version": "2008-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "events.rds.amazonaws.com"
            },
            "Action": ["sns:Publish"],
            "Condition": {
                "ArnLike": {
                },
                "StringEquals": {
                    "aws:SourceAccount": "123456789012"
                }
            }
        }
    ]
}
```
Subscribing to Amazon RDS event notification

The simplest way to create a subscription is with the RDS console. If you choose to create event notification subscriptions using the CLI or API, you must create an Amazon Simple Notification Service topic and subscribe to that topic with the Amazon SNS console or Amazon SNS API. You will also need to retain the Amazon Resource Name (ARN) of the topic because it is used when submitting CLI commands or API operations. For information on creating an SNS topic and subscribing to it, see Getting started with Amazon SNS in the Amazon Simple Notification Service Developer Guide.

You can specify the type of source you want to be notified of and the Amazon RDS source that triggers the event:

**Source type**

The type of source. For example, **Source type** might be **Instances**. You must choose a source type.

**Resources to include**

The Amazon RDS resources that are generating the events. For example, you might choose **Select specific instances** and then **myDBInstance1**.

The following table explains the result when you specify or don't specify **Resources to include**.

<table>
<thead>
<tr>
<th>Resources to include</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specified</td>
<td>RDS notifies you about all events for the specified resource only.</td>
<td>If your <strong>Source type</strong> is <strong>Instances</strong> and your resource is <strong>myDBInstance1</strong>, RDS notifies you about all events for myDBInstance1 only.</td>
</tr>
<tr>
<td>Not specified</td>
<td>RDS notifies you about the events for the specified source type for all your Amazon RDS resources.</td>
<td>If your <strong>Source type</strong> is <strong>Instances</strong>, RDS notifies you about all instance-related events in your account.</td>
</tr>
</tbody>
</table>

**Console**

**To subscribe to RDS event notification**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose **Create event subscription**.
4. Enter your subscription details as follows:
   a. For **Name**, enter a name for the event notification subscription.
   b. For **Send notifications to**, do one of the following:
      - Choose **New email topic**. Enter a name for your email topic and a list of recipients.
      - Choose **Amazon Resource Name (ARN)**. Then choose existing Amazon SNS ARN for an Amazon SNS topic.

      If you want to use a topic that has been enabled for server-side encryption (SSE), grant Amazon RDS the necessary permissions to access the AWS KMS key. For more information, see
Enable compatibility between event sources from AWS services and encrypted topics in the *Amazon Simple Notification Service Developer Guide*.

c. For **Source type**, choose a source type. For example, choose **Clusters** or **Cluster snapshots**.

d. Choose the event categories and resources that you want to receive event notifications for.

The following example configures event notifications for the DB instance named **testinst**.

```
Source

Source type
Source type of resource this subscription will consume events from

Instances ▼

Instances to include
Instances that this subscription will consume events from

□ All instances
□ Select specific instances

Specific instances
Select Instances ▼

[ ] testinst

Event categories to include
Event categories that this subscription will consume events from

□ All event categories
□ Select specific event categories
```

e. Choose **Create**.

The Amazon RDS console indicates that the subscription is being created.

**AWS CLI**

To subscribe to RDS event notification, use the AWS CLI `create-event-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

**Example**

For Linux, macOS, or Unix:

```
aws rds create-event-subscription \
  --subscription-name myeventssubscription \
  --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS \
  --enabled
```
For Windows:

```bash
aws rds create-event-subscription ^
   --subscription-name myeventsubscription ^
   --sns-topic-arn arn:aws:sns:us-east-1:123456789012:myawsuser-RDS ^
   --enabled
```

**API**

To subscribe to Amazon RDS event notification, call the Amazon RDS API function `CreateEventSubscription`. Include the following required parameters:

- SubscriptionName
- SnsTopicArn
Listing Amazon RDS event notification subscriptions

You can list your current Amazon RDS event notification subscriptions.

Console

To list your current Amazon RDS event notification subscriptions

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Event subscriptions. The Event subscriptions pane shows all your event notification subscriptions.

AWS CLI

To list your current Amazon RDS event notification subscriptions, use the AWS CLI describe-event-subscriptions command.

Example

The following example describes all event subscriptions.

```
aws rds describe-event-subscriptions
```

The following example describes the myfirsteventsubscription.

```
aws rds describe-event-subscriptions --subscription-name myfirsteventsubscription
```

API

To list your current Amazon RDS event notification subscriptions, call the Amazon RDS API DescribeEventSubscriptions action.
Modifying an Amazon RDS event notification subscription

After you have created a subscription, you can change the subscription name, source identifier, categories, or topic ARN.

Console

To modify an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Event subscriptions.
3. In the Event subscriptions pane, choose the subscription that you want to modify and choose Edit.
4. Make your changes to the subscription in either the Target or Source section.
5. Choose Edit. The Amazon RDS console indicates that the subscription is being modified.

AWS CLI

To modify an Amazon RDS event notification subscription, use the AWS CLI modify-event-subscription command. Include the following required parameter:

- --subscription-name

Example

The following code enables myeventsubscription.

For Linux, macOS, or Unix:

```
aws rds modify-event-subscription \
   --subscription-name myeventsubscription \
   --enabled
```

For Windows:

```
aws rds modify-event-subscription ^
   --subscription-name myeventsubscription ^
   --enabled
```

API

To modify an Amazon RDS event, call the Amazon RDS API operation ModifyEventSubscription. Include the following required parameter:

- SubscriptionName
Adding a source identifier to an Amazon RDS event notification subscription

You can add a source identifier (the Amazon RDS source generating the event) to an existing subscription.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see Modifying an Amazon RDS event notification subscription (p. 582).

AWS CLI

To add a source identifier to an Amazon RDS event notification subscription, use the AWS CLI add-source-identifier-to-subscription command. Include the following required parameters:

- --subscription-name
- --source-identifier

Example

The following example adds the source identifier mysqldb to the myrdseventsubscription subscription.

For Linux, macOS, or Unix:

```bash
aws rds add-source-identifier-to-subscription \
  --subscription-name myrdseventsubscription \
  --source-identifier mysqldb
```

For Windows:

```bash
aws rds add-source-identifier-to-subscription ^
  --subscription-name myrdseventsubscription ^
  --source-identifier mysqldb
```

API

To add a source identifier to an Amazon RDS event notification subscription, call the Amazon RDS API AddSourceIdentifierToSubscription. Include the following required parameters:

- SubscriptionName
- SourceIdentifier
Removing a source identifier from an Amazon RDS event notification subscription

You can remove a source identifier (the Amazon RDS source generating the event) from a subscription if you no longer want to be notified of events for that source.

**Console**

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see Modifying an Amazon RDS event notification subscription (p. 582).

**AWS CLI**

To remove a source identifier from an Amazon RDS event notification subscription, use the AWS CLI `remove-source-identifier-from-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

**Example**

The following example removes the source identifier `mysqldb` from the `myrdseventsubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds remove-source-identifier-from-subscription \
  --subscription-name myrdseventsubscription \
  --source-identifier mysql
```

For Windows:

```
aws rds remove-source-identifier-from-subscription ^
  --subscription-name myrdseventsubscription ^
  --source-identifier mysql
```

**API**

To remove a source identifier from an Amazon RDS event notification subscription, use the Amazon RDS API `RemoveSourceIdentifierFromSubscription` command. Include the following required parameters:

- `SubscriptionName`
- `SourceIdentifier`
Listing the Amazon RDS event notification categories

All events for a resource type are grouped into categories. To view the list of categories available, use the following procedures.

**Console**

When you create or modify an event notification subscription, the event categories are displayed in the Amazon RDS console. For more information, see Modifying an Amazon RDS event notification subscription (p. 582).

**AWS CLI**

To list the Amazon RDS event notification categories, use the AWS CLI `describe-event-categories` command. This command has no required parameters.

**Example**

```
aws rds describe-event-categories
```

**API**

To list the Amazon RDS event notification categories, use the Amazon RDS API `DescribeEventCategories` command. This command has no required parameters.
Deleting an Amazon RDS event notification subscription

You can delete a subscription when you no longer need it. All subscribers to the topic will no longer receive event notifications specified by the subscription.

Console

To delete an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose DB Event Subscriptions.
3. In the My DB Event Subscriptions pane, choose the subscription that you want to delete.
4. Choose Delete.
5. The Amazon RDS console indicates that the subscription is being deleted.

AWS CLI

To delete an Amazon RDS event notification subscription, use the AWS CLI delete-event-subscription command. Include the following required parameter:

- --subscription-name

Example

The following example deletes the subscription myrdssubscription.

```bash
code
aws rds delete-event-subscription --subscription-name myrdssubscription
```

API

To delete an Amazon RDS event notification subscription, use the RDS API DeleteEventSubscription command. Include the following required parameter:

- SubscriptionName
Creating a rule that triggers on an Amazon Aurora event

Using Amazon CloudWatch Events and Amazon EventBridge, you can automate AWS services and respond to system events such as application availability issues or resource changes.

Topics
• Tutorial: Log DB instance state changes using Amazon EventBridge (p. 587)

Tutorial: Log DB instance state changes using Amazon EventBridge

In this tutorial, you create an AWS Lambda function that logs the state changes for an instance. You then create a rule that runs the function whenever there is a state change of an existing RDS DB instance. The tutorial assumes that you have a small running test instance that you can shut down temporarily.

Important
Don't perform this tutorial on a running production DB instance.

Topics
• Step 1: Create an AWS Lambda function (p. 587)
• Step 2: Create a rule (p. 588)
• Step 3: Test the rule (p. 588)

Step 1: Create an AWS Lambda function

Create a Lambda function to log the state change events. You specify this function when you create your rule.

To create a Lambda function

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. If you're new to Lambda, you see a welcome page. Choose Get Started Now. Otherwise, choose Create function.
3. Choose Author from scratch.
4. On the Create function page, do the following:
   a. Enter a name and description for the Lambda function. For example, name the function RDSInstanceStateChange.
   b. In Runtime, select Node.js 16x.
   c. For Architecture, choose x86_64.
   d. For Execution role, do either of the following:
      • Choose Create a new role with basic Lambda permissions.
      • For Existing role, choose Use an existing role. Choose the role that you want to use.
   e. Choose Create function.
5. On the RDSInstanceStateChange page, do the following:
   a. In Code source, select index.js.
   b. In the index.js pane, delete the existing code.
   c. Enter the following code:
console.log('Loading function');
exports.handler = async (event, context) => {
    console.log('Received event: ', JSON.stringify(event));
};

d. Choose **Deploy**.

**Step 2: Create a rule**

Create a rule to run your Lambda function whenever you launch an Amazon RDS instance.

**To create the EventBridge rule**

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule. For example, enter **RDSInstanceStateChangeRule**.
5. Choose **Rule with an event pattern**, and then choose **Next**.
6. For **Event source**, choose **AWS events or EventBridge partner events**.
7. Scroll down to the **Event pattern** section.
8. For **Event source**, choose **AWS services**.
9. For **AWS service**, choose **Relational Database Service (RDS)**.
10. For **Event type**, choose **RDS DB Instance Event**.
11. Leave the default event pattern. Then choose **Next**.
12. For **Target types**, choose **AWS services**.
13. For **Select a target**, choose **Lambda function**.
14. For **Function**, choose the Lambda function that you created. Then choose **Next**.
15. In **Configure tags**, choose **Next**.
16. Review the steps in your rule. Then choose **Create rule**.

**Step 3: Test the rule**

To test your rule, shut down an RDS DB instance. After waiting a few minutes for the instance to shut down, verify that your Lambda function was invoked.

**To test your rule by stopping a DB instance**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Stop an RDS DB instance.
3. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
4. In the navigation pane, choose **Rules**, choose the name of the rule that you created.
5. In **Rule details**, choose **Metrics for the rule**.
   You are redirected to the Amazon CloudWatch console.
6. In **All metrics**, choose the name of the rule that you created.
   The graph should indicate that the rule was invoked.
7. In the navigation pane, choose **Log groups**.
8. Choose the name of the log group for your Lambda function (/aws/lambda/function-name).
9. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```json
{
  "version": "0",
  "id": "12a345b6-78c9-01d2-34e5-123f4ghi5j6k",
  "detail-type": "RDS DB Instance Event",
  "source": "aws.rds",
  "account": "111111111111",
  "time": "2021-03-19T19:34:09Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:rds:us-east-1:111111111111:db:testdb"
  ],
  "detail": {
    "EventCategories": ["notification"],
    "SourceType": "DB_INSTANCE",
    "Date": "2021-03-19T19:34:09.293Z",
    "Message": "DB instance stopped",
    "SourceIdentifier": "testdb",
    "EventID": "RDS-EVENT-0087"
  }
}
```

For more examples of RDS events in JSON format, see Overview of events for Aurora (p. 568).

10. (Optional) When you're finished, you can open the Amazon RDS console and start the instance that you stopped.
Amazon RDS event categories and event messages

Amazon RDS generates a significant number of events in categories that you can subscribe to using the Amazon RDS Console, AWS CLI, or the API. Each category applies to a source type.

Topics

- DB cluster events (p. 590)
- DB instance events (p. 592)
- DB parameter group events (p. 595)
- DB security group events (p. 595)
- DB cluster snapshot events (p. 595)
- RDS Proxy events (p. 596)

DB cluster events

The following table shows the event category and a list of events when an Aurora DB cluster is the source type.

**Note**
No event category exists for Aurora Serverless in the DB cluster event type. The Aurora Serverless events range from RDS-EVENT-0141 to RDS-EVENT-0149.

<table>
<thead>
<tr>
<th>Category</th>
<th>RDS event ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration</td>
<td>RDS-EVENT-0179</td>
<td>Database Activity Streams is started on your database cluster. For more information see <a href="https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/Aurora-DB-Events.html">Monitoring Amazon Aurora with Database Activity Streams (p. 619)</a></td>
</tr>
<tr>

Monitoring Amazon Aurora log files

Every RDS database engine generates logs that you can access for auditing and troubleshooting. The type of logs depends on your database engine.

You can access database logs using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. You can't view, watch, or download transaction logs.

**Note**
In some cases, logs contain hidden data. Therefore, the AWS Management Console might show content in a log file, but the log file might be empty when you download it.

**Topics**
- Viewing and listing database log files (p. 597)
- Downloading a database log file (p. 598)
- Watching a database log file (p. 599)
- Publishing database logs to Amazon CloudWatch Logs (p. 601)
- Reading log file contents using REST (p. 602)
- Aurora MySQL database log files (p. 604)
- PostgreSQL database log files (p. 610)

**Viewing and listing database log files**

You can view database log files for your Amazon Aurora DB engine by using the AWS Management Console. You can list what log files are available for download or monitoring by using the AWS CLI or Amazon RDS API.

**Note**
You can't view the log files for Aurora Serverless v1 DB clusters in the RDS console. However, you can view them in the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.

**Console**

**To view a database log file**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. (Optional) Enter a search term to filter your results.

   The following example lists logs filtered by the text **error**.
7. Choose the log that you want to view, and then choose View.

**AWS CLI**

To list the available database log files for a DB instance, use the AWS CLI `describe-db-log-files` command.

The following example returns a list of log files for a DB instance named `my-db-instance`.

**Example**

```bash
aws rds describe-db-log-files --db-instance-identifier my-db-instance
```

**RDS API**

To list the available database log files for a DB instance, use the Amazon RDS API `DescribeDBLogFile` action.

**Downloading a database log file**

You can use the AWS Management Console, AWS CLI, or API to download a database log file.

**Console**

**To download a database log file**

1. Open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. In the navigation pane, choose Databases.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the Logs & events tab.
5. Scroll down to the Logs section.
6. In the Logs section, choose the button next to the log that you want to download, and then choose Download.
7. Open the context (right-click) menu for the link provided, and then choose Save Link As. Enter the location where you want the log file to be saved, and then choose Save.
AWS CLI

To download a database log file, use the AWS CLI command `download-db-log-file-portion`. By default, this command downloads only the latest portion of a log file. However, you can download an entire file by specifying the parameter `--starting-token 0`.

The following example shows how to download the entire contents of a log file called `log/ERROR.4` and store it in a local file called `errorlog.txt`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds download-db-log-file-portion \
--db-instance-identifier myexampledb \
--starting-token 0 --output text \ 
--log-file-name log/ERROR.4 > errorlog.txt
```

For Windows:

```bash
aws rds download-db-log-file-portion ^
--db-instance-identifier myexampledb ^
--starting-token 0 --output text ^
--log-file-name log/ERROR.4 > errorlog.txt
```

RDS API

To download a database log file, use the Amazon RDS API `DownloadDBLogFilePortion` action.

**Watching a database log file**

Watching a database log file is equivalent to tailing the file on a UNIX or Linux system. You can watch a log file by using the AWS Management Console. RDS refreshes the tail of the log every 5 seconds.

**To watch a database log file**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. In the **Logs** section, choose a log file, and then choose **Watch**.

RDS shows the tail of the log, as in the following MySQL example.

Watching Log: error/mysql-error-running.log.2022-08-02.14 (2.9 kB)

```

Watching error/mysql-error-running.log.2022-08-02.14, updates every 5 seconds.
Publishing database logs to Amazon CloudWatch Logs

In an on-premises database, the database logs reside on the file system. Amazon RDS doesn't provide host access to the database logs on the file system of your DB cluster. For this reason, Amazon RDS lets you export database logs to Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, store the data in highly durable storage, and manage the data with the CloudWatch Logs Agent.

Topics

- Overview of RDS integration with CloudWatch Logs (p. 601)
- Deciding which logs to publish to CloudWatch Logs (p. 601)
- Specifying the logs to publish to CloudWatch Logs (p. 601)
- Searching and filtering your logs in CloudWatch Logs (p. 602)

Overview of RDS integration with CloudWatch Logs

In CloudWatch Logs, a log stream is a sequence of log events that share the same source. Each separate source of logs in CloudWatch Logs makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

Amazon Aurora continuously streams your DB cluster log records to a log group. For example, you have a log group /aws/rds/cluster/cluster_name/log_type for each type of log that you publish. This log group is in the same AWS Region as the database instance that generates the log.

AWS retains log data published to CloudWatch Logs for an indefinite time period unless you specify a retention period. For more information, see Change log data retention in CloudWatch Logs.

Deciding which logs to publish to CloudWatch Logs

Each RDS database engine supports its own set of logs. To learn about the options for your database engine, review the following topics:

- the section called “Publishing Aurora MySQL logs to CloudWatch Logs” (p. 925)
- the section called “Publishing Aurora PostgreSQL logs to CloudWatch Logs” (p. 1264)

Specifying the logs to publish to CloudWatch Logs

You specify which logs to publish in the console. Make sure that you have a service-linked role in AWS Identity and Access Management (IAM). For more information about service-linked roles, see Using service-linked roles for Amazon Aurora (p. 1723).

To specify the logs to publish

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Do either of the following:
   - Choose Create database.
   - Choose a database from the list, and then choose Modify.
4. In Logs exports, choose which logs to publish.
The following example specifies the audit log, error logs, general log, and slow query log.

Searching and filtering your logs in CloudWatch Logs

You can search for log entries that meet a specified criteria using the CloudWatch Logs console. You can access the logs either through the RDS console, which leads you to the CloudWatch Logs console, or from the CloudWatch Logs console directly.

To search your RDS logs using the RDS console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose a DB cluster or a DB instance.
4. Choose Configuration.
5. Under Published logs, choose the database log that you want to view.

To search your RDS logs using the CloudWatch Logs console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Log groups.
3. In the filter box, enter /aws/rds.
4. For Log Groups, choose the name of the log group containing the log stream to search.
5. For Log Streams, choose the name of the log stream to search.
6. Under Log events, enter the filter syntax to use.

For more information, see Searching and filtering log data in the Amazon CloudWatch Logs User Guide. For a blog tutorial explaining how to monitor RDS logs, see Build proactive database monitoring for Amazon RDS with Amazon CloudWatch Logs, AWS Lambda, and Amazon SNS.

Reading log file contents using REST

Amazon RDS provides a REST endpoint that allows access to DB instance log files. This is useful if you need to write an application to stream Amazon RDS log file contents.
The syntax is:

```plaintext
GET /v13/downloadCompleteLogFile/DBInstanceIdentifier/LogFileName HTTP/1.1
Content-type: application/json
host: rds.region.amazonaws.com
```

The following parameters are required:

- **DBInstanceIdentifier**—the name of the DB instance that contains the log file you want to download.
- **LogFileName**—the name of the log file to be downloaded.

The response contains the contents of the requested log file, as a stream.

The following example downloads the log file named `log/ERROR.6` for the DB instance named `sample-sql` in the `us-west-2` region.

```plaintext
GET /v13/downloadCompleteLogFile/sample-sql/log/ERROR.6 HTTP/1.1
host: rds.us-west-2.amazonaws.com
X-Amz-Security-Token: AQoDYXdzEIH//////////wEa0AIXLhngC5zp9CyB1R6abwKrXHVR5efnAVN3XvR7IwqKYaLFSn6UyJuEFTft9Obglx4QJ+GXY9cpACkETq=
X-Amz-Date: 20140903T233749Z
X-Amz-Algorithm: AWS4-HMAC-SHA256
X-Amz-Credential: AKIADQKE4SARGYLE/20140903/us-west-2/rds/aws4_request
X-Amz-SignedHeaders: host
X-Amz-Content-SHA256: e3b0c44298fc1c229abf4c4c8996fb92427ae41e4649b93de495991b7852b855
X-Amz-Expires: 86400
X-Amz-Signature: 353a4f14b3f250142d9afc34f9f9948154d46ce7d4ec091d0cdabc8b40c558
```

If you specify a nonexistent DB instance, the response consists of the following error:

- **DBInstanceNotFound**—`DBInstanceIdentifier` does not refer to an existing DB instance. (HTTP status code: 404)
Aurora MySQL database log files

You can monitor the Aurora MySQL logs directly through the Amazon RDS console, Amazon RDS API, AWS CLI, or AWS SDKs. You can also access MySQL logs by directing the logs to a database table in the main database and querying that table. You can use the mysqlbinlog utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see Monitoring Amazon Aurora log files (p. 597).

Topics
- Overview of Aurora MySQL database logs (p. 604)
- Publishing Aurora MySQL logs to Amazon CloudWatch Logs (p. 606)
- Managing table-based Aurora MySQL logs (p. 606)
- Configuring Aurora MySQL binary logging (p. 607)
- Accessing MySQL binary logs (p. 608)

Overview of Aurora MySQL database logs

You can monitor the following types of Aurora MySQL log files:

- Error log
- Slow query log
- General log
- Audit log

The Aurora MySQL error log is generated by default. You can generate the slow query and general logs by setting parameters in your DB parameter group.

Topics
- Aurora MySQL error logs (p. 604)
- Aurora MySQL slow query and general logs (p. 605)
- Aurora MySQL audit log (p. 605)
- Log rotation and retention for Aurora MySQL (p. 605)
- Size limits on BLOBs (p. 606)

Aurora MySQL error logs

Aurora MySQL writes errors in the mysql-error.log file. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

Aurora MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server didn't encounter an error that would result in a log entry.

By design, the error logs are filtered so that only unexpected events such as errors are shown. However, the error logs also contain some additional database information, for example query progress, that isn't shown. Therefore, even without any actual errors the size of the error logs might increase because of ongoing database activities.

Aurora MySQL writes mysql-error.log to disk every 5 minutes. It appends the contents of the log to mysql-error-running.log.
Aurora MySQL rotates the `mysql-error-running.log` file every hour. It removes the audit, general, slow query, and SDK logs after either 24 hours or when 15% of storage has been consumed.

**Note**
The log retention period is different between Amazon RDS and Aurora.

**Aurora MySQL slow query and general logs**

The Aurora MySQL slow query log and the general log can be written to a file or a database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see Working with parameter groups (p. 215). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs.

You can control Aurora MySQL logging by using the parameters in this list:

- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds; the minimum is 0. If `log_output = FILE`, you can specify a floating point value that goes to microsecond resolution. If `log_output = TABLE`, you must specify an integer value with second resolution. Only queries whose run time exceeds the `long_query_time` value are logged. For example, setting `long_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set to 1. Queries that don't use an index are logged even if their run time is less than the value of the `long_query_time` parameter. The default is 0.
- `log_output option`: You can specify one of the following options for the `log_output` parameter.
  - `TABLE`: Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
  - `FILE`: Write both general and slow query logs to the file system.
  - `NONE`: Disable logging.

For Aurora MySQL 5.6, the default for `log_output` is `TABLE`. For Aurora MySQL 5.7, the default for `log_output` is `FILE`.

For more information about the slow query and general logs, go to the following topics in the MySQL documentation:

- The slow query log
- The general query log

**Aurora MySQL audit log**

Audit logging for Aurora MySQL is called Advanced Auditing. To turn on Advanced Auditing, you set certain DB cluster parameters. For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 824).

**Log rotation and retention for Aurora MySQL**

When logging is enabled, Amazon Aurora rotates or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. Aurora MySQL handles rotation and deletion as follows:
• The Aurora MySQL error log file sizes are constrained to no more than 15 percent of the local storage for a DB instance. To maintain this threshold, logs are automatically rotated every hour. Aurora MySQL removes logs after 30 days or when 15% of disk space is reached. If the combined log file size exceeds the threshold after removing old log files, then the oldest log files are deleted until the log file size no longer exceeds the threshold.

• When FILE logging is enabled, general log and slow query log files are examined every hour and log files more than 24 hours old are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 15 percent of a DB instance's local space. In these cases, the oldest log files are deleted until the log file size no longer exceeds the threshold.

• When TABLE logging is enabled, log tables aren't rotated or deleted. Log tables are truncated when the size of all logs combined is too large. You can subscribe to the low_free_storage event to be notified when log tables should be manually rotated or deleted to free up space. For more information, see Working with Amazon RDS event notification (p. 572).

You can rotate the mysql.general_log table manually by calling the mysql.rds_rotate_general_log procedure. You can rotate the mysql.slow_log table by calling the mysql.rds_rotate_slow_log procedure.

When you rotate log tables manually, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the mysql.general_log table is named mysql.general_log_backup. The backup log table for the mysql.slow_log table is named mysql.slow_log_backup.

• The Aurora MySQL audit logs are rotated when the file size reaches 100 MB, and removed after 24 hours.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the log_output parameter to FILE. Like the Aurora MySQL error log, these log files are rotated hourly. The log files that were generated during the previous 24 hours are retained. Note that the retention period is different between Amazon RDS and Aurora.

**Size limits on BLOBs**

For Aurora MySQL, there is a size limit on BLOBs written to the redo log. To account for this limit, ensure that the innodb_log_file_size parameter for your Aurora MySQL DB instance is 10 times larger than the largest BLOB data size found in your tables, plus the length of other variable length fields (VARCHAR, VARBINARY, TEXT) in the same tables. For information on how to set parameter values, see Working with parameter groups (p. 215). For information on the redo log BLOB size limit, go to Changes in MySQL 5.6.20.

**Publishing Aurora MySQL logs to Amazon CloudWatch Logs**

You can configure your Aurora MySQL DB cluster to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 925).

**Managing table-based Aurora MySQL logs**

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the log_output server parameter to TABLE. General queries are then logged to the mysql.general_log table, and slow queries are logged to the mysql.slow_log table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.
Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the `general_log` and `slow_query_log` server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to 0. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon Aurora doesn't allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by `PROMPT>`:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

**Configuring Aurora MySQL binary logging**

The binary log is a set of log files that contain information about data modifications made to an Aurora MySQL server instance. The binary log contains information such as the following:

- Events that describe database changes such as table creation or row modifications
- Information about the duration of each statement that updated data
- Events for statements that could have updated data but didn't

The binary log records statements that are sent during replication. It is also required for some recovery operations. For more information, see The Binary Log and Binary Log Overview in the MySQL documentation.

Binary logs are accessible only from the primary DB instance, not from the replicas.

MySQL on Amazon Aurora supports the row-based, statement-based, and mixed binary logging formats. We recommend mixed unless you need a specific binlog format. For details on the different Aurora MySQL binary log formats, see Binary logging formats in the MySQL documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

**Important**

Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB cluster and can increase the amount of time to perform a restore operation of a DB cluster.

Statement-based replication can cause inconsistencies between the source DB cluster and a read replica. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

**To set the MySQL binary logging format**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group used by the DB cluster you want to modify.

You can't modify a default parameter group. If the DB cluster is using a default parameter group, create a new parameter group and associate it with the DB cluster.
4. From **Parameter group actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (**ROW**, **STATEMENT**, or **MIXED**). You can also use the value **OFF** to turn off binary logging.
6. Choose **Save changes** to save the updates to the DB cluster parameter group.

**Important**
Changing a DB cluster parameter group affects all DB clusters that use that parameter group. If you want to specify different binary logging formats for different Aurora MySQL DB clusters in an AWS Region, the DB clusters must use different DB cluster parameter groups. These parameter groups identify different logging formats. Assign the appropriate DB cluster parameter group to each DB clusters. For more information about Aurora MySQL parameters, see [Aurora MySQL configuration parameters](p. 950).

### Accessing MySQL binary logs

You can use the `mysqlbinlog` utility to download or stream binary logs from RDS for MySQL DB instances. The binary log is downloaded to your local computer, where you can perform actions such as replaying the log using the `mysql` utility. For more information about using the `mysqlbinlog` utility, go to [Using `mysqlbinlog` to back up binary log files](p. 608).

To run the `mysqlbinlog` utility against an Amazon RDS instance, use the following options:

- Specify the `--read-from-remote-server` option.
- `--host`: Specify the DNS name from the endpoint of the instance.
- `--port`: Specify the port used by the instance.
- `--user`: Specify a MySQL user that has been granted the replication slave permission.
- `--password`: Specify the password for the user, or omit a password value so that the utility prompts you for a password.
- To have the file downloaded in binary format, specify the `--raw` option.
- `--result-file`: Specify the local file to receive the raw output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command `SHOW BINARY LOGS`.
- To stream the binary log files, specify the `--stop-never` option.

For more information about `mysqlbinlog` options, go to [mysqlbinlog - utility for processing binary log files](p. 608).

For example, see the following.

**For Linux, macOS, or Unix:**

```bash
mysqlbinlog \
    --read-from-remote-server \
    --host=MySQL56Instance1.cg034hpkmjtm.region.rds.amazonaws.com \
    --port=3306  \
    --user ReplUser \
    --password \
    --raw \
    --result-file=/tmp/ \
    binlog.00098
```

**For Windows:**

---

608
Amazon Aurora User Guide for Aurora
MySQL database log files

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don’t take up too much storage.

The following example sets the retention period to 1 day.

```sql
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure.

```sql
call mysql.rds_show_configuration;
```
PostgreSQL database log files

Aurora PostgreSQL generates query and error logs. You can use log messages to troubleshoot performance and auditing issues while using the database.

To view, download, and watch file-based database logs, see Monitoring Amazon Aurora log files (p. 597).

Topics

- Overview of PostgreSQL logs (p. 610)
- Enabling query logging (p. 613)

Overview of PostgreSQL logs

PostgreSQL generates event log files that contain useful information for DBAs.

Log contents

The default logging level captures errors that affect your server. By default, Aurora PostgreSQL logging parameters capture all server errors, including the following:

- Query failures
- Login failures
- Fatal server errors
- Deadlocks

To identify application issues, you can look for query failures, login failures, deadlocks, and fatal server errors in the log. For example, if you converted a legacy application from Oracle to Aurora PostgreSQL, some queries may not convert correctly. These incorrectly formatted queries generate error messages in the logs, which you can use to identify the problematic code.

You can modify PostgreSQL logging parameters to capture additional information based on the following categories:

- Connections and disconnections
- Checkpoints
- Schema modification queries
- Queries waiting for locks
- Queries consuming temporary disk storage
- Backend autovacuum process consuming resources

By logging information for various categories such as shown in the list, you can troubleshoot potential performance and auditing issues. For more information, see Error reporting and logging in the PostgreSQL documentation. For a useful AWS blog about PostgreSQL logging, see Working with RDS and Aurora PostgreSQL logs: Part 1 and Working with RDS and Aurora PostgreSQL logs: Part 2.

Parameters that affect logging behavior

Each Aurora PostgreSQL instance has a parameter group that specifies its configuration, including various aspects of logging. The default parameter group settings apply to every Aurora PostgreSQL DB cluster in a given AWS Region. You can't change the defaults because they apply to all instances of a given engine, even those that aren't yours. To modify any parameter values, you create a custom parameter group and modify its settings. For example, to set or change logging parameters, you make changes in the custom
parameter group associated with your Aurora PostgreSQL DB cluster. To learn how, see Working with parameter groups (p. 215).

For an Aurora PostgreSQL DB cluster, the parameters that affect logging behavior include the following:

- **rds.log_retention_period** – PostgreSQL logs that are older than the specified number of minutes are deleted. The default value of 4320 minutes deletes log files after 3 days. For more information, see Setting the log retention period (p. 611).

- **log_rotation_age** – Specifies number of minutes after which Amazon RDS automatically rotates the logs. The default is 60 minutes, but you can specify anywhere from 1 to 1440 minutes. For more information, see Setting log file rotation (p. 611).

- **log_rotation_size** – Sets the size, in kilobytes, at which the Amazon RDS should automatically rotate the logs. There is no value by default because the logs are rotated based on age alone, as specified by the log_rotation_age parameter. For more information, see Setting log file rotation (p. 611).

- **log_line_prefix** – Specifies the information that gets prefixed in front of each line that gets logged. The default string for this parameter is %t:%r:%u@%d::[%p]:, which notes the time (%t) and other distinguishing characteristics such as the database name (%d) for the log entry. You can't change this parameter. It applies to the stderr messages that get logged.

- **log_destination** – Sets the output format for server logs. The default value for this parameter is standard error (stderr), but csvlog (comma-separated value log files) is also supported. For more information, see Setting the log destination (p. 612).

### Setting the log retention period

To set the retention period for system logs, use the `rds.log_retention_period` parameter. You can find `rds.log_retention_period` in the DB parameter group associated with your Aurora PostgreSQL DB cluster. The unit for this parameter is minutes. For example, a setting of 1,440 retains logs for one day. The default value is 4,320 (three days). The maximum value is 10,080 (seven days). Your instance needs enough allocated storage to contain the retained log files.

Amazon Aurora compresses older PostgreSQL logs when storage for the DB instance reaches a threshold. Aurora compresses the files using the gzip compression utility. For more information, see the gzip website.

When storage for the DB instance is low and all available logs are compressed, you get a warning such as the following:

```
Warning: local storage for PostgreSQL log files is critically low for this Aurora PostgreSQL instance, and could lead to a database outage.
```

If there's not enough storage, Aurora might delete compressed PostgreSQL logs before the end of specified retention period. If that happens, you see a message similar to the following:

```
The oldest PostgreSQL log files were deleted due to local storage constraints.
```

We recommend that you have your logs routinely published to Amazon CloudWatch Logs, so you can view and analyze system data long after the logs have been removed from your Aurora PostgreSQL DB cluster. For more information, see Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs (p. 1264). After you set up CloudWatch publishing, Aurora doesn't delete a log until after it's published to CloudWatch Logs.

### Setting log file rotation

New log files are created by Aurora every hour by default. The timing is controlled by the `log_rotation_age` parameter. This parameter has a default value of 60 (minutes), but you can set to
Log files can also be rotated according to their size, as specified in the `log_rotation_size` parameter. This parameter specifies that the log should be rotated when it reaches the size (in kilobytes). The default `log_rotation_size` is 100000 kB (kilobytes) for an Aurora PostgreSQL DB cluster, but you can set this to anywhere from 50,000 to 1,000,000 kilobytes.

The log file names are based on the file name pattern specified in the `log_filename` parameter. The available settings for this parameter are as follows:

- `postgresql.log.%Y-%m-%d` – Default format for the log file name. Includes the year, month, and date.
- `postgresql.log.%Y-%m-%d-%H%I` – Hour format for log file name. Sets the granularity of log to hours.
- `postgresql.log.%Y-%m-%d-%H%I%M` – Minute format for log file name. Sets the granularity of the log to less than an hour.

If you set `log_rotation_age` parameter to less than 60 minutes, be sure to also set the `log_filename` parameter to the minute format.

For more information, see `log_rotation_age` and `log_rotation_size` in the PostgreSQL documentation.

### Setting the log destination

By default, Aurora PostgreSQL generates logs in standard error (stderr) format. This is the default setting for the `log_destination` parameter. This format prefixes each log message with the time, database, and other details specified by the `log_line_prefix` parameter. The `log_line_prefix` is set to the following text string, which can't be changed:

```
%t:%r:%u@%d:[%p]:t
```

This parameter specifies the following details for each log entry:

- `%t` – Time of log entry.
- `%r` – Remote host address.
- `%u@%d` – User name @ database name.

For example, the following error message results from querying a column using the wrong name.

```
2019-03-10 03:54:59 UTC:10.0.0.123(52834):postgres@tstdb:[20175]:ERROR: column "wrong" does not exist at character 8
```

Aurora PostgreSQL can generate the logs in `csvlog` format in addition to the default `stderr` specified by the `log_destination` parameter. The `csvlog` is useful for analyzing the log data as CSV data. For example, say that you use the `log_fdw` extension to work with your logs as foreign tables. The foreign table created on `stderr` log files contains a single column with log event data. For the CSV formatted log file, the foreign table has multiple columns, so you can sort and analyze your logs much more easily.

You must be using a custom parameter group so that you change the `log_destination` setting. The `log_destination` parameter is dynamic, that is, the change takes effect immediately, without rebooting.
If you do change this parameter, you need to be aware that csvlog files are generated in addition to the stderr logs. We recommend that you pay attention to the storage consumed by the logs, taking into account the rds.log_retention_period and other settings that affect log storage and turnover. Using both stderr and csvlog more than doubles the storage consumed by the logs.

If you do set the log_destination to include csvlog and you later decide that you want to revert to the default only (stderr), you can open the custom parameter group for your instance using the AWS Management Console, choose the log_destination parameter from the list, choose Edit parameter and then choose Reset. This reverts the log_destination parameter to its default setting, stderr.

For more information about configuring logging, see Working with Amazon RDS and Aurora PostgreSQL logs: Part 1.

**Enabling query logging**

To enable query logging for your PostgreSQL DB instance, set two parameters in the DB parameter group associated with your DB instance: log_statement and log_min_duration_statement.

The log_statement parameter controls which SQL statements are logged. The default value is none. We recommend that when you debug issues in your DB instance, set this parameter to all to log all statements. To log all data definition language (DDL) statements (CREATE, ALTER, DROP, and so on), set this value to ddl. To log all DDL and data modification language (DML) statements (INSERT, UPDATE, DELETE, and so on), set the value to mod.

**Warning**
Sensitive information such as passwords can be exposed if you set the log_statement parameter to ddl, mod, or all. To avoid this risk, set the log_statement to none. Also consider the following solutions:

- Encrypt the sensitive information on the client side and use the ENCRYPTED and UNENCRYPTED options of the CREATE and ALTER statements.
- Restrict access to the CloudWatch logs.
- Use stronger authentication mechanisms such as IAM.

For auditing, you can use the PostgreSQL Auditing (pgAudit) extension because it redacts the sensitive information for CREATE and ALTER commands.

The log_min_duration_statement parameter sets the limit in milliseconds of a statement to be logged. All SQL statements that run longer than the parameter setting are logged. This parameter is disabled and set to -1 by default. Enabling this parameter can help you find unoptimized queries.

To set up query logging, take the following steps:

1. Set the log_statement parameter to all. The following example shows the information that is written to the postgresql.log file.

```
2013-11-05 16:48:56 UTC::@:[2952]:LOG: received SIGHUP, reloading configuration files
2013-11-05 16:48:56 UTC::@:[2952]:LOG: parameter "log_statement" changed to "all"
```

Additional information is written to the postgresql.log file when you run a query. The following example shows the type of information written to the file after a query.

```
2013-11-05 16:41:07 UTC::@:[2955]:LOG: checkpoint starting: time
2013-11-05 16:41:07 UTC::@:[2955]:LOG: checkpoint complete: wrote 1 buffers (0.3%);
  0 transaction log file(s) added, 0 removed, 1 recycled; write=0.000 s, sync=0.003 s,
  total=0.012 s; sync files=1, longest=0.003 s, average=0.003 s
2013-11-05 16:45:14 UTC:[local]:master@postgres:[8839]:LOG: statement: SELECT d.datname as "Name",
```
2. Set the `log_min_duration_statement` parameter. The following example shows the information that is written to the `postgresql.log` file when the parameter is set to 1.

Additional information is written to the `postgresql.log` file when you run a query that exceeds the duration parameter setting. The following example shows the type of information written to the file after a query.
Monitoring Amazon Aurora API calls in AWS CloudTrail

AWS CloudTrail is an AWS service that helps you audit your AWS account. AWS CloudTrail is turned on for your AWS account when you create it. For more information about CloudTrail, see the AWS CloudTrail User Guide.

Topics
- CloudTrail integration with Amazon Aurora (p. 615)
- Amazon Aurora log file entries (p. 615)

CloudTrail integration with Amazon Aurora

All Amazon Aurora actions are logged by CloudTrail. CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon Aurora.

CloudTrail events

CloudTrail captures API calls for Amazon Aurora as events. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations.

Amazon Aurora activity is recorded in a CloudTrail event in Event history. You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see Viewing events with CloudTrail event history.

CloudTrail trails

For an ongoing record of events in your AWS account, including events for Amazon Aurora, create a trail. A trail is a configuration that enables delivery of events to a specified Amazon S3 bucket. CloudTrail typically delivers log files within 15 minutes of account activity.

Note
If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history.

You can create two types of trails for an AWS account: a trail that applies to all Regions, or a trail that applies to one Region. By default, when you create a trail in the console, the trail applies to all Regions.

Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:
- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

Amazon Aurora log file entries

CloudTrail log files contain one or more log entries. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.
The following example shows a CloudTrail log entry that demonstrates the `CreateDBInstance` action.

```
{

"eventID": "797163d3-5726-441d-80a7-6eeb7464acd4"}
As shown in the `userIdentity` element in the preceding example, every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information about the `userIdentity`, see the CloudTrail `userIdentity` element. For more information about CreateDBInstance and other Amazon Aurora actions, see the Amazon RDS API Reference.
Monitoring Amazon Aurora with Database Activity Streams

By using Database Activity Streams, you can monitor near-real-time streams of database activity.

Topics
- Overview of Database Activity Streams (p. 619)
- Network prerequisites for Aurora MySQL database activity streams (p. 622)
- Starting a database activity stream (p. 623)
- Getting the status of a database activity stream (p. 624)
- Stopping a database activity stream (p. 625)
- Monitoring database activity streams (p. 626)
- Managing access to database activity streams (p. 648)

Overview of Database Activity Streams

As an Amazon Aurora database administrator, you need to safeguard your database and meet compliance and regulatory requirements. One strategy is to integrate database activity streams with your monitoring tools. In this way, you monitor and set alarms for auditing activity in your Amazon Aurora cluster.

Security threats are both external and internal. To protect against internal threats, you can control administrator access to data streams by configuring the Database Activity Streams feature. DBAs don't have access to the collection, transmission, storage, and processing of the streams.

Topics
- How database activity streams work (p. 619)
- Asynchronous and synchronous mode for database activity streams (p. 620)
- Requirements for database activity streams (p. 621)
- Supported Aurora engine versions for database activity streams (p. 621)
- Supported DB instance classes for database activity streams (p. 621)

How database activity streams work

In Amazon Aurora, you start a database activity stream at the cluster level. All DB instances within your cluster have database activity streams enabled.

Your Aurora DB cluster pushes activities to an Amazon Kinesis data stream in near real time. The Kinesis stream is created automatically. From Kinesis, you can configure AWS services such as Amazon Kinesis Data Firehose and AWS Lambda to consume the stream and store the data.

Important
Use of the Database Activity Streams feature in Amazon Aurora is free, but Amazon Kinesis charges for a data stream. For more information, see Amazon Kinesis Data Streams pricing.

If you use an Aurora global database, start a database activity stream on each DB cluster separately. Each cluster delivers audit data to its own Kinesis stream within its own AWS Region. The activity streams don't operate differently during a failover. They continue to audit your global database as usual.
You can configure applications for compliance management to consume database activity streams. For Aurora PostgreSQL, compliance applications include IBM's Security Guardium and Imperva's SecureSphere Database Audit and Protection. These applications can use the stream to generate alerts and audit activity on your Aurora DB cluster.

The following graphic shows an Aurora DB cluster configured with Amazon Kinesis Data Firehose.

**Asynchronous and synchronous mode for database activity streams**

You can choose to have the database session handle database activity events in either of the following modes:

- **Asynchronous mode** – When a database session generates an activity stream event, the session returns to normal activities immediately. In the background, the activity stream event is made a durable record. If an error occurs in the background task, an RDS event is sent. This event indicates the beginning and end of any time windows where activity stream event records might have been lost.

  Asynchronous mode favors database performance over the accuracy of the activity stream.

  **Note**

  Asynchronous mode is available for both Aurora PostgreSQL and Aurora MySQL.

- **Synchronous mode** – When a database session generates an activity stream event, the session blocks other activities until the event is made durable. If the event can't be made durable for some reason,
the database session returns to normal activities. However, an RDS event is sent indicating that activity stream records might be lost for some time. A second RDS event is sent after the system is back to a healthy state.

The synchronous mode favors the accuracy of the activity stream over database performance.

**Note**
Synchronous mode is available for Aurora PostgreSQL. You can’t use synchronous mode with Aurora MySQL.

### Requirements for database activity streams

In Aurora, database activity streams have the following requirements and limitations:

- Amazon Kinesis is required for database activity streams.
- AWS Key Management Service (AWS KMS) is required for database activity streams because they are always encrypted.
- Applying additional encryption to your Amazon Kinesis data stream is incompatible with database activity streams, which are already encrypted with your AWS KMS key.
- Start your database activity stream at the DB cluster level. If you add a DB instance to your cluster, you don’t need to start an activity stream on the instance: it is audited automatically.
- In an Aurora global database, make sure to start an activity stream on each DB cluster separately. Each cluster delivers audit data to its own Kinesis stream within its own AWS Region.

### Supported Aurora engine versions for database activity streams

For **Aurora PostgreSQL**, database activity streams are supported for the following versions:

- All 14, 13, and 12 versions
- Version 11.6 and higher 11 versions
- Version 10.11 and higher 10 versions

For **Aurora MySQL**, database activity streams are supported for the following versions:

- 2.08 or higher, which is compatible with MySQL version 5.7

**Database activity streams aren’t supported for the following features:**

- Aurora Serverless v1
- Aurora Serverless v2
- Babelfish for Aurora PostgreSQL

For more information about **Aurora PostgreSQL** versions, see [Amazon Aurora PostgreSQL releases and engine versions](https://aws.amazon.com/documentation/aurora/release-notes/postgresql/).

### Supported DB instance classes for database activity streams

For **Aurora MySQL**, you can use database activity streams with the following DB instance classes:

- `db.r6g`
- `db.r5`
- `db.r4`
- `db.r3`
- `db.x2g`
For Aurora PostgreSQL, you can use database activity streams with the following DB instance classes:

- `db.r6g`
- `db.r5`
- `db.r4`
- `db.x2g`

**Network prerequisites for Aurora MySQL database activity streams**

In the following section, you can find how to configure your virtual private cloud (VPC) for use with database activity streams.

**Topics**

- Prerequisites for AWS KMS endpoints (p. 622)
- Prerequisites for public availability (p. 622)
- Prerequisites for private availability (p. 622)

**Prerequisites for AWS KMS endpoints**

Instances in an Aurora MySQL cluster that use activity streams must be able to access AWS KMS endpoints. Make sure this requirement is satisfied before enabling database activity streams for your Aurora MySQL cluster. If the Aurora cluster is publicly available, this requirement is satisfied automatically.

**Important**

If the Aurora MySQL DB cluster can't access the AWS KMS endpoint, the activity stream stops. In that case, Aurora notifies you about this issue using RDS Events.

**Prerequisites for public availability**

For an Aurora DB cluster to be public, it must meet the following requirements:

- **Publicly Accessible** is Yes in the AWS Management Console cluster details page.
- The DB cluster is in an Amazon VPC public subnet. For more information about publicly accessible DB instances, see Working with a DB cluster in a VPC (p. 1728). For more information about public Amazon VPC subnets, see Your VPC and Subnets.

**Prerequisites for private availability**

If your Aurora DB cluster isn't publicly accessible, and it's in a VPC public subnet, it's private. To keep your cluster private and use it with database activity streams, you have the following options:

- Configure Network Address Translation (NAT) in your VPC. For more information, see NAT Gateways.
- Create an AWS KMS endpoint in your VPC. This option is recommended because it's easier to configure.

**To create an AWS KMS endpoint in your VPC**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. Choose **Create Endpoint**.
   
   The **Create Endpoint** page appears.

4. Do the following:
   
   - In **Service category**, choose **AWS services**.
   - In **Service Name**, choose `com.amazonaws.region.kms`, where `region` is the AWS Region where your cluster is located.
   - For **VPC**, choose the VPC where your cluster is located.

5. Choose **Create Endpoint**.

For more information about configuring VPC endpoints, see VPC Endpoints.

### Starting a database activity stream

To monitor database activity for all instances in your Aurora DB cluster, start an activity stream at the cluster level. Any DB instances that you add to the cluster are also automatically monitored. If you use an Aurora global database, start a database activity stream on each DB cluster separately. Each cluster delivers audit data to its own Kinesis stream within its own AWS Region.

When you start an activity stream, each database activity event, such as a change or access, generates an activity stream event. SQL commands such as `CONNECT` and `SELECT` generate access events. SQL commands such as `CREATE` and `INSERT` generate change events.

### Console

**To start a database activity stream**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster on which you want to start an activity stream.
4. For **Actions**, choose **Start activity stream**.
   
   The **Start database activity stream: name** window appears, where `name` is your DB cluster.

5. Enter the following settings:
   
   - For **AWS KMS key**, choose a key from the list of AWS KMS keys.
     
     **Note**
     
     If your Aurora MySQL cluster can't access KMS keys, follow the instructions in Network prerequisites for Aurora MySQL database activity streams (p. 622) to enable such access first.

     Aurora uses the KMS key to encrypt the key that in turn encrypts database activity. Choose a KMS key other than the default key. For more information about encryption keys and AWS KMS, see What is AWS Key Management Service? in the AWS Key Management Service Developer Guide.

   - For **Database activity stream mode**, choose **Asynchronous** or **Synchronous**.
     
     **Note**
     
     This choice applies only to Aurora PostgreSQL. For Aurora MySQL, you can use only asynchronous mode.

   - Choose **Immediately**.

     When you choose **Immediately**, the DB cluster restarts right away. If you choose **During the next maintenance window**, the DB cluster doesn't restart right away. In this case, the database activity stream doesn't start until the next maintenance window.
When you're done entering settings, choose **Start database activity stream**.

The status for the DB cluster shows that the activity stream is starting.

**AWS CLI**

To start database activity streams for a DB cluster, configure the DB cluster using the `start-activity-stream` AWS CLI command.

- **--resource-arn** `arn` – Specifies the Amazon Resource Name (ARN) of the DB cluster.
- **--mode** `sync-or-async` – Specifies either synchronous (`sync`) or asynchronous (`async`) mode. For Aurora PostgreSQL, you can choose either value. For Aurora MySQL, specify `async`.
- **--kms-key-id** `key` – Specifies the KMS key identifier for encrypting messages in the database activity stream. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the AWS KMS key.

The following example starts a database activity stream for a DB cluster in asynchronous mode.

For Linux, macOS, or Unix:

```
aws rds start-activity-stream
  --mode async
  --kms-key-id my-kms-key-arn
  --resource-arn my-cluster-arn
  --apply-immediately
```

For Windows:

```
aws rds start-activity-stream
  --mode async
  --kms-key-id my-kms-key-arn
  --resource-arn my-cluster-arn
  --apply-immediately
```

**RDS API**

To start database activity streams for a DB cluster, configure the cluster using the `StartActivityStream` operation.

Call the action with the parameters below:

- **Region**
- **KmsKeyId**
- **ResourceArn**
- **Mode**

**Getting the status of a database activity stream**

You can get the status of an activity stream using the console or AWS CLI.
Console

To get the status of a database activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB cluster link.
3. Choose the Configuration tab, and check Database activity stream for status.

AWS CLI

You can get the activity stream configuration for a DB cluster as the response to a describe-db-clusters CLI request.

The following example describes my-cluster.

```bash
aws rds --region my-region describe-db-clusters --db-cluster-identifier my-cluster
```

The following example shows a JSON response. The following fields are shown:

- ActivityStreamKinesisStreamName
- ActivityStreamKmsKeyId
- ActivityStreamStatus
- ActivityStreamMode

These fields are the same for Aurora PostgreSQL and Aurora MySQL, except that ActivityStreamMode is always async for Aurora MySQL, while for Aurora PostgreSQL it might be sync or async.

```json
{
   "DBClusters": [
      {
         "DBClusterIdentifier": "my-cluster",
         ... 
         "ActivityStreamKinesisStreamName": "aws-rds-das-cluster-A6TSYXITZCXJHIVFUBZULTWY",
         "ActivityStreamStatus": "starting",
         "ActivityStreamKmsKeyId": "12345678-abcd-efgh-ijkl-bd041f170262",
         "ActivityStreamMode": "async",
         "DbClusterResourceId": "cluster-ABCD123456"
      }
   ]
}
```

RDS API

You can get the activity stream configuration for a DB cluster as the response to a DescribeDBClusters operation.

Stopping a database activity stream

You can stop an activity stream using the console or AWS CLI.

If you delete your DB cluster, the activity stream is stopped and the underlying Amazon Kinesis stream is deleted automatically.
Console

To turn off an activity stream

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose a DB cluster that you want to stop the database activity stream for.
4. For Actions, choose Stop activity stream. The Database Activity Stream window appears.
   a. Choose Immediately.
      
      When you choose Immediately, the DB cluster restarts right away. If you choose During the next maintenance window, the DB cluster doesn't restart right away. In this case, the database activity stream doesn't stop until the next maintenance window.
   b. Choose Continue.

AWS CLI

To stop database activity streams for your DB cluster, configure the DB cluster using the AWS CLI command stop-activity-stream. Identify the AWS Region for the DB cluster using the --region parameter. The --apply-immediately parameter is optional.

For Linux, macOS, or Unix:

```
aws rds --region MY_REGION 
  stop-activity-stream 
    --resource-arn MY_CLUSTER_ARN 
    --apply-immediately
```

For Windows:

```
aws rds --region MY_REGION ^
  stop-activity-stream ^
    --resource-arn MY_CLUSTER_ARN ^
    --apply-immediately
```

RDS API

To stop database activity streams for your DB cluster, configure the cluster using the StopActivityStream operation. Identify the AWS Region for the DB cluster using the Region parameter. The ApplyImmediately parameter is optional.

Monitoring database activity streams

Database activity streams monitor and report activities. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream, or other services and applications can consume the activity stream for further analysis. You can find the underlying Kinesis stream name by using the AWS CLI command describe-db-clusters or the RDS API DescribeDBClusters operation.

Aurora manages the Kinesis stream for you as follows:

- Aurora creates the Kinesis stream automatically with a 24-hour retention period.
Aurora scales the Kinesis stream if necessary.

If you stop the database activity stream or delete the DB cluster, Aurora deletes the Kinesis stream.

The following categories of activity are monitored and put in the activity stream audit log:

- **SQL commands** – All SQL commands are audited, and also prepared statements, built-in functions, and functions in PL/SQL. Calls to stored procedures are audited. Any SQL statements issued inside stored procedures or functions are also audited.

- **Other database information** – Activity monitored includes the full SQL statement, the row count of affected rows from DML commands, accessed objects, and the unique database name. For Aurora PostgreSQL, database activity streams also monitor the bind variables and stored procedure parameters.

  **Important**
  The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Aurora can determine them from the context, such as in the following SQL statement.

  ```sql
  ALTER ROLE role-name WITH password
  ```

- **Connection information** – Activity monitored includes session and network information, the server process ID, and exit codes.

If an activity stream has a failure while monitoring your DB instance, you are notified through RDS events.

**Topics**
- Accessing an activity stream from Kinesis (p. 627)
- Audit log contents and examples (p. 628)
- Processing a database activity stream using the AWS SDK (p. 642)

**Accessing an activity stream from Kinesis**

When you enable an activity stream for a DB cluster, a Kinesis stream is created for you. From Kinesis, you can monitor your database activity in real time. To further analyze database activity, you can connect your Kinesis stream to consumer applications. You can also connect the stream to compliance management applications such as IBM's Security Guardium or Imperva's SecureSphere Database Audit and Protection.

**To access an activity stream from Kinesis**

2. Choose your activity stream from the list of Kinesis streams.

   An activity stream's name includes the prefix `aws-rds-das-cluster-` followed by the resource ID of the DB cluster. The following is an example.

   ```plaintext
   aws-rds-das-cluster-NHVOV4PCLWNGF52NP
   ```

   To use the Amazon RDS console to find the resource ID for the DB cluster, choose your DB cluster from the list of databases, and then choose the **Configuration** tab.

   To use the AWS CLI to find the full Kinesis stream name for an activity stream, use a `describe-db-clusters` CLI request and note the value of `ActivityStreamKinesisStreamName` in the response.
3. Choose **Monitoring** to begin observing the database activity.

For more information about using Amazon Kinesis, see [What Is Amazon Kinesis Data Streams?](#).

**Audit log contents and examples**

Monitored events are represented in the database activity stream as JSON strings. The structure consists of a JSON object containing a `DatabaseActivityMonitoringRecord`, which in turn contains a `databaseActivityEventList` array of activity events.

**Topics**
- Examples of an audit log for an activity stream (p. 628)
- `DatabaseActivityMonitoringRecords` JSON object (p. 634)
- `databaseActivityEvents` JSON Object (p. 634)
- `databaseActivityEventList` JSON array (p. 635)

**Examples of an audit log for an activity stream**

Following are sample decrypted JSON audit logs of activity event records.

**Example Activity event record of an Aurora PostgreSQL CONNECT SQL statement**

Following is an activity event record of a login with the use of a `CONNECT` SQL statement (**command**) by a `psql` client (**clientApplication**).

```json
{
  "type": "DatabaseActivityMonitoringRecords",
  "version": "1.1",
  "databaseActivityEvents": {
    "type": "DatabaseActivityMonitoringRecord",
    "clusterId": "cluster-4NYY5V4RRNPYYB7ICKE5JBQQ",
    "instanceId": "db-FZ7MYKXQBUUZ6VLW7NW31TCM",

      "transactionId": "0",
      "dbProtocol": "MySQL",
      "netProtocol": "TCP",
      "errorMessage": "",
      "class": "AUX"
    }
  ]
}
```
Example Activity event record of an Aurora PostgreSQL SELECT statement

Following is an example of a SELECT event.

```json
{
  "type":"DatabaseActivityMonitoringRecords",
  "version":"1.1",
  "databaseActivityEvents":
  {
    "type":"DatabaseActivityMonitoringRecord",
    "clusterId":"cluster-4HYY5V4RNNKPKYB71CFKE5JBQQ",
    "instanceId":"db-FZJTMKCBQNUZ6VL7NW3ITCM",
    "databaseActivityEventList":[
      {
        "startTime": "2019-05-24 00:39:49.920564+00",
        "logTime": "2019-05-24 00:39:49.940668+00",
        "statementId": 6,
        "substatementId": 1,
        "objectType": "TABLE",
        "command": "SELECT",
        "objectName": "public.my_table",
        "databaseName": "postgres",
        "dbUserName": "rdsadmin",
        "remoteHost": "172.31.3.195",
        "remotePort": "34534",
        "sessionId": "5ce73c6f.7e64",
        "rowCount": 10,
        "commandText": "select * from my_table;",
        "paramList": [],
        "pid": 32356,
        "clientApplication": "psql",
        "exitCode": null,
        "class": "READ",
        "serverVersion": "2.3.1",
        "serverType": "PostgreSQL",
        "serviceName": "Amazon Aurora PostgreSQL-Compatible edition",
        "serverHost": "172.31.3.192",
        "netProtocol": "TCP",
        "dbProtocol": "Postgres 3.0",
        "type": "record",
        "errorMessage": null
      }
    ],
  }
}
```

Example Activity event record of an Aurora MySQL SELECT statement

Following is an example of a SELECT event.

The following example shows the event with a class value of MAIN.

```json
{
  "type":"DatabaseActivityMonitoringRecord",
  "clusterId":"cluster-some_id",
  "instanceId":"db-some_id",
  "databaseActivityEventList":[
    {
      "logTime": "2020-05-22 18:29:57.986467+00",
      "type": "record",
      "clientApplication":null,
      "pid":12345
    }
  ]
}
```
The following example shows the corresponding event with a class value of AUX.

```json
{
    "type": "DatabaseActivityMonitoringRecord",
    "instanceId": "db-some_id",
    "databaseActivityEventList": [
        {

DatabaseActivityMonitoringRecords JSON object

The database activity event records are in a JSON object that contains the following information.

<table>
<thead>
<tr>
<th>JSON Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>The type of JSON record. The value is DatabaseActivityMonitoringRecords.</td>
</tr>
<tr>
<td>version</td>
<td>string</td>
<td>The version of the database activity monitoring records. The version of the generated database activity records depends on the engine version of the DB cluster:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Version 1.1 database activity records are generated for Aurora PostgreSQL DB clusters running the engine versions 10.10 and later minor versions and engine versions 11.5 and later.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Version 1.0 database activity records are generated for Aurora PostgreSQL DB clusters running the engine versions 10.7 and 11.4.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>All of the following fields are in both version 1.0 and version 1.1 except where specifically noted.</td>
</tr>
<tr>
<td>databaseActivityEvents</td>
<td>string[]</td>
<td>A JSON object containing the activity events.</td>
</tr>
<tr>
<td>key</td>
<td>string</td>
<td>An encryption key you use to decrypt the databaseActivityEventList JSON array.</td>
</tr>
</tbody>
</table>

databaseActivityEvents JSON Object

The databaseActivityEvents JSON object contains the following information.

Top-level fields in JSON record

Each event in the audit log is wrapped inside a record in JSON format. This record contains the following fields.

**type**

This field always has the value DatabaseActivityMonitoringRecords.

**version**

This field represents the version of the database activity stream data protocol or contract. It defines which fields are available.

Version 1.0 represents the original data activity streams support for Aurora PostgreSQL versions 10.7 and 11.4. Version 1.1 represents the data activity streams support for Aurora PostgreSQL versions 10.10 and higher and Aurora PostgreSQL 11.5 and higher. Version 1.1 includes the additional fields errorMessage and startTime. Version 1.2 represents the data activity streams...
support for Aurora MySQL 2.08 and higher. Version 1.2 includes the additional fields `endTime` and `transactionId`.

**databaseActivityEvents**

An encrypted string representing one or more activity events. It's represented as a base64 byte array. When you decrypt the string, the result is a record in JSON format with fields as shown in the examples in this section.

**key**

The encrypted data key used to encrypt the `databaseActivityEvents` string. This is the same AWS KMS key that you provided when you started the database activity stream.

The following example shows the format of this record.

```json
{
  "type":"DatabaseActivityMonitoringRecords",
  "version":"1.1",
  "databaseActivityEvents":"encrypted audit records",
  "key":"encrypted key"
}
```

Take the following steps to decrypt the contents of the `databaseActivityEvents` field:

1. Decrypt the value in the `key` JSON field using the KMS key you provided when starting database activity stream. Doing so returns the data encryption key in clear text.
2. Base64-decode the value in the `databaseActivityEvents` JSON field to obtain the ciphertext, in binary format, of the audit payload.
3. Decrypt the binary ciphertext with the data encryption key that you decoded in the first step.
4. Decompress the decrypted payload.
   - The encrypted payload is in the `databaseActivityEvents` field.
   - The `databaseActivityEventList` field contains an array of audit records. The `type` fields in the array can be record or heartbeat.

The audit log activity event record is a JSON object that contains the following information.

<table>
<thead>
<tr>
<th>JSON Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>The type of JSON record. The value is <code>DatabaseActivityMonitoringRecord</code>.</td>
</tr>
<tr>
<td>clusterId</td>
<td>string</td>
<td>The DB cluster resource identifier. It corresponds to the DB cluster attribute <code>DbClusterResourceId</code>.</td>
</tr>
<tr>
<td>instanceId</td>
<td>string</td>
<td>The DB instance resource identifier. It corresponds to the DB instance attribute <code>DbiResourceId</code>.</td>
</tr>
<tr>
<td>databaseActivityEventList</td>
<td>string</td>
<td>An array of activity audit records or heartbeat messages.</td>
</tr>
</tbody>
</table>

**databaseActivityEventList JSON array**

The audit log payload is an encrypted `databaseActivityEventList` JSON array. The following tables lists alphabetically the fields for each activity event in the decrypted `DatabaseActivityEventList` array of an audit log. The fields differ depending on whether you use Aurora PostgreSQL or Aurora MySQL. Consult the table that applies to your database engine.
**Important**

The event structure is subject to change. Aurora might add new fields to activity events in the future. In applications that parse the JSON data, make sure that your code can ignore or take appropriate actions for unknown field names.

### databaseActivityEventList fields for Aurora PostgreSQL

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>string</td>
<td>The class of activity event. Valid values for Aurora PostgreSQL are the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ALL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CONNECT – A connect or disconnect event.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DDL – A DDL statement that is not included in the list of statements for the ROLE class.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- FUNCTION – A function call or a DO block.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- MISC – A miscellaneous command such as DISCARD, FETCH, CHECKPOINT, or VACUUM.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- NONE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- READ – A SELECT or COPY statement when the source is a relation or a query.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ROLE – A statement related to roles and privileges including GRANT, REVOKE, and CREATE/ALTER/DROP ROLE.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- WRITE – An INSERT, UPDATE, DELETE, TRUNCATE, or COPY statement when the destination is a relation.</td>
</tr>
<tr>
<td>clientApplication</td>
<td>string</td>
<td>The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null.</td>
</tr>
<tr>
<td>command</td>
<td>string</td>
<td>The name of the SQL command without any command details.</td>
</tr>
<tr>
<td>commandText</td>
<td>string</td>
<td>The actual SQL statement passed in by the user. For Aurora PostgreSQL, the value is identical to the original SQL statement. This field is used for all types of records except for connect or disconnect records, in which case the value is null.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Important</strong> The full SQL text of each statement is visible in the activity stream audit log, including any sensitive data. However, database user passwords are redacted if Aurora can determine them from the context, such as in the following SQL statement.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ALTER ROLE role-name WITH password</td>
</tr>
<tr>
<td>databaseName</td>
<td>string</td>
<td>The database to which the user connected.</td>
</tr>
<tr>
<td>dbProtocol</td>
<td>string</td>
<td>The database protocol, for example Postgres 3.0.</td>
</tr>
<tr>
<td>dbUserName</td>
<td>string</td>
<td>The database user with which the client authenticated.</td>
</tr>
<tr>
<td>errorMessage</td>
<td>string</td>
<td>If there was any error, this field is populated with the error message that would've been generated by the DB server. The errorMessage value is null for normal statements that didn't result in an error.</td>
</tr>
</tbody>
</table>
An error is defined as any activity that would produce a client-visible PostgreSQL error log event at a severity level of \texttt{ERROR} or greater. For more information, see PostgreSQL Message Severity Levels. For example, syntax errors and query cancellations generate an error message.

Internal PostgreSQL server errors such as background checkpointer process errors do not generate an error message. However, records for such events are still emitted regardless of the setting of the log severity level. This prevents attackers from turning off logging to attempt avoiding detection.

See also the \texttt{exitCode} field.

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(version 1.1 database activity records only)</td>
<td>int</td>
<td>A value used for a session exit record. On a clean exit, this contains the exit code. An exit code can't always be obtained in some failure scenarios. Examples are if PostgreSQL does an \texttt{exit()} or if an operator performs a command such as \texttt{kill -9}. If there was any error, the \texttt{exitCode} field shows the SQL error code, SQLSTATE, as listed in PostgreSQL Error Codes. See also the errorMessage field.</td>
</tr>
<tr>
<td>\texttt{exitCode}</td>
<td>string</td>
<td>A timestamp as recorded in the auditing code path. This represents the SQL statement execution end time. See also the start\texttt{Time} field.</td>
</tr>
<tr>
<td>logTime</td>
<td>string</td>
<td>The network communication protocol.</td>
</tr>
<tr>
<td>netProtocol</td>
<td>string</td>
<td>The name of the database object if the SQL statement is operating on one. This field is used only where the SQL statement operates on a database object. If the SQL statement is not operating on an object, this value is null.</td>
</tr>
<tr>
<td>objectName</td>
<td>string</td>
<td>The database object type such as table, index, view, and so on. This field is used only where the SQL statement operates on a database object. If the SQL statement is not operating on an object, this value is null. Valid values include the following:</td>
</tr>
<tr>
<td>objectType</td>
<td>string</td>
<td>An array of comma-separated parameters passed to the SQL statement. If the SQL statement has no parameters, this value is an empty array.</td>
</tr>
</tbody>
</table>

See also the errorMessage field.
### Field | Data Type | Description
--- | --- | ---
pid | int | The process ID of the backend process that is allocated for serving the client connection.
remoteHost | string | Either the client IP address or hostname. For Aurora PostgreSQL, which one is used depends on the database's log.hostname parameter setting.
remotePort | string | The client port number.
rowCount | int | The number of rows returned by the SQL statement. For example, if a SELECT statement returns 10 rows, rowCount is 10. For INSERT or UPDATE statements, rowCount is 0.
serverHost | string | The database server host IP address.
serverType | string | The database server type, for example PostgreSQL.
serverVersion | string | The database server version, for example 2.3.1 for Aurora PostgreSQL.
serviceName | string | The name of the service, for example Amazon Aurora PostgreSQL-Compatible edition.
sessionId | int | A pseudo-unique session identifier.
startTime | string | The time when execution began for the SQL statement. To calculate the approximate execution time of the SQL statement, use logTime - startTime. See also the logTime field.
statementId | int | An identifier for the client's SQL statement. The counter is at the session level and increments with each SQL statement entered by the client.
substatementId | int | An identifier for a SQL substatement. This value counts the contained substatements for each SQL statement identified by the statementId field.
type | string | The event type. Valid values are record or heartbeat.

### databaseActivityEventList fields for Aurora MySQL

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
</table>
class | string | The class of activity event. Valid values for Aurora MySQL are the following:

- MAIN – The primary event representing a SQL statement.
- AUX – A supplemental event containing additional details. For example, a statement that renames an object might have an event with class AUX that reflects the new name.
<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clientApplication</td>
<td>string</td>
<td>The application the client used to connect as reported by the client. The client doesn't have to provide this information, so the value can be null.</td>
</tr>
<tr>
<td>command</td>
<td>string</td>
<td>The general category of the SQL statement. The values for this field depend on the value of class.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The values when class is MAIN include the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CONNECT – When a client session is connected.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• QUERY – A SQL statement. Accompanied by one or more events with a class value of AUX.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DISCONNECT – When a client session is disconnected.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FAILED_CONNECT – When a client attempts to connect but isn't able to.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CHANGEUSER – A state change that's part of the MySQL network protocol, not from a statement that you issue.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The values when class is AUX include the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• READ – A SELECT or COPY statement when the source is a relation or a query.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• WRITE – An INSERT, UPDATE, DELETE, TRUNCATE, or COPY statement when the destination is a relation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DROP – Deleting an object.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CREATE – Creating an object.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• RENAME – Renaming an object.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ALTER – Changing the properties of an object.</td>
</tr>
</tbody>
</table>
### Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>commandText</td>
<td>string</td>
<td>For events with a class value of MAIN, this field represents the actual SQL statement passed in by the user. This field is used for all types of records except for connect or disconnect records, in which case the value is null. For events with a class value of AUX, this field contains supplemental information about the objects involved in the event. For Aurora MySQL, characters such as quotation marks are preceded by a backslash, representing an escape character. <strong>Important</strong> The full SQL text of each statement is visible in the audit log, including any sensitive data. However, database user passwords are redacted if Aurora can determine them from the context, such as in the following SQL statement.</td>
</tr>
<tr>
<td>databaseName</td>
<td>string</td>
<td>The database to which the user connected.</td>
</tr>
<tr>
<td>dbProtocol</td>
<td>string</td>
<td>The database protocol. Currently, this value is always MySQL for Aurora MySQL.</td>
</tr>
<tr>
<td>dbUserName</td>
<td>string</td>
<td>The database user with which the client authenticated.</td>
</tr>
<tr>
<td>endTime</td>
<td>string</td>
<td>The time when execution ended for the SQL statement. It is represented in Coordinated Universal Time (UTC) format. To calculate the execution time of the SQL statement, use endTime - startTime. See also the startTime field.</td>
</tr>
<tr>
<td>errorMessage</td>
<td>string</td>
<td>If there was any error, this field is populated with the error message that would've been generated by the DB server. The errorMessage value is null for normal statements that didn't result in an error. An error is defined as any activity that would produce a client-visible MySQL error log event at a severity level of ERROR or greater. For more information, see The Error Log in the MySQL Reference Manual. For example, syntax errors and query cancellations generate an error message. Internal MySQL server errors such as background checkpointer process errors do not generate an error message. However, records for such events are still emitted regardless of the setting of the log severity level. This prevents attackers from turning off logging to attempt avoiding detection. See also the exitCode field.</td>
</tr>
</tbody>
</table>

640
<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exitCode</td>
<td>int</td>
<td>A value used for a session exit record. On a clean exit, this contains the exit code. An exit code can't always be obtained in some failure scenarios. In such cases, this value might be zero or might be blank.</td>
</tr>
<tr>
<td>logTime</td>
<td>string</td>
<td>A timestamp as recorded in the auditing code path. It is represented in Coordinated Universal Time (UTC) format. For the most accurate way to calculate statement duration, see the startTime and endTime fields.</td>
</tr>
<tr>
<td>netProtocol</td>
<td>string</td>
<td>The network communication protocol. Currently, this value is always TCP for Aurora MySQL.</td>
</tr>
<tr>
<td>objectName</td>
<td>string</td>
<td>The name of the database object if the SQL statement is operating on one. This field is used only where the SQL statement operates on a database object. If the SQL statement isn't operating on an object, this value is blank. To construct the fully qualified name of the object, combine databaseName and objectName. If the query involves multiple objects, this field can be a comma-separated list of names.</td>
</tr>
<tr>
<td>objectType</td>
<td>string</td>
<td>The database object type such as table, index, and so on. This field is used only where the SQL statement operates on a database object. If the SQL statement is not operating on an object, this value is null. Valid values for Aurora MySQL include the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• INDEX</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• TABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UNKNOWN</td>
</tr>
<tr>
<td>paramList</td>
<td>string</td>
<td>This field isn't used for Aurora MySQL and is always null.</td>
</tr>
<tr>
<td>pid</td>
<td>int</td>
<td>The process ID of the backend process that is allocated for serving the client connection. When the database server is restarted, the pid changes and the counter for the statementId field starts over.</td>
</tr>
<tr>
<td>remoteHost</td>
<td>string</td>
<td>Either the IP address or hostname of the client that issued the SQL statement. For Aurora MySQL, which one is used depends on the database's skip_name_resolve parameter setting. The value localhost indicates activity from the rdsadmin special user.</td>
</tr>
<tr>
<td>remotePort</td>
<td>string</td>
<td>The client port number.</td>
</tr>
<tr>
<td>rowCount</td>
<td>int</td>
<td>The number of table rows affected or retrieved by the SQL statement. This field is used only for SQL statements that are data manipulation language (DML) statements. If the SQL statement is not a DML statement, this value is null.</td>
</tr>
<tr>
<td>serverHost</td>
<td>string</td>
<td>The database server instance identifier. This value is represented differently for Aurora MySQL than for Aurora PostgreSQL. Aurora PostgreSQL uses an IP address instead of an identifier.</td>
</tr>
<tr>
<td>serverType</td>
<td>string</td>
<td>The database server type, for example MySQL.</td>
</tr>
</tbody>
</table>
### Field | Data Type | Description
--- | --- | ---
serverVersion | string | The database server version. Currently, this value is always MySQL 5.7.12 for Aurora MySQL.
serviceName | string | The name of the service. Currently, this value is always Amazon Aurora MySQL for Aurora MySQL.
sessionId | int | A pseudo-unique session identifier.
startTime | string | The time when execution began for the SQL statement. It is represented in Coordinated Universal Time (UTC) format. To calculate the execution time of the SQL statement, use endTime - startTime. See also the endTime field.
statementId | int | An identifier for the client's SQL statement. The counter increments with each SQL statement entered by the client. The counter is reset when the DB instance is restarted.
substatementId | int | An identifier for a SQL substatement. This value is 1 for events with class MAIN and 2 for events with class AUX. Use the statementId field to identify all the events generated by the same statement.
transactionId | int | An identifier for a transaction. (version 1.2 database activity records only)
type | string | The event type. Valid values are record or heartbeat.

### Processing a database activity stream using the AWS SDK

You can programmatically process an activity stream by using the AWS SDK. The following are fully functioning Java and Python examples of how you might process the Kinesis data stream.

#### Java

```java
import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;
import java.io.IOException;
import java.net.InetAddress;
import java.nio.ByteBuffer;
import java.nio.charset.StandardCharsets;
import java.security.NoSuchAlgorithmException;
import java.security.NoSuchProviderException;
import java.security.Security;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import java.util.UUID;
import java.util.zip.GZIPInputStream;
import javax.crypto.Cipher;
import javax.crypto.NoSuchPaddingException;
import javax.crypto.spec.SecretKeySpec;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
```

[642]
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.encryptionsdk.AwsCrypto;
import com.amazonaws.encryptionsdk.CryptoInputStream;
import com.amazonaws.encryptionsdk.jce.JceMasterKey;
import com.amazonaws.services.kinesis.clientlibrary.exceptions.InvalidStateException;
import com.amazonaws.services.kinesis.clientlibrary.exceptions.ShutdownException;
import com.amazonaws.services.kinesis.clientlibrary.exceptions.ThrottlingException;
import com.amazonaws.services.kinesis.clientlibrary.interfaces.IRecordProcessor;
import com.amazonaws.services.kinesis.clientlibrary.interfaces.IRecordProcessorCheckpointer;

Managing access to database activity streams

Any user with appropriate AWS Identity and Access Management (IAM) role privileges for database activity streams can create, start, stop, and modify the activity stream settings for a DB cluster. These actions are included in the audit log of the stream. For best compliance practices, we recommend that you don't provide these privileges to DBAs.

You set access to database activity streams using IAM policies. For more information about Aurora authentication, see Identity and access management for Amazon Aurora (p. 1653). For more information about creating IAM policies, see Creating and using an IAM policy for IAM database access (p. 1685).

Example Policy to allow configuring database activity streams

To give users fine-grained access to modify activity streams, use the service-specific operation context keys rds:StartActivityStream and rds:StopActivityStream in an IAM policy. The following IAM policy example allows a user or role to configure activity streams.

```json
{
  "Version": "2012-10-17",
  "Statement": 
    
```
Example Policy to allow starting database activity streams

The following IAM policy example allows a user or role to start activity streams.

```json
{  
  "Version":"2012-10-17",
  "Statement": [
    {  
      "Sid":"AllowStartActivityStreams",
      "Effect":"Allow",
      "Action": "rds:StartActivityStream",
      "Resource":"*"
    }
  ]
}
```

Example Policy to allow stopping database activity streams

The following IAM policy example allows a user or role to stop activity streams.

```json
{  
  "Version":"2012-10-17",
  "Statement": [
    {  
      "Sid":"AllowStopActivityStreams",
      "Effect":"Allow",
      "Action": "rds:StopActivityStream",
      "Resource":"*"
    }
  ]
}
```

Example Policy to deny starting database activity streams

The following IAM policy example prevents a user or role from starting activity streams.

```json
{  
  "Version":"2012-10-17",
  "Statement": [
    {  
      "Sid":"DenyStartActivityStreams",
      "Effect":"Deny",
      "Action": "rds:StartActivityStream",
      "Resource":"*"
    }
  ]
}
```
Example Policy to deny stopping database activity streams

The following IAM policy example prevents a user or role from stopping activity streams.

```json
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyStopActivityStreams",
         "Effect":"Deny",
         "Action":"rds:StopActivityStream",
         "Resource":"*"
      }
   ]
}
```
Working with Amazon Aurora MySQL

Amazon Aurora MySQL is a fully managed, MySQL-compatible, relational database engine that combines the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases. Aurora MySQL is a drop-in replacement for MySQL and makes it simple and cost-effective to set up, operate, and scale your new and existing MySQL deployments, thus freeing you to focus on your business and applications. Amazon RDS provides administration for Aurora by handling routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair. Amazon RDS also provides push-button migration tools to convert your existing Amazon RDS for MySQL applications to Aurora MySQL.

Overview of Amazon Aurora MySQL

The following sections provide an overview of Amazon Aurora MySQL.

Topics
- Amazon Aurora MySQL performance enhancements (p. 651)
- Amazon Aurora MySQL and spatial data (p. 652)
- Aurora MySQL version 3 compatible with MySQL 8.0 (p. 653)
- Aurora MySQL version 2 compatible with MySQL 5.7 (p. 680)

Amazon Aurora MySQL performance enhancements

Amazon Aurora includes performance enhancements to support the diverse needs of high-end commercial databases.
**Fast insert**

Fast insert accelerates parallel inserts sorted by primary key and applies specifically to `LOAD DATA` and `INSERT INTO ... SELECT ...` statements. Fast insert caches the position of a cursor in an index traversal while executing the statement. This avoids unnecessarily traversing the index again.

You can monitor the following metrics to determine the effectiveness of fast insert for your DB cluster:

- `aurora_fast_insert_cache_hits`: A counter that is incremented when the cached cursor is successfully retrieved and verified.
- `aurora_fast_insert_cache_misses`: A counter that is incremented when the cached cursor is no longer valid and Aurora performs a normal index traversal.

You can retrieve the current value of the fast insert metrics using the following command:

```sql
mysql> show global status like 'Aurora_fast_insert%';
```

You will get output similar to the following:

```
+---------------------------------+-----------+
| Variable_name                   | Value     |
|---------------------------------+-----------|
| Aurora_fast_insert_cache_hits   | 3598300   |
| Aurora_fast_insert_cache_misses | 436401336 |
+---------------------------------+-----------+
```

**Amazon Aurora MySQL and spatial data**

The following list summarizes the main Aurora MySQL spatial features and explains how they correspond to spatial features in MySQL:

- **Aurora MySQL 1.x** supports the same spatial data types and spatial relation functions as MySQL 5.6. For more information about these data types and functions, see Spatial Data Types and Spatial Relation Functions in the MySQL 5.6 documentation.
- **Aurora MySQL 2.x** supports the same spatial data types and spatial relation functions as MySQL 5.7. For more information about these data types and functions, see Spatial Data Types and Spatial Relation Functions in the MySQL 5.7 documentation.
- **Aurora MySQL 3.x** supports the same spatial data types and spatial relation functions as MySQL 8.0. For more information about these data types and functions, see Spatial Data Types and Spatial Relation Functions in the MySQL 8.0 documentation.
- **Aurora MySQL** supports spatial indexing on InnoDB tables. Spatial indexing improves query performance on large datasets for queries on spatial data. In MySQL, spatial indexing for InnoDB tables isn't available in MySQL 5.6, but is available in MySQL 5.7 and 8.0. Aurora MySQL uses a different spatial indexing strategy than MySQL for high performance with spatial queries. The Aurora spatial index implementation uses a space-filling curve on a B-tree, which is intended to provide higher performance for spatial range scans than an R-tree.

The following data definition language (DDL) statements are supported for creating indexes on columns that use spatial data types.
CREATE TABLE

You can use the SPATIAL INDEX keywords in a CREATE TABLE statement to add a spatial index to a column in a new table. Following is an example.

```
CREATE TABLE test (shape POLYGON NOT NULL, SPATIAL INDEX(shape));
```

ALTER TABLE

You can use the SPATIAL INDEX keywords in an ALTER TABLE statement to add a spatial index to a column in an existing table. Following is an example.

```
ALTER TABLE test ADD SPATIAL INDEX(shape);
```

CREATE INDEX

You can use the SPATIAL keyword in a CREATE INDEX statement to add a spatial index to a column in an existing table. Following is an example.

```
CREATE SPATIAL INDEX shape_index ON test (shape);
```

Aurora MySQL version 3 compatible with MySQL 8.0

You can use Aurora MySQL version 3 to get the latest MySQL-compatible features, performance enhancements, and bug fixes. Following, you can learn about Aurora MySQL version 3, with MySQL 8.0 compatibility. You can learn how to upgrade your clusters and applications to Aurora MySQL version 3.

Some Aurora features, such as Aurora Serverless v2, require Aurora MySQL version 3.

Topics
- Features from MySQL 8.0 Community Edition (p. 653)
- Aurora MySQL version 3 prerequisite for Aurora MySQL Serverless v2 (p. 654)
- Release notes for Aurora MySQL version 3 (p. 654)
- New parallel query optimizations (p. 654)
- New temporary table behavior in Aurora MySQL version 3 (p. 655)
- Comparison of Aurora MySQL version 2 and Aurora MySQL version 3 (p. 658)
- Comparison of Aurora MySQL version 3 and MySQL 8.0 Community Edition (p. 663)
- Upgrading to Aurora MySQL version 3 (p. 666)

Features from MySQL 8.0 Community Edition

The initial release of Aurora MySQL version 3 is compatible with MySQL 8.0.23 Community Edition. MySQL 8.0 introduces several new features, including the following:

- JSON functions. For usage information, see JSON Functions in the MySQL Reference Manual.
- Window functions. For usage information, see Window Functions in the MySQL Reference Manual.
- Common table expressions (CTEs), using the WITH clause. For usage information, see WITH (Common Table Expressions) in the MySQL Reference Manual.
• Optimized `ADD COLUMN` and `RENAME COLUMN` clauses for the `ALTER TABLE` statement. These optimizations are called "instant DDL." Aurora MySQL version 3 is compatible with the community MySQL instant DDL feature. The former Aurora fast DDL feature isn't used. For usage information for instant DDL, see [Instant DDL (Aurora MySQL version 3)](p. 742).

• Descending, functional, and invisible indexes. For usage information, see [Invisible Indexes, Descending Indexes, and CREATE INDEX Statement](p. 664) in the MySQL Reference Manual.

• Role-based privileges controlled through SQL statements. For more information on changes to the privilege model, see [Role-based privilege model](p. 664).

• `NOWAIT` and `SKIP LOCKED` clauses with the `SELECT ... FOR SHARE` statement. These clauses avoid waiting for other transactions to release row locks. For usage information, see [Locking Reads](p. 664) in the MySQL Reference Manual.

• Improvements to binary log (binlog) replication. For the Aurora MySQL details, see [Binary log replication](p. 662). In particular, you can perform filtered replication. For usage information about filtered replication, see [How Servers Evaluate Replication Filtering Rules](p. 662) in the MySQL Reference Manual.

• Hints. Some of the MySQL 8.0–compatible hints were already backported to Aurora MySQL version 2. For information about using hints with Aurora MySQL, see [Aurora MySQL hints](p. 983). For the full list of hints in community MySQL 8.0, see [Optimizer Hints](p. 742) in the MySQL Reference Manual.

For the full list of features added to MySQL 8.0 community edition, see the blog post [The complete list of new features in MySQL 8.0](p. 660).

Aurora MySQL version 3 also includes changes to keywords for inclusive language, backported from community MySQL 8.0.26. For details about those changes, see [Inclusive language changes for Aurora MySQL version 3](p. 660).

### Aurora MySQL version 3 prerequisite for Aurora MySQL Serverless v2

Aurora MySQL version 3 is a prerequisite for all DB instances in an Aurora MySQL Serverless v2 cluster. Aurora MySQL Serverless v2 includes support for reader instances in a DB cluster, and other Aurora features that aren't available for Aurora MySQL Serverless v1. It also has faster and more granular scaling than Aurora MySQL Serverless v1.

### Release notes for Aurora MySQL version 3

For the release notes for all Aurora MySQL version 3 releases, see [Database engine updates for Amazon Aurora MySQL version 3](p. 660) in the Release Notes for Aurora MySQL.

### New parallel query optimizations

The Aurora parallel query optimization now applies to more SQL operations:

• Parallel query now applies to tables containing the data types `TEXT`, `BLOB`, `JSON`, `GEOMETRY`, and `VARCHAR` and `CHAR` longer than 768 bytes.

• Parallel query can optimize queries involving partitioned tables.

• Parallel query can optimize queries involving aggregate function calls in the select list and the `HAVING` clause.

For more information about these enhancements, see [Upgrading parallel query clusters to Aurora MySQL version 3](p. 803). For general information about Aurora parallel query, see [Working with parallel query for Amazon Aurora MySQL](p. 791).
New temporary table behavior in Aurora MySQL version 3

Aurora MySQL version 3 handles temporary tables differently from earlier Aurora MySQL versions. This new behavior is inherited from MySQL 8.0 Community Edition. There are two types of temporary tables that can be created with Aurora MySQL version 3:

- **Internal (or implicit)** temporary tables – Created by the Aurora MySQL engine to handle operations such as sorting, aggregation, derived tables, or common table expressions (CTEs).
- **User-created (or explicit)** temporary tables – Created by the Aurora MySQL engine when you use the `CREATE TEMPORARY TABLE` statement.

There are additional considerations for both internal and user-created temporary tables on Aurora reader DB instances. We discuss these changes in the following sections.

**Topics**
- Storage engine for internal (implicit) temporary tables (p. 655)
- Mitigating fullness issues for internal temporary tables on Aurora Replicas (p. 656)
- User-created (explicit) temporary tables on reader DB instances (p. 657)
- Temporary table creation errors and mitigation (p. 657)

**Storage engine for internal (implicit) temporary tables**

When generating intermediate result sets, Aurora MySQL initially attempts to write to in-memory temporary tables. If this is unsuccessful, because of either incompatible data types or configured limits, the temporary table is converted to an on-disk temporary table rather than being held in memory. More information on this can be found in the Internal Temporary Table Use in MySQL in the MySQL documentation.

In Aurora MySQL version 3, the way internal temporary tables work is different from earlier Aurora MySQL versions. Instead of choosing between the InnoDB and MyISAM storage engines for such temporary tables, now you choose between the `TempTable` and InnoDB storage engines.

With the `TempTable` storage engine, you can make an additional choice for how to handle certain data. The data affected overflows the memory pool that holds all the internal temporary tables for the DB instance.

Those choices can influence the performance for queries that generate high volumes of temporary data, for example while performing aggregations such as `GROUP BY` on large tables.

**Tip**

If your workload includes queries that generate internal temporary tables, confirm how your application performs with this change by running benchmarks and monitoring performance-related metrics.

In some cases, the amount of temporary data fits within the `TempTable` memory pool or only overflows the memory pool by a small amount. In these cases, we recommend using the `TempTable` setting for internal temporary tables and memory-mapped files to hold any overflow data. This setting is the default.

The `TempTable` storage engine is the default. `TempTable` uses a common memory pool for all temporary tables that use this engine, instead of a maximum memory limit per table. The size of this memory pool is specified by the `temptable_max_ram` parameter. It defaults to 1 GiB on DB instances with 16 or more GiB of memory, and 16 MB on DB instances with less than 16 GiB of memory. The size of the memory pool influences session-level memory consumption.

If you use the `TempTable` storage engine and the temporary data exceeds the size of the memory pool, Aurora MySQL stores the overflow data using a secondary mechanism.
You can set the `temptable_max_mmap` parameter to specify if the data overflows to memory-mapped temporary files or to InnoDB internal temporary tables on disk. The different data formats and overflow criteria of these overflow mechanisms can affect query performance. They do so by influencing the amount of data written to disk and the demand on disk storage throughput.

Aurora MySQL stores the overflow data differently depending on your choice of data overflow destination and whether the query runs on a writer or reader DB instance:

- On the writer instance, data that overflows to InnoDB internal temporary tables is stored in the Aurora cluster volume.
- On the writer instance, data that overflows to memory-mapped temporary files resides on local storage on the Aurora MySQL version 3 instance.
- On reader instances, overflow data always resides on memory-mapped temporary files on local storage. That's because read-only instances can't store any data on the Aurora cluster volume.

**Note**
The configuration parameters related to internal temporary tables apply differently to the writer and reader instances in your cluster. For reader instances, Aurora MySQL always uses the TempTable storage engine and a value of 1 for `temptable_use_mmap`. The size for `temptable_max_mmap` defaults to 1 GiB, for both writer and reader instances, regardless of the DB instance memory size. You can adjust this value the same way as on the writer instance, except that you can't specify a value of zero for `temptable_max_mmap` on reader instances.

**Mitigating fullness issues for internal temporary tables on Aurora Replicas**

To avoid size limitation issues for temporary tables, set the `temptable_max_ram` and `temptable_max_mmap` parameters to a combined value that can fit the requirements of your workload.

Be careful when setting the value of the `temptable_max_ram` parameter. Setting the value too high reduces the available memory on the database instance, which can cause an out-of-memory condition. Monitor the average freeable memory on the DB instance, and then determine an appropriate value for `temptable_max_ram` so that you will still have a reasonable amount of free memory left on the instance. For more information, see [Freeable memory issues in Amazon Aurora (p. 1763)](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-query-plan.html).

It is also important to monitor the size of the local storage and the temporary table space consumption. For more information on monitoring local storage on an instance, see the AWS Knowledge Center article [What is stored in Aurora MySQL-compatible local storage, and how can I troubleshoot local storage issues?](https://docs.aws.amazon.com/AWSSolutions/latest/Compute-Solution/html/AuroraMySQL-LikeLocalStorage.html).

**Example 1**

You know that your temporary tables grow to a cumulative size of 20 GiB. You want to set in-memory temporary tables to 2 GiB and to grow to a maximum of 20 GiB on disk.

Set `temptable_max_ram` to 2,147,483,648 and `temptable_max_mmap` to 21,474,836,480. These values are in bytes.

These parameter settings make sure that your temporary tables can grow to a cumulative total of 22 GiB.

**Example 2**

Your current instance size is 16xlarge or larger. You don't know the total size of the temporary tables that you might need. You want to be able to use up to 4 GiB in memory and up to the maximum available storage size on disk.

Set `temptable_max_ram` to 4,294,967,296 and `temptable_max_mmap` to 1,099,511,627,776. These values are in bytes.
Here you're setting `temptable_max_mmap` to 1 TiB, which is less than the maximum local storage of 1.2 TiB on a 16xlarge Aurora DB instance.

On a smaller instance size, adjust the value of `temptable_max_mmap` so that it doesn't fill up the available local storage. For example, a 2xlarge instance has only 160 GiB of local storage available. Hence, we recommend setting the value to less than 160 GiB. For more information on the available local storage for DB instance sizes, see Temporary storage limits for Aurora MySQL (p. 724).

**User-created (explicit) temporary tables on reader DB instances**

You can create explicit temporary tables using the `TEMPORARY` keyword in your `CREATE TABLE` statement. Explicit temporary tables are supported on the writer DB instance in an Aurora DB cluster. You can also use explicit temporary tables on reader DB instances, but the tables can't enforce the use of the InnoDB storage engine.

To avoid errors while creating explicit temporary tables on Aurora reader DB instances, make sure that all `CREATE TEMPORARY TABLE` statements on reader DB instances are run in either of the following ways:

- Without specifying the `ENGINE=InnoDB` clause
- With the SQL mode `NO_ENGINE_SUBSTITUTION=OFF`

**Temporary table creation errors and mitigation**

The error that you receive is different depending on whether you use a plain `CREATE TEMPORARY TABLE` statement or the variation `CREATE TEMPORARY TABLE AS SELECT`. The following examples show the different kinds of errors.

This temporary table behavior only applies to read-only instances. This first example confirms that's the kind of instance the session is connected to.

```
mysql> select @@innodb_read_only;
+--------------------+
| @@innodb_read_only |
+--------------------+
|                  1 |  
```

For plain `CREATE TEMPORARY TABLE` statements, the statement fails when the `NO_ENGINE_SUBSTITUTION` SQL mode is turned on. When `NO_ENGINE_SUBSTITUTION` is turned off (default), the appropriate engine substitution is made, and the temporary table creation succeeds.

```
mysql> set sql_mode = 'NO_ENGINE_SUBSTITUTION';

mysql> CREATE TEMPORARY TABLE tt2 (id int) ENGINE=InnoDB;
ERROR 3161 (HY000): Storage engine InnoDB is disabled (Table creation is disallowed).
mysql> set sql_mode = ' ';  

mysql> CREATE TEMPORARY TABLE tt4 (id int) ENGINE=InnoDB;
```

For `CREATE TEMPORARY TABLE AS SELECT` statements, the statement fails whether or not the `NO_ENGINE_SUBSTITUTION` SQL mode is turned on. MySQL Community Edition doesn't support
storage engine substitution with `CREATE TABLE AS SELECT` or `CREATE TEMPORARY TABLE AS SELECT` statements. For those statements, remove the `ENGINE=InnoDB` clause from your SQL code.

```sql
mysql> set sql_mode = 'NO_ENGINE_SUBSTITUTION';

mysql> CREATE TEMPORARY TABLE tt1 ENGINE=InnoDB AS SELECT * FROM t1;
ERROR 3161 (HY000): Storage engine InnoDB is disabled (Table creation is disallowed).

mysql> SET sql_mode = '';

mysql> CREATE TEMPORARY TABLE tt3 ENGINE=InnoDB AS SELECT * FROM t1;
ERROR 1874 (HY000): InnoDB is in read only mode.
```

For more information about the storage aspects and performance implications of temporary tables in Aurora MySQL version 3, see the blog post Use the TempTable storage engine on Amazon RDS for MySQL and Amazon Aurora MySQL.

**Comparison of Aurora MySQL version 2 and Aurora MySQL version 3**

Use the following to learn about changes to be aware of when you upgrade your Aurora MySQL version 2 cluster to version 3.

**Topics**
- Feature differences between Aurora MySQL version 2 and 3 (p. 658)
- Instance class support (p. 659)
- Parameter changes for Aurora MySQL version 3 (p. 659)
- Status variables (p. 660)
- Inclusive language changes for Aurora MySQL version 3 (p. 660)
- AUTO_INCREMENT values (p. 662)
- Binary log replication (p. 662)

**Feature differences between Aurora MySQL version 2 and 3**

The following Amazon Aurora MySQL features are supported in Aurora MySQL for MySQL 5.7, but these features aren't supported in Aurora MySQL for MySQL 8.0:

- Backtrack currently isn't available for Aurora MySQL version 3 clusters. We intend to make this feature available in a subsequent minor version.

  If you have an Aurora MySQL version 2 cluster that uses backtrack, currently you can't use the snapshot restore method to upgrade to Aurora MySQL version 3. This limitation applies to all clusters that use backtrack clusters, regardless of whether the backtrack setting is turned on. For details about upgrade procedures, see Upgrading to Aurora MySQL version 3 (p. 666).

- You can't use Aurora MySQL version 3 for Aurora Serverless v1 clusters. Aurora MySQL version 3 works with Aurora Serverless v2.

- Lab mode doesn't apply to Aurora MySQL version 3. There aren't any lab mode features in Aurora MySQL version 3. Instant DDL supersedes the fast online DDL feature that was formerly available in lab mode. For an example, see Instant DDL (Aurora MySQL version 3) (p. 742).

- The query cache is removed from community MySQL 8.0 and also from Aurora MySQL version 3.

- Aurora MySQL version 3 is compatible with the community MySQL hash join feature. The Aurora-specific implementation of hash joins in Aurora MySQL version 2 isn't used. For information about using hash joins with Aurora parallel query, see Turning on hash join for parallel query.
clusters (p. 801) and Aurora MySQL hints (p. 983). For general usage information about hash joins, see Hash Join Optimization in the MySQL Reference Manual.

- Currently, you can’t restore a physical backup from the Percona XtraBackup tool to an Aurora MySQL version 3 cluster. We intend to support this feature in a subsequent minor version.
- The mysql.lambda_async stored procedure that was deprecated in Aurora MySQL version 2 is removed in version 3. For version 3, use the asynchronous function lambda_async instead.
- The default character set in Aurora MySQL version 3 is utf8mb4. In Aurora MySQL version 2, the default character set was latin1. For information about this character set, see The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding) in the MySQL Reference Manual.
- The innodb_flush_log_at_trx_commit configuration parameter can’t be modified. The default value of 1 always applies.

Some Aurora MySQL features are available for certain combinations of AWS Region and DB engine version. For details, see Supported features in Amazon Aurora by AWS Region and Aurora DB engine (p. 19).

Instance class support

Aurora MySQL version 3 supports a different set of instance classes than Aurora MySQL version 2 does:

- For larger instances, you can use the modern instance classes such as db.r5, db.r6g, and db.x2g.
- For smaller instances, you can use the modern instance classes such as db.t3 and db.t4g.

The following instance classes from Aurora MySQL version 2 aren’t available for Aurora MySQL version 3:

- db.r4
- db.r3
- db.t3.small
- db.t2

Check your administration scripts for any CLI statements that create Aurora MySQL DB instances and hardcode instance class names that aren’t available for Aurora MySQL version 3. If necessary, modify the instance class names to ones that Aurora MySQL version 3 supports.

Tip
To check the instance classes that you can use for a specific combination of Aurora MySQL version and AWS Region, use the describe-orderable-db-instance-options AWS CLI command.

For full details about Aurora instance classes, see Aurora DB instance classes (p. 56).

Parameter changes for Aurora MySQL version 3

Aurora MySQL version 3 includes new cluster-level and instance-level configuration parameters. Aurora MySQL version 3 also removes some parameters that were present in Aurora MySQL version 2. Some parameter names are changed as a result of the initiative for inclusive language. For backward compatibility, you can still retrieve the parameter values using either the old names or the new names. However, you must use the new names to specify parameter values in a custom parameter group.

In Aurora MySQL version 3, the value of the lower_case_table_names parameter is set permanently at the time the cluster is created. If you use a nondefault value for this option, set up your Aurora MySQL version 3 custom parameter group before upgrading. Then specify the parameter group during the create cluster or snapshot restore operation.
For the full list of Aurora MySQL cluster parameters, see Cluster-level parameters (p. 951). The table covers all the parameters from Aurora MySQL version 1, 2, and 3. The table includes notes showing which parameters are new in Aurora MySQL version 3 or were removed from Aurora MySQL version 3.

For the full list of Aurora MySQL instance parameters, see Instance-level parameters (p. 957). The table covers all the parameters from Aurora MySQL version 1, 2, and 3. The table includes notes showing which parameters are new in Aurora MySQL version 3 and which parameters were removed from Aurora MySQL version 3. It also includes notes showing which parameters were modifiable in earlier versions but not Aurora MySQL version 3.

For information about parameter names that changed, see Inclusive language changes for Aurora MySQL version 3 (p. 660).

### Status variables

For information about status variables that aren't applicable to Aurora MySQL, see MySQL status variables that don't apply to Aurora MySQL (p. 971).

### Inclusive language changes for Aurora MySQL version 3

Aurora MySQL version 3 is compatible with version 8.0.23 from the MySQL community edition. Aurora MySQL version 3 also includes changes from MySQL 8.0.26 related to keywords and system schemas for inclusive language. For example, the `SHOW REPLICA STATUS` command is now preferred instead of `SHOW SLAVE STATUS`.

The following Amazon CloudWatch metrics have new names in Aurora MySQL version 3. In Aurora MySQL version 3, only the new metric names are available. Make sure to update any alarms or other automation that relies on metric names when you upgrade to Aurora MySQL version 3.

<table>
<thead>
<tr>
<th>Old name</th>
<th>New name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ForwardingMasterDMLLatency</td>
<td>ForwardingWriterDMLLatency</td>
</tr>
<tr>
<td>ForwardingMasterOpenSessions</td>
<td>ForwardingWriterOpenSessions</td>
</tr>
<tr>
<td>AuroraDMLRejectedMasterFull</td>
<td>AuroraDMLRejectedWriterFull</td>
</tr>
<tr>
<td>ForwardingMasterDMLThroughput</td>
<td>ForwardingWriterDMLThroughput</td>
</tr>
</tbody>
</table>

The following status variables have new names in Aurora MySQL version 3. For compatibility, you can use either name in the initial Aurora MySQL version 3 release. The old status variable names are to be removed in a future release.

<table>
<thead>
<tr>
<th>Name to be removed</th>
<th>New or preferred name</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
The following stored procedures have new names in Aurora MySQL version 3.

For compatibility, you can use either name in the initial Aurora MySQL version 3 release. The old procedure names are to be removed in a future release.

### AUTO_INCREMENT values

In Aurora MySQL version 3, Aurora preserves the `AUTO_INCREMENT` value for each table when it restarts each DB instance. In Aurora MySQL version 2, the `AUTO_INCREMENT` value wasn't preserved after a restart.

The `AUTO_INCREMENT` value isn't preserved when you set up a new cluster by restoring from a snapshot, performing a point-in-time recovery, and cloning a cluster. In these cases, the `AUTO_INCREMENT` value is initialized to the value based on the largest column value in the table at the time the snapshot was created. This behavior is different than in RDS for MySQL 8.0, where the `AUTO_INCREMENT` value is preserved during these operations.

### Binary log replication

In MySQL 8.0 community edition, binary log replication is turned on by default. In Aurora MySQL version 3, binary log replication is turned off by default.

**Tip**

If your high availability requirements are fulfilled by the Aurora built-in replication features, you can leave binary log replication turned off. That way, you can avoid the performance overhead of binary log replication. You can also avoid the associated monitoring and troubleshooting that are needed to manage binary log replication.

Aurora supports binary log replication from a MySQL 5.7–compatible source to Aurora MySQL version 3. The source system can be an Aurora MySQL DB cluster, an RDS for MySQL DB instance, or an on-premises MySQL instance.

As does community MySQL, Aurora MySQL supports replication from a source running a specific version to a target running the same major version or one major version higher. For example, replication from a MySQL 5.6–compatible system to Aurora MySQL version 3 isn't supported. Replicating from Aurora MySQL version 3 to a MySQL 5.7–compatible or MySQL 5.6–compatible system isn't supported. For
details about using binary log replication, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 842).

Aurora MySQL version 3 includes improvements to binary log replication in community MySQL 8.0, such as filtered replication. For details about the community MySQL 8.0 improvements, see How Servers Evaluate Replication Filtering Rules in the MySQL Reference Manual.

Multithreaded replication

With Aurora MySQL version 3, Aurora MySQL supports multithreaded replication. For usage information, see Multithreaded binary log replication (Aurora MySQL version 3 and higher) (p. 858).

Note
We still recommend not using multithreaded replication with Aurora MySQL version 1 and version 2.

Transaction compression for binary log replication

For usage information about binary log compression, see Binary Log Transaction Compression in the MySQL Reference Manual.

The following limitations apply to binary log compression in Aurora MySQL version 3:

• Transactions whose binary log data is larger than the maximum allowed packet size aren't compressed, regardless of whether the Aurora MySQL binary log compression setting is turned on. Such transactions are replicated without being compressed.
• If you use a connector for change data capture (CDC) that doesn't support MySQL 8.0 yet, you can't use this feature. We recommend that you test any third-party connectors thoroughly with binary log compression before turning on binlog compression on systems that use binlog replication for CDC.

Comparison of Aurora MySQL version 3 and MySQL 8.0 Community Edition

You can use the following information to learn about the changes to be aware of when you convert from a different MySQL 8.0–compatible system to Aurora MySQL version 3.

In general, Aurora MySQL version 3 supports the feature set of community MySQL 8.0.23. Some new features from MySQL 8.0 community edition don't apply to Aurora MySQL. Some of those features aren't compatible with some aspect of Aurora, such as the Aurora storage architecture. Other features aren't needed because the Amazon RDS management service provides equivalent functionality. The following features in community MySQL 8.0 aren't supported or work differently in Aurora MySQL version 3.

For release notes for all Aurora MySQL version 3 releases, see Database engine updates for Amazon Aurora MySQL version 3 in the Release Notes for Aurora MySQL.

Topics

• MySQL 8.0 features not available in Aurora MySQL version 3 (p. 663)
• Role-based privilege model (p. 664)
• Authentication (p. 666)

MySQL 8.0 features not available in Aurora MySQL version 3

The following features from community MySQL 8.0 aren't available or work differently in Aurora MySQL version 3.

• Resource groups and associated SQL statements aren't supported in Aurora MySQL.
• The Aurora storage architecture means that you don’t have to manually manage files and the underlying storage for your database. In particular, Aurora handles the undo tablespace differently than community MySQL does. This difference from community MySQL has the following consequences:
  • Aurora MySQL doesn't support named tablespaces.
  • The `innodb_undo_log_truncate` configuration setting is turned off and can't be turned on. Aurora has its own mechanism for reclaiming storage space.
  • Aurora MySQL doesn't have the `CREATE UNDO TABLESPACE`, `ALTER UNDO TABLESPACE ... SET INACTIVE`, and `DROP UNDO TABLESPACE` statements.
  • Aurora sets the number of undo tablespaces automatically and manages those tablespaces for you.
  • TLS 1.3 isn't supported in Aurora MySQL version 3.
  • The `aurora_hot_page_contention` status variable isn't available. The hot page contention feature isn't supported. For the full list of status variables not available in Aurora MySQL version 3, see Status variables (p. 660).
  • You can't modify the settings of any MySQL plugins.
  • The X plugin isn't supported.

Role-based privilege model

With Aurora MySQL version 3, you can't modify the tables in the mysql database directly. In particular, you can't set up users by inserting into the mysql.user table. Instead, you use SQL statements to grant role-based privileges. You also can't create other kinds of objects such as stored procedures in the mysql database. You can still query the mysql tables. If you use binary log replication, changes made directly to the mysql tables on the source cluster aren't replicated to the target cluster.

In some cases, your application might use shortcuts to create users or other objects by inserting into the mysql tables. If so, change your application code to use the corresponding statements such as `CREATE USER`. If your application creates stored procedures or other objects in the mysql database, use a different database instead.

To export metadata for database users during the migration from an external MySQL database, you can use `mysqlpump` command instead of `mysqldump`. Use the following syntax.

```
mysqlpump --exclude-databases=mysql --users
```

This statement dumps all databases except for the tables in the mysql system database. It also includes `CREATE USER` and `GRANT` statements to reproduce all MySQL users in the migrated database. You can also use the `pt-show-grants` tool on the source system to list `CREATE USER` and `GRANT` statements to reproduce all the database users.

To simplify managing permissions for many users or applications, you can use the `CREATE ROLE` statement to create a role that has a set of permissions. Then you can use the `GRANT` and `SET ROLE` statements and the `current_role` function to assign roles to users or applications, switch the current role, and check which roles are in effect. For more information on the role-based permission system in MySQL 8.0, see Using Roles in the MySQL Reference Manual.

Aurora MySQL version 3 includes a special role that has all of the following privileges. This role is named `rds_superuser_role`. The primary administrative user for each cluster already has this role granted. The `rds_superuser_role` role includes the following privileges for all database objects:

• `ALTER`
• `APPLICATION_PASSWORD_ADMIN`
• `ALTER ROUTINE`
The role definition also includes WITH GRANT OPTION so that an administrative user can grant that role to other users. In particular, the administrator must grant any privileges needed to perform binary log replication with the Aurora MySQL cluster as the target.

**Tip**
To see the full details of the permissions, enter the following statements.

```
SHOW GRANTS FOR rds_superuser_role '@%';
SHOW GRANTS FOR name_of_administrative_user_for_your_cluster '@%';
```

Aurora MySQL version 3 also includes roles that you can use to access other AWS services. You can set these roles as an alternative to GRANT statements. For example, you specify GRANT AWS_LAMBDA_ACCESS TO user instead of GRANT INVOKE LAMBDA ON *.* TO user. For the procedures to access other AWS services, see Integrating Amazon Aurora MySQL with other AWS services (p. 891). Aurora MySQL version 3 includes the following roles related to accessing other AWS services:
• **AWS_LAMBDA_ACCESS** role, as an alternative to the `INVOKER` LAMBDA privilege. For usage information, read the Amazon Aurora User Guide for Aurora MySQL version 3 (p. 918).

• **AWS_LOAD_S3_ACCESS** role, as an alternative to the `LOAD FROM S3` privilege. For usage information, see *Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket* (p. 904).

• **AWS_SELECT_S3_ACCESS** role, as an alternative to the `SELECT INTO S3` privilege. For usage information, see *Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket* (p. 912).

• **AWS_SAGEMAKER_ACCESS** role, as an alternative to the `INVOKESAGEMAKER` privilege. For usage information, see *Using machine learning (ML) with Aurora MySQL* (p. 928).

• **AWS_COMPREHEND_ACCESS** role, as an alternative to the `INVOKECOMPREHEND` privilege. For usage information, see *Using machine learning (ML) with Aurora MySQL* (p. 928).

When you grant access by using roles in Aurora MySQL version 3, you also activate the role by using the `SET ROLE` command. The following example shows how. Substitute the appropriate role name for `AWS_SELECT_S3_ACCESS`.

```sql
# Grant role to user
mysql> GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'

# Check the current roles for your user. In this case, the AWS_SELECT_S3_ACCESS role has not been activated.
# Only the rds_superuser_role is currently in effect.
mysql> SELECT CURRENT_ROLE();
+--------------------------+
| CURRENT_ROLE()           |
+--------------------------+
| `rds_superuser_role`@`%` |
+--------------------------+
1 row in set (0.00 sec)

# Activate all roles associated with this user using SET ROLE.
# You can activate specific roles or all roles.
# In this case, the user only has 2 roles, so we specify ALL.
mysql> SET ROLE ALL;
Query OK, 0 rows affected (0.00 sec)

# Verify role is now active
mysql> SELECT CURRENT_ROLE();
+--------------------------------------------------+
| CURRENT_ROLE()                                   |
+--------------------------------------------------+
| `AWS_LAMBDA_ACCESS`@`%`,`rds_superuser_role`@`%` |
+--------------------------------------------------+
```

**Authentication**

In community MySQL 8.0, the default authentication plugin is `caching_sha2_password`. Aurora MySQL version 3 still uses the `mysql_native_password` plugin. You can't change the default_authentication_plugin setting.

**Upgrading to Aurora MySQL version 3**

For specific upgrade paths to upgrade your database from Aurora MySQL version 1 or 2 to version 3, you can use one of the following approaches:

• To upgrade an Aurora MySQL version 2 cluster to version 3, create a snapshot of the version 2 cluster and restore the snapshot to create a new version 3 cluster. Follow the procedure in *Restoring from a...*
To upgrade from Aurora MySQL version 1, first do an intermediate upgrade to AuroraMySQL version 2. To do the upgrade to Aurora MySQL version 2, use any of the upgrade methods in Upgrading Amazon Aurora MySQL DB clusters (p. 997). Then use the snapshot restore technique to upgrade from Aurora MySQL version 2 to Aurora MySQL version 3. Snapshot restore isn't available from Aurora MySQL version 1 clusters (MySQL 5.6–compatible) to Aurora MySQL version 3.

Currently, you can't clone a MySQL 5.7–compatible Aurora cluster to a MySQL 8.0–compatible one. Use the snapshot restore technique instead.

If you have an Aurora MySQL version 2 cluster that uses backtrack, currently you can't use the snapshot restore method to upgrade to Aurora MySQL version 3. This limitation applies to all clusters that use backtrack, regardless of whether the backtrack setting is turned on. In this case, perform a logical dump and restore by using a tool such as the `mysqldump` command. For more information about using `mysqldump` for Aurora MySQL, see Migrating from MySQL to Amazon Aurora by using `mysqldump` (p. 705).

Tip

In some cases, you might specify the option to upload database logs to CloudWatch when you restore the snapshot. If so, examine the logs in CloudWatch to diagnose any issues that occur during the restore and associated upgrade operation. The CLI examples in this section demonstrate how to do so using the `--enable-cloudwatch-logs-exports` option.

Topics

- Upgrade planning for Aurora MySQL version 3 (p. 667)
- Example of upgrading from Aurora MySQL version 2 to version 3 (p. 668)
- Example of upgrading from Aurora MySQL version 1 to version 3 (p. 670)
- Troubleshooting upgrade issues with Aurora MySQL version 3 (p. 672)
- Post-upgrade cleanup for Aurora MySQL version 3 (p. 680)

Upgrade planning for Aurora MySQL version 3

To help you decide the right time and approach to upgrade, you can learn the differences between Aurora MySQL version 3 and your current Aurora and MySQL environment:

- If you are converting from RDS for MySQL 8.0 or MySQL 8.0 Community Edition, see Comparison of Aurora MySQL version 3 and MySQL 8.0 Community Edition (p. 663).
- If you are upgrading from Aurora MySQL version 2, RDS for MySQL 5.7, or community MySQL 5.7, see Comparison of Aurora MySQL version 2 and Aurora MySQL version 3 (p. 658).
- Create new MySQL 8.0–compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups. Consult Parameter changes for Aurora MySQL version 3 (p. 659) to learn about parameter changes.

Note

For most parameter settings, you can choose the custom parameter group either when you create the cluster or associate the parameter group with the cluster later. However, if you use a nondefault setting for the `lower_case_table_names` parameter, you must set up the custom parameter group with this setting in advance. Then specify the parameter group when you perform the snapshot restore to create the cluster. Any change to the `lower_case_table_names` parameter has no effect after the cluster is created. We recommend that you use the same setting for `lower_case_table_names` when you upgrade from Aurora MySQL version 2 to version 3.

- Review your Aurora MySQL version 2 database schema and object definitions for the usage of new reserved keywords introduced in MySQL 8.0 Community Edition, before you upgrade. For more information, see MySQL 8.0 New Keywords and Reserved Words in the MySQL documentation.
You can also find more MySQL-specific upgrade considerations and tips in Changes in MySQL 8.0 in the MySQL Reference Manual. For example, you can use the command `mysqlcheck --check-upgrade` to analyze your existing Aurora MySQL databases and identify potential upgrade issues.

Currently, the primary upgrade path from earlier Aurora MySQL versions to Aurora MySQL version 3 is by restoring a snapshot to create a new cluster. You can restore a snapshot of a cluster running any minor version of Aurora MySQL version 2 (MySQL 5.7–compatible) to Aurora MySQL version 3. To upgrade from Aurora MySQL version 1, you use a two-step process. First restore a snapshot to an Aurora MySQL version 2 cluster, then make a snapshot of that cluster and restore it to an Aurora MySQL version 3 cluster. For the upgrade procedure from Aurora MySQL version 1 or 2, see Upgrading to Aurora MySQL version 3 (p. 666). For general information about upgrading by restoring a snapshot, see Upgrading Amazon Aurora MySQL DB clusters (p. 997).

**Note**

We recommend using larger DB instance classes, such as `db.r5.24xlarge`, when upgrading to Aurora MySQL version 3 using the snapshot restore technique. This helps the upgrade process to complete faster by using the majority of available CPU capacity on the DB instance. You can change to the DB instance class that you want after the major version upgrade is complete.

After you finish the upgrade itself, you can follow the post-upgrade procedures in Post-upgrade cleanup for Aurora MySQL version 3 (p. 680). Finally, test your application's functionality and performance.

If you are converting from RDS from MySQL or community MySQL, follow the migration procedure explained in Migrating data to an Amazon Aurora MySQL DB cluster (p. 690). In some cases, you might use binary log replication to synchronize your data with an Aurora MySQL version 3 cluster as part of the migration. If so, the source system must run a version that's compatible with MySQL 5.7, or a MySQL 8.0–compatible version that is 8.0.23 or lower.

**Example of upgrading from Aurora MySQL version 2 to version 3**

The following AWS CLI example demonstrates the steps to upgrade an Aurora MySQL version 2 cluster to Aurora MySQL version 3.

The first step is to determine the version of the cluster that you want to upgrade. The following AWS CLI command shows how. The output confirms that the original cluster is a MySQL 5.7–compatible one that's running Aurora MySQL version 2.09.2.

This cluster has at least one DB instance. For the upgrade process to work properly, this original cluster requires a writer instance.

```
# aws rds describe-db-clusters --db-cluster-id cluster-57-upgrade-ok \
    --query '*[].EngineVersion' --output text
5.7.mysql_aurora.2.09.2
```

The following command shows how to check which upgrade paths are available from a specific version. In this case, the original cluster is running version `5.7.mysql_aurora.2.09.2`. The output shows that this version can be upgraded to Aurora MySQL version 3.

If the original cluster uses a version number that is too low to upgrade to Aurora MySQL version 3, the upgrade requires an additional step. First, restore the snapshot to create a new cluster that could be upgraded to Aurora MySQL version 3. Then, take a snapshot of that intermediate cluster. Finally, restore the snapshot of the intermediate cluster to create a new Aurora MySQL version 3 cluster.

```
# aws rds describe-db-engine-versions --engine aurora-mysql \
    --engine-version 5.7.mysql_aurora.2.09.2 \
    --query 'DBEngineVersions[].ValidUpgradeTarget[].EngineVersion'
    "5.7.mysql_aurora.2.09.3",
```
The following command creates a snapshot of the cluster to upgrade to Aurora MySQL version 3. The original cluster remains intact. You later create a new Aurora MySQL version 3 cluster from the snapshot.

```
aws rds create-db-cluster-snapshot --db-cluster-id cluster-57-upgrade-ok \
    --db-cluster-snapshot-id cluster-57-upgrade-ok-snapshot

{  "DBClusterSnapshotIdentifier": "cluster-57-upgrade-ok-snapshot",  "DBClusterIdentifier": "cluster-57-upgrade-ok",  "SnapshotCreateTime": "2021-10-06T23:20:18.087000+00:00"
}
```

The following command restores the snapshot to a new cluster that's running Aurora MySQL version 3.

```
$ aws rds restore-db-cluster-from-snapshot \
    --snapshot-id cluster-57-upgrade-ok-snapshot \
    --db-cluster-id cluster-80-restored --engine aurora-mysql \
    --engine-version 8.0.mysql_aurora.3.02.0 \
    --enable-cloudwatch-logs-exports '"error","general","slowquery","audit"'

{  "DBClusterIdentifier": "cluster-80-restored",  "Engine": "aurora-mysql",  "EngineVersion": "8.0.mysql_aurora.3.02.0",  "Status": "creating"
}
```

Restoring the snapshot sets up the storage for the cluster and establishes the database version that the cluster can use. Because the compute capacity of the cluster is separate from the storage, you set up any DB instances for the cluster once the cluster itself is created. The following example creates a writer DB instance using one of the db.r5 instance classes.

```
Tip
You might have administration scripts that create DB instances using older instance classes such as db.r3, db.r4, db.t2, or db.t3. If so, modify your scripts to use one of the instance classes that are supported with Aurora MySQL version 3. For information about the instance classes that you can use with Aurora MySQL version 3, see Instance class support (p. 659).

```
$ aws rds create-db-instance --db-instance-identifier instance-running-version-3 \
    --db-cluster-identifier cluster-80-restored \
    --db-instance-class db.r5.xlarge --engine aurora-mysql

{  "DBInstanceIdentifier": "instance-running-version-3",  "DBClusterIdentifier": "cluster-80-restored",  "DBInstanceClass": "db.r5.xlarge",  "EngineVersion": "8.0.mysql_aurora.3.02.0",  "DBInstanceStatus": "creating"
}
```

After the upgrade is finished, you can verify the Aurora-specific version number of the cluster by using the AWS CLI.

```
$ aws rds describe-db-clusters --db-cluster-id cluster-80-restored \    --query '[].EngineVersion' --output text

```

669
You can also verify the MySQL-specific version of the database engine by calling the `version` function.

```sql
mysql> select version();
+-----------+
| version() |
+-----------+
| 8.0.23    |
+-----------+
```

### Example of upgrading from Aurora MySQL version 1 to version 3

The following example shows the two-stage upgrade process if the original snapshot is from a version that can't be directly restored to Aurora MySQL version 3. Instead, that snapshot is restored to a cluster running an intermediate version that you can upgrade to Aurora MySQL version 3. This intermediate cluster doesn't need any associated DB instances. Then, another snapshot is created from the intermediate cluster. Finally, the second snapshot is restored to create a new Aurora MySQL version 3 cluster and a writer DB instance.

The Aurora MySQL version 1 cluster that we start with is named `aurora-mysql-v1-to-v2`. It's running Aurora MySQL version 1.23.4. It has at least one DB instance in the cluster.

This example checks which Aurora MySQL version 2 versions can be upgraded to the `8.0.mysql_aurora.3.02.0` version to use on the upgraded cluster. For this example, we choose version 2.10.0 as the intermediate version.

```bash
$ aws rds describe-db-engine-versions --engine aurora-mysql \
   --query '*[].{EngineVersion:EngineVersion,TargetVersions:ValidUpgradeTarget[*].EngineVersion} | \
   [?contains(TargetVersions, "8.0.mysql_aurora.3.02.0") == true][] |[].EngineVersion' \
   --output text
... 5.7.mysql_aurora.2.08.3
5.7.mysql_aurora.2.09.1
5.7.mysql_aurora.2.09.2
5.7.mysql_aurora.2.10.0
...  
```

The following example verifies that Aurora MySQL version 1.23.4 to 2.10.0 is an available upgrade path. Thus, the Aurora MySQL version that we're running can be upgraded to 2.10.0. Then that cluster can be upgraded to 3.02.0.

```bash
aws rds describe-db-engine-versions --engine aurora \
   --query '[]'.
{EngineVersion:EngineVersion,TargetVersions:ValidUpgradeTarget[*].EngineVersion} | \
   [?contains(TargetVersions, "5.7.mysql_aurora.2.10.0") == true][] ][[.EngineVersion]' \
   --output text
... 5.6.mysql_aurora.1.22.5
5.6.mysql_aurora.1.23.0
5.6.mysql_aurora.1.23.1
5.6.mysql_aurora.1.23.2
5.6.mysql_aurora.1.23.3
5.6.mysql_aurora.1.23.4
...  
```

The following example creates a snapshot named `aurora-mysql-v1-to-v2-snapshot` that's based on the original Aurora MySQL version 1 cluster.
The following example creates the intermediate Aurora MySQL version 2 cluster from the version 1 snapshot. This intermediate cluster is named aurora-mysql-v1-to-v2-to-v3. It’s running Aurora MySQL version 2.10.0.

The example also creates a writer instance for the cluster. For the upgrade process to work properly, this intermediate cluster requires a writer instance.

The following example creates a snapshot from the intermediate Aurora MySQL version 2 cluster. This snapshot is named aurora-mysql-v2-to-v3-snapshot. This is the snapshot to be restored to create the Aurora MySQL version 3 cluster.

The following command creates the Aurora MySQL version 3 cluster. This cluster is named aurora-mysql-v3-fully-upgraded.
Now that the Aurora MySQL version 3 cluster is created, the following example creates a writer DB instance for it. When the cluster and the writer instance become available, you can connect to the cluster and begin using it. All of the data from the original cluster is preserved through each of the snapshot stages.

```bash
$ aws rds create-db-instance
  --db-instance-identifier instance-also-running-v3
  --db-cluster-identifier aurora-mysql-v3-fully-upgraded
  --db-instance-class db.r5.xlarge --engine aurora-mysql
{
  "DBInstanceIdentifier": "instance-also-running-v3",
  "DBClusterIdentifier": "aurora-mysql-v3-fully-upgraded",
  "DBInstanceClass": "db.r5.xlarge",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "DBInstanceStatus": "creating"
}
```

Troubleshooting upgrade issues with Aurora MySQL version 3

If your upgrade to Aurora MySQL version 3 doesn't complete successfully, you can diagnose the cause of the problem. Then you can make any required changes to the original database schema or table data and run the upgrade process again.

If the upgrade process to Aurora MySQL version 3 fails, the problem is detected while creating and then upgrading the writer instance for the restored snapshot. Aurora leaves behind the original 5.7-compatible writer instance. That way, you can examine the log from the preliminary checks that Aurora runs before performing the upgrade. The following examples start with a 5.7-compatible database that requires some changes before it can be upgraded to Aurora MySQL version 3. The examples demonstrate how the first attempted upgrade doesn't succeed, how to examine the log file, and how to fix the problems and run a successful upgrade.

First, we create a new MySQL 5.7-compatible cluster named problematic-57-80-upgrade. As the name suggests, this cluster contains at least one schema object that causes a problem during an upgrade to a MySQL 8.0-compatible version.

```bash
$ aws rds create-db-cluster
  --engine aurora-mysql
  --engine-version 5.7.mysql_aurora.2.10.0
  --db-cluster-identifier problematic-57-80-upgrade
  --master-username my_username
  --master-user-password my_password
{
  "DBClusterIdentifier": "problematic-57-80-upgrade",
  "Status": "creating"
}
```

```bash
$ aws rds create-db-instance
  --db-instance-identifier instance-preupgrade
  --db-cluster-identifier problematic-57-80-upgrade
  --db-instance-class db.t2.small --engine aurora-mysql
{
  "DBInstanceIdentifier": "instance-preupgrade",
  "DBClusterIdentifier": "problematic-57-80-upgrade",
  "DBInstanceClass": "db.t2.small",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "DBInstanceStatus": "creating"
}
```

Troubleshooting upgrade issues with Aurora MySQL version 3

If your upgrade to Aurora MySQL version 3 doesn't complete successfully, you can diagnose the cause of the problem. Then you can make any required changes to the original database schema or table data and run the upgrade process again.

If the upgrade process to Aurora MySQL version 3 fails, the problem is detected while creating and then upgrading the writer instance for the restored snapshot. Aurora leaves behind the original 5.7-compatible writer instance. That way, you can examine the log from the preliminary checks that Aurora runs before performing the upgrade. The following examples start with a 5.7-compatible database that requires some changes before it can be upgraded to Aurora MySQL version 3. The examples demonstrate how the first attempted upgrade doesn't succeed, how to examine the log file, and how to fix the problems and run a successful upgrade.

First, we create a new MySQL 5.7-compatible cluster named problematic-57-80-upgrade. As the name suggests, this cluster contains at least one schema object that causes a problem during an upgrade to a MySQL 8.0-compatible version.

```bash
$ aws rds create-db-cluster
  --engine aurora-mysql
  --engine-version 5.7.mysql_aurora.2.10.0
  --db-cluster-identifier problematic-57-80-upgrade
  --master-username my_username
  --master-user-password my_password
{
  "DBClusterIdentifier": "problematic-57-80-upgrade",
  "Status": "creating"
}
```

```bash
$ aws rds create-db-instance
  --db-instance-identifier instance-preupgrade
  --db-cluster-identifier problematic-57-80-upgrade
  --db-instance-class db.t2.small --engine aurora-mysql
{
  "DBInstanceIdentifier": "instance-preupgrade",
  "DBClusterIdentifier": "problematic-57-80-upgrade",
  "DBInstanceClass": "db.t2.small",
  "EngineVersion": "8.0.mysql_aurora.3.02.0",
  "DBInstanceStatus": "creating"
}
```
In the cluster that we intend to upgrade, we introduce a problematic table. Creating a FULLTEXT index and then dropping the index leaves behind some metadata that causes a problem during the upgrade.

```
$ mysql -u my_username -p 
-h problematic-57-80-upgrade.cluster-example123.us-east-1.rds.amazonaws.com

mysql> create database problematic_upgrade;
Query OK, 1 row affected (0.02 sec)

mysql> use problematic_upgrade;
Database changed

mysql> CREATE TABLE dangling_fulltext_index
  -> (id INT AUTO_INCREMENT PRIMARY KEY, txtcol TEXT NOT NULL)
  -> ENGINE=InnoDB;
Query OK, 0 rows affected (0.05 sec)

mysql> ALTER TABLE dangling_fulltext_index ADD FULLTEXT(txtcol);
Query OK, 0 rows affected, 1 warning (0.14 sec)

mysql> ALTER TABLE dangling_fulltext_index DROP INDEX txtcol;
Query OK, 0 rows affected (0.06 sec)
```

This example attempts to perform the upgrade procedure. We take a snapshot of the original cluster and wait for snapshot creation to complete. Then we restore the snapshot, specifying the MySQL 8.0-compatible version number. We also create the writer instance for the cluster. That is the point where the upgrade processing actually happens. Then we wait for the writer instance to become available. That's the point where the upgrade process is finished, whether it succeeded or failed.

**Tip**

If you restore the snapshot using the AWS Management Console, Aurora creates the writer instance automatically and upgrades it to the requested engine version.
Now we examine the newly created cluster and associated instance to verify if the upgrade succeeded. The cluster and instance are still running a MySQL 5.7-compatible version. That means that the upgrade failed. When an upgrade fails, Aurora only leaves the writer instance behind so that you can examine any log files. You can't restart the upgrade process with that newly created cluster. After you correct the problem by making changes in your original cluster, you must run the upgrade steps again: make a new snapshot of the original cluster and restore it to another MySQL 8.0-compatible cluster.

To get a summary of what happened during the upgrade process, we get a listing of events for the newly created writer instance. In this example, we list the events over the last 600 minutes to cover the whole time interval of the upgrade process. The events in the listing aren't necessarily in chronological order. The highlighted event shows the problem that confirms the cluster couldn't be upgraded.
To diagnose the exact cause of the problem, examine the database logs for the newly created writer instance. When an upgrade to an 8.0-compatible version fails, the instance contains a log file with the file name `upgrade-prechecks.log`. This example shows how to detect the presence of that log and then download it to a local file for examination.

```bash
$ aws rds describe-db-log-files --db-instance-identifier instance-attempt-1 --query '*[].[LogFileName]' --output text
error/mysql-error-running.log
error/mysql-error-running.log.2021-12-03.20
error/mysql-error-running.log.2021-12-03.21
error/mysql-error.log
external/mysql-external.log
upgrade-prechecks.log
```

The `upgrade-prechecks.log` file is in JSON format. We download it using the `--output text` option to avoid encoding JSON output within another JSON wrapper. For Aurora MySQL version 3 upgrades, this log always includes certain informational and warning messages. It only includes error messages if the upgrade fails. If the upgrade succeeds, the log file isn't produced at all. The following excerpts show the kinds of entries you can expect to find.

```bash
$ aws rds download-db-log-file-portion --db-instance-identifier instance-attempt-1 --log-file-name upgrade-prechecks.log --starting-token 0 --output text >upgrade_prechecks.log
```

If "detectedProblems" is empty, the upgrade didn't encounter any occurrences of that type of problem. You can ignore those entries.

```json
{
    "detectedProblems": [],
    "id": "oldTemporalCheck",
    "title": "Usage of old temporal type",
    "status": "OK"
}
```
Checks for removed variables or changed default values aren't performed automatically. Aurora uses the parameter group mechanism instead of a physical configuration file. You always receive some messages with this CONFIGURATION_ERROR status, whether or not the variable changes have any effect on your database. You can consult the MySQL documentation for details about these changes.

This warning about obsolete date and time data types occurs if the SQL_MODE setting in your parameter group is left at the default value. Your database might or might not contain columns with the affected types.

When the detectedProblems field contains entries with a level value of Error, that means that the upgrade can't succeed until you correct those issues.
Tip
To summarize all of those errors and display the associated object and description fields, you can run the command `grep -A 2 "level": "Error"` on the contents of the `upgrade-prechecks.log` file. Doing so displays each error line and the two lines after it, which contain the name of the corresponding database object and guidance about how to correct the problem.

```
$ cat upgrade-prechecks.log | grep -A 2 "level": "Error"
"level": "Error",
"dbObject": "problematic_upgrade.dangling_fulltext_index",
"description": "Table `problematic_upgrade.dangling_fulltext_index` contains dangling FULLTEXT index. Kindly recreate the table before upgrade."
```

This `defaultAuthenticationPlugin` check always displays this warning message for Aurora MySQL version 3 upgrades. That's because Aurora MySQL version 3 uses the `mysql_native_password` plugin instead of `caching_sha2_password`. You don't need to take any action for this warning.

```
{
  "id": "defaultAuthenticationPlugin",
  "title": "New default authentication plugin considerations",
  "description": "Warning: The new default authentication plugin 'caching_sha2_password' offers more secure password hashing than previously used 'mysql_native_password' (and consequent improved client connection ..."
}
```

The end of the `upgrade-prechecks.log` file summarizes how many checks encountered each type of minor or severe problem. A nonzero `errorCount` indicates that the upgrade failed.

```
},
  "errorCount": 1,
  "warningCount": 2,
  "noticeCount": 0,
  "Summary": "1 errors were found. Please correct these issues before upgrading to avoid compatibility issues."
}
```

The next sequence of examples demonstrates how to fix this particular issue and run the upgrade process again. This time, the upgrade succeeds.

First, we go back to the original cluster. Then we run `OPTIMIZE TABLE tbl_name [, tbl_name] ...` on the tables causing the following error:

```
Table `tbl_name` contains dangling FULLTEXT index. Kindly recreate the table before upgrade.
```

```bash
$ mysql -u my_username -p \
  -h problematic-57-80-upgrade.cluster-example123.us-east-1.rds.amazonaws.com
mysql> show databases;
+---------------------+
| Database            |
+---------------------+
| information_schema  |
```
For more information, see Optimizing InnoDB Full-Text Indexes and OPTIMIZE TABLE Statement in the MySQL documentation.

As an alternative solution you could create a new table with the same structure and contents as the one with faulty metadata. In practice, you would probably rename this table back to the original table name after the upgrade.

```sql
mysql> CREATE TABLE recreated_table LIKE dangling_fulltext_index;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO recreated_table SELECT * FROM dangling_fulltext_index;
Query OK, 0 rows affected (0.00 sec)

mysql> drop table dangling_fulltext_index;
```
Now we go through the same process as before: creating a snapshot from the original cluster, restoring the snapshot to a new MySQL 8.0-compatible cluster, and creating a writer instance to complete the upgrade process.

```bash
$ aws rds create-db-cluster-snapshot --db-cluster-id problematic-57-80-upgrade \
   --db-cluster-snapshot-id problematic-57-80-upgrade-snapshot-2
{
 "DBClusterSnapshotIdentifier": "problematic-57-80-upgrade-snapshot-2",
 "DBClusterIdentifier": "problematic-57-80-upgrade",
 "Engine": "aurora-mysql",
 "EngineVersion": "5.7.mysql_aurora.2.10.0"
}

$ aws rds wait db-cluster-snapshot-available \
   --db-cluster-snapshot-id problematic-57-80-upgrade-snapshot-2

$ aws rds restore-db-cluster-from-snapshot \
   --snapshot-id problematic-57-80-upgrade-snapshot-2 \
   --db-cluster-id cluster-80-attempt-2 --engine aurora-mysql \
   --engine-version 8.0.mysql_aurora.3.02.0 \
   --enable-cloudwatch-logs-exports ['"error","general","slowquery","audit"]
{
 "DBClusterIdentifier": "cluster-80-attempt-2",
 "Engine": "aurora-mysql",
 "EngineVersion": "8.0.mysql_aurora.3.02.0",
 "Status": "creating"
}

$ aws rds create-db-instance --db-instance-identifier instance-attempt-2 \
   --db-cluster-identifier cluster-80-attempt-2 \
   --db-instance-class db.r5.xlarge --engine aurora-mysql
{
 "DBInstanceIdentifier": "instance-attempt-2",
 "DBClusterIdentifier": "cluster-80-attempt-2",
 "DBInstanceClass": "db.r5.xlarge",
 "EngineVersion": "8.0.mysql_aurora.3.02.0",
 "DBInstanceStatus": "creating"
}

$ aws rds wait db-instance-available \
   --db-instance-identifier instance-attempt-2

This time, checking the version after the upgrade completes confirms that the version number changed to reflect Aurora MySQL version 3. We can connect to the database and confirm the MySQL engine version is an 8.0-compatible one. We confirm that the upgraded cluster contains the fixed version of the table that caused the original upgrade problem.

```bash
$ aws rds describe-db-clusters \
   --db-cluster-identifier cluster-80-attempt-2 \
   --query "[*][EngineVersion]" --output text
8.0.mysql_aurora.3.02.0
$ aws rds describe-db-instances \
   --db-instance-identifier instance-attempt-2 \
   --query "[*][EngineVersion]" --output text
8.0.mysql_aurora.3.02.0
$ mysql -h cluster-80-attempt-2.cluster-example123.us-east-1.rds.amazonaws.com \
   -u my_username -p
mysql>
select version();
+-----------+
| version() |
+-----------+
| 8.0        |
+-----------+
```
Post-upgrade cleanup for Aurora MySQL version 3

After you finish upgrading any Aurora MySQL version 1 or 2 clusters to Aurora MySQL version 3, you can perform these other cleanup actions:

- Create new MySQL 8.0–compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups.
- Update any CloudWatch alarms, setup scripts, and so on to use the new names for any metrics whose names were affected by inclusive language changes. For a list of such metrics, see Inclusive language changes for Aurora MySQL version 3 (p. 660).
- Update any AWS CloudFormation templates to use the new names for any configuration parameters whose names were affected by inclusive language changes. For a list of such parameters, see Inclusive language changes for Aurora MySQL version 3 (p. 660).

Spatial indexes

After upgrading to Aurora MySQL version 3, check if you need to drop or recreate objects and indexes related to spatial indexes. Before MySQL 8.0, Aurora could optimize spatial queries using indexes that didn't contain a spatial resource identifier (SRID). Aurora MySQL version 3 only uses spatial indexes containing SRIDs. During an upgrade, Aurora automatically drops any spatial indexes without SRIDs and prints warning messages in the database log. If you observe such warning messages, create new spatial indexes with SRIDs after the upgrade. For more information about changes to spatial functions and data types in MySQL 8.0, see Changes in MySQL 8.0 in the MySQL Reference Manual.

Aurora MySQL version 2 compatible with MySQL 5.7

The following features are supported in MySQL 5.7.12 but are currently not supported in Aurora MySQL version 2:

- CREATE TABLESPACE SQL statement
- Group replication plugin
Security with Amazon Aurora MySQL

Security for Amazon Aurora MySQL is managed at three levels:

- To control who can perform Amazon RDS management actions on Aurora MySQL DB clusters and DB instances, you use AWS Identity and Access Management (IAM). When you connect to AWS using IAM credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management for Amazon Aurora (p. 1653).

  If you are using IAM to access the Amazon RDS console, make sure to first sign in to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at https://console.aws.amazon.com/rds/.

- Make sure to create Aurora MySQL DB clusters in a virtual public cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora MySQL DB clusters in a VPC, use a VPC security group. You can make these endpoint and port connections by using Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see Amazon VPC VPCs and Amazon Aurora (p. 1728).
The supported VPC tenancy depends on the DB instance class used by your Aurora MySQL DB clusters. With default VPC tenancy, the VPC runs on shared hardware. With dedicated VPC tenancy, the VPC runs on a dedicated hardware instance. The burstable performance DB instance classes support default VPC tenancy only. The burstable performance DB instance classes include the db.t2, db.t3, and db.t4g DB instance classes. All other Aurora MySQL DB instance classes support both default and dedicated VPC tenancy.

For more information about instance classes, see Aurora DB instance classes (p. 56). For more information about default and dedicated VPC tenancy, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

- To authenticate login and permissions for an Amazon Aurora MySQL DB cluster, you can take either of the following approaches, or a combination of them:
  - You can take the same approach as with a standalone instance of MySQL.
    
    Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in on-premises databases, as does directly modifying database schema tables. For more information, see Access control and account management in the MySQL documentation.
  - You can also use IAM database authentication.
    
    With IAM database authentication, you authenticate to your DB cluster by using an IAM user or IAM role and an authentication token. An authentication token is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see IAM database authentication (p. 1682).

Note
For more information, see Security in Amazon Aurora (p. 1634).

Master user privileges with Amazon Aurora MySQL

When you create an Amazon Aurora MySQL DB instance, the master user has the following default privileges:

- ALTER
- ALTER ROUTINE
- CREATE
- CREATE ROUTINE
- CREATE TEMPORARY TABLES
- CREATE USER
- CREATE VIEW
- DELETE
- DROP
- EVENT
- EXECUTE
- GRANT OPTION
- INDEX
- INSERT
- LOAD FROM S3
- LOCK TABLES
- PROCESS
To provide management services for each DB cluster, the rdsadmin user is created when the DB cluster is created. Attempting to drop, rename, change the password, or change privileges for the rdsadmin account results in an error.

For management of the Aurora MySQL DB cluster, the standard kill and kill_query commands have been restricted. Instead, use the Amazon RDS commands rds_kill and rds_kill_query to terminate user sessions or queries on Aurora MySQL DB instances.

Note
Encryption of a database instance and snapshots is not supported for the China (Ningxia) region.

Using SSL/TLS with Aurora MySQL DB clusters

Amazon Aurora MySQL DB clusters support Secure Sockets Layer (SSL) and Transport Layer Security (TLS) connections from applications using the same process and public key as RDS for MySQL DB instances.

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks. As a result, you can only use the DB cluster endpoint to connect to a DB cluster using SSL/TLS if your client supports Subject Alternative Names (SAN). Otherwise, you must use the instance endpoint of a writer instance.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1642).

We recommend the AWS JDBC Driver for MySQL as a client that supports SAN with SSL/TLS. For more information about the AWS JDBC Driver for MySQL and complete instructions for using it, see the AWS JDBC Driver for MySQL GitHub repository.

Topics

- Requiring an SSL/TLS connection to an Aurora MySQL DB cluster (p. 683)
- TLS versions for Aurora MySQL (p. 684)
- Encrypting connections to an Aurora MySQL DB cluster (p. 685)
- Configuring cipher suites for connections to Aurora MySQL DB clusters (p. 685)

Requiring an SSL/TLS connection to an Aurora MySQL DB cluster

You can require that all user connections to your Aurora MySQL DB cluster use SSL/TLS by using the require_secure_transport DB cluster parameter. By default, the require_secure_transport
parameter is set to OFF. You can set the require_secure_transport parameter to ON to require SSL/TLS for connections to your DB cluster.

You can set the require_secure_transport parameter value by updating the DB cluster parameter group for your DB cluster. You don't need to reboot your DB cluster for the change to take effect. For more information on parameter groups, see Working with parameter groups (p. 215).

**Note**
The require_secure_transport parameter is only available for Aurora MySQL version 5.7. You can set this parameter in a custom DB cluster parameter group. The parameter isn’t available in DB instance parameter groups.

When the require_secure_transport parameter is set to ON for a DB cluster, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --require_secure_transport=ON.
```

**TLS versions for Aurora MySQL**

Aurora MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, and 1.2. The following table shows the TLS support for Aurora MySQL versions.

<table>
<thead>
<tr>
<th>Aurora MySQL version</th>
<th>TLS 1.0</th>
<th>TLS 1.1</th>
<th>TLS 1.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL version 3</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Aurora MySQL version 2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Aurora MySQL version 1</td>
<td>Supported</td>
<td>Supported for Aurora MySQL 1.23.1 and higher</td>
<td>Supported for Aurora MySQL 1.23.1 and higher</td>
</tr>
</tbody>
</table>

Although the community edition of MySQL 8.0 supports TLS 1.3, the MySQL 8.0-compatible Aurora MySQL version 3 currently doesn't support TLS 1.3.

For an Aurora MySQL 5.7 DB cluster, you can use the tls_version DB cluster parameter to indicate the permitted protocol versions. Similar client parameters exist for most client tools or database drivers. Some older clients might not support newer TLS versions. By default, the DB cluster attempts to use the highest TLS protocol version allowed by both the server and client configuration.

Set the tls_version DB cluster parameter to one of the following values:

- **TLSv1.2** – Only the TLS version 1.2 protocol is permitted for encrypted connections.
- **TLSv1.1** – TLS version 1.1 and 1.2 protocols are permitted for encrypted connections.
- **TLSv1** – TLS version 1.0, 1.1, and 1.2 protocols are permitted for encrypted connections.

If the parameter isn't set, then TLS version 1.0, 1.1, and 1.2 protocols are permitted for encrypted connections.

For information about modifying parameters in a DB cluster parameter group, see Modifying parameters in a DB cluster parameter group (p. 221). If you use the AWS CLI to modify the tls_version DB cluster parameter, the ApplyMethod must be set to pending-reboot. When the application method
is pending-reboot, changes to parameters are applied after you stop and restart the DB clusters associated with the parameter group.

**Note**

The `tls_version` DB cluster parameter isn't available for Aurora MySQL 5.6.

### Encrypting connections to an Aurora MySQL DB cluster

To encrypt connections using the default `mysql` client, launch the `mysql` client using the `--ssl-ca` parameter to reference the public key, for example:

For MySQL 5.7 and 8.0:

```bash
mysql -h myinstance.123456789012.rds-us-east-1.amazonaws.com
--ssl-ca=full_path_to_CA_certificate --ssl-mode=VERIFY_IDENTITY
```

For MySQL 5.6:

```bash
mysql -h myinstance.123456789012.rds-us-east-1.amazonaws.com
--ssl-ca=full_path_to_CA_certificate --ssl-verify-server-cert
```

Replace `full_path_to_CA_certificate` with the full path to your Certificate Authority (CA) certificate. For information about downloading a certificate, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1642).

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MySQL version, to require SSL/TLS connections on the user account `encrypted_user`.

For MySQL 5.7 and 8.0:

```sql
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For MySQL 5.6:

```sql
GRANT USAGE ON *.* TO 'encrypted_user'@'%' REQUIRE SSL;
```

When you use an RDS proxy, you connect to the proxy endpoint instead of the usual cluster endpoint. You can make SSL/TLS required or optional for connections to the proxy, in the same way as for connections directly to the Aurora DB cluster. For information about using the RDS Proxy, see Using Amazon RDS Proxy (p. 1429).

**Note**

For more information on SSL/TLS connections with MySQL, see the MySQL documentation.

### Configuring cipher suites for connections to Aurora MySQL DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client SSL/TLS connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of insecure or deprecated ciphers.
Configurable cipher suites is supported in Aurora MySQL version 3 and Aurora MySQL version 2.

To specify the list of permissible ciphers for encrypting connections, modify the `ssl_cipher` cluster parameter. Set the `ssl_cipher` parameter in a cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

For information about modifying parameters in a DB cluster parameter group, see [Modifying parameters in a DB cluster parameter group](p. 221). If you use the CLI to modify the `ssl_cipher` DB cluster parameter, make sure to set the `ApplyMethod` to `pending-reboot`. When the application method is `pending-reboot`, changes to parameters are applied after you stop and restart the DB clusters associated with the parameter group.

For the client application, you can specify the ciphers to use for encrypted connections by using the `--ssl-cipher` option when connecting to the database. For more about connecting to your database, see [Connecting to an Amazon Aurora MySQL DB cluster](p. 207).

Set the `ssl_cipher` parameter to a string of comma-separated cipher values. The following table shows the supported ciphers along with the TLS encryption protocol and valid Aurora MySQL engine versions for each cipher.

<table>
<thead>
<tr>
<th>Cipher</th>
<th>Encryption protocol</th>
<th>Supported Aurora MySQL versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHE-RSA-AES128-SHA</td>
<td>TLS 1.0</td>
<td>3.01.0 and higher, 2.10.2, 2.10.1, 2.09.3, 2.08.4, 2.07.7, 2.04.9</td>
</tr>
<tr>
<td>DHE-RSA-AES128-SHA256</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, 2.10.2, 2.10.1, 2.09.3, 2.08.4, 2.07.7, 2.04.9</td>
</tr>
<tr>
<td>DHE-RSA-AES128-GCM-SHA256</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, 2.10.2, 2.10.1, 2.09.3, 2.08.4, 2.07.7, 2.04.9</td>
</tr>
<tr>
<td>DHE-RSA-AES256-SHA</td>
<td>TLS 1.0</td>
<td>3.01.0 and higher, 2.10.2, 2.10.1, 2.09.3, 2.08.4, 2.07.7, 2.04.9</td>
</tr>
<tr>
<td>DHE-RSA-AES256-SHA256</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, 2.10.2, 2.10.1, 2.09.3, 2.08.4, 2.07.7, 2.04.9</td>
</tr>
<tr>
<td>DHE-RSA-AES256-GCM-SHA384</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, 2.10.2, 2.10.1, 2.09.3, 2.08.4, 2.07.7, 2.04.9</td>
</tr>
<tr>
<td>ECDHE-RSA-AES128-SHA</td>

<tr>
<td>ECDHE-RSA-AES256-GCM-SHA384</td>
<td>TLS 1.2</td>
<td>3.01.0 and higher, 2.10.2, 2.10.1, 2.09.3</td>
</tr>
</tbody>
</table>

You can also use the `describe-engine-default-cluster-parameters` CLI command to determine which cipher suites are currently supported for a specific parameter group family. The following example shows how to get the allowed values for the `ssl_cipher` cluster parameter for Aurora MySQL 5.7.

```
aws rds describe-engine-default-cluster-parameters --db-parameter-group-family aurora-mysql5.7
```
For more information about ciphers, see the `ssl_cipher` variable in the MySQL documentation. For more information about cipher suite formats, see the openssl-ciphers list format and openssl-ciphers string format documentation on the OpenSSL website.

### Updating applications to connect to Aurora MySQL DB clusters using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your Aurora DB clusters using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB clusters. If they do, you can further check whether those applications require certificate verification to connect.

**Note**

Some applications are configured to connect to Aurora MySQL DB clusters only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB clusters. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 1644). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1642). For information about using SSL/TLS with Aurora MySQL DB clusters, see Using SSL/TLS with Aurora MySQL DB clusters (p. 683).

**Topics**

- Determining whether any applications are connecting to your Aurora MySQL DB cluster using SSL (p. 688)
Determining whether any applications are connecting to your Aurora MySQL DB cluster using SSL

If you are using Aurora MySQL version 2 (compatible with MySQL 5.7) and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see Performance Schema quick start in the MySQL documentation.

```
mysql> SELECT id, user, host, connection_type
    FROM performance_schema.threads pst
    INNER JOIN information_schema.processlist isp
    ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (admin) and an application logged in as webapp1 are using SSL.

<table>
<thead>
<tr>
<th>id</th>
<th>user</th>
<th>host</th>
<th>connection_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>admin</td>
<td>10.0.4.249:42590</td>
<td>SSL/TLS</td>
</tr>
<tr>
<td>4</td>
<td>event_scheduler</td>
<td>localhost</td>
<td>NULL</td>
</tr>
<tr>
<td>10</td>
<td>webapp1</td>
<td>159.28.1.1:42189</td>
<td>SSL/TLS</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

If you are using Aurora MySQL version 1 (compatible with MySQL 5.6), then you can't determine from the server side whether applications are connecting with or without SSL. For those versions, you can determine whether SSL is used by examining the application's connection method. You can find more information on examining the client connection configuration in the following section.

Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

**JDBC**

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```java
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
```
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);

**Note**

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

**MySQL**

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-verify-server-cert
```

**Updating your application trust store**

For information about updating the trust store for MySQL applications, see Installing SSL certificates in the MySQL documentation.

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

**Updating your application trust store for JDBC**

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1642).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 1651).

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```
When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```java
public class MySQLSSLTest {
    private static final String DB_USER = "user name";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void test(String[] args) throws Exception {
        Class.forName("com.mysql.jdbc.Driver");
        System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

        Properties properties = new Properties();
        properties.setProperty("sslMode", "VERIFY_IDENTITY");
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);

        Connection connection = DriverManager.getConnection("jdbc:mysql://jagdeeps-ssl-test.cni62e2e7kwh.us-east-1.rds.amazonaws.com:3306",properties);
        Statement stmt=connection.createStatement();
        ResultSet rs=stmt.executeQuery("SELECT 1 from dual");
        return;
    }
}
```

**Important**

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 1644).

Migrating data to an Amazon Aurora MySQL DB cluster

You have several options for migrating data from your existing database to an Amazon Aurora MySQL DB cluster. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating.

There are two different types of migration: physical and logical. Physical migration means that physical copies of database files are used to migrate the database. Logical migration means that the migration is accomplished by applying logical database changes, such as inserts, updates, and deletes.
Physical migration has the following advantages:

- Physical migration is faster than logical migration, especially for large databases.
- Database performance does not suffer when a backup is taken for physical migration.
- Physical migration can migrate everything in the source database, including complex database components.

Physical migration has the following limitations:

- The `innodb_page_size` parameter must be set to its default value (16KB).
- The `innodb_data_file_path` parameter must be configured with only one data file that uses the default data file name "ibdata1:12M:autoextend". Databases with two data files, or with a data file with a different name, can't be migrated using this method.

  The following are examples of file names that are not allowed:
  "innodb_data_file_path=ibdata1:50M; ibdata2:50M:autoextend" and "innodb_data_file_path=ibdata01:50M:autoextend".
- The `innodb_log_files_in_group` parameter must be set to its default value (2).

Logical migration has the following advantages:

- You can migrate subsets of the database, such as specific tables or parts of a table.
- The data can be migrated regardless of the physical storage structure.

Logical migration has the following limitations:

- Logical migration is usually slower than physical migration.
- Complex database components can slow down the logical migration process. In some cases, complex database components can even block logical migration.

The following table describes your options and the type of migration for each option.

<table>
<thead>
<tr>
<th>Migrating from</th>
<th>Migration type</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>An RDS for MySQL DB instance</td>
<td>Physical</td>
<td>You can migrate from an RDS for MySQL DB instance by first creating an Aurora MySQL read replica of a MySQL DB instance. When the replica lag between the MySQL DB instance and the Aurora MySQL read replica is 0, you can direct your client applications to read from the Aurora read replica and then stop replication to make the Aurora MySQL read replica a standalone Aurora MySQL DB cluster for reading and writing. For details, see Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica (p. 712).</td>
</tr>
<tr>
<td>An RDS for MySQL DB snapshot</td>
<td>Physical</td>
<td>You can migrate data directly from an RDS for MySQL DB snapshot to an Amazon Aurora MySQL DB cluster. For details, see Migrating data from a MySQL DB instance...</td>
</tr>
</tbody>
</table>
### Migrating from MySQL to Amazon Aurora MySQL

<table>
<thead>
<tr>
<th>Migrating from</th>
<th>Migration type</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>A MySQL database external to Amazon RDS</td>
<td>Logical</td>
<td>You can create a dump of your data using the <code>mysqldump</code> utility, and then import that data into an existing Amazon Aurora MySQL DB cluster. For details, see Migrating from MySQL to Amazon Aurora by using <code>mysqldump</code> (p. 705).</td>
</tr>
<tr>
<td>A MySQL database external to Amazon RDS</td>
<td>Physical</td>
<td>You can copy the backup files from your database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora MySQL DB cluster from those files. This option can be considerably faster than migrating data using <code>mysqldump</code>. For details, see Migrating data from MySQL by using an Amazon S3 bucket (p. 693).</td>
</tr>
<tr>
<td>A MySQL database external to Amazon RDS</td>
<td>Logical</td>
<td>You can save data from your database as text files and copy those files to an Amazon S3 bucket. You can then load that data into an existing Aurora MySQL DB cluster using the <code>LOAD DATA FROM S3</code> MySQL command. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 904).</td>
</tr>
<tr>
<td>A database that is not MySQL-compatible</td>
<td>Logical</td>
<td>You can use AWS Database Migration Service (AWS DMS) to migrate data from a database that is not MySQL-compatible. For more information on AWS DMS, see What is AWS database migration service?</td>
</tr>
</tbody>
</table>

### Note

- If you are migrating a MySQL database external to Amazon RDS, the migration options described in the table are supported only if your database supports the InnoDB or MyISAM tablespaces.
- If the MySQL database you are migrating to Aurora MySQL uses `memcached`, remove `memcached` before migrating it.

### Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster

If your database supports the InnoDB or MyISAM tablespaces, you have these options for migrating your data to an Amazon Aurora MySQL DB cluster:

- You can create a dump of your data using the `mysqldump` utility, and then import that data into an existing Amazon Aurora MySQL DB cluster. For more information, see Migrating from MySQL to Amazon Aurora by using `mysqldump` (p. 705).
• You can copy the full and incremental backup files from your database to an Amazon S3 bucket, and then restore an Amazon Aurora MySQL DB cluster from those files. This option can be considerably faster than migrating data using mysqldump. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 693).

Migrating data from MySQL by using an Amazon S3 bucket

You can copy the full and incremental backup files from your source MySQL version 5.5, 5.6, or 5.7 database to an Amazon S3 bucket, and then restore an Amazon Aurora MySQL DB cluster from those files.

This option can be considerably faster than migrating data using mysqldump, because using mysqldump replays all of the commands to recreate the schema and data from your source database in your new Aurora MySQL DB cluster. By copying your source MySQL data files, Aurora MySQL can immediately use those files as the data for an Aurora MySQL DB cluster.

Note
The Amazon S3 bucket and the Amazon Aurora MySQL DB cluster must be in the same AWS Region.

Aurora MySQL doesn't restore everything from your database. You should save the database schema and values for the following items from your source MySQL database and add them to your restored Aurora MySQL DB cluster after it has been created:

• User accounts
• Functions
• Stored procedures
• Time zone information. Time zone information is loaded from the local operating system of your Amazon Aurora MySQL DB cluster. For more information, see Local time zone for Amazon Aurora DB clusters (p. 16).

You can't migrate data from a DB snapshot export to Amazon S3. You use Percona XtraBackup to back up your data to S3. For more information, see Installing Percona XtraBackup (p. 694).

You can't restore from an encrypted source database, but you can encrypt the data being migrated. You can also leave the data unencrypted during the migration process.

You can't restore to an Aurora Serverless DB cluster.

You can't migrate from a source database that has tables defined outside of the default MySQL data directory.

Also, decide whether you want to minimize downtime by using binary log replication during the migration process. If you use binary log replication, the external MySQL database remains open to transactions while the data is being migrated to the Aurora MySQL DB cluster. After the Aurora MySQL DB cluster has been created, you use binary log replication to synchronize the Aurora MySQL DB cluster with the transactions that happened after the backup. When the Aurora MySQL DB cluster is caught up with the MySQL database, you finish the migration by completely switching to the Aurora MySQL DB cluster for new transactions.

Topics
• Before you begin (p. 694)
• Backing up files to be restored as an Amazon Aurora MySQL DB cluster (p. 695)
• Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket (p. 697)
• Synchronizing the Amazon Aurora MySQL DB cluster with the MySQL database using replication (p. 700)

Before you begin

Before you can copy your data to an Amazon S3 bucket and restore a DB cluster from those files, you must do the following:

• Install Percona XtraBackup on your local server.
• Permit Aurora MySQL to access your Amazon S3 bucket on your behalf.

Installing Percona XtraBackup

Amazon Aurora can restore a DB cluster from files that were created using Percona XtraBackup. You can install Percona XtraBackup from Download Percona XtraBackup.

**Note**

For MySQL 5.7 migration, you must use Percona XtraBackup 2.4. For earlier MySQL versions, use Percona XtraBackup 2.3 or 2.4.

Required permissions

To migrate your MySQL data to an Amazon Aurora MySQL DB cluster, several permissions are required:

• The user that is requesting that Aurora create a new cluster from an Amazon S3 bucket must have permission to list the buckets for your AWS account. You grant the user this permission using an AWS Identity and Access Management (IAM) policy.
• Aurora requires permission to act on your behalf to access the Amazon S3 bucket where you store the files used to create your Amazon Aurora MySQL DB cluster. You grant Aurora the required permissions using an IAM service role.
• The user making the request must also have permission to list the IAM roles for your AWS account.
• If the user making the request is to create the IAM service role or request that Aurora create the IAM service role (by using the console), then the user must have permission to create an IAM role for your AWS account.
• If you plan to encrypt the data during the migration process, update the IAM policy of the user who will perform the migration to grant RDS access to the AWS KMS keys used for encrypting the backups. For instructions, see Creating an IAM policy to access AWS KMS resources (p. 897).

For example, the following IAM policy grants a user the minimum required permissions to use the console to list IAM roles, create an IAM role, list the Amazon S3 buckets for your account, and list the KMS keys.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:ListRoles",
        "iam:CreateRole",
        "iam:CreatePolicy",
        "iam:AttachRolePolicy",
        "s3:ListBucket",
        "kms:ListKeys"
      ],
      "Resource": "*"
    }
  ]
}
```
Additionally, for a user to associate an IAM role with an Amazon S3 bucket, the IAM user must have the `iam:PassRole` permission for that IAM role. This permission allows an administrator to restrict which IAM roles a user can associate with Amazon S3 buckets.

For example, the following IAM policy allows a user to associate the role named `S3Access` with an Amazon S3 bucket.

```json
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"AllowS3AccessRole",
            "Effect":"Allow",
            "Action":"iam:PassRole",
            "Resource":"arn:aws:iam::123456789012:role/S3Access"
        }
    ]
}
```

For more information on IAM user permissions, see Managing access using policies (p. 1655).

Creating the IAM service role

You can have the AWS Management Console create a role for you by choosing the Create a New Role option (shown later in this topic). If you select this option and specify a name for the new role, then Aurora creates the IAM service role required for Aurora to access your Amazon S3 bucket with the name that you supply.

As an alternative, you can manually create the role using the following procedure.

**To create an IAM role for Aurora to access Amazon S3**

1. Complete the steps in Creating an IAM policy to access Amazon S3 resources (p. 893).
2. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898).
3. Complete the steps in Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 899).

Backing up files to be restored as an Amazon Aurora MySQL DB cluster

You can create a full backup of your MySQL database files using Percona XtraBackup and upload the backup files to an Amazon S3 bucket. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files to an Amazon S3 bucket.

**Creating a full backup with Percona XtraBackup**

To create a full backup of your MySQL database files that can be restored from Amazon S3 to create an Amazon Aurora MySQL DB cluster, use the Percona XtraBackup utility (`xtrabackup`) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the `/on-premises/s3-restore/backup` folder.

```bash
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=/on-premises/s3-restore/backup
```
If you want to compress your backup into a single file (which can be split, if needed), you can use the --stream option to save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xbstream (.xbstream)

The following command creates a backup of your MySQL database split into multiple Gzip files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \
   --target-dir=/on-premises/s3-restore/backup | gzip - | split -d --bytes=500MB \
   - /on-premises/s3-restore/backup/backup*.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \
   --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB \
   - /on-premises/s3-restore/backup/backup*.tar
```

The following command creates a backup of your MySQL database split into multiple xbstream files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=xbstream \
   --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB \
   - /on-premises/s3-restore/backup/backup*.xbstream
```

Once you have backed up your MySQL database using the Percona XtraBackup utility, you can copy your backup directories and files to an Amazon S3 bucket.

For information on creating and uploading a file to an Amazon S3 bucket, see Getting started with Amazon Simple Storage Service in the Amazon S3 Getting Started Guide.

Using incremental backups with Percona XtraBackup

Amazon Aurora MySQL supports both full and incremental backups created using Percona XtraBackup. If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files for your full and incremental backups to an Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see Incremental backup.

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Aurora iterates through all files and directories. Aurora uses the xtrabackup-checkpoints file included with each incremental backup to identify the base directory and to order incremental backups by log sequence number (LSN) range.

For information on creating and uploading a file to an Amazon S3 bucket, see Getting started with Amazon Simple Storage Service in the Amazon S3 Getting Started Guide.

Backup considerations

Aurora doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: --tables, --tables-exclude, --table-file, --databases, --databases-exclude, or --databases-file.
For more information about backing up your database with Percona XtraBackup, see Percona XtraBackup documentation and The xtrabackup binary on the Percona website.

Aurora supports incremental backups created using Percona XtraBackup. For more information about creating incremental backups using Percona XtraBackup, see Incremental backup.

Aurora consumes your backup files based on the file name. Be sure to name your backup files with the appropriate file extension based on the file format—for example, .xbstream for files stored using the Percona xbstream format.

Aurora consumes your backup files in alphabetical order and also in natural number order. Always use the split option when you issue the xtrabackup command to ensure that your backup files are written and named in the proper order.

Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If the backup data for your database exceeds 5 TB, use the split command to split the backup files into multiple files that are each less than 5 TB.

Aurora limits the number of source files uploaded to an Amazon S3 bucket to 1 million files. In some cases, backup data for your database, including all full and incremental backups, can come to a large number of files. In these cases, use a tarball (.tar.gz) file to store full and incremental backup files in the Amazon S3 bucket.

When you upload a file to an Amazon S3 bucket, you can use server-side encryption to encrypt the data. You can then restore an Amazon Aurora MySQL DB cluster from those encrypted files. Amazon Aurora MySQL can restore a DB cluster with files encrypted using the following types of server-side encryption:

- Server-side encryption with Amazon S3–managed keys (SSE-S3) – Each object is encrypted with a unique key employing strong multifactor encryption.
- Server-side encryption with AWS KMS–managed keys (SSE-KMS) – Similar to SSE-S3, but you have the option to create and manage encryption keys yourself, and also other differences.

For information about using server-side encryption when uploading files to an Amazon S3 bucket, see Protecting data using server-side encryption in the Amazon S3 Developer Guide.

**Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket**

You can restore your backup files from your Amazon S3 bucket to create a new Amazon Aurora MySQL DB cluster by using the Amazon RDS console.

**To restore an Amazon Aurora MySQL DB cluster from files on an Amazon S3 bucket**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB cluster. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose Databases, and then choose Restore from S3.
4. Choose Restore from S3.

The Create database by restoring from S3 page appears.
Create database by restoring from S3

S3 destination
Write audit logs to S3
Enter a destination in Amazon S3 where your audit logs will be stored. Amazon S3 is object storage built to store and retrieve any amount of data from anywhere.

S3 bucket
- test-eu1-bucket

S3 prefix (optional)

Engine options

Engine type
- Amazon Aurora
- MySQL

Edition
- Amazon Aurora with MySQL compatibility

Version
- Aurora (MySQL 5.7) 2.07.2

IAM role

IAM role
Choose or create an IAM role to grant write access to your S3 bucket.
- Choose an option

Settings

DB cluster identifier
Type a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.
- database-1

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

▲ Credentials Settings

Master username
Type a login ID for the master user of your DB instance.
- admin
5. Under **S3 destination**:
   a. Choose the **S3 bucket** that contains the backup files.
   b. (Optional) For **S3 folder path prefix**, enter a file path prefix for the files stored in your Amazon S3 bucket.

   If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

   For example, suppose that you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, you specify a prefix of backups/gzip_backup1 to restore from the files in the gzip_backup1 folder.

6. Under **Engine options**:
   a. For **Engine type**, choose **Amazon Aurora**.
   b. For **Version**, choose the Aurora MySQL engine version for your restored DB instance.

7. For **IAM role**, you can choose an existing IAM role.

8. (Optional) You can also have a new IAM role created for you by choosing **Create a new role**. If so:
   a. Enter the **IAM role name**.
   b. Choose whether to **Allow access to KMS key**:
      - If you didn't encrypt the backup files, choose **No**.
      - If you encrypted the backup files with AES-256 (SSE-S3) when you uploaded them to Amazon S3, choose **No**. In this case, the data is decrypted automatically.
      - If you encrypted the backup files with AWS KMS (SSE-KMS) server-side encryption when you uploaded them to Amazon S3, choose **Yes**. Next, choose the correct KMS key for **AWS KMS key**.

      The AWS Management Console creates an IAM policy that enables Aurora to decrypt the data.

      For more information, see [Protecting data using server-side encryption](https://docs.aws.amazon.com/AmazonS3/latest/userguide/) in the Amazon S3 Developer Guide.

9. Choose settings for your DB cluster, such as the DB cluster identifier and the login credentials. For information about each setting, see [Settings for Aurora DB clusters](p. 137).

10. Customize additional settings for your Aurora MySQL DB cluster as needed.

11. Choose **Create database** to launch your Aurora DB instance.

On the Amazon RDS console, the new DB instance appears in the list of DB instances. The DB instance has a status of **creating** until the DB instance is created and ready for use. When the state changes to **available**, you can connect to the primary instance for your DB cluster. Depending on the DB instance class and store allocated, it can take several minutes for the new instance to be available.

To view the newly created cluster, choose the **Databases** view in the Amazon RDS console and choose the DB cluster. For more information, see [Viewing an Amazon Aurora DB cluster](p. 433).
Note the port and the writer endpoint of the DB cluster. Use the writer endpoint and port of the DB cluster in your JDBC and ODBC connection strings for any application that performs write or read operations.

**Synchronizing the Amazon Aurora MySQL DB cluster with the MySQL database using replication**

To achieve little or no downtime during the migration, you can replicate transactions that were committed on your MySQL database to your Aurora MySQL DB cluster. Replication enables the DB cluster to catch up with the transactions on the MySQL database that happened during the migration. When the DB cluster is completely caught up, you can stop the replication and finish the migration to Aurora MySQL.
Topics

- Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication (p. 701)
- Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database (p. 702)

Configuring your external MySQL database and your Aurora MySQL DB cluster for encrypted replication

To replicate data securely, you can use encrypted replication.

**Note**

If you don't need to use encrypted replication, you can skip these steps and move on to the instructions in Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database (p. 702).

The following are prerequisites for using encrypted replication:

- Secure Sockets Layer (SSL) must be enabled on the external MySQL primary database.
- A client key and client certificate must be prepared for the Aurora MySQL DB cluster.

During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

**To configure your external MySQL database and your Aurora MySQL DB cluster for encrypted replication**

1. Ensure that you are prepared for encrypted replication:
   - If you don't have SSL enabled on the external MySQL primary database and don't have a client key and client certificate prepared, enable SSL on the MySQL database server and generate the required client key and client certificate.
   - If SSL is enabled on the external primary, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key that you used to configure SSL on the external MySQL primary database.

   For more information, see [Creating SSL certificates and keys using openssl](https://dev.mysql.com/doc/refman/8.0/en/ssl.html) in the MySQL documentation.

   You need the certificate authority certificate, the client key, and the client certificate.

2. Connect to the Aurora MySQL DB cluster as the primary user using SSL.

   For information about connecting to an Aurora MySQL DB cluster with SSL, see Using SSL/TLS with Aurora MySQL DB clusters (p. 683).

3. Run the `mysql.rds_import_binlog_ssl_material` stored procedure to import the SSL information into the Aurora MySQL DB cluster.

   For the `ssl_material_value` parameter, insert the information from the .pem format files for the Aurora MySQL DB cluster in the correct JSON payload.

   The following example imports SSL information into an Aurora MySQL DB cluster. In .pem format files, the body code typically is longer than the body code shown in the example.

   ```sql
   call mysql.rds_import_binlog_ssl_material(
   '{"ssl_ca":"-----BEGIN CERTIFICATE-----
   ...'
   ```
For more information, see mysql_rds_import_binlog_ssl_material Using SSL/TLS with Aurora MySQL DB clusters (p. 683).

Note
After running the procedure, the secrets are stored in files. To erase the files later, you can run the mysql_rds_remove_binlog_ssl_material stored procedure.

Synchronizing the Amazon Aurora MySQL DB cluster with the external MySQL database

You can synchronize your Amazon Aurora MySQL DB cluster with the MySQL database using replication.

To synchronize your Aurora MySQL DB cluster with the MySQL database using replication

1. Ensure that the /etc/my.cnf file for the external MySQL database has the relevant entries.

   If encrypted replication is not required, ensure that the external MySQL database is started with binary logs (binlogs) enabled and SSL disabled. The following are the relevant entries in the /etc/my.cnf file for unencrypted data.

   ```
   log-bin=mysql-bin
   server-id=2133421
   innodb_flush_log_at_trx_commit=1
   sync_binlog=1
   ```

   If encrypted replication is required, ensure that the external MySQL database is started with SSL and binlogs enabled. The entries in the /etc/my.cnf file include the .pem file locations for the MySQL database server.

   ```
   log-bin=mysql-bin
   server-id=2133421
   innodb_flush_log_at_trx_commit=1
   sync_binlog=1
   
   # Setup SSL.
   ssl-ca=/home/sslcerts/ca.pem
   ssl-cert=/home/sslcerts/server-cert.pem
   ssl-key=/home/sslcerts/server-key.pem
   ```

   You can verify that SSL is enabled with the following command.
mysql> show variables like 'have_ssl';

Your output should be similar the following.

+---------------------------------------+------------------+
| Variable_name | Value |------------------|
+---------------------------------------+------------------+
| have_ssl     | YES   |------------------|
+---------------------------------------+------------------+
1 row in set (0.00 sec)

2. Determine the starting binary log position for replication. You specify the position to start replication in a later step.

**Using the AWS Management Console**

a. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
b. In the navigation pane, choose *Events*.
c. In the *Events* list, note the position in the *Recovered from Binary log filename* event.

**Using the AWS CLI**

You can also get the binlog file name and position by calling the `describe-events` command from the AWS CLI. The following shows an example `describe-events` command.

PROMPT> aws rds describe-events

In the output, identify the event that shows the binlog position.

3. While connected to the external MySQL database, create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```sql
mysql> CREATE USER '<user_name>'@'<domain_name>' IDENTIFIED BY '<password>';
```

The user requires the **REPLICATION CLIENT** and **REPLICATION SLAVE** privileges. Grant these privileges to the user.
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO '<user_name>':'<domain_name>';

If you need to use encrypted replication, require SSL connections for the replication user. For example, you can use the following statement to require SSL connections on the user account <user_name>.

GRANT USAGE ON *.* TO '<user_name>':'<domain_name>' REQUIRE SSL;

Note
If REQUIRE SSL is not included, the replication connection might silently fall back to an unencrypted connection.

4. In the Amazon RDS console, add the IP address of the server that hosts the external MySQL database to the VPC security group for the Aurora MySQL DB cluster. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Aurora MySQL DB cluster, so that it can communicate with your external MySQL database. To find the IP address of the Aurora MySQL DB cluster, use the host command.

host <db_cluster_endpoint>

The host name is the DNS name from the Aurora MySQL DB cluster endpoint.

5. Enable binary log replication by running the mysql.rds_set_external_master (Aurora MySQL version 1 and 2) or mysql.rds_set_external_source (Aurora MySQL version 3 and higher) stored procedure. This stored procedure has the following syntax.

CALL mysql.rds_set_external_master (host_name, host_port, replication_user_name, replication_user_password, mysql_binary_log_file_name, mysql_binary_log_file_location, ssl_encryption);

CALL mysql.rds_set_external_source (host_name, host_port, replication_user_name, replication_user_password, mysql_binary_log_file_name, mysql_binary_log_file_location, ssl_encryption);

For information about the parameters, see mysql_rds_set_external_master.

For mysql_binary_log_file_name and mysql_binary_log_file_location, use the position in the Recovered from Binary log filename event you noted earlier.
If the data in the Aurora MySQL DB cluster is not encrypted, the `ssl_encryption` parameter must be set to 0. If the data is encrypted, the `ssl_encryption` parameter must be set to 1.

The following example runs the procedure for an Aurora MySQL DB cluster that has encrypted data.

```sql
CALL mysql.rds_set_external_master('Externaldb.some.com', 3306, 'repl_user'@'mydomain.com', 'password', 'mysql-bin.000010', 120, 1);
CALL mysql.rds_set_external_source('Externaldb.some.com', 3306, 'repl_user'@'mydomain.com', 'password', 'mysql-bin.000010', 120, 1);

This stored procedure sets the parameters that the Aurora MySQL DB cluster uses for connecting to the external MySQL database and reading its binary log. If the data is encrypted, it also downloads the SSL certificate authority certificate, client certificate, and client key to the local disk.

6. Start binary log replication by running the `mysql.rds_start_replication` stored procedure.

```sql
CALL mysql.rds_start_replication;
```

7. Monitor how far the Aurora MySQL DB cluster is behind the MySQL replication primary database. To do so, connect to the Aurora MySQL DB cluster and run the following command.

```sql
Aurora MySQL version 1 and 2:
SHOW SLAVE STATUS;

Aurora MySQL version 3:
SHOW REPLICA STATUS;
```

In the command output, the `Seconds Behind Master` field shows how far the Aurora MySQL DB cluster is behind the MySQL primary. When this value is 0 (zero), the Aurora MySQL DB cluster has caught up to the primary, and you can move on to the next step to stop replication.

8. Connect to the MySQL replication primary database and stop replication. To do so, run the following command.

```sql
CALL mysql.rds_stop_replication;
```

### Migrating from MySQL to Amazon Aurora by using mysqldump

Because Amazon Aurora MySQL is a MySQL-compatible database, you can use the `mysqldump` utility to copy data from your MySQL or MariaDB database to an existing Aurora MySQL DB cluster.
For a discussion of how to do so with MySQL databases that are very large, see Importing data to a MySQL or MariaDB DB instance with reduced downtime. For MySQL databases that have smaller amounts of data, see Importing data from a MySQL or MariaDB DB to a MySQL or MariaDB DB instance.

Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using a DB snapshot

You can migrate (copy) data to an Amazon Aurora MySQL DB cluster from an RDS for MySQL DB snapshot, as described following.

Topics
- Migrating an RDS for MySQL snapshot to Aurora (p. 706)
- Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica (p. 712)

Note
Because Amazon Aurora MySQL is compatible with MySQL, you can migrate data from your MySQL database by setting up replication between your MySQL database and an Amazon Aurora MySQL DB cluster. If you want to use replication to migrate data from your MySQL database, we recommend that your MySQL database run MySQL version 5.5 or later. For more information, see Replication with Amazon Aurora (p. 73).

Migrating an RDS for MySQL snapshot to Aurora

You can migrate a DB snapshot of an RDS for MySQL DB instance to create an Aurora MySQL DB cluster. The new Aurora MySQL DB cluster is populated with the data from the original RDS for MySQL DB instance. The DB snapshot must have been made from an Amazon RDS DB instance running MySQL version 5.6 or 5.7.

You can migrate either a manual or automated DB snapshot. After the DB cluster is created, you can then create optional Aurora Replicas.

When the MySQL DB instance and the Aurora DB cluster are running the same version of MySQL, you can restore the MySQL snapshot directly to the Aurora DB cluster. For example, you can restore a MySQL version 5.6 snapshot directly to Aurora MySQL version 5.6, but you can't restore a MySQL version 5.6 snapshot directly to Aurora MySQL version 5.7.

If you want to migrate a MySQL version 5.6 snapshot to Aurora MySQL version 5.7, you can perform the migration in one of the following ways:

- Migrate the MySQL version 5.6 snapshot to Aurora MySQL version 5.6, take a snapshot of the Aurora MySQL version 5.6 DB cluster, and then restore the Aurora MySQL version 5.6 snapshot to Aurora MySQL version 5.7.

- Upgrade the MySQL version 5.6 snapshot to MySQL version 5.7, take a snapshot of the MySQL version 5.7 DB instance, and then restore the MySQL version 5.7 snapshot to Aurora MySQL version 5.7.

Note
You can also migrate a MySQL DB instance to an Aurora MySQL DB cluster by creating an Aurora read replica of your source MySQL DB instance. For more information, see Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica (p. 712).

You can't migrate a MySQL version 5.7 snapshot to Aurora MySQL version 5.6.
The general steps you must take are as follows:

1. Determine the amount of space to provision for your Aurora MySQL DB cluster. For more information, see How much space do I need? (p. 707)
2. Use the console to create the snapshot in the AWS Region where the Amazon RDS MySQL instance is located. For information about creating a DB snapshot, see Creating a DB snapshot.
3. If the DB snapshot is not in the same AWS Region as your DB cluster, use the Amazon RDS console to copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see Copying a DB snapshot.
4. Use the console to migrate the DB snapshot and create an Aurora MySQL DB cluster with the same databases as the original MySQL DB instance.

**Warning**

Amazon RDS limits each AWS account to one snapshot copy into each AWS Region at a time.

**How much space do I need?**

When you migrate a snapshot of a MySQL DB instance into an Aurora MySQL DB cluster, Aurora uses an Amazon Elastic Block Store (Amazon EBS) volume to format the data from the snapshot before migrating it. In some cases, additional space is needed to format the data for migration.

Tables that are not MyISAM tables and are not compressed can be up to 16 TB in size. If you have MyISAM tables, then Aurora must use additional space in the volume to convert the tables to be compatible with Aurora MySQL. If you have compressed tables, then Aurora must use additional space in the volume to expand these tables before storing them on the Aurora cluster volume. Because of this additional space requirement, you should ensure that none of the MyISAM and compressed tables being migrated from your MySQL DB instance exceeds 8 TB in size.

**Reducing the amount of space required to migrate data into Amazon Aurora MySQL**

You might want to modify your database schema prior to migrating it into Amazon Aurora. Such modification can be helpful in the following cases:

- You want to speed up the migration process.
- You are unsure of how much space you need to provision.
- You have attempted to migrate your data and the migration has failed due to a lack of provisioned space.

You can make the following changes to improve the process of migrating a database into Amazon Aurora.

**Important**

Be sure to perform these updates on a new DB instance restored from a snapshot of a production database, rather than on a production instance. You can then migrate the data from the snapshot of your new DB instance into your Aurora DB cluster to avoid any service interruptions on your production database.

<table>
<thead>
<tr>
<th>Table type</th>
<th>Limitation or guideline</th>
</tr>
</thead>
<tbody>
<tr>
<td>MyISAM tables</td>
<td>Aurora MySQL supports InnoDB tables only. If you have MyISAM tables in your database, then those tables must be converted before being migrated into Aurora MySQL. The conversion process requires additional space for the MyISAM to InnoDB conversion during the migration procedure.</td>
</tr>
</tbody>
</table>
To reduce your chances of running out of space or to speed up the migration process, convert all of your MyISAM tables to InnoDB tables before migrating them. The size of the resulting InnoDB table is equivalent to the size required by Aurora MySQL for that table. To convert a MyISAM table to InnoDB, run the following command:

```
alter table <schema>.<table_name> engine=innodb,
        algorithm=copy;
```

Compressed tables

Aurora MySQL doesn't support compressed tables (that is, tables created with `ROW_FORMAT=COMPRESSED`).

To reduce your chances of running out of space or to speed up the migration process, expand your compressed tables by setting `ROW_FORMAT` to `DEFAULT`, `COMPACT`, `DYNAMIC`, or `REDUNDANT`. For more information, see [https://dev.mysql.com/doc/refman/5.6/en/innodb-row-format.html](https://dev.mysql.com/doc/refman/5.6/en/innodb-row-format.html).

You can use the following SQL script on your existing MySQL DB instance to list the tables in your database that are MyISAM tables or compressed tables.

```sql
-- This script examines a MySQL database for conditions that block
-- migrating the database into Amazon Aurora.
-- It needs to be run from an account that has read permission for the
-- INFORMATION_SCHEMA database.
-- Verify that this is a supported version of MySQL.
select msg as "==> Checking current version of MySQL."
from
    (select
        'This script should be run on MySQL version 5.6. ' +
        'Earlier versions are not supported.' as msg,
        cast(substring_index(version(), '.', 1) as unsigned) * 100 +
        cast(substring_index(substring_index(version(), '.', 2), '.', -1)
        as unsigned)
    ) as T
where major_minor <= 506;

-- List MyISAM and compressed tables. Include the table size.
select concat(TABLE_SCHEMA, '.', TABLE_NAME) as "==> MyISAM or Compressed Tables",
    round(((data_length + index_length) / 1024 / 1024), 2) "Approx size (MB)"
from INFORMATION_SCHEMA.TABLES
where
    ENGINE <> 'InnoDB'
    and
    ( -- User tables
        TABLE_SCHEMA not in ('mysql', 'performance_schema',
                             'information_schema')
    )
    or
    -- Non-standard system tables
    ( TABLE_SCHEMA = 'mysql' and TABLE_NAME not in
       ('columns_priv', 'db', 'event', 'func', 'general_log',
```
The script produces output similar to the output in the following example. The example shows two tables that must be converted from MyISAM to InnoDB. The output also includes the approximate size of each table in megabytes (MB).

<table>
<thead>
<tr>
<th>==&gt; MyISAM or Compressed Tables</th>
<th>Approx size (MB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.name_table</td>
<td>2102.25</td>
</tr>
<tr>
<td>test.my_table</td>
<td>65.25</td>
</tr>
</tbody>
</table>

2 rows in set (0.01 sec)

Migrating an RDS for MySQL DB snapshot to an Aurora MySQL DB cluster

You can migrate a DB snapshot of an RDS for MySQL DB instance to create an Aurora MySQL DB cluster using the AWS Management Console or the AWS CLI. The new Aurora MySQL DB cluster is populated with the data from the original RDS for MySQL DB instance. The DB snapshot must have been made from an Amazon RDS DB instance running MySQL version 5.6 or 5.7. For information about creating a DB snapshot, see Creating a DB snapshot.

If the DB snapshot is not in the AWS Region where you want to locate your data, copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see Copying a DB snapshot.

Console

When you migrate the DB snapshot by using the AWS Management Console, the console takes the actions necessary to create both the DB cluster and the primary instance.

You can also choose for your new Aurora MySQL DB cluster to be encrypted at rest using an AWS KMS key.

To migrate a MySQL DB snapshot by using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Either start the migration from the MySQL DB instance or from the snapshot:
   - To start the migration from the DB instance:
     1. In the navigation pane, choose Databases, and then select the MySQL DB instance.
     2. For Actions, choose Migrate latest snapshot.
   - To start the migration from the snapshot:
     1. Choose Snapshots.
2. On the Snapshots page, choose the snapshot that you want to migrate into an Aurora MySQL DB cluster.

3. Choose Snapshot Actions, and then choose Migrate Snapshot.

The Migrate Database page appears.

3. Set the following values on the Migrate Database page:

   • Migrate to DB Engine: Select aurora.
   • DB Engine Version: Select the DB engine version for the Aurora MySQL DB cluster.
   • DB Instance Class: Select a DB instance class that has the required storage and capacity for your database, for example db.r3.large. Aurora cluster volumes automatically grow as the amount of data in your database increases. An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB). So you only need to select a DB instance class that meets your current storage requirements. For more information, see Overview of Aurora storage (p. 67).
   • DB Instance Identifier: Type a name for the DB cluster that is unique for your account in the AWS Region you selected. This identifier is used in the endpoint addresses for the instances in your DB cluster. You might choose to add some intelligence to the name, such as including the AWS Region and DB engine you selected, for example aurora-cluster1.

   The DB instance identifier has the following constraints:
   • It must contain from 1 to 63 alphanumeric characters or hyphens.
   • Its first character must be a letter.
   • It cannot end with a hyphen or contain two consecutive hyphens.
   • It must be unique for all DB instances per AWS account, per AWS Region.
   • Virtual Private Cloud (VPC): If you have an existing VPC, then you can use that VPC with your Aurora MySQL DB cluster by selecting your VPC identifier, for example vpc-a464d1c1. For information on creating a VPC, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) (p. 1743).

   Otherwise, you can choose to have Aurora create a VPC for you by selecting Create a new VPC.

   • Subnet group: If you have an existing subnet group, then you can use that subnet group with your Aurora MySQL DB cluster by selecting your subnet group identifier, for example gs-subnet-group1.

   Otherwise, you can choose to have Aurora create a subnet group for you by selecting Create a new subnet group.

   • Public accessibility: Select No to specify that instances in your DB cluster can only be accessed by resources inside of your VPC. Select Yes to specify that instances in your DB cluster can be accessed by resources on the public network. The default is Yes.

   Note
   Your production DB cluster might not need to be in a public subnet, because only your application servers require access to your DB cluster. If your DB cluster doesn't need to be in a public subnet, set Publicly Accessible to No.

   • Availability Zone: Select the Availability Zone to host the primary instance for your Aurora MySQL DB cluster. To have Aurora select an Availability Zone for you, select No Preference.

   • Database Port: Type the default port to be used when connecting to instances in the Aurora MySQL DB cluster. The default is 3306.

   Note
   You might be behind a corporate firewall that doesn't allow access to default ports such as the MySQL default port, 3306. In this case, provide a port value that your corporate firewall allows. Remember that port value later when you connect to the Aurora MySQL DB cluster.
• **Encryption**: Choose **Enable Encryption** for your new Aurora MySQL DB cluster to be encrypted at rest. If you choose **Enable Encryption**, you must choose a KMS key as the **AWS KMS key** value.

If your DB snapshot isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest.

If your DB snapshot is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. You can specify the encryption key used by the DB snapshot or a different key. You can't create an unencrypted DB cluster from an encrypted DB snapshot.

• **Auto Minor Version Upgrade**: This setting doesn't apply to Aurora MySQL DB clusters.

For more information about engine updates for Aurora MySQL, see Database engine updates for Amazon Aurora MySQL (p. 991).

4. Choose **Migrate** to migrate your DB snapshot.
5. Choose **Instances**, and then choose the arrow icon to show the DB cluster details and monitor the progress of the migration. On the details page, you can find the cluster endpoint used to connect to the primary instance of the DB cluster. For more information on connecting to an Aurora MySQL DB cluster, see Connecting to an Amazon Aurora DB cluster (p. 207).

**AWS CLI**

You can create an Aurora DB cluster from a DB snapshot of an RDS for MySQL DB instance by using the `restore-db-cluster-from-snapshot` command with the following parameters:

- `--db-cluster-identifier`
  The name of the DB cluster to create.
- `--engine aurora-mysql` for a MySQL 5.7–compatible or 8.0–compatible DB cluster, or `--engine aurora` for a MySQL 5.6–compatible DB cluster
- `--kms-key-id`
  The AWS KMS key to optionally encrypt the DB cluster with, depending on whether your DB snapshot is encrypted.
  - If your DB snapshot isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest. Otherwise, your DB cluster isn't encrypted.
  - If your DB snapshot is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. Otherwise, your DB cluster is encrypted at rest using the encryption key for the DB snapshot.

  **Note**
  You can't create an unencrypted DB cluster from an encrypted DB snapshot.

- `--snapshot-identifier`
  The Amazon Resource Name (ARN) of the DB snapshot to migrate. For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS).

When you migrate the DB snapshot by using the `RestoreDBClusterFromSnapshot` command, the command creates both the DB cluster and the primary instance.

In this example, you create a MySQL 5.7–compatible DB cluster named `mydbcluster` from a DB snapshot with an ARN set to `mydbsnapshotARN`.

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot
```
For Windows:

```bash
aws rds restore-db-cluster-from-snapshot
    --db-cluster-identifier mydbcluster
    --snapshot-identifier mydbsnapshotARN
    --engine aurora-mysql
```

In this example, you create a MySQL 5.6–compatible DB cluster named `mydbcluster` from a DB snapshot with an ARN set to `mydbsnapshotARN`.

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot
    --db-cluster-identifier mydbcluster
    --snapshot-identifier mydbsnapshotARN
    --engine aurora
```

Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica

Aurora uses the MySQL DB engines' binary log replication functionality to create a special type of DB cluster called an Aurora read replica for a source MySQL DB instance. Updates made to the source MySQL DB instance are asynchronously replicated to the Aurora read replica.

We recommend using this functionality to migrate from a MySQL DB instance to an Aurora MySQL DB cluster by creating an Aurora read replica of your source MySQL DB instance. When the replica lag between the MySQL DB instance and the Aurora read replica is 0, you can direct your client applications to the Aurora read replica and then stop replication to make the Aurora read replica a standalone Aurora MySQL DB cluster. Be prepared for migration to take a while, roughly several hours per tebibyte (TiB) of data.

For a list of regions where Aurora is available, see Amazon Aurora in the AWS General Reference.

When you create an Aurora read replica of a MySQL DB instance, Amazon RDS creates a DB snapshot of your source MySQL DB instance (private to Amazon RDS, and incurring no charges). Amazon RDS then migrates the data from the DB snapshot to the Aurora read replica. After the data from the DB snapshot has been migrated to the new Aurora MySQL DB cluster, Amazon RDS starts replication between your MySQL DB instance and the Aurora MySQL DB cluster. If your MySQL DB instance contains tables that use storage engines other than InnoDB, or that use compressed row format, you can speed up the process of creating an Aurora read replica by altering those tables to use the InnoDB storage engine and dynamic row format before you create your Aurora read replica. For more information about the process of copying a MySQL DB snapshot to an Aurora MySQL DB cluster, see Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using a DB snapshot (p. 706).

You can only have one Aurora read replica for a MySQL DB instance.
Note
Replication issues can arise due to feature differences between Amazon Aurora MySQL and the MySQL database engine version of your RDS for MySQL DB instance that is the replication primary. If you encounter an error, you can find help in the Amazon RDS community forum or by contacting AWS Support.

For more information on MySQL read replicas, see Working with read replicas of MariaDB, MySQL, and PostgreSQL DB instances.

Creating an Aurora read replica

You can create an Aurora read replica for a MySQL DB instance by using the console, the AWS CLI, or the RDS API.

Console

To create an Aurora read replica from a source MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the MySQL DB instance that you want to use as the source for your Aurora read replica.
4. For Actions, choose Create Aurora read replica.
5. Choose the DB cluster specifications you want to use for the Aurora read replica, as described in the following table.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB instance class</td>
<td>Choose a DB instance class that defines the processing and memory requirements for the primary instance in the DB cluster. For more information about DB instance class options, see Aurora DB instance classes (p. 56).</td>
</tr>
<tr>
<td>Multi-AZ deployment</td>
<td>Choose Create Replica in Different Zone to create a standby replica of the new DB cluster in another Availability Zone in the target AWS Region for failover support. For more information about multiple Availability Zones, see Regions and Availability Zones (p. 11).</td>
</tr>
<tr>
<td>DB instance identifier</td>
<td>Type a name for the primary instance in your Aurora read replica DB cluster. This identifier is used in the endpoint address for the primary instance of the new DB cluster. The DB instance identifier has the following constraints: • It must contain from 1 to 63 alphanumeric characters or hyphens. • Its first character must be a letter. • It cannot end with a hyphen or contain two consecutive hyphens. • It must be unique for all DB instances for each AWS account, for each AWS Region. Because the Aurora read replica DB cluster is created from a snapshot of the source DB instance, the master user name and master password for the Aurora read replica are...</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>the same as the master user name and master password for the source DB instance.</td>
<td></td>
</tr>
<tr>
<td>Virtual Private Cloud (VPC)</td>
<td>Select the VPC to host the DB cluster. Select <strong>Create new VPC</strong> to have Aurora create a VPC for you. For more information, see <strong>DB cluster prerequisites (p. 127)</strong>.</td>
</tr>
<tr>
<td>Subnet group</td>
<td>Select the DB subnet group to use for the DB cluster. Select <strong>Create new DB subnet group</strong> to have Aurora create a DB subnet group for you. For more information, see <strong>DB cluster prerequisites (p. 127)</strong>.</td>
</tr>
<tr>
<td>Public accessibility</td>
<td>Select <strong>Yes</strong> to give the DB cluster a public IP address; otherwise, select <strong>No</strong>. The instances in your DB cluster can be a mix of both public and private DB instances. For more information about hiding instances from public access, see <strong>Hiding a DB cluster in a VPC from the internet (p. 1734)</strong>.</td>
</tr>
<tr>
<td>Availability zone</td>
<td>Determine if you want to specify a particular Availability Zone. For more information about Availability Zones, see <strong>Regions and Availability Zones (p. 11)</strong>.</td>
</tr>
<tr>
<td>VPC security groups</td>
<td>Select <strong>Create new VPC security group</strong> to have Aurora create a VPC security group for you. Select <strong>Select existing VPC security groups</strong> to specify one or more VPC security groups to secure network access to the DB cluster. For more information, see <strong>DB cluster prerequisites (p. 127)</strong>.</td>
</tr>
<tr>
<td>Database port</td>
<td>Specify the port for applications and utilities to use to access the database. Aurora MySQL DB clusters default to the default MySQL port, 3306. Firewalls at some companies block connections to this port. If your company firewall blocks the default port, choose another port for the new DB cluster.</td>
</tr>
<tr>
<td>DB parameter group</td>
<td>Select a DB parameter group for the Aurora MySQL DB cluster. Aurora has a default DB parameter group you can use, or you can create your own DB parameter group. For more information about DB parameter groups, see <strong>Working with parameter groups (p. 215)</strong>.</td>
</tr>
<tr>
<td>DB cluster parameter group</td>
<td>Select a DB cluster parameter group for the Aurora MySQL DB cluster. Aurora has a default DB cluster parameter group you can use, or you can create your own DB cluster parameter group. For more information about DB cluster parameter groups, see <strong>Working with parameter groups (p. 215)</strong>.</td>
</tr>
</tbody>
</table>
### Option | Description
--- | ---
**Encryption** | Choose **Disable encryption** if you don't want your new Aurora DB cluster to be encrypted. Choose **Enable encryption** for your new Aurora DB cluster to be encrypted at rest. If you choose **Enable encryption**, you must choose a KMS key as the **AWS KMS key** value.

If your MySQL DB instance isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest.

If your MySQL DB instance is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. You can specify the encryption key used by the MySQL DB instance or a different key. You can't create an unencrypted DB cluster from an encrypted MySQL DB instance.

**Priority** | Choose a failover priority for the DB cluster. If you don't select a value, the default is **tier-1**. This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. For more information, see Fault tolerance for an Aurora DB cluster (p. 72).

**Backup retention period** | Select the length of time, from 1 to 35 days, that Aurora retains backup copies of the database. Backup copies can be used for point-in-time restores (PITR) of your database down to the second.

**Enhanced Monitoring** | Choose **Enable enhanced monitoring** to enable gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 518).

**Monitoring Role** | Only available if **Enhanced Monitoring** is set to **Enable enhanced monitoring**. Choose the IAM role that you created to permit Aurora to communicate with Amazon CloudWatch Logs for you, or choose **Default** to have Aurora create a role for you named `rds-monitoring-role`. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 518).

**Granularity** | Only available if **Enhanced Monitoring** is set to **Enable enhanced monitoring**. Set the interval, in seconds, between when metrics are collected for your DB cluster.

**Auto minor version upgrade** | This setting doesn't apply to Aurora MySQL DB clusters. For more information about engine updates for Aurora MySQL, see Database engine updates for Amazon Aurora MySQL (p. 991).

**Maintenance window** | Select **Select window** and specify the weekly time range during which system maintenance can occur. Or, select **No preference** for Aurora to assign a period randomly.

6. Choose **Create read replica**.
AWS CLI

To create an Aurora read replica from a source MySQL DB instance, use the `create-db-cluster` and `create-db-instance` AWS CLI commands to create a new Aurora MySQL DB cluster. When you call the `create-db-cluster` command, include the `--replication-source-identifier` parameter to identify the Amazon Resource Name (ARN) for the source MySQL DB instance. For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS).

Don't specify the master username, master password, or database name as the Aurora read replica uses the same master username, master password, and database name as the source MySQL DB instance.

For Linux, macOS, or Unix:

```bash
```

For Windows:

```bash
```

If you use the console to create an Aurora read replica, then Aurora automatically creates the primary instance for your DB cluster Aurora read replica. If you use the AWS CLI to create an Aurora read replica, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

You can create a primary instance for your DB cluster by using the `create-db-instance` AWS CLI command with the following parameters.

- `--db-cluster-identifier`
  The name of your DB cluster.
- `--db-instance-class`
  The name of the DB instance class to use for your primary instance.
- `--db-instance-identifier`
  The name of your primary instance.
- `--engine aurora`

In this example, you create a primary instance named `myreadreplicainstance` for the DB cluster named `myreadreplicacluster`, using the DB instance class specified in `myinstanceclass`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
--db-cluster-identifier myreadreplicacluster
--db-instance-class myinstanceclass
--db-instance-identifier myreadreplicainstance
--engine aurora
```

For Windows:
aws rds create-db-instance ^
   --db-cluster-identifier myreadreplicacluster ^
   --db-instance-class myinstanceclass ^
   --db-instance-identifier myreadreplicainstance ^
   --engine aurora

RDS API

To create an Aurora read replica from a source MySQL DB instance, use the CreateDBCluster and CreateDBInstance Amazon RDS API commands to create a new Aurora DB cluster and primary instance. Do not specify the master username, master password, or database name as the Aurora read replica uses the same master username, master password, and database name as the source MySQL DB instance.

You can create a new Aurora DB cluster for an Aurora read replica from a source MySQL DB instance by using the CreateDBCluster Amazon RDS API command with the following parameters:

- **DBClusterIdentifier**
  The name of the DB cluster to create.
- **DBSubnetGroupName**
  The name of the DB subnet group to associate with this DB cluster.
- **Engine=aurora**
- **KmsKeyId**
  The AWS KMS key to optionally encrypt the DB cluster with, depending on whether your MySQL DB instance is encrypted.
  - If your MySQL DB instance isn't encrypted, specify an encryption key to have your DB cluster encrypted at rest. Otherwise, your DB cluster is encrypted at rest using the default encryption key for your account.
  - If your MySQL DB instance is encrypted, specify an encryption key to have your DB cluster encrypted at rest using the specified encryption key. Otherwise, your DB cluster is encrypted at rest using the encryption key for the MySQL DB instance.

  **Note**
  You can't create an unencrypted DB cluster from an encrypted MySQL DB instance.
- **ReplicationSourceIdentifier**
  The Amazon Resource Name (ARN) for the source MySQL DB instance. For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS).
- **VpcSecurityGroupIds**
  The list of EC2 VPC security groups to associate with this DB cluster.

In this example, you create a DB cluster named `myreadreplicacluster` from a source MySQL DB instance with an ARN set to `mysqlprimaryARN`, associated with a DB subnet group named `mysubnetgroup` and a VPC security group named `mysecuritygroup`.

**Example**

https://rds.us-east-1.amazonaws.com/
?Action=CreateDBCluster
&DBClusterIdentifier=myreadreplicacluster
&DBSubnetGroupName=mysubnetgroup
&Engine=aurora
&ReplicationSourceIdentifier=mysqlprimaryARN
If you use the console to create an Aurora read replica, then Aurora automatically creates the primary instance for your DB cluster Aurora read replica. If you use the AWS CLI to create an Aurora read replica, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

You can create a primary instance for your DB cluster by using the `CreateDBInstance` Amazon RDS API command with the following parameters:

- **DBClusterIdentifier**
  The name of your DB cluster.
- **DBInstanceClass**
  The name of the DB instance class to use for your primary instance.
- **DBInstanceIdentifier**
  The name of your primary instance.
- **Engine=aurora**

In this example, you create a primary instance named `myreadreplicainstance` for the DB cluster named `myreadreplicaclustere`, using the DB instance class specified in `myinstanceclass`.

**Example**

https://rds.us-east-1.amazonaws.com/
?Action=CreateDBInstance
&DBClusterIdentifier=myreadreplicaclustere
&DBInstanceClass=myinstanceclass
&DBInstanceIdentifier=myreadreplicainstance
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-09-01
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140424/us-east-1/rds/aws4_request
&X-Amz-Date=20140424T194844Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=bee4aab4750bf77ad00d9e12b952d6089d91e2a16592c2293e532eaaeb8bc77

**Viewing an Aurora read replica**

You can view the MySQL to Aurora MySQL replication relationships for your Aurora MySQL DB clusters by using the AWS Management Console or the AWS CLI.

**Console**

**To view the primary MySQL DB instance for an Aurora read replica**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster for the Aurora read replica to display its details. The primary MySQL DB instance information is in the **Replication source** field.

**AWS CLI**

To view the MySQL to Aurora MySQL replication relationships for your Aurora MySQL DB clusters by using the AWS CLI, use the `describe-db-clusters` and `describe-db-instances` commands.

To determine which MySQL DB instance is the primary, use the `describe-db-clusters` and specify the cluster identifier of the Aurora read replica for the `--db-cluster-identifier` option. Refer to the `ReplicationSourceIdentifier` element in the output for the ARN of the DB instance that is the replication primary.

To determine which DB cluster is the Aurora read replica, use the `describe-db-instances` and specify the instance identifier of the MySQL DB instance for the `--db-instance-identifier` option. Refer to the `Read Replica DB Cluster Identifiers` element in the output for the DB cluster identifier of the Aurora read replica.
Example

For Linux, macOS, or Unix:

```bash
aws rds describe-db-clusters --db-cluster-identifier myreadrepliccluster
aws rds describe-db-instances --db-instance-identifier mysqlprimary
```

For Windows:

```bash
aws rds describe-db-clusters --db-cluster-identifier myreadrepliccluster
aws rds describe-db-instances --db-instance-identifier mysqlprimary
```

Promoting an Aurora read replica

After migration completes, you can promote the Aurora read replica to a stand-alone DB cluster using the AWS Management Console or AWS CLI.

Then you can direct your client applications to the endpoint for the Aurora read replica. For more information on the Aurora endpoints, see Amazon Aurora connection management (p. 35). Promotion should complete fairly quickly, and you can read from and write to the Aurora read replica during promotion. However, you can't delete the primary MySQL DB instance or unlink the DB Instance and the Aurora read replica during this time.

Before you promote your Aurora read replica, stop any transactions from being written to the source MySQL DB instance, and then wait for the replica lag on the Aurora read replica to reach 0. You can view the replica lag for an Aurora read replica by calling the `SHOW SLAVE STATUS` (Aurora MySQL version 1 and 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command on your Aurora read replica. Check the `Seconds behind master` value.

You can start writing to the Aurora read replica after write transactions to the primary have stopped and replica lag is 0. If you write to the Aurora read replica before this and you modify tables that are also being modified on the MySQL primary, you risk breaking replication to Aurora. If this happens, you must delete and recreate your Aurora read replica.

Console

To promote an Aurora read replica to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB cluster for the Aurora read replica.
4. For Actions, choose Promote.
5. Choose Promote read replica.

After you promote, confirm that the promotion has completed by using the following procedure.
To confirm that the Aurora read replica was promoted

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Events.
3. On the Events page, verify that there is a Promoted Read Replica cluster to a stand-alone database cluster event for the cluster that you promoted.

After promotion is complete, the primary MySQL DB instance and the Aurora read replica are unlinked, and you can safely delete the DB instance if you want.

AWS CLI

To promote an Aurora read replica to a stand-alone DB cluster, use the `promote-read-replica-db-cluster` AWS CLI command.

Example

For Linux, macOS, or Unix:

```bash
aws rds promote-read-replica-db-cluster \
    --db-cluster-identifier myreadreplicaccluster
```

For Windows:

```bash
aws rds promote-read-replica-db-cluster ^
    --db-cluster-identifier myreadreplicaccluster
```

Managing Amazon Aurora MySQL

The following sections discuss managing an Amazon Aurora MySQL DB cluster.

Topics
- Managing performance and scaling for Amazon Aurora MySQL (p. 721)
- Backtracking an Aurora DB cluster (p. 725)
- Testing Amazon Aurora using fault injection queries (p. 739)
- Altering tables in Amazon Aurora using fast DDL (p. 742)
- Displaying volume status for an Aurora MySQL DB cluster (p. 747)

Managing performance and scaling for Amazon Aurora MySQL

Scaling Aurora MySQL DB instances

You can scale Aurora MySQL DB instances in two ways, instance scaling and read scaling. For more information about read scaling, see Read scaling (p. 278).

You can scale your Aurora MySQL DB cluster by modifying the DB instance class for each DB instance in the DB cluster. Aurora MySQL supports several DB instance classes optimized for Aurora. Don't use db.t2
or db.t3 instance classes for larger Aurora clusters of size greater than 40 TB. For the specifications of the DB instance classes supported by Aurora MySQL, see Aurora DB instance classes (p. 56).

## Maximum connections to an Aurora MySQL DB instance

The maximum number of connections allowed to an Aurora MySQL DB instance is determined by the `max_connections` parameter in the instance-level parameter group for the DB instance.

The following table lists the resulting default value of `max_connections` for each DB instance class available to Aurora MySQL. You can increase the maximum number of connections to your Aurora MySQL DB instance by scaling the instance up to a DB instance class with more memory, or by setting a larger value for the `max_connections` parameter in the DB parameter group for your instance, up to 16,000.

For details about how Aurora Serverless v2 instances handle this parameter, see Parameters that Aurora computes based on Aurora Serverless v2 maximum capacity (p. 1536).

<table>
<thead>
<tr>
<th>Instance class</th>
<th><code>max_connections</code> default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.t2.small</td>
<td>45</td>
</tr>
<tr>
<td>db.t2.medium</td>
<td>90</td>
</tr>
<tr>
<td>db.t3.small</td>
<td>45</td>
</tr>
<tr>
<td>db.t3.medium</td>
<td>90</td>
</tr>
<tr>
<td>db.t3.large</td>
<td>135</td>
</tr>
<tr>
<td>db.t4g.medium</td>
<td>90</td>
</tr>
<tr>
<td>db.t4g.large</td>
<td>135</td>
</tr>
<tr>
<td>db.r3.large</td>
<td>1000</td>
</tr>
<tr>
<td>db.r3.xlarge</td>
<td>2000</td>
</tr>
<tr>
<td>db.r3.2xlarge</td>
<td>3000</td>
</tr>
<tr>
<td>db.r3.4xlarge</td>
<td>4000</td>
</tr>
<tr>
<td>db.r3.8xlarge</td>
<td>5000</td>
</tr>
<tr>
<td>db.r4.large</td>
<td>1000</td>
</tr>
<tr>
<td>db.r4.xlarge</td>
<td>2000</td>
</tr>
<tr>
<td>db.r4.2xlarge</td>
<td>3000</td>
</tr>
<tr>
<td>db.r4.4xlarge</td>
<td>4000</td>
</tr>
<tr>
<td>db.r4.8xlarge</td>
<td>5000</td>
</tr>
<tr>
<td>db.r4.16xlarge</td>
<td>6000</td>
</tr>
<tr>
<td>db.r5.large</td>
<td>1000</td>
</tr>
<tr>
<td>db.r5.xlarge</td>
<td>2000</td>
</tr>
<tr>
<td>db.r5.2xlarge</td>
<td>3000</td>
</tr>
</tbody>
</table>
If you create a new parameter group to customize your own default for the connection limit, you’ll see that the default connection limit is derived using a formula based on the DBInstanceClassMemory value. As shown in the preceding table, the formula produces connection limits that increase by 1000 as the memory doubles between progressively larger R3, R4, and R5 instances, and by 45 for different memory sizes of T2 and T3 instances.

See Specifying DB parameters (p. 238) for more details on how DBInstanceClassMemory is calculated.

Aurora MySQL and RDS for MySQL DB instances have different amounts of memory overhead. Therefore, the max_connections value can be different for Aurora MySQL and RDS for MySQL DB instances that use the same instance class. The values in the table only apply to Aurora MySQL DB instances.

The much lower connectivity limits for T2 and T3 instances are because with Aurora, those instance classes are intended only for development and test scenarios, not for production workloads.

The default connection limits are tuned for systems that use the default values for other major memory consumers, such as the buffer pool and query cache. If you change those other settings for your cluster, consider adjusting the connection limit to account for the increase or decrease in available memory on the DB instances.
Temporary storage limits for Aurora MySQL

Aurora MySQL stores tables and indexes in the Aurora storage subsystem. Aurora MySQL uses separate temporary storage for non-persistent temporary files. This includes files that are used for such purposes as sorting large datasets during query processing or for index build operations. These local storage volumes are backed by Amazon Elastic Block Store and can be extended. For more information about storage, see Amazon Aurora storage and reliability (p. 67).

**Note**
You might see storage-optimization events when scaling DB instances, for example, from db.r5.2xlarge to db.r5.4xlarge.

The following table shows the maximum amount of temporary storage available for each Aurora MySQL DB instance class.

<table>
<thead>
<tr>
<th>DB instance class</th>
<th>Maximum temporary storage available (GiB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.x2g.16xlarge</td>
<td>1280</td>

**Important**

These values represent the theoretical maximum amount of free storage on each DB instance. The actual local storage available to you might be lower. Aurora uses some local storage for its management processes, and the DB instance uses some local storage even before you load any data. You can monitor the temporary storage available for a specific DB instance with the FreeLocalStorage CloudWatch metric, described in Amazon CloudWatch metrics for Amazon Aurora (p. 525). You can check the amount of free storage at the present time. You can also chart the amount of free storage over time. Monitoring the free storage over time helps you to determine whether the value is increasing or decreasing, or to find the minimum, maximum, or average values.

(This doesn’t apply to Aurora Serverless v2.)

**Backtracking an Aurora DB cluster**

With Amazon Aurora MySQL-Compatible Edition, you can backtrack a DB cluster to a specific time, without restoring data from a backup.

**Overview of backtracking**

Backtracking "rewinds" the DB cluster to the time you specify. Backtracking is not a replacement for backing up your DB cluster so that you can restore it to a point in time. However, backtracking provides the following advantages over traditional backup and restore:

- You can easily undo mistakes. If you mistakenly perform a destructive action, such as a DELETE without a WHERE clause, you can backtrack the DB cluster to a time before the destructive action with minimal interruption of service.
- You can backtrack a DB cluster quickly. Restoring a DB cluster to a point in time launches a new DB cluster and restores it from backup data or a DB cluster snapshot, which can take hours. Backtracking a DB cluster doesn’t require a new DB cluster and rewinds the DB cluster in minutes.
- You can explore earlier data changes. You can repeatedly backtrack a DB cluster back and forth in time to help determine when a particular data change occurred. For example, you can backtrack a DB
cluster three hours and then backtrack forward in time one hour. In this case, the backtrack time is two hours before the original time.

**Note**

For information about restoring a DB cluster to a point in time, see Overview of backing up and restoring an Aurora DB cluster (p. 369).

### Backtrack window

With backtracking, there is a target backtrack window and an actual backtrack window:

- **The target backtrack window** is the amount of time you want to be able to backtrack your DB cluster. When you enable backtracking, you specify a target backtrack window. For example, you might specify a target backtrack window of 24 hours if you want to be able to backtrack the DB cluster one day.
- **The actual backtrack window** is the actual amount of time you can backtrack your DB cluster, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for storing information about database changes, called change records.

As you make updates to your Aurora DB cluster with backtracking enabled, you generate change records. Aurora retains change records for the target backtrack window, and you pay an hourly rate for storing them. Both the target backtrack window and the workload on your DB cluster determine the number of change records you store. The workload is the number of changes you make to your DB cluster in a given amount of time. If your workload is heavy, you store more change records in your backtrack window than you do if your workload is light.

You can think of your target backtrack window as the goal for the maximum amount of time you want to be able to backtrack your DB cluster. In most cases, you can backtrack the maximum amount of time that you specified. However, in some cases, the DB cluster can't store enough change records to backtrack the maximum amount of time, and your actual backtrack window is smaller than your target. Typically, the actual backtrack window is smaller than the target when you have extremely heavy workload on your DB cluster. When your actual backtrack window is smaller than your target, we send you a notification.

When backtracking is enabled for a DB cluster, and you delete a table stored in the DB cluster, Aurora keeps that table in the backtrack change records. It does this so that you can revert back to a time before you deleted the table. If you don't have enough space in your backtrack window to store the table, the table might be removed from the backtrack change records eventually.

### Backtracking time

Aurora always backtracks to a time that is consistent for the DB cluster. Doing so eliminates the possibility of uncommitted transactions when the backtrack is complete. When you specify a time for a backtrack, Aurora automatically chooses the nearest possible consistent time. This approach means that the completed backtrack might not exactly match the time you specify, but you can determine the exact time for a backtrack by using the describe-db-cluster-backtracks AWS CLI command. For more information, see Retrieving existing backtracks (p. 738).

### Backtracking limitations

The following limitations apply to backtracking:

- Backtracking an Aurora DB cluster is available in certain AWS Regions and for specific Aurora MySQL versions only. For more information, see Backtracking in Aurora (p. 19).
- Backtracking is only available for DB clusters that were created with the Backtrack feature enabled. You can enable the Backtrack feature when you create a new DB cluster or restore a snapshot of a DB cluster. For DB clusters that were created with the Backtrack feature enabled, you can create a
clone DB cluster with the Backtrack feature enabled. Currently, you can’t perform backtracking on DB clusters that were created with the Backtrack feature disabled.

- The limit for a backtrack window is 72 hours.
- Backtracking affects the entire DB cluster. For example, you can’t selectively backtrack a single table or a single data update.
- Backtracking isn’t supported with binary log (binlog) replication. Cross-Region replication must be disabled before you can configure or use backtracking.
- You can’t backtrack a database clone to a time before that database clone was created. However, you can use the original database to backtrack to a time before the clone was created. For more information about database cloning, see Cloning a volume for an Amazon Aurora DB cluster (p. 280).
- Backtracking causes a brief DB instance disruption. You must stop or pause your applications before starting a backtrack operation to ensure that there are no new read or write requests. During the backtrack operation, Aurora pauses the database, closes any open connections, and drops any uncommitted reads and writes. It then waits for the backtrack operation to complete.
- Backtracking isn’t supported for the following AWS Regions:
  - Africa (Cape Town)
  - China (Ningxia)
  - Asia Pacific (Hong Kong)
  - Europe (Milan)
  - Europe (Stockholm)
  - Middle East (Bahrain)
  - South America (São Paulo)
- You can’t restore a cross-Region snapshot of a backtrack-enabled cluster in an AWS Region that doesn’t support backtracking.
- You can’t use Backtrack with Aurora multi-master clusters.
- If you perform an in-place upgrade for a backtrack-enabled cluster from Aurora MySQL version 1 to version 2, you can’t backtrack to a point in time before the upgrade happened.

**Upgrade considerations for backtrack-enabled clusters**

Backtracking is available for Aurora MySQL 1.*, which is compatible with MySQL 5.6. It’s also available for Aurora MySQL 2.06 and higher, which is compatible with MySQL 5.7. Because of the Aurora MySQL 2.* version requirement, if you created the Aurora MySQL 1.* cluster with the Backtrack setting enabled, you can only upgrade to a Backtrack-compatible version of Aurora MySQL 2.*. This requirement affects the following types of upgrade paths:

- You can only restore a snapshot of the Aurora MySQL 1.* DB cluster to a Backtrack-compatible version of Aurora MySQL 2.*.
- You can only perform point-in-time recovery on the Aurora MySQL 1.* DB cluster to restore it to a Backtrack-compatible version of Aurora MySQL 2.*.

These upgrade requirements still apply even if you turn off Backtrack for the Aurora MySQL 1.* cluster.

**Configuring backtracking**

To use the Backtrack feature, you must enable backtracking and specify a target backtrack window. Otherwise, backtracking is disabled.

For the target backtrack window, specify the amount of time that you want to be able to rewind your database using Backtrack. Aurora tries to retain enough change records to support that window of time.
Console

You can use the console to configure backtracking when you create a new DB cluster. You can also modify a DB cluster to change the backtrack window for a backtrack-enabled cluster. If you turn off backtracking entirely for a cluster by setting the backtrack window to 0, you can't enable backtracking again for that cluster.

Topics

- Configuring backtracking with the console when creating a DB cluster (p. 728)
- Configuring backtrack with the console when modifying a DB cluster (p. 728)

Configuring backtracking with the console when creating a DB cluster

When you create a new Aurora MySQL DB cluster, backtracking is configured when you choose Enable Backtrack and specify a Target Backtrack window value that is greater than zero in the Backtrack section.

To create a DB cluster, follow the instructions in Creating an Amazon Aurora DB cluster (p. 127). The following image shows the Backtrack section.

![Backtrack Section Image]

When you create a new DB cluster, Aurora has no data for the DB cluster's workload. So it can't estimate a cost specifically for the new DB cluster. Instead, the console presents a typical user cost for the specified target backtrack window based on a typical workload. The typical cost is meant to provide a general reference for the cost of the Backtrack feature.

**Important**
Your actual cost might not match the typical cost, because your actual cost is based on your DB cluster's workload.

Configuring backtrack with the console when modifying a DB cluster

You can modify backtracking for a DB cluster using the console.

**Note**
Currently, you can modify backtracking only for a DB cluster that has the Backtrack feature enabled. The Backtrack section doesn't appear for a DB cluster that was created with the Backtrack feature disabled or if the Backtrack feature has been disabled for the DB cluster.
To modify backtracking for a DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. Choose the cluster that you want to modify, and choose Modify.
4. For Target Backtrack window, modify the amount of time that you want to be able to backtrack. The limit is 72 hours.

The console shows the estimated cost for the amount of time you specified based on the DB cluster’s past workload:

- If backtracking was disabled on the DB cluster, the cost estimate is based on the VolumeWriteIOPS metric for the DB cluster in Amazon CloudWatch.
- If backtracking was enabled previously on the DB cluster, the cost estimate is based on the BacktrackChangeRecordsCreationRate metric for the DB cluster in Amazon CloudWatch.

5. Choose Continue.
6. For Scheduling of Modifications, choose one of the following:

   - Apply during the next scheduled maintenance window – Wait to apply the Target Backtrack window modification until the next maintenance window.
   - Apply immediately – Apply the Target Backtrack window modification as soon as possible.

7. Choose Modify cluster.

AWS CLI

When you create a new Aurora MySQL DB cluster using the create-db-cluster AWS CLI command, backtracking is configured when you specify a --backtrack-window value that is greater than zero. The --backtrack-window value specifies the target backtrack window. For more information, see Creating an Amazon Aurora DB cluster (p. 127).

You can also specify the --backtrack-window value using the following AWS CLI commands:

- modify-db-cluster
- restore-db-cluster-from-s3
The following procedure describes how to modify the target backtrack window for a DB cluster using the AWS CLI.

**To modify the target backtrack window for a DB cluster using the AWS CLI**

- Call the `modify-db-cluster` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--backtrack-window` – The maximum number of seconds that you want to be able to backtrack the DB cluster.

The following example sets the target backtrack window for `sample-cluster` to one day (86,400 seconds).

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster
   --db-cluster-identifier sample-cluster
   --backtrack-window 86400
```

For Windows:

```
aws rds modify-db-cluster ^
   --db-cluster-identifier sample-cluster ^
   --backtrack-window 86400
```

**Note**
Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.

**RDS API**

When you create a new Aurora MySQL DB cluster using the `CreateDBCluster` Amazon RDS API operation, backtracking is configured when you specify a `BacktrackWindow` value that is greater than zero. The `BacktrackWindow` value specifies the target backtrack window for the DB cluster specified in the `DBClusterIdentifier` value. For more information, see Creating an Amazon Aurora DB cluster (p. 127).

You can also specify the `BacktrackWindow` value using the following API operations:

- `ModifyDBCluster`
- `RestoreDBClusterFromS3`
- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`

**Note**
Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.
Performing a backtrack

You can backtrack a DB cluster to a specified backtrack time stamp. If the backtrack time stamp isn't earlier than the earliest possible backtrack time, and isn't in the future, the DB cluster is backtracked to that time stamp.

Otherwise, an error typically occurs. Also, if you try to backtrack a DB cluster for which binary logging is enabled, an error typically occurs unless you've chosen to force the backtrack to occur. Forcing a backtrack to occur can interfere with other operations that use binary logging.

**Important**
Backtracking doesn't generate binlog entries for the changes that it makes. If you have binary logging enabled for the DB cluster, backtracking might not be compatible with your binlog implementation.

**Note**
For database clones, you can't backtrack the DB cluster earlier than the date and time when the clone was created. For more information about database cloning, see Cloning a volume for an Amazon Aurora DB cluster (p. 280).

**Console**

The following procedure describes how to perform a backtrack operation for a DB cluster using the console.

**To perform a backtrack operation using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Instances**.
3. Choose the primary instance for the DB cluster that you want to backtrack.
4. For **Actions**, choose **Backtrack DB cluster**.
5. On the **Backtrack DB cluster** page, enter the backtrack time stamp to backtrack the DB cluster to.
6. Choose **Backtrack DB cluster**.
**AWS CLI**

The following procedure describes how to backtrack a DB cluster using the AWS CLI.

**To backtrack a DB cluster using the AWS CLI**

- Call the `backtrack-db-cluster` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--backtrack-to` – The backtrack time stamp to backtrack the DB cluster to, specified in ISO 8601 format.

The following example backtracks the DB cluster `sample-cluster` to March 19, 2018, at 10 a.m.

For Linux, macOS, or Unix:

```
aws rds backtrack-db-cluster \
  --db-cluster-identifier sample-cluster \
  --backtrack-to 2018-03-19T10:00:00+00:00
```

For Windows:

```
aws rds backtrack-db-cluster ^
  --db-cluster-identifier sample-cluster ^
  --backtrack-to 2018-03-19T10:00:00+00:00
```

**RDS API**

To backtrack a DB cluster using the Amazon RDS API, use the `BacktrackDBCluster` operation. This operation backtracks the DB cluster specified in the `DBClusterIdentifier` value to the specified time.

**Monitoring backtracking**

You can view backtracking information and monitor backtracking metrics for a DB cluster.

**Console**

**To view backtracking information and monitor backtracking metrics using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. Choose **Databases**.
3. Choose the DB cluster name to open information about it.
   - The backtrack information is in the Backtrack section.
When backtracking is enabled, the following information is available:

- **Target window** – The current amount of time specified for the target backtrack window. The target is the maximum amount of time that you can backtrack if there is sufficient storage.

- **Actual window** – The actual amount of time you can backtrack, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for retaining backtrack change records.

- **Earliest backtrack time** – The earliest possible backtrack time for the DB cluster. You can't backtrack the DB cluster to a time before the displayed time.

4. Do the following to view backtracking metrics for the DB cluster:

   a. In the navigation pane, choose **Instances**.

   b. Choose the name of the primary instance for the DB cluster to display its details.

   c. In the **CloudWatch** section, type **Backtrack** into the **CloudWatch** box to show only the Backtrack metrics.
The following metrics are displayed:

- **Backtrack Change Records Creation Rate (Count)** – This metric shows the number of backtrack change records created over five minutes for your DB cluster. You can use this metric to estimate the backtrack cost for your target backtrack window.

- **[Billed] Backtrack Change Records Stored (Count)** – This metric shows the actual number of backtrack change records used by your DB cluster.

- **Backtrack Window Actual (Minutes)** – This metric shows whether there is a difference between the target backtrack window and the actual backtrack window. For example, if your target backtrack window is 2 hours (120 minutes), and this metric shows that the actual backtrack window is 100 minutes, then the actual backtrack window is smaller than the target.

- **Backtrack Window Alert (Count)** – This metric shows how often the actual backtrack window is smaller than the target backtrack window for a given period of time.

**Note**
The following metrics might lag behind the current time:
Backtracking a DB cluster

- Backtrack Change Records Creation Rate (Count)
- [Billed] Backtrack Change Records Stored (Count)

**AWS CLI**

The following procedure describes how to view backtrack information for a DB cluster using the AWS CLI.

**To view backtrack information for a DB cluster using the AWS CLI**

- Call the `describe-db-clusters` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.

The following example lists backtrack information for `sample-cluster`.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-clusters
  --db-cluster-identifier sample-cluster
```

For Windows:

```bash
aws rds describe-db-clusters ^
  --db-cluster-identifier sample-cluster
```

**RDS API**

To view backtrack information for a DB cluster using the Amazon RDS API, use the `DescribeDBClusters` operation. This operation returns backtrack information for the DB cluster specified in the `DBClusterIdentifier` value.

**Subscribing to a backtrack event with the console**

The following procedure describes how to subscribe to a backtrack event using the console. The event sends you an email or text notification when your actual backtrack window is smaller than your target backtrack window.

**To view backtrack information using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`.
2. Choose **Event subscriptions**.
3. Choose **Create event subscription**.
4. In the **Name** box, type a name for the event subscription, and ensure that **Yes** is selected for **Enabled**.
5. In the **Target** section, choose **New email topic**.
6. For **Topic name**, type a name for the topic, and for **With these recipients**, enter the email addresses or phone numbers to receive the notifications.
7. In the **Source** section, choose **Instances** for **Source type**.
8. For **Instances to include**, choose **Select specific instances**, and choose your DB instance.

9. For **Event categories to include**, choose **Select specific event categories**, and choose **backtrack**.

Your page should look similar to the following page.
### Create event subscription

**Details**

*Name*
Name of the Subscription.
BacktrackEventSubscription

**Enabled**
- Yes
- No

**Target**

*Send notifications to*
- ARN
- New email topic
- New SMS topic

*Topic name*
Name of the topic.
TargetBacktrackWindowAlert

*With these recipients*
Email addresses or phone numbers of SMS enabled devices to send the notifications to
user@domain.com
e.g. user@domain.com

**Source**

*Source type*
Source type of resource this subscription will consume event from
Instances

*Instances to include*
Instances that this subscription will consume events from
- All instances
- Select specific instances

*Specific instances*

*Select specific event categories*

*Specific event*
10. Choose **Create**.

**Retrieving existing backtracks**

You can retrieve information about existing backtracks for a DB cluster. This information includes the unique identifier of the backtrack, the date and time backtracked to and from, the date and time the backtrack was requested, and the current status of the backtrack.

**Note**
Currently, you can't retrieve existing backtracks using the console.

**AWS CLI**

The following procedure describes how to retrieve existing backtracks for a DB cluster using the AWS CLI.

**To retrieve existing backtracks using the AWS CLI**

- Call the `describe-db-cluster-backtracks` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.

The following example retrieves existing backtracks for `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-backtracks \
   --db-cluster-identifier sample-cluster
```

For Windows:

```
aws rds describe-db-cluster-backtracks ^
   --db-cluster-identifier sample-cluster
```

**RDS API**

To retrieve information about the backtracks for a DB cluster using the Amazon RDS API, use the `DescribeDBClusterBacktracks` operation. This operation returns information about backtracks for the DB cluster specified in the `DBClusterIdentifier` value.

**Disabling backtracking for a DB cluster**

You can disable the Backtrack feature for a DB cluster.

**Console**

You can disable backtracking for a DB cluster using the console. After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

**To disable the Backtrack feature for a DB cluster using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at `https://console.aws.amazon.com/rds/`. 
2. Choose **Databases**.
3. Choose the cluster you want to modify, and choose **Modify**.
4. In the **Backtrack** section, choose **Disable Backtrack**.
5. Choose **Continue**.
6. For **Scheduling of Modifications**, choose one of the following:
   - **Apply during the next scheduled maintenance window** – Wait to apply the modification until the next maintenance window.
   - **Apply immediately** – Apply the modification as soon as possible.
7. Choose **Modify Cluster**.

**AWS CLI**

You can disable the Backtrack feature for a DB cluster using the AWS CLI by setting the target backtrack window to 0 (zero). After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

**To modify the target backtrack window for a DB cluster using the AWS CLI**

- Call the `modify-db-cluster` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--backtrack-window` – specify 0 to turn off backtracking.

The following example disables the Backtrack feature for the `sample-cluster` by setting `--backtrack-window` to 0.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier sample-cluster \
  --backtrack-window 0
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier sample-cluster ^
  --backtrack-window 0
```

**RDS API**

To disable the Backtrack feature for a DB cluster using the Amazon RDS API, use the `ModifyDBCluster` operation. Set the `BacktrackWindow` value to 0 (zero), and specify the DB cluster in the `DBClusterIdentifier` value. After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

**Testing Amazon Aurora using fault injection queries**

You can test the fault tolerance of your Amazon Aurora DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance and they enable you to schedule a simulated occurrence of one of the following events:
• A crash of a writer or reader DB instance
• A failure of an Aurora Replica
• A disk failure
• Disk congestion

When a fault injection query specifies a crash, it forces a crash of the Aurora DB instance. The other fault injection queries result in simulations of failure events, but don’t cause the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur for.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see Amazon Aurora connection management (p. 35).

Testing an instance crash

You can force a crash of an Amazon Aurora instance using the `ALTER SYSTEM CRASH` fault injection query.

For this fault injection query, a failover will not occur. If you want to test a failover, then you can choose the `Failover` instance action for your DB cluster in the RDS console, or use the `failover-db-cluster` AWS CLI command or the `FailoverDBCluster` RDS API operation.

**Syntax**

```
ALTER SYSTEM CRASH [ INSTANCE | DISPATCHER | NODE ];
```

**Options**

This fault injection query takes one of the following crash types:

• **INSTANCE** — A crash of the MySQL-compatible database for the Amazon Aurora instance is simulated.
• **DISPATCHER** — A crash of the dispatcher on the writer instance for the Aurora DB cluster is simulated. The dispatcher writes updates to the cluster volume for an Amazon Aurora DB cluster.
• **NODE** — A crash of both the MySQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated. For this fault injection simulation, the cache is also deleted.

The default crash type is **INSTANCE**.

Testing an Aurora replica failure

You can simulate the failure of an Aurora Replica using the `ALTER SYSTEM SIMULATE READ REPLICA FAILURE` fault injection query.

An Aurora Replica failure blocks all requests from the writer instance to an Aurora Replica or all Aurora Replicas in the DB cluster for a specified time interval. When the time interval completes, the affected Aurora Replicas will be automatically synced up with master instance.

**Syntax**

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT READ REPLICA FAILURE
```
Testing Amazon Aurora using fault injection queries

[ TO ALL | TO "replica name" ]
FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of requests to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no requests are blocked. If you specify 100, then all requests are blocked.

- **Failure type** — The type of failure to simulate. Specify TO ALL to simulate failures for all Aurora Replicas in the DB cluster. Specify TO and the name of the Aurora Replica to simulate a failure of a single Aurora Replica. The default failure type is TO ALL.

- **quantity** — The amount of time for which to simulate the Aurora Replica failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, 20 MINUTE will result in the simulation running for 20 minutes.

**Note**
Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long of a time interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.

Testing a disk failure

You can simulate a disk failure for an Aurora DB cluster using the ALTER SYSTEM SIMULATE DISK FAILURE fault injection query.

During a disk failure simulation, the Aurora DB cluster randomly marks disk segments as faulting. Requests to those segments will be blocked for the duration of the simulation.

Syntax

ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK FAILURE
[ IN DISK index | NODE index ]
FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.

- **DISK index** — A specific logical block of data to simulate the failure event for. If you exceed the range of available logical blocks of data, you will receive an error that tells you the maximum index value that you can specify. For more information, see Displaying volume status for an Aurora MySQL DB cluster (p. 747).

- **NODE index** — A specific storage node to simulate the failure event for. If you exceed the range of available storage nodes, you will receive an error that tells you the maximum index value that you can specify. For more information, see Displaying volume status for an Aurora MySQL DB cluster (p. 747).

- **quantity** — The amount of time for which to simulate the disk failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, 20 MINUTE will result in the simulation running for 20 minutes.
Testing disk congestion

You can simulate a disk failure for an Aurora DB cluster using the `ALTER SYSTEM SIMULATE DISK CONGESTION` fault injection query.

During a disk congestion simulation, the Aurora DB cluster randomly marks disk segments as congested. Requests to those segments will be delayed between the specified minimum and maximum delay time for the duration of the simulation.

**Syntax**

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK CONGESTION
   BETWEEN minimum AND maximum MILLISECONDS
   [ IN DISK index | NODE index ]
   FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };
```

**Options**

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of the disk to mark as congested during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.

- **DISK index Or NODE index** — A specific disk or node to simulate the failure event for. If you exceed the range of indexes for the disk or node, you will receive an error that tells you the maximum index value that you can specify.

- **minimum And maximum** — The minimum and maximum amount of congestion delay, in milliseconds. Disk segments marked as congested will be delayed for a random amount of time within the range of the minimum and maximum amount of milliseconds for the duration of the simulation.

- **quantity** — The amount of time for which to simulate the disk congestion. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified time unit. For example, `20 MINUTE` will result in the simulation running for 20 minutes.

Altering tables in Amazon Aurora using fast DDL

Amazon Aurora includes optimizations to run an `ALTER TABLE` operation in place, nearly instantaneously. The operation completes without requiring the table to be copied and without having a material impact on other DML statements. Because the operation doesn't consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes.

Aurora MySQL version 3 is compatible with the MySQL 8.0 feature called instant DDL. Aurora MySQL versions 1 and 2 use a different implementation called fast DDL.

**Topics**

- Instant DDL (Aurora MySQL version 3) (p. 742)
- Fast DDL (Aurora MySQL version 1 and 2) (p. 744)

**Instant DDL (Aurora MySQL version 3)**

The optimization performed by Aurora MySQL version 3 to improve the efficiency of some DDL operations is called instant DDL.
Aurora MySQL version 3 is compatible with the instant DDL from community MySQL 8.0. You perform an instant DDL operation by using the clause ALGORITHM=INSTANT with the ALTER TABLE statement. For syntax and usage details about instant DDL, see ALTER TABLE and Online DDL Operations in the MySQL documentation.

The following examples demonstrate the instant DDL feature. The ALTER TABLE statements add columns and change default column values. The examples include both regular and virtual columns, and both regular and partitioned tables. At each step, you can see the results by issuing SHOW CREATE TABLE and DESCRIBE statements.

```sql
mysql> CREATE TABLE t1 (a INT, b INT, KEY(b)) PARTITION BY KEY(b) PARTITIONS 6;
Query OK, 0 rows affected (0.02 sec)

mysql> ALTER TABLE t1 RENAME TO t2, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b SET DEFAULT 100, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b DROP DEFAULT, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ADD COLUMN c ENUM('a', 'b', 'c'), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 MODIFY COLUMN c ENUM('a', 'b', 'c', 'd', 'e'), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ADD COLUMN (d INT GENERATED ALWAYS AS (a + 1) VIRTUAL), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.02 sec)

mysql> ALTER TABLE t2 ALTER COLUMN a SET DEFAULT 20,
   ->   ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t2 (a INT, b INT) PARTITION BY LIST(a)(
   ->   PARTITION mypart1 VALUES IN (1,3,5),
   ->   PARTITION MyPart2 VALUES IN (2,4,6)
   -> )
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE t3 ALTER COLUMN a SET DEFAULT 20, ALTER COLUMN b SET DEFAULT 200,
   ->   ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (a INT, b INT) PARTITION BY RANGE(a)
   ->   (PARTITION p0 VALUES LESS THAN(100), PARTITION p1 VALUES LESS THAN(1000),
   ->   PARTITION p2 VALUES LESS THAN MAXVALUE);
Query OK, 0 rows affected (0.05 sec)

mysql> ALTER TABLE t4 ALTER COLUMN a SET DEFAULT 20,
   ->   ALTER COLUMN b SET DEFAULT 200, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

/* Sub-partitioning example */

mysql> CREATE TABLE ts (id INT, purchased DATE, a INT, b INT)
   ->   PARTITION BY RANGE( YEAR(purchased) )
   ->   SUBPARTITION BY HASH( TO_DAYS(purchased) )
   ->   SUBPARTITIONS 2 {
   ->   PARTICION p0 VALUES LESS THAN (1990),
   ->   PARTICION p1 VALUES LESS THAN (2000),
   ->   PARTICION p2 VALUES LESS THAN MAXVALUE
   -> };
```
Fast DDL (Aurora MySQL version 1 and 2)

In MySQL, many data definition language (DDL) operations have a significant performance impact. For example, suppose that you use an `ALTER TABLE` operation to add a column to a table. Depending on the algorithm specified for the operation, this operation can involve the following:

- Creating a full copy of the table
- Creating a temporary table to process concurrent data manipulation language (DML) operations
- Rebuilding all indexes for the table
- Applying table locks while applying concurrent DML changes
- Slowing concurrent DML throughput

The optimization performed by Aurora MySQL version 1 and 2 to improve the efficiency of some DDL operations is called fast DDL.

In Aurora MySQL version 3, Aurora uses the MySQL 8.0 feature called instant DDL. Aurora MySQL versions 1 and 2 use a different implementation called fast DDL.

**Important**
Currently, Aurora lab mode must be enabled to use fast DDL for Aurora MySQL. We don't recommend using fast DDL for production DB clusters. For information about enabling Aurora lab mode, see Amazon Aurora MySQL lab mode (p. 940).

Fast DDL limitations

Currently, fast DDL has the following limitations:

- Fast DDL only supports adding nullable columns, without default values, to the end of an existing table.
- Fast DDL doesn't work for partitioned tables.
- Fast DDL doesn't work for InnoDB tables that use the REDUNDANT row format.
- Fast DDL doesn't work for tables with full-text search indexes.
- If the maximum possible record size for the DDL operation is too large, fast DDL is not used. A record size is too large if it is greater than half the page size. The maximum size of a record is computed by adding the maximum sizes of all columns. For variable sized columns, according to InnoDB standards, extern bytes are not included for computation.

**Note**
The maximum record size check was added in Aurora 1.15.

Fast DDL syntax

```
ALTER TABLE `tbl_name` ADD COLUMN `col_name` `column_definition`
```

This statement takes the following options:
Altering tables in Amazon Aurora using fast DDL

- **tbl_name** — The name of the table to be modified.
- **col_name** — The name of the column to be added.
- **col_definition** — The definition of the column to be added.

**Note**
You must specify a nullable column definition without a default value. Otherwise, fast DDL isn't used.

**Fast DDL examples**

The following examples demonstrate the speedup from fast DDL operations. The first SQL example runs `ALTER TABLE` statements on a large table without using fast DDL. This operation takes substantial time. A CLI example shows how to enable fast DDL for the cluster. Then another SQL example runs the same `ALTER TABLE` statements on an identical table. With fast DDL enabled, the operation is very fast.

This example uses the `ORDERS` table from the TPC-H benchmark, containing 150 million rows. This cluster intentionally uses a relatively small instance class, to demonstrate how long `ALTER TABLE` statements can take when you can't use fast DDL. The example creates a clone of the original table containing identical data. Checking the `aurora_lab_mode` setting confirms that the cluster can't use fast DDL, because lab mode isn't enabled. Then `ALTER TABLE ADD COLUMN` statements take substantial time to add new columns at the end of the table.

```sql
mysql> create table orders_regular_ddl like orders;
Query OK, 0 rows affected (0.06 sec)

mysql> insert into orders_regular_ddl select * from orders;
Query OK, 150000000 rows affected (1 hour 1 min 25.46 sec)

mysql> select @@aurora_lab_mode;
+-------------------+
| @@aurora_lab_mode |
+-------------------+
|                 0 |
+-------------------+

mysql> ALTER TABLE orders_regular_ddl ADD COLUMN o_refunded boolean;
Query OK, 0 rows affected (40 min 31.41 sec)

mysql> ALTER TABLE orders_regular_ddl ADD COLUMN o_coverletter varchar(512);
Query OK, 0 rows affected (40 min 44.45 sec)
```

This example does the same preparation of a large table as the previous example. However, you can't simply enable lab mode within an interactive SQL session. That setting must be enabled in a custom parameter group. Doing so requires switching out of the `mysql` session and running some AWS CLI commands or using the AWS Management Console.

```sql
mysql> create table orders_fast_ddl like orders;
Query OK, 0 rows affected (0.02 sec)

mysql> insert into orders_fast_ddl select * from orders;
Query OK, 150000000 rows affected (58 min 3.25 sec)

mysql> set aurora_lab_mode=1;
ERROR 1238 (HY000): Variable 'aurora_lab_mode' is a read only variable
```

Enabling lab mode for the cluster requires some work with a parameter group. This AWS CLI example uses a cluster parameter group, to ensure that all DB instances in the cluster use the same value for the lab mode setting.
The following example shows the remaining steps after the parameter group change takes effect. It tests the \texttt{aurora\_lab\_mode} setting to make sure that the cluster can use fast DDL. Then it runs ALTER TABLE statements to add columns to the end of another large table. This time, the statements finish very quickly.

```sql
mysql> select @@aurora\_lab\_mode;
+-------------------+
| @@aurora\_lab\_mode |
+-------------------+
|                 1 |
+-------------------+

mysql> ALTER TABLE orders\_fast\_ddl ADD COLUMN o\_refunded boolean;
Query OK, 0 rows affected (1.51 sec)

mysql> ALTER TABLE orders\_fast\_ddl ADD COLUMN o\_coverletter varchar(512);
Query OK, 0 rows affected (0.40 sec)
```
Displaying volume status for an Aurora MySQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called protection groups.

The data in each protection group is replicated across six physical storage devices, called storage nodes. These storage nodes are allocated across three Availability Zones (AZs) in the AWS Region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see Introducing the Aurora storage engine on the AWS Database Blog.

You can simulate the failure of an entire storage node, or a single logical block of data within a storage node. To do so, you use the \texttt{ALTER SYSTEM SIMULATE DISK FAILURE} fault injection statement. For the statement, you specify the index value of a specific logical block of data or storage node. However, if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume, the statement returns an error. For more information about fault injection queries, see Testing Amazon Aurora using fault injection queries (p. 739).

You can avoid that error by using the \texttt{SHOW VOLUME STATUS} statement. The statement returns two server status variables, \texttt{Disks} and \texttt{Nodes}. These variables represent the total number of logical blocks of data and storage nodes, respectively, for the DB cluster volume.

\textbf{Note}

The \texttt{SHOW VOLUME STATUS} statement is available for Aurora version 1.12 and later. For more information about Aurora versions, see Database engine updates for Amazon Aurora MySQL (p. 991).

\section*{Syntax}

\texttt{SHOW VOLUME STATUS}

\section*{Example}

The following example illustrates a typical \texttt{SHOW VOLUME STATUS} result.

\begin{verbatim}
mysql> SHOW VOLUME STATUS;
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Disks         | 96    |
| Nodes         | 74    |
+---------------+-------+
\end{verbatim}

\section*{Tuning Aurora MySQL with wait events and thread states}

Wait events and thread states are an important tuning tool for Aurora MySQL. If you can find out why sessions are waiting for resources and what they are doing, you are better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions.
Important
The wait events and thread states in this section are specific to Aurora MySQL. Use the information in this section to tune only Amazon Aurora, not Amazon RDS for MySQL. Some wait events in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently. For example, Amazon Aurora storage works different from open source storage, so storage-related wait events indicate different resource conditions.

Topics
- Essential concepts for Aurora MySQL tuning (p. 748)
- Tuning Aurora MySQL with wait events (p. 750)
- Tuning Aurora MySQL with thread states (p. 786)

Essential concepts for Aurora MySQL tuning
Before you tune your Aurora MySQL database, make sure to learn what wait events and thread states are and why they occur. Also review the basic memory and disk architecture of Aurora MySQL when using the InnoDB storage engine. For a helpful architecture diagram, see the MySQL Reference Manual.

Topics
- Aurora MySQL wait events (p. 748)
- Aurora MySQL thread states (p. 749)
- Aurora MySQL memory (p. 749)
- Aurora MySQL processes (p. 749)

Aurora MySQL wait events
A wait event indicates a resource for which a session is waiting. For example, the wait event io/socket/sql/client_connection indicates that a thread is in the process of handling a new connection. Typical resources that a session waits for include the following:

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.
Aurora MySQL thread states

A general thread state is a state value that is associated with general query processing. For example, the thread state sending data indicates that a thread is reading and filtering rows for a query to determine the correct result set.

You can use thread states to tune Aurora MySQL in a similar fashion to how you use wait events. For example, frequent occurrences of sending data usually indicate that a query isn't using an index. For more information about thread states, see General Thread States in the MySQL Reference Manual.

When you use Performance Insights, one of the following conditions is true:

- Performance Schema is turned on – Aurora MySQL shows wait events rather than the thread state.
- Performance Schema isn't turned on – Aurora MySQL shows the thread state.

We recommend that you configure the Performance Schema for automatic management. The Performance Schema provides additional insights and better tools to investigate potential performance problems. For more information, see Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 469).

Aurora MySQL memory

In Aurora MySQL, the most important memory areas are the buffer pool and log buffer.

Topics

- Buffer pool (p. 749)

Buffer pool

The buffer pool is the shared memory area where Aurora MySQL caches table and index data. Queries can access frequently used data directly from memory without reading from disk.

The buffer pool is structured as a linked list of pages. A page can hold multiple rows. Aurora MySQL uses a least recently used (LRU) algorithm to age pages out of the pool.

For more information, see Buffer Pool in the MySQL Reference Manual.

Aurora MySQL processes

Aurora MySQL uses a process model that is very different from Aurora PostgreSQL.

Topics

- MySQL server (mysqld) (p. 749)
- Threads (p. 750)
- Thread pool (p. 750)

MySQL server (mysqld)

The MySQL server is a single operating-system process named mysqld. The MySQL server doesn't spawn additional processes. Thus, an Aurora MySQL database uses mysqld to perform most of its work.

When the MySQL server starts, it listens for network connections from MySQL clients. When a client connects to the database, mysqld opens a thread.
Threads

Connection manager threads associate each client connection with a dedicated thread. This thread manages authentication, runs statements, and returns results to the client. Connection manager creates new threads when necessary.

The thread cache is the set of available threads. When a connection ends, MySQL returns the thread to the thread cache if the cache isn’t full. The thread_cache_size system variable determines the thread cache size.

Thread pool

The thread pool consists of a number of thread groups. Each group manages a set of client connections. When a client connects to the database, the thread pool assigns the connections to thread groups in round-robin fashion. The thread pool separates connections and threads. There is no fixed relationship between connections and the threads that run statements received from those connections.

Tuning Aurora MySQL with wait events

The following table summarizes the Aurora MySQL wait events that most commonly indicate performance problems. The following wait events are a subset of the list in Aurora MySQL wait events (p. 972).

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpu (p. 751)</td>
<td>This event occurs when a thread is active in CPU or is waiting for CPU.</td>
</tr>
<tr>
<td>io/aurora_redo_log_flush (p. 754)</td>
<td>This event occurs when a session is writing persistent data to Aurora storage.</td>
</tr>
<tr>
<td>io/aurora_respond_to_client (p. 757)</td>
<td>This event occurs when a thread is waiting to return a result set to a client.</td>
</tr>
<tr>
<td>io/file/innodb/innodb_data_file (p. 759)</td>
<td>This event occurs when there are threads waiting on I/O operations from storage.</td>
</tr>
<tr>
<td>io/socket/sql/client_connection (p. 761)</td>
<td>This event occurs when a thread is in the process of handling a new connection.</td>
</tr>
<tr>
<td>io/table/sql/handler (p. 763)</td>
<td>This event occurs when work has been delegated to a storage engine.</td>
</tr>
<tr>
<td>synch/cond/mysys/my_thread_var::suspend (p. 766)</td>
<td>This event occurs when threads are suspended because they are waiting on a condition.</td>
</tr>
<tr>
<td>synch/cond/sql/MDL_context::COND_wait_status (p. 767)</td>
<td>This event occurs when there are threads waiting on a table metadata lock.</td>
</tr>
<tr>
<td>synch/mutex/innodb/aurora_lock_thread_slot_futex (p. 774)</td>
<td>This event occurs when one session has locked a row for an update, and another session tries to update the same row.</td>
</tr>
<tr>
<td>synch/mutex/innodb/buf_pool_mutex (p. 776)</td>
<td>This event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.</td>
</tr>
<tr>
<td>synch/mutex/innodb/fil_system_mutex (p. 778)</td>
<td>This event occurs when a session is waiting to access the tablespace memory cache.</td>
</tr>
</tbody>
</table>
### CPU

The **cpu** wait event occurs when a thread is active in CPU or is waiting for CPU.

**Topics**

- Supported engine versions (p. 751)
- Context (p. 751)
- Likely causes of increased waits (p. 752)
- Actions (p. 752)

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

**Context**

For every vCPU, a connection can run work on this CPU. In some situations, the number of active connections that are ready to run is higher than the number of vCPUs. This imbalance results in connections waiting for CPU resources. If the number of active connections stays consistently higher than the number of vCPUs, then your instance experiences CPU contention. The contention causes the cpu wait event to occur.

**Note**

The Performance Insights metric for CPU is `DBLoadCPU`. The value for `DBLoadCPU` can differ from the value for the CloudWatch metric `CPUUtilization`. The latter metric is collected from the HyperVisor for a database instance.

Performance Insights OS metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>synch/mutex/innodb/trx_sys_mutex (p. 781)</td>
<td>This event occurs when there is high database activity with a large number of transactions.</td>
</tr>
<tr>
<td>synch/rwlock/innodb/hash_table_locks (p. 782)</td>
<td>This event occurs when there is contention on modifying the hash table that maps the buffer cache.</td>
</tr>
<tr>
<td>synch/sxlock/innodb/hash_table_locks (p. 784)</td>
<td>This event occurs when pages not found in the buffer pool must be read from a file.</td>
</tr>
</tbody>
</table>
Likely causes of increased waits

When this event occurs more than normal, possibly indicating a performance problem, typical causes include the following:

- Analytic queries
- Highly concurrent transactions
- Long-running transactions
- A sudden increase in the number of connections, known as a *login storm*
- An increase in context switching

Actions

If the *cpu* wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Depending on the cause of the increase in CPU utilization, consider the following strategies:

- Increase the CPU capacity of the host. This approach typically gives only temporary relief.
- Identify top queries for potential optimization.
- Redirect some read-only workload to reader nodes, if applicable.

Topics

- Identify the sessions or queries that are causing the problem (p. 752)
- Analyze and optimize the high CPU workload (p. 753)

Identify the sessions or queries that are causing the problem

To find the sessions and queries, look at the Top SQL table in Performance Insights for the SQL statements that have the highest CPU load. For more information, see Analyzing metrics with the Performance Insights dashboard (p. 476).

Typically, one or two SQL statements consume the majority of CPU cycles. Concentrate your efforts on these statements. Suppose that your DB instance has 2 vCPUs with a DB load of 3.1 average active sessions (AAS), all in the CPU state. In this case, your instance is CPU bound. Consider the following strategies:

- Upgrade to a larger instance class with more vCPUs.
- Tune your queries to have lower CPU load.

In this example, the top SQL queries have a DB load of 1.5 AAS, all in the CPU state. Another SQL statement has a load of 0.1 in the CPU state. In this example, if you stopped the lowest-load SQL statement, you don't significantly reduce database load. However, if you optimize the two high-load queries to be twice as efficient, you eliminate the CPU bottleneck. If you reduce the CPU load of 1.5 AAS by 50 percent, the AAS for each statement decreases to 0.75. The total DB load spent on CPU is now 1.6 AAS. This value is below the maximum vCPU line of 2.0.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights. Also see the AWS Support article How can I troubleshoot and resolve high CPU utilization on my Amazon RDS for MySQL instances?
Analyze and optimize the high CPU workload

After you identify the query or queries increasing CPU usage, you can either optimize them or end the connection. The following example shows how to end a connection.

```
CALL mysql.rds_kill(processID);
```

For more information, see `mysql.rds_kill` in the Amazon RDS User Guide.

If you end a session, the action might trigger a long rollback.

Follow the guidelines for optimizing queries

To optimize queries, consider the following guidelines:

- Run the `EXPLAIN` statement.
  
  This command shows the individual steps involved in running a query. For more information, see Optimizing Queries with EXPLAIN in the MySQL documentation.

- Run the `SHOW PROFILE` statement.
  
  Use this statement to review profile details that can indicate resource usage for statements that are run during the current session. For more information, see SHOW PROFILE Statement in the MySQL documentation.

- Run the `ANALYZE TABLE` statement.
  
  Use this statement to refresh the index statistics for the tables accessed by the high-CPU consuming query. By analyzing the statement, you can help the optimizer choose an appropriate execution plan. For more information, see ANALYZE TABLE Statement in the MySQL documentation.

Follow the guidelines for improving CPU usage

To improve CPU usage in a database instance, follow these guidelines:

- Ensure that all queries are using proper indexes.
- Find out whether you can use Aurora parallel queries. You can use this technique to reduce CPU usage on the head node by pushing down function processing, row filtering, and column projection for the WHERE clause.
- Find out whether the number of SQL executions per second meets the expected thresholds.
- Find out whether index maintenance or new index creation takes up CPU cycles needed by your production workload. Schedule maintenance activities outside of peak activity times.
- Find out whether you can use partitioning to help reduce the query data set. For more information, see the blog post How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads.

Check for connection storms

If the `DBLoadCPU` metric is not very high, but the `CPUUtilization` metric is high, the cause of the high CPU utilization lies outside of the database engine. A classic example is a connection storm.

Check whether the following conditions are true:

- There is an increase in both the Performance Insights CPUUtilization metric and the Amazon CloudWatch DatabaseConnections metric.
• The number of threads in the CPU is greater than the number of vCPUs.

If the preceding conditions are true, consider decreasing the number of database connections. For example, you can use a connection pool such as RDS Proxy. To learn the best practices for effective connection management and scaling, see the whitepaper Amazon Aurora MySQL DBA Handbook for Connection Management.

io/aurora_redo_log_flush

The io/aurora_redo_log_flush event occurs when a session is writing persistent data to Amazon Aurora storage.

Topics

• Supported engine versions (p. 754)
• Context (p. 754)
• Likely causes of increased waits (p. 754)
• Actions (p. 755)

Supported engine versions

This wait event information is supported for the following engine versions:

• Aurora MySQL version 2.x up to 2.09.2
• Aurora MySQL version 1.x up to 1.23.1

Context

The io/aurora_redo_log_flush event is for a write input/output (I/O) operation in Aurora MySQL.

Likely causes of increased waits

For data persistence, commits require a durable write to stable storage. If the database is doing too many commits, there is a wait event on the write I/O operation, the io/aurora_redo_log_flush wait event.

In the following examples, 50,000 records are inserted into an Aurora MySQL DB cluster using the db.r5.xlarge DB instance class:

• In the first example, each session inserts 10,000 records row by row. By default, if a data manipulation language (DML) command isn't within a transaction, Aurora MySQL uses implicit commits. Autocommit is turned on. This means that for each row insertion there is a commit. Performance Insights shows that the connections spend most of their time waiting on the io/aurora_redo_log_flush wait event.
This is caused by the simple insert statements used.

The 50,000 records take 3.5 minutes to be inserted.
- In the second example, inserts are made in 1,000 batches, that is each connection performs 10 commits instead of 10,000. Performance Insights shows that the connections don’t spend most of their time on the `io/aurora_redo_log_flush` wait event.

The 50,000 records take 4 seconds to be inserted.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Identify the problematic sessions and queries**

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful AWS Database Blog post, see Analyze Amazon Aurora MySQL Workloads with Performance Insights.

**To identify sessions and queries causing a bottleneck**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose your DB instance.
4. In Database load, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

    The queries at the top of the list are causing the highest load on the database.

**Group your write operations**

The following examples trigger the `io/aurora_redo_log_flush` wait event. (Autocommit is turned on.)

```sql
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx', 'xxxxx');
... 
```
To reduce the time spent waiting on the `io/aurora_redo_log_flush` wait event, group your write operations logically into a single commit to reduce persistent calls to storage.

**Turn off autocommit**

Turn off autocommit before making large changes that aren't within a transaction, as shown in the following example.

```sql
SET SESSION AUTOCOMMIT=OFF;
UPDATE `sampleDB`.'sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.'sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.'sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
....
UPDATE `sampleDB`.'sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
DELETE FROM `sampleDB`.'sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.'sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.'sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.'sampleTable` WHERE sampleCol1=xx;
-- Other DML statements here
COMMIT;
SET SESSION AUTOCOMMIT=ON;
```

**Use transactions**

You can use transactions, as shown in the following example.

```sql
BEGIN
INSERT INTO `sampleDB`.'sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.'sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.'sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
INSERT INTO `sampleDB`.'sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
DELETE FROM `sampleDB`.'sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.'sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.'sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.'sampleTable` WHERE sampleCol1=xx;
-- Other DML statements here
END
```

**Use batches**

You can make changes in batches, as shown in the following example. However, using batches that are too large can cause performance issues, especially in read replicas or when doing point-in-time recovery (PITR).

```sql
INSERT INTO `sampleDB`.'sampleTable` (sampleCol2, sampleCol3) VALUES
```
io/aurora_respond_to_client

The io/aurora_respond_to_client event occurs when a thread is waiting to return a result set to a client.

Topics
- Supported engine versions (p. 757)
- Context (p. 757)
- Likely causes of increased waits (p. 757)
- Actions (p. 758)

Supported engine versions

This wait event information is supported for the following engine versions:

- For Aurora MySQL version 2, version 2.07.7 and higher 2.07 versions, 2.09.3 and higher 2.09 versions, and 2.10.2 and higher 2.10 versions
- For Aurora MySQL version 1, version 1.22.6 and higher

In versions before version 1.22.6, 2.07.7, 2.09.3, and 2.10.2, this wait event erroneously includes idle time.

Context

The event io/aurora_respond_to_client indicates that a thread is waiting to return a result set to a client.

The query processing is complete, and the results are being returned back to the application client. However, because there isn't enough network bandwidth on the DB cluster, a thread is waiting to return the result set.

Likely causes of increased waits

When the io/aurora_respond_to_client event appears more than normal, possibly indicating a performance problem, typical causes include the following:

DB instance class insufficient for the workload

The DB instance class used by the DB cluster doesn't have the necessary network bandwidth to process the workload efficiently.

Large result sets

There was an increase in size of the result set being returned, because the query returns higher numbers of rows. The larger result set consumes more network bandwidth.

Increased load on the client

There might be CPU pressure, memory pressure, or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora MySQL DB cluster.
Increased network latency

There might be increased network latency between the Aurora MySQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Identify the sessions and queries causing the events (p. 758)
- Scale the DB instance class (p. 758)
- Check workload for unexpected results (p. 758)
- Distribute workload with reader instances (p. 759)
- Use the SQL_BUFFER_RESULT modifier (p. 759)

Identify the sessions and queries causing the events

You can use Performance Insights to show queries blocked by the io/aurora_respond_to_client wait event. Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Scale the DB instance class

Check for the increase in the value of the Amazon CloudWatch metrics related to network throughput, such as NetworkReceiveThroughput and NetworkTransmitThroughput. If the DB instance class network bandwidth is being reached, you can scale the DB instance class used by the DB cluster by modifying the DB cluster. A DB instance class with larger network bandwidth returns data to clients more efficiently.

For information about monitoring Amazon CloudWatch metrics, see Viewing metrics in the Amazon RDS console (p. 449). For information about DB instance classes, see Aurora DB instance classes (p. 56). For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 248).

Check workload for unexpected results

Check the workload on the DB cluster and make sure that it isn't producing unexpected results. For example, there might be queries that are returning a higher number of rows than expected. In this case,
you can use Performance Insights counter metrics such as `Innodb_rows_read`. For more information, see Performance Insights counter metrics (p. 546).

**Distribute workload with reader instances**

You can distribute read-only workload with Aurora replicas. You can scale horizontally by adding more Aurora replicas. Doing so can result in an increase in the throttling limits for network bandwidth. For more information, see Amazon Aurora DB clusters (p. 3).

**Use the SQL_BUFFER_RESULT modifier**

You can add the `SQL_BUFFER_RESULT` modifier to `SELECT` statements to force the result into a temporary table before they are returned to the client. This modifier can help with performance issues when InnoDB locks aren't being freed because queries are in the `io/aurora_respond_to_client` wait state. For more information, see SELECT Statement in the MySQL documentation.

**io/file/innodb/innodb_data_file**

The `io/file/innodb/innodb_data_file` event occurs when there are threads waiting on I/O operations from storage.

**Topics**

- Supported engine versions (p. 759)
- Context (p. 759)
- Likely causes of increased waits (p. 759)
- Actions (p. 760)

**Supported engine versions**

This wait event information is supported for the following engine versions:

Aurora MySQL version 1, up to 1.23.1

**Context**

The InnoDB buffer pool is the shared memory area where Aurora MySQL caches table and index data. Queries can access frequently used data directly from memory without reading from disk. The event `io/file/innodb/innodb_data_file` indicates that processing the query requires a storage I/O operation because the data isn't available in the buffer pool.

RDS typically generates this event when it performs I/O operations such as reads, writes, or flushes. RDS also generates this event when it runs data definition language (DDL) statements. This happens because these statements involve creating, deleting, opening, closing, or renaming InnoDB data files.

**Likely causes of increased waits**

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A spike in an application workload that's I/O intensive can increase the occurrence of this wait event because more queries need to read from storage.

  A significant increase in the number of pages being scanned causes least recently used (LRU) pages to be evicted from the buffer pool at a faster rate. Inefficient query plans can contribute to the problem.
Query plans can be inefficient because of outdated states, missing indexes, or inefficiently written queries.

- Storage capacity is sufficient but network throughput exceeds the maximum bandwidth for the instance class, causing I/O throttling. For information about network throughput capacity for different instance classes, see Hardware specifications for DB instance classes for Aurora (p. 64).
- Operations involving DDL statements or transactions that read, insert, or modify a large number of rows. For example, bulk inserts or update or delete statements can specify a wide range of values in the WHERE clause.
- SELECT queries that scan a large number of rows. For example, queries that use BETWEEN or IN clauses can specify wide ranges of data.
- A low buffer pool hit ratio because the buffer pool is too small. The smaller the buffer pool, the more frequently LRU pages are flushed out. This increases the likelihood that the requested data is read from disk.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Identify and optimize problem queries (p. 760)
- Scale up your instance (p. 760)
- Make your buffer scan resistant (p. 761)

**Identify and optimize problem queries**

Find the query digest responsible for this wait from Performance Insights. Check the query's statement execution plan to see if the query can be optimized to read fewer pages into the InnoDB buffer pool. Doing so reduces the number of least recently used pages that are evicted from the buffer pool. This increases the cache hit efficiency of the buffer pool, which lessens the load on the I/O subsystem.

To check a query's statement execution plan, run the `EXPLAIN` statement. This command shows the individual steps involved in query execution. For more information, see Optimizing Queries with EXPLAIN in the MySQL documentation.

**Scale up your instance**

If your `io/file/innodb/innodb_data_file` wait events are caused by insufficient network or buffer pool capacity, consider scaling up your RDS instance to a higher instance class type.

- Network throughput – Check for an increase in the value of the Amazon CloudWatch metrics `network receive throughput` and `network transmit throughput`. If your instance has reached the network bandwidth limit for your instance class, consider scaling up your RDS instance to a higher instance class type. For more information, see Hardware specifications for DB instance classes for Aurora (p. 64).
- Buffer pool size – Check for a low buffer pool hit ratio. To monitor this value in Performance Insights, check the `db.Cache.innoDB_buffer_pool_hit_rate.avg` metric. To add this metric, choose Manage metrics, and choose `innoDB_buffer_pool_hit_rate` under Cache on the Database metrics tab.

If the hit ratio is low, consider scaling up your RDS instance to a higher instance class type.

**Note**

The DB instance parameter that controls the buffer pool size is `innodb_buffer_pool_size`. You can modify this parameter value, but we recommend that you scale up your instance class instead because the default value is optimized for each instance class.
Make your buffer scan resistant

If you have a mix of reporting and online transaction processing (OLTP) queries, consider making your buffer pool scan resistant. To do this, tune the parameters `innodb_old_blocks_pct` and `innodb_old_blocks_time`. The effects of these parameters can vary based on your instance class hardware, data, and workload type. We highly recommend that you benchmark your system before you set these parameters in your production environment. For more information, see Making the Buffer Pool Scan Resistant in the MySQL documentation.

**io/socket/sql/client_connection**

The `io/socket/sql/client_connection` event occurs when a thread is in the process of handling a new connection.

**Topics**
- Supported engine versions (p. 761)
- Context (p. 761)
- Likely causes of increased waits (p. 761)
- Actions (p. 761)

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

**Context**

The event `io/socket/sql/client_connection` indicates that mysqld is busy creating threads to handle incoming new client connections. In this scenario, the processing of servicing new client connection requests slows down while connections wait for the thread to be assigned. For more information, see MySQL server (mysqld) (p. 749).

** Likely causes of increased waits**

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- There is a sudden increase in new user connections from the application to your Amazon RDS instance.
- Your DB instance can't process new connections because the network, CPU, or memory is being throttled.

**Actions**

If `io/socket/sql/client_connection` dominates database activity, it doesn't necessarily indicate a performance problem. In a database that isn't idle, a wait event is always on top. Act only when performance degrades. We recommend different actions depending on the causes of your wait event.

**Topics**
- Identify the problematic sessions and queries (p. 762)
- Follow best practices for connection management (p. 762)
Identify the problematic sessions and queries

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful blog post, see Analyze Amazon Aurora MySQL Workloads with Performance Insights.

To identify sessions and queries causing a bottleneck

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose your DB instance.
4. In Database load, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The queries at the top of the list are causing the highest load on the database.

Follow best practices for connection management

To manage your connections, consider the following strategies:

- Use connection pooling.
  
  You can gradually increase the number of connections as required. For more information, see the whitepaper Amazon Aurora MySQL Database Administrator's Handbook.
- Use a reader node to redistribute read-only traffic.
  
  For more information, see Aurora Replicas (p. 73) and Amazon Aurora connection management (p. 35).

Scale up your instance if resources are being throttled

Look for examples of throttling in the following resources:

- CPU
  
  Check your Amazon CloudWatch metrics for high CPU usage.
- Network
  
  Check for an increase in the value of the CloudWatch metrics network receive throughput and network transmit throughput. If your instance has reached the network bandwidth limit for your instance class, consider scaling up your RDS instance to a higher instance class type. For more information, see Aurora DB instance classes (p. 56).
- Freeable memory
  
  Check for a drop in the CloudWatch metric FreeableMemory. Also, consider turning on Enhanced Monitoring. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 518).
Check the top hosts and top users

Use Performance Insights to check the top hosts and top users. For more information, see Analyzing metrics with the Performance Insights dashboard (p. 476).

Query the performance_schema tables

To get an accurate count of the current and total connections, query the performance_schema tables. With this technique, you identify the source user or host that is responsible for creating a high number of connections. For example, query the performance_schema tables as follows.

```sql
SELECT * FROM performance_schema.accounts;
SELECT * FROM performance_schema.users;
SELECT * FROM performance_schema.hosts;
```

Check the thread states of your queries

If your performance issue is ongoing, check the thread states of your queries. In the mysql client, issue the following command.

```sql
show processlist;
```

Audit your requests and queries

To check the nature of the requests and queries from user accounts, use Aurora MySQL Advanced Auditing. To learn how to turn on auditing, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 824).

Pool your database connections

Consider using Amazon RDS Proxy for connection management. By using RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. For more information, see Using Amazon RDS Proxy (p. 1429).

io/table/sql/handler

The io/table/sql/handler event occurs when work has been delegated to a storage engine.

Topics

- Supported engine versions (p. 763)
- Context (p. 764)
- Likely causes of increased waits (p. 764)
- Actions (p. 764)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1
Context

The event `io/table` indicates a wait for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. The `io/table/sql/handler` event indicates an increase in workload activity.

A `handler` is a routine specialized in a certain type of data or focused on certain special tasks. For example, an event handler receives and digests events and signals from the operating system or from a user interface. A memory handler performs tasks related to memory. A file input handler is a function that receives file input and performs special tasks on the data, according to context.

Views such as `performance_schema.events_waits_current` often show `io/table/sql/handler` when the actual wait is a nested wait event such as a lock. When the actual wait isn't `io/table/sql/handler`, Performance Insights reports the nested wait event. When Performance Insights reports `io/table/sql/handler`, it represents the actual I/O wait and not a hidden nested wait event. For more information, see Performance Schema Atom and Molecule Events in the MySQL Reference Manual.

The `io/table/sql/handler` event often appears in top wait events with I/O waits such as `io/aurora_redo_log_flush` and `io/file/innodb/innodb_data_file`.

Likely causes of increased waits

In Performance Insights, sudden spikes in the `io/table/sql/handler` event indicate an increase in workload activity. Increased activity means increased I/O.

Performance Insights filters the nesting event IDs and doesn't report a `io/table/sql/handler` wait when the underlying nested event is a lock wait. For example, if the root cause event is `synch/mutex/innodb/aurora_lock_thread_slot_futex`, Performance Insights displays this wait in top wait events and not `io/table/sql/handler`.

In views such as `performance_schema.events_waits_current`, waits for `io/table/sql/handler` often appear when the actual wait is a nested wait event such as a lock. When the actual wait differs from `io/table/sql/handler`, Performance Insights looks up the nested wait and reports the actual wait instead of `io/table/sql/handler`. When Performance Insights reports `io/table/sql/handler`, the real wait is `io/table/sql/handler` and not a hidden nested wait event. For more information, see Performance Schema Atom and Molecule Events in the MySQL 5.7 Reference Manual.

Actions

If this wait event dominates database activity, it doesn't necessarily indicate a performance problem. A wait event is always on top when the database is active. You need to act only when performance degrades.

We recommend different actions depending on the other wait events that you see.

Topics

- Identify the sessions and queries causing the events (p. 764)
- Check for a correlation with Performance Insights counter metrics (p. 765)
- Check for other correlated wait events (p. 765)

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.
To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Check for a correlation with Performance Insights counter metrics

Check for Performance Insights counter metrics such as Innodb_rows_changed. If counter metrics are correlated with io/table/sql/handler, follow these steps:

1. In Performance Insights, look for the SQL statements accounting for the io/table/sql/handler top wait event. If possible, optimize this statement so that it returns fewer rows.
2. Retrieve the top tables from the schema_table_statistics and x$schema_table_statistics views. These views show the amount of time spent per table. For more information, see The schema_table_statistics and x$schema_table_statistics Views in the MySQL Reference Manual.

By default, rows are sorted by descending total wait time. Tables with the most contention appear first. The output indicates whether time is spent on reads, writes, fetches, inserts, updates, or deletes. The following example was run on an Aurora MySQL 2.09.1 instance.

```sql
mysql> select * from sys.schema_table_statistics limit 1\G
*************************** 1. row ***************************
table_schema: read_only_db
table_name: sbtest41
total_latency: 54.11 m
rows_fetched: 6001557
fetch_latency: 39.14 m
rows_inserted: 14833
insert_latency: 5.78 m
rows_updated: 30470
update_latency: 5.39 m
rows_deleted: 14833
delete_latency: 3.81 m
io_read_requests: NULL
io_read: NULL
io_read_latency: NULL
io_write_requests: NULL
io_write: NULL
io_write_latency: NULL
io_misc_requests: NULL
io_misc_latency: NULL
1 row in set (0.11 sec)
```

Check for other correlated wait events

If synch/sxlock/innodb/btr_search_latch and io/table/sql/handler contribute most to the DB load anomaly together, check whether the innodb_adaptive_hash_index variable is turned on. If it is, consider increasing the innodb_adaptive_hash_index_parts parameter value.
If the Adaptive Hash Index is turned off, and the situation warrants it, consider turning it on. To learn more about the MySQL Adaptive Hash Index, see the following resources:

- The article Is Adaptive Hash Index in InnoDB right for my workload? on the Percona website
- Adaptive Hash Index in the *MySQL Reference Manual*
- The article Contention in MySQL InnoDB: Useful Info From the Semaphores Section on the Percona website

The Adaptive Hash Index isn’t a viable option for Aurora reader nodes. In some cases, performance might be poor on a reader node when `synch/sxlock/innodb/btr_search_latch` and `io/table/sql/handler` are dominant. If so, consider redirecting the workload temporarily to the writer node and turning on the Adaptive Hash Index.

**synch/cond/mysys/my_thread_var::suspend**

The `synch/cond/mysys/my_thread_var::suspend` wait event indicates that threads are suspended because they are waiting on a condition.

**Topics**

- Supported engine versions (p. 766)
- Context (p. 766)
- Likely causes of increased waits (p. 766)
- Actions (p. 767)

**Supported engine versions**

This wait event information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2
- Aurora MySQL version 1 up to 1.23.1

**Context**

The event `synch/cond/mysys/my_thread_var::suspend` indicates that threads are suspended because they are waiting on a condition. For example, this wait event occurs when threads are waiting for a table-level lock. In this case, we recommend that you investigate your workload to determine which threads might be acquiring table locks on your DB instance.

**Likely causes of increased waits**

When the `synch/cond/mysys/my_thread_var::suspend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

**Thread waiting on a table-level lock**

One or more threads are waiting on a table-level lock. In this case, the thread state is *Waiting for table level lock*.

**Data being sent to the mysqldump client**

One or more threads are waiting because you are using mysqldump, and the result is being sent to the mysqldump client. In this case, the thread state is *Writing to net*.
Actions

We recommend different actions depending on the causes of your wait event.

Topics

• Avoid locking tables (p. 767)
• Make sure that backup tools don’t lock tables (p. 767)
• Long-running sessions that lock tables (p. 767)
• Non-InnoDB temporary table (p. 767)

Avoid locking tables

Make sure that the application is not explicitly locking the tables using the `LOCK TABLE` statement. You can check the statements run by applications using Advanced Auditing. For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 824).

Make sure that backup tools don’t lock tables

If you are using a backup tool, make sure that it isn’t locking tables. For example, if you are using `mysqldump`, use the `--single-transaction` option so that it doesn’t lock tables.

Long-running sessions that lock tables

There might be long-running sessions that have explicitly locked tables. Run the following SQL statement to check for such sessions.

```
SELECT p.id as session_id, p.user, p.host, p.db, p.command, p.time, p.state,
      SUBSTRING(p.info, 1, 50) AS INFO,
      t.trx_started, unix_timestamp(now()) - unix_timestamp(t.trx_started) as trx_age_seconds,
      t.trx_rows_modified, t.trx_isolation_level
FROM information_schema.processlist p
LEFT JOIN information_schema.innodb_trx t
ON p.id = t.trx_mysql_thread_id;
```

When you identify the session, your options include the following:

• Contact the application owner or the user.
• If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see Ending a session or query in the Amazon RDS User Guide.

For more information about identifying blocking transactions, see Using InnoDB Transaction and Locking Information in the MySQL documentation.

Non-InnoDB temporary table

If you are using a non-InnoDB temporary table, then the database doesn't use row-level locking, which can result in table locks. MyISAM and MEMORY tables are examples of a non-InnoDB temporary table. If you are using a non-InnoDB temporary table, consider switching to an InnoDB memory table.

synch/cond/sql/MDL_context::COND_wait_status

The synch/cond/sql/MDL_context::COND_wait_status event occurs when there are threads waiting on a table metadata lock.

Topics
• Supported engine versions (p. 768)
• Context (p. 768)
• Likely causes of increased waits (p. 768)
• Actions (p. 769)

Supported engine versions

This wait event information is supported for the following engine versions:

• Aurora MySQL version 2, up to 2.09.2
• Aurora MySQL version 1, up to 1.23.1

Context

The event `synch/cond/sql/MDL_context::COND_wait_status` indicates that there are threads waiting on a table metadata lock. In some cases, one session holds a metadata lock on a table and another session tries to get the same lock on the same table. In such a case, the second session waits on the `synch/cond/sql/MDL_context::COND_wait_status` wait event.

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies to tables, schemas, scheduled events, tablespaces, and user locks acquired with the `get_lock` function, and stored programs. Stored programs include procedures, functions, and triggers. For more information, see Metadata locking in the MySQL documentation.

The MySQL process list shows this session in the state `waiting for metadata lock`. In Performance Insights, if `Performance_schema` is turned on, the event `synch/cond/sql/MDL_context::COND_wait_status` appears.

The default timeout for a query waiting on a metadata lock is based on the value of the `lock_wait_timeout` parameter, which defaults to 31,536,000 seconds (365 days).

For more details on different InnoDB locks and the types of locks that can cause conflicts, see InnoDB Locking in the MySQL documentation.

Likely causes of increased waits

When the `synch/cond/sql/MDL_context::COND_wait_status` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Long-running transactions

One or more transactions are modifying a large amount of data and holding locks on tables for a very long time.

Idle transactions

One or more transactions remain open for a long time, without being committed or rolled back.

DDL statements on large tables

One or more data definition statements (DDL) statements, such as `ALTER TABLE` commands, were run on very large tables.

Explicit table locks

There are explicit locks on tables that aren't being released in a timely manner. For example, an application might run `LOCK TABLE` statements improperly.
Actions

We recommend different actions depending on the causes of your wait event and on the version of the Aurora MySQL DB cluster.

Topics

- Identify the sessions and queries causing the events (p. 769)
- Check for past events (p. 769)
- Run queries on Aurora MySQL version 1 (p. 770)
- Run queries on Aurora MySQL version 2 (p. 772)
- Respond to the blocking session (p. 774)

Identify the sessions and queries causing the events

You can use Performance Insights to show queries blocked by the `synch/cond/sql/MDL_context::COND_wait_status` wait event. However, to identify the blocking session, query metadata tables from `performance_schema` and `information_schema` on the DB cluster.

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn’t optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard for that DB instance appears.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

    The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Check for past events

You can gain insight into this wait event to check for past occurrences of it. To do so, complete the following actions:

- Check the data manipulation language (DML) and DDL throughput and latency to see if there were any changes in workload.

    You can use Performance Insights to find queries waiting on this event at the time of the issue. Also, you can view the digest of the queries run near the time of issue.

- If audit logs or general logs are turned on for the DB cluster, you can check for all queries run on the objects (schema.table) involved in the waiting transaction. You can also check for the queries that completed running before the transaction.

The information available to troubleshoot past events is limited. Performing these checks doesn’t show which object is waiting for information. However, you can identify tables with heavy load at the time of
the event and the set of frequently operated rows causing conflict at the time of issue. You can then use
this information to reproduce the issue in a test environment and provide insights about its cause.

Run queries on Aurora MySQL version 1

In Aurora MySQL version 1, you can query tables in information_schema and performance_schema
to identify a blocking session. To run the queries, make sure that the DB cluster is configured
with the performance_schema consumer events_statements_history. Also,
maintain an adequate number of queries in events_statements_history table in
performance_schema. You control the number of queries maintained in that table with the
performance_schema_events_statements_history_size parameter. If the required data isn't
available in performance_schema, you can check the audit logs or general logs.

An example can illustrate how to query tables to identify blocking queries and sessions. In this example,
every session runs fewer than 10 statements and required consumers are enabled on the DB cluster.

In the following process list output, process ID 59 (running the TRUNCATE command) and process ID 53
(running the INSERT command) have been waiting on a metadata lock for 33 seconds. Also, both of the
threads are running queries on same table named sbtest.sbtest1.

```
MySQL [(none)]> select @@version, @@aurora_version;

| 16 rows in set (0.00 sec)

Given this output, run the following query. This query identifies transactions that have been running for longer than 33 seconds with connection ID 59 waiting for a lock on a table for same amount of time.

```
MySQL [performance_schema]> select
    b.id,
b.trx_id,
a.trx_state,
a.trx_started,
TIMESTAMPDIFF(SECOND,a.trx_started, now()) as "Seconds Transaction Has Been Open",
a.trx_rows_modified,
b.USER,
b.host,
b.db,
b.command,
b.time,
b.state
```
from information_schema.innodb_trx a,
    information_schema.processlist b
where a.trx_mysql_thread_id=b.id
    and TIMESTAMPDIFF(SECOND,a.trx_started, now()) > 33 order by trx_started;

+-------------------+------------------+--------------------+-----------+---------+------+
| id |trx_id|trx_state|trx_started|Seconds Transaction Has Been Open|
|trx_rows_modified|USER|host|db|command|time|
+-------------------+------------------+--------------------+-----------+---------+------+
| 40 | 1907737 | RUNNING | 2021-02-02 12:58:16 | 1955 | User sleep |
| 0 | auroramysql56123 | 172.31.21.51:44876 | sbtest123 | Query | 1955 | User |
| 56 | 3797992 | RUNNING | 2021-02-02 13:27:01 | 230 | User sleep |
| 0 | auroramysql56123 | 172.31.21.51:44908 | NULL | Query | 230 | User |
| 58 | 3895074 | RUNNING | 2021-02-02 13:28:18 | 153 | Sleep cleaned up |

+-------------------+------------------+--------------------+-----------+---------+------+
3 rows in set (0.00 sec)

In the output, processes 40, 56, and 58 have been active for long time. Let’s identify queries run by these sessions on the sbtest.sbtest1 table.

MySQL [performance_schema] > select
    t.processlist_id,
    t.thread_id,
    sql_text
from performance_schema.threads t
join events_statements_history sh
on t.thread_id=sh.thread_id
where processlist_id in (40,56,58)
    and SQL_TEXT like '%sbtest1%' order by 1;

+-----------------+-----------+------------------------------------------+
| processlist_id | thread_id | sql_text                                 |
+-----------------+-----------+------------------------------------------+
| 56 | 84 | select * from sbtest123.sbtest10 limit 1 |
| 58 | 86 | select * from sbtest.sbtest1 limit 1     |
+-----------------+-----------+------------------------------------------+
2 rows in set (0.01 sec)

In this output, the session with a processlist_id of 58 ran a query on the table and holds an open transaction. That open transaction is blocking the TRUNCATE command.

Run queries on Aurora MySQL version 2

In Aurora MySQL version 2, you can identify the blocked session directly by querying performance_schema tables or sys schema views. An example can illustrate how to query tables to identify blocking queries and sessions.

In the following process list output, the connection ID 89 is waiting on a metadata lock, and it’s running a TRUNCATE TABLE command. In a query on the performance_schema tables or sys schema views, the output shows that the blocking session is 76.

MySQL [(none)] > select @@version, @@aurora_version;
#-----------------------------
Next, a query on the `performance_schema` tables or `sys` schema views shows that the blocking session is 76.

MySQL [(none)]> select * from sys.schema_table_lock_waits;

18 rows in set (0.00 sec)

1 row in set (0.00 sec)

Respond to the blocking session

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see Ending a session or query in the Amazon RDS User Guide.

For more information about identifying blocking transactions, see Using InnoDB Transaction and Locking Information in the MySQL documentation.

**synch/mutex/innodb/aurora_lock_thread_slot_futex**

The synch/mutex/innodb/aurora_lock_thread_slot_futex event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see InnoDB locking in the MySQL Reference.

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

**Likely causes of increased waits**

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

**Actions**

We recommend different actions depending on the other wait events that you see.
Find and respond to the SQL statements responsible for this wait event

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

- If row locks are a persistent problem, consider rewriting the application to use optimistic locking.
- Use multirow statements.
- Spread the workload over different database objects. One way to do achieve this is through partitioning.
- Check the value of the `innodb_lock_wait_timeout` parameter. It controls how long transactions wait before generating a timeout error.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Find and respond to the blocking session

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```sql
mysql> SHOW ENGINE INNODB STATUS;
```

```
---------------------TRANSACTION 302631452, ACTIVE 2 sec starting index read mysql tables in use 1, locked 1 LOCK WAIT 2 lock struct(s), heap size 376, 1 row lock(s) MySQL thread id 80109, OS thread handle 0x2ae915060700, query id 938819 10.0.4.12 reinvent updating UPDATE sbtest1 SET k=k+1 WHERE id=503 ------- TRX HAS BEEN WAITING 2 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 148 page no 11 n bits 30 index `PRIMARY` of table `sysbench2`.`sbtest1` trx id 302631452 lock_mode X locks rec but not gap waiting Record lock, heap no 30 PHYSICAL RECORD: n_fields 6; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```sql
mysql> SELECT p1.id waiting_thread, p1.user waiting_user, p1.host waiting_host, it1.trx_query waiting_query, ilw.requesting_trx_id waiting_transaction, ilw.blocking_lock_id blocking_lock, il.lock_mode blocking_mode, il.lock_table locked_table, CASE it.trx_state WHEN 'LOCK WAIT' THEN it.trx_state ELSE p.state END blocker_state, il.lock_table locked_table,
```

775
When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see Ending a session or query in the Amazon RDS User Guide.

For more information about identifying blocking transactions, see Using InnoDB Transaction and Locking Information in the MySQL Reference Manual.

synch/mutex/innodb/buf_pool_mutex

The synch/mutex/innodb/buf_pool_mutex event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.

Topics
- Relevant engine versions (p. 776)
- Context (p. 777)
- Likely causes of increased waits (p. 777)
- Actions (p. 777)

Relevant engine versions

This wait event information is supported for the following engine versions:
- Aurora MySQL version 2.x up to 2.09.2
• Aurora MySQL version 1.x up to 1.23.1

Context

The buf_pool mutex is a single mutex that protects the control data structures of the buffer pool.

For more information, see Monitoring InnoDB Mutex Waits Using Performance Schema in the MySQL documentation.

Likely causes of increased waits

This is a workload-specific wait event. Common causes for synch/mutex/innodb/buf_pool_mutex to appear among the top wait events include the following:

• The buffer pool size isn't large enough to hold the working set of data.
• The workload is more specific to certain pages from a specific table in the database, leading to contention in the buffer pool.

Actions

We recommend different actions depending on the causes of your wait event.

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To view the Top SQL chart in the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. Underneath the Database load chart, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Use Performance Insights

This event is related to workload. You can use Performance Insights to do the following:

• Identify when wait events start, and whether there's any change in the workload around that time from the application logs or related sources.
• Identify the SQL statements responsible for this wait event. Examine the execution plan of the queries to make sure that these queries are optimized and using appropriate indexes.

If the top queries responsible for the wait event are related to the same database object or table, then consider partitioning that object or table.
Create Aurora Replicas

You can create Aurora Replicas to serve read-only traffic. You can also use Aurora Auto Scaling to handle surges in read traffic. Make sure to run scheduled read-only tasks and logical backups on Aurora Replicas.

For more information, see Using Amazon Aurora Auto Scaling with Aurora replicas (p. 305).

Examine the buffer pool size

Check whether the buffer pool size is sufficient for the workload by looking at the metric `innodb_buffer_pool_wait_free`. If the value of this metric is high and increasing continuously, that indicates that the size of the buffer pool isn't sufficient to handle the workload. If `innodb_buffer_pool_size` has been set properly, the value of `innodb_buffer_pool_wait_free` should be small. For more information, see `innodb_buffer_pool_wait_free` in the MySQL documentation.

Increase the buffer pool size if the DB instance has enough memory for session buffers and operating-system tasks. If it doesn't, change the DB instance to a larger DB instance class to get additional memory that can be allocated to the buffer pool.

**Note**

Aurora MySQL automatically adjusts the value of `innodb_buffer_pool_instances` based on the configured `innodb_buffer_pool_size`.

Monitor the global status history

By monitoring the change rates of status variables, you can detect locking or memory issues on your DB instance. Turn on Global Status History (GoSH) if it isn't already turned on. For more information on GoSH, see Managing the global status history.

You can also create custom Amazon CloudWatch metrics to monitor status variables. For more information, see Publishing custom metrics.

**synch/mutex/innodb/fil_system_mutex**

The `synch/mutex/innodb/fil_system_mutex` event occurs when a session is waiting to access the tablespace memory cache.

**Topics**

- Supported engine versions (p. 778)
- Context (p. 778)
- Likely causes of increased waits (p. 779)
- Actions (p. 779)

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2, up to 2.09.2
- Aurora MySQL version 1, up to 1.23.1

**Context**

InnoDB uses tablespaces to manage the storage area for tables and log files. The `tablespace memory cache` is a global memory structure that maintains information about tablespaces. MySQL uses `synch`/
mutex/innodb/fil_system_mutex waits to control concurrent access to the tablespace memory cache.

The event synch/mutex/innodb/fil_system_mutex indicates that there is currently more than one operation that needs to retrieve and manipulate information in the tablespace memory cache for the same tablespace.

Likely causes of increased waits

When the synch/mutex/innodb/fil_system_mutex event appears more than normal, possibly indicating a performance problem, this typically occurs when all of the following conditions are present:

- An increase in concurrent data manipulation language (DML) operations that update or delete data in the same table.
- The tablespace for this table is very large and has a lot of data pages.
- The fill factor for these data pages is low.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Identify the sessions and queries causing the events (p. 779)
- Reorganize large tables during off-peak hours (p. 780)

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard appears for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Another way to find out which queries are causing high numbers of synch/mutex/innodb/fil_system_mutex waits is to check performance_schema, as in the following example.

```
mysql> select * from performance_schema.events_waits_current where EVENT_NAME='wait/synch/mutex/innodb/fil_system_mutex'
```
Reorganize large tables during off-peak hours

Reorganize large tables that you identify as the source of high numbers of `synch/mutex/innodb/fil_system_mutex` wait events during a maintenance window outside of production hours. Doing so
ensures that the internal tablespaces map cleanup doesn't occur when quick access to the table is critical. For information about reorganizing tables, see OPTIMIZE TABLE Statement in the MySQL Reference.

**synch/mutex/innodb/trx_sys_mutex**

The **synch/mutex/innodb/trx_sys_mutex** event occurs when there is high database activity with a large number of transactions.

**Topics**
- Relevant engine versions (p. 781)
- Context (p. 781)
- Likely causes of increased waits (p. 781)
- Actions (p. 782)

**Relevant engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2.x up to 2.09.2
- Aurora MySQL version 1.x up to 1.23.1

**Context**

Internally, the InnoDB database engine uses the repeatable read isolation level with snapshots to provide read consistency. This gives you a point-in-time view of the database at the time the snapshot was created.

In InnoDB, all changes are applied to the database as soon as they arrive, regardless of whether they're committed. This approach means that without multiversion concurrency control (MVCC), all users connected to the database see all of the changes and the latest rows. Therefore, InnoDB requires a way to track the changes to understand what to roll back when necessary.

To do this, InnoDB uses a transaction system (**trx_sys**) to track snapshots. The transaction system does the following:

- Tracks the transaction ID for each row in the undo logs.
- Uses an internal InnoDB structure called **ReadView** that helps to identify which transaction IDs are visible for a snapshot.

**Likely causes of increased waits**

Any database operation that requires the consistent and controlled handling (creating, reading, updating, and deleting) of transactions IDs generates a call from **trx_sys** to the mutex.

These calls happen inside three functions:

- **trx_sys_mutex_enter** – Creates the mutex.
- **trx_sys_mutex_exit** – Releases the mutex.
- **trx_sys_mutex_own** – Tests whether the mutex is owned.

The InnoDB Performance Schema instrumentation tracks all **trx_sys** mutex calls. Tracking includes, but isn’t limited to, management of **trx_sys** on database startup or shutdown, rollback operations,
undo cleanups, row read access, and buffer pool loads. High database activity with a large number of transactions results in `synch/mutex/innodb/trx_sys_mutex` appearing among the top wait events.

For more information, see Monitoring InnoDB Mutex Waits Using Performance Schema in the MySQL documentation.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Identify the sessions and queries causing the events**

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn’t optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load. Find out whether you can optimize the database and application to reduce those events.

**To view the Top SQL chart in the AWS Management Console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. Under the Database load chart, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

**Examine other wait events**

Examine the other wait events associated with the `synch/mutex/innodb/trx_sys_mutex` wait event. Doing this can provide more information about the nature of the workload. A large number of transactions might reduce throughput, but the workload might also make this necessary.

For more information on how to optimize transactions, see Optimizing InnoDB Transaction Management in the MySQL documentation.

**synch/rwlock/innodb/hash_table_locks**

The `synch/rwlock/innodb/hash_table_locks` event occurs when there is contention on modifying the hash table that maps the buffer cache.

**Topics**

- Supported engine versions (p. 782)
- Context (p. 783)
- Likely causes of increased waits (p. 783)
- Actions (p. 783)

**Supported engine versions**

This wait event information is supported for Aurora MySQL version 1, up to 1.23.1.
Context

The event `synch/rwlock/innodb/hash_table_locks` indicates that there is contention on modifying the hash table that maps the buffer cache. A hash table is a table in memory designed to improve buffer pool access performance. This wait event is invoked when the hash table needs to be modified.

For more information, see Buffer Pool in the MySQL documentation.

Likely causes of increased waits

When the `synch/rwlock/innodb/hash_table_locks` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

An undersized buffer pool

The size of the buffer pool is too small to keep all of the frequently accessed pages in memory.

Heavy workload

The workload is causing frequent evictions and data pages reloads in the buffer cache.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Increase the size of the buffer pool (p. 783)
- Improve data access patterns (p. 783)
- Find SQL queries responsible for high load (p. 783)
- Reduce or avoid full-table scans (p. 784)

Increase the size of the buffer pool

Make sure that the buffer pool is appropriately sized for the workload. To do so, you can check the buffer pool cache hit rate. Typically, if the value drops below 95 percent, consider increasing the buffer pool size. A larger buffer pool can keep frequently accessed pages in memory longer.

To increase the size of the buffer pool, modify the value of the `innodb_buffer_pool_size` parameter. The default value of this parameter is based on the DB instance class size. For more information, see the AWS Database Blog post Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance.

Improve data access patterns

Check the queries affected by this wait and their execution plans. Consider improving data access patterns. For example, if you are using `mysqli_result::fetch_array`, you can try increasing the array fetch size.

You can use Performance Insights to show queries and sessions that might be causing the `synch/rwlock/innodb/hash_table_locks` wait event.

Find SQL queries responsible for high load

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn’t optimal, then examine where the database
is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

**To find SQL queries that are responsible for high load**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

   The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post *Analyze Amazon Aurora MySQL Workloads with Performance Insights*.

**Reduce or avoid full-table scans**

Monitor your workload to see if it's running full-table scans, and, if it is, reduce or avoid them. For example, you can monitor status variables such as `Handler_read_rnd_next`. For more information, see Server Status Variables in the MySQL documentation.

**synch/sxlock/innodb/hash_table_locks**

The `synch/sxlock/innodb/hash_table_locks` event occurs when pages not found in the buffer pool must be read from a file.

**Topics**

- Supported engine versions (p. 784)
- Context (p. 784)
- Likely causes of increased waits (p. 785)
- Actions (p. 785)

**Supported engine versions**

This wait event information is supported for Aurora MySQL version 2, up to 2.09.2.

**Context**

The event `synch/sxlock/innodb/hash_table_locks` indicates that a workload is frequently accessing data that isn't stored in the buffer pool. This wait event is associated with new page additions and old data evictions from the buffer pool. The data stored in the buffer pool aged and new data must be cached, so the aged pages are evicted to allow caching of the new pages. MySQL uses a least recently used (LRU) algorithm to evict pages from the buffer pool. The workload is trying to access data that hasn't been loaded into the buffer pool or data that has been evicted from the buffer pool.

This wait event occurs when the workload must access the data in files on disk or when blocks are freed from or added to the buffer pool's LRU list. These operations wait to obtain a shared excluded lock (SX-lock). This SX-lock is used for the synchronization over the *hash table*, which is a table in memory designed to improve buffer pool access performance.

For more information, see Buffer Pool in the MySQL documentation.
Likely causes of increased waits

When the synch/sxlock/innodb/hash_table_locks wait event appears more than normal, possibly indicating a performance problem, typical causes include the following:

An undersized buffer pool

The size of the buffer pool is too small to keep all of the frequently accessed pages in memory.

Heavy workload

The workload is causing frequent evictions and data pages reloads in the buffer cache.

Errors reading the pages

There are errors reading pages in the buffer pool, which might indicate data corruption.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Increase the size of the buffer pool (p. 785)
- Improve data access patterns (p. 785)
- Reduce or avoid full-table scans (p. 786)
- Check the error logs for page corruption (p. 786)

Increase the size of the buffer pool

Make sure that the buffer pool is appropriately sized for the workload. To do so, you can check the buffer pool cache hit rate. Typically, if the value drops below 95 percent, consider increasing the buffer pool size. A larger buffer pool can keep frequently accessed pages in memory longer. To increase the size of the buffer pool, modify the value of the innodb_buffer_pool_size parameter. The default value of this parameter is based on the DB instance class size. For more information, see Best practices for Amazon Aurora MySQL database configuration.

Improve data access patterns

Check the queries affected by this wait and their execution plans. Consider improving data access patterns. For example, if you are using mysqli_result::fetch_array, you can try increasing the array fetch size.

You can use Performance Insights to show queries and sessions that might be causing the synch/sxlock/innodb/hash_table_locks wait event.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.
For a useful overview of troubleshooting using Performance Insights, see the AWS Database Blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

**Reduce or avoid full-table scans**

Monitor your workload to see if it's running full-table scans, and, if it is, reduce or avoid them. For example, you can monitor status variables such as `Handler_read_rnd_next`. For more information, see Server Status Variables in the MySQL documentation.

**Check the error logs for page corruption**

You can check the mysql-error.log for corruption-related messages that were detected near the time of the issue. Messages that you can work with to resolve the issue are in the error log. You might need to recreate objects that were reported as corrupted.

## Tuning Aurora MySQL with thread states

The following table summarizes the most common general thread states for Aurora MySQL.

<table>
<thead>
<tr>
<th>General thread state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>??? (p. 786)</td>
<td>This thread state indicates that a thread is processing a SELECT statement that requires the use of an internal temporary table to sort the data.</td>
</tr>
<tr>
<td>??? (p. 789)</td>
<td>This thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set.</td>
</tr>
</tbody>
</table>

### creating sort index

The creating sort index thread state indicates that a thread is processing a SELECT statement that requires the use of an internal temporary table to sort the data.

**Topics**

- Supported engine versions (p. 786)
- Context (p. 786)
- Likely causes of increased waits (p. 787)
- Actions (p. 787)

### Supported engine versions

This thread state information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2
- Aurora MySQL version 1 up to 1.23.1

### Context

The creating sort index state appears when a query with an ORDER BY or GROUP BY clause can't use an existing index to perform the operation. In this case, MySQL needs to perform a more expensive `filesort` operation. This operation is typically performed in memory if the result set isn't too large. Otherwise, it involves creating a file on disk.
Likely causes of increased waits

The appearance of creating sort index doesn’t by itself indicate a problem. If performance is poor, and you see frequent instances of creating sort index, the most likely cause is slow queries with ORDER BY or GROUP BY operators.

Actions

The general guideline is to find queries with ORDER BY or GROUP BY clauses that are associated with the increases in the creating sort index state. Then see whether adding an index or increasing the sort buffer size solves the problem.

Topics

- Turn on the Performance Schema if it isn’t turned on (p. 787)
- Identify the problem queries (p. 787)
- Examine the explain plans for filesort usage (p. 787)
- Increase the sort buffer size (p. 788)

Turn on the Performance Schema if it isn’t turned on

Performance Insights reports thread states only if Performance Schema instruments aren’t turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see Turning on the Performance Schema for Performance Insights on Aurora MySQL (p. 469).

Identify the problem queries

To identify current queries that are causing increases in the creating sort index state, run show processlist and see if any of the queries have ORDER BY or GROUP BY. Optionally, run explain for connection N, where N is the process list ID of the query with filesort.

To identify past queries that are causing these increases, turn on the slow query log and find the queries with ORDER BY. Run EXPLAIN on the slow queries and look for “using filesort.” For more information, see Examine the explain plans for filesort usage (p. 787).

Examine the explain plans for filesort usage

Identify the statements with ORDER BY or GROUP BY clauses that result in the creating sort index state.

The following example shows how to run explain on a query. The Extra column shows that this query uses filesort.

```
mysql> explain select * from mytable order by c1 limit 10
*************************** 1. row ***************************
    id: 1
  select_type: SIMPLE
    table: mytable
  partitions: NULL
    type: ALL
possible_keys: NULL
    key: NULL
  key_len: NULL
    ref: NULL
  rows: 2064548
```
The following example shows the result of running `EXPLAIN` on the same query after an index is created on column `c1`.

```
mysql> alter table mytable add index (c1);
```

```
mysql> explain select * from mytable order by c1 limit 10\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: mytable
partitions: NULL
type: index
possible_keys: NULL
key: c1
key_len: 1023
ref: NULL
rows: 10
filtered: 100.00
Extra: Using index
1 row in set, 1 warning (0.01 sec)
```

For information on using indexes for sort order optimization, see ORDER BY Optimization in the MySQL documentation.

### Increase the sort buffer size

To see whether a specific query required a `filesort` process that created a file on disk, check the `sort_merge_passes` variable value after running the query. The following shows an example.

```
mysql> show session status like 'sort_merge_passes';
+-------------------+-------+
| Variable_name     | Value |
|--------------------+-------|
| Sort_merge_passes  | 0     |
+-------------------+-------+
1 row in set (0.01 sec)

--- run query
mysql> select * from mytable order by u limit 10;
--- run status again:

mysql> show session status like 'sort_merge_passes';
+-------------------+-------+
| Variable_name     | Value |
|--------------------+-------|
| Sort_merge_passes  | 0     |
+-------------------+-------+
1 row in set (0.01 sec)
```

If the value of `sort_merge_passes` is high, consider increasing the sort buffer size. Apply the increase at the session level, because increasing it globally can significantly increase the amount of RAM MySQL uses. The following example shows how to change the sort buffer size before running a query.

```
mysql> set session sort_buffer_size=10*1024*1024;
Query OK, 0 rows affected (0.00 sec)
```
sending data

The sending data thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set. The name is misleading because it implies the state is transferring data, not collecting and preparing data to be sent later.

Topics
- Supported engine versions (p. 789)
- Context (p. 789)
- Likely causes of increased waits (p. 789)
- Actions (p. 790)

Supported engine versions

This thread state information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2
- Aurora MySQL version 1 up to 1.23.1

Context

Many thread states are short-lasting. Operations occurring during sending data tend to perform large numbers of disk or cache reads. Therefore, sending data is often the longest-running state over the lifetime of a given query. This state appears when Aurora MySQL is doing the following:

- Reading and processing rows for a SELECT statement
- Performing a large number of reads from either disk or memory
- Completing a full read of all data from a specific query
- Reading data from a table, an index, or the work of a stored procedure
- Sorting, grouping, or ordering data

After the sending data state finishes preparing the data, the thread state writing to net indicates the return of data to the client. Typically, writing to net is captured only when the result set is very large or severe network latency is slowing the transfer.

Likely causes of increased waits

The appearance of sending data doesn't by itself indicate a problem. If performance is poor, and you see frequent instances of sending data, the most likely causes are as follows.

Topics
- Inefficient query (p. 789)
- Suboptimal server configuration (p. 790)

Inefficient query

In most cases, what's responsible for this state is a query that isn't using an appropriate index to find the result set of a specific query. For example, consider a query reading a 10 million record table for all
orders placed in California, where the state column isn't indexed or is poorly indexed. In the latter case, the index might exist, but the optimizer ignores it because of low cardinality.

**Suboptimal server configuration**

If several queries appear in the sending data state, the database server might be configured poorly. Specifically, the server might have the following issues:

- The database server doesn't have enough computing capacity: disk I/O, disk type and speed, CPU, or number of CPUs.
- The server is starved for allocated resources, such as the InnoDB buffer pool for InnoDB tables or the key buffer for MyIsam tables.
- Per-thread memory settings such as `sort_buffer`, `read_buffer`, and `join_buffer` consume more RAM than required, starving the physical server for memory resources.

**Actions**

The general guideline is to find queries that return large numbers of rows by checking the Performance Schema. If logging queries that don't use indexes is turned on, you can also examine the results from the slow logs.

**Topics**

- Turn on the Performance Schema if it isn't turned on (p. 790)
- Examine memory settings (p. 790)
- Examine the explain plans for index usage (p. 791)
- Check the volume of data returned (p. 791)
- Check for concurrency issues (p. 791)
- Check the structure of your queries (p. 791)

**Turn on the Performance Schema if it isn't turned on**

Performance Insights reports thread states only if Performance Schema instruments aren't turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see [Turning on the Performance Schema for Performance Insights on Aurora MySQL](p. 469).

**Examine memory settings**

Examine the memory settings for the primary buffer pools. Make sure that these pools are appropriately sized for the workload. If your database uses multiple buffer pool instances, make sure that they aren't divided into many small buffer pools. Threads can only use one buffer pool at a time.

Make sure that the following memory settings used for each thread are properly sized:

- `read_buffer`
- `read_rnd_buffer`
- `sort_buffer`
- `join_buffer`
- `binlog_cache`

Unless you have a specific reason to modify the settings, use the default values.
Examine the explain plans for index usage

For queries in the sending data thread state, examine the plan to determine whether appropriate indexes are used. If a query isn't using a useful index, consider adding hints like `USE INDEX` or `FORCE INDEX`. Hints can greatly increase or decrease the time it takes to run a query, so use care before adding them.

Check the volume of data returned

Check the tables that are being queried and the amount of data that they contain. Can any of this data be archived? In many cases, the cause of poor query execution times isn't the result of the query plan, but the volume of data to be processed. Many developers are very efficient in adding data to a database but seldom consider dataset life cycle in the design and development phases.

Look for queries that perform well in low-volume databases but perform poorly in your current system. Sometimes developers who design specific queries might not realize that these queries are returning 350,000 rows. The developers might have developed the queries in a lower-volume environment with smaller datasets than production environments have.

Check for concurrency issues

Check whether multiple queries of the same type are running at the same time. Some forms of queries run efficiently when they run alone. However, if similar forms of query run together, or in high volume, they can cause concurrency issues. Often, these issues are caused when the database uses temp tables to render results. A restrictive transaction isolation level can also cause concurrency issues.

If tables are read and written to concurrently, the database might be using locks. To help identify periods of poor performance, examine the use of databases through large-scale batch processes. To see recent locks and rollbacks, examine the output of the `SHOW ENGINE INNODB STATUS` command.

Check the structure of your queries

Check whether captured queries from these states use subqueries. This type of query often leads to poor performance because the database compiles the results internally and then substitutes them back into the query to render data. This process is an extra step for the database. In many cases, this step can cause poor performance in a highly concurrent loading condition.

Also check whether your queries use large numbers of `ORDER BY` and `GROUP BY` clauses. In such operations, often the database must first form the entire dataset in memory. Then it must order or group it in a specific manner before returning it to the client.

Working with parallel query for Amazon Aurora MySQL

Following, you can find a description of the parallel query performance optimization for Amazon Aurora MySQL-Compatible Edition. This feature uses a special processing path for certain data-intensive queries, taking advantage of the Aurora shared storage architecture. Parallel query works best with Aurora MySQL DB clusters that have tables with millions of rows and analytic queries that take minutes or hours to complete. For information about Aurora MySQL versions that support parallel query in an AWS Region, see Aurora parallel queries (p. 27).

Contents

- Overview of parallel query for Aurora MySQL (p. 792)
  - Benefits (p. 793)
  - Architecture (p. 793)
  - Prerequisites (p. 794)
Overview of parallel query for Aurora MySQL

Aurora MySQL parallel query is an optimization that parallelizes some of the I/O and computation involved in processing data-intensive queries. The work that is parallelized includes retrieving rows from storage, extracting column values, and determining which rows match the conditions in the WHERE clause.
clause and join clauses. This data-intensive work is delegated (in database optimization terms, *pushed down*) to multiple nodes in the Aurora distributed storage layer. Without parallel query, each query brings all the scanned data to a single node within the Aurora MySQL cluster (the head node) and performs all the query processing there.

**Tip**

The PostgreSQL database engine also has a feature that's also called "parallel query". That feature is unrelated to Aurora parallel query.

When the parallel query feature is turned on, the Aurora MySQL engine automatically determines when queries can benefit, without requiring SQL changes such as hints or table attributes. In the following sections, you can find an explanation of when parallel query is applied to a query. You can also find how to make sure that parallel query is applied where it provides the most benefit.

**Note**

The parallel query optimization provides the most benefit for long-running queries that take minutes or hours to complete. Aurora MySQL generally doesn't perform parallel query optimization for inexpensive queries. It also generally doesn't perform parallel query optimization if another optimization technique makes more sense, such as query caching, buffer pool caching, or index lookups. If you find that parallel query isn't being used when you expect it, see [Verifying which statements use parallel query](p. 804).

**Topics**

- Benefits (p. 793)
- Architecture (p. 793)
- Prerequisites (p. 794)
- Limitations (p. 794)

**Benefits**

With parallel query, you can run data-intensive analytic queries on Aurora MySQL tables. In many cases, you can get an order-of-magnitude performance improvement over the traditional division of labor for query processing.

Benefits of parallel query include the following:

- Improved I/O performance, due to parallelizing physical read requests across multiple storage nodes.
- Reduced network traffic. Aurora doesn't transmit entire data pages from storage nodes to the head node and then filter out unnecessary rows and columns afterward. Instead, Aurora transmits compact tuples containing only the column values needed for the result set.
- Reduced CPU usage on the head node, due to pushing down function processing, row filtering, and column projection for the *WHERE* clause.
- Reduced memory pressure on the buffer pool. The pages processed by the parallel query aren't added to the buffer pool. This approach reduces the chance of a data-intensive scan evicting frequently used data from the buffer pool.
- Potentially reduced data duplication in your extract, transform, load (ETL) pipeline, by making it practical to perform long-running analytic queries on existing data.

**Architecture**

The parallel query feature uses the major architectural principles of Aurora MySQL: decoupling the database engine from the storage subsystem, and reducing network traffic by streamlining communication protocols. Aurora MySQL uses these techniques to speed up write-intensive operations such as redo log processing. Parallel query applies the same principles to read operations.
Note
The architecture of Aurora MySQL parallel query differs from that of similarly named features in other database systems. Aurora MySQL parallel query doesn't involve symmetric multiprocessing (SMP) and so doesn't depend on the CPU capacity of the database server. The parallel processing happens in the storage layer, independent of the Aurora MySQL server that serves as the query coordinator.

By default, without parallel query, the processing for an Aurora query involves transmitting raw data to a single node within the Aurora cluster (the head node). Aurora then performs all further processing for that query in a single thread on that single node. With parallel query, much of this I/O-intensive and CPU-intensive work is delegated to nodes in the storage layer. Only the compact rows of the result set are transmitted back to the head node, with rows already filtered, and column values already extracted and transformed. The performance benefit comes from the reduction in network traffic, reduction in CPU usage on the head node, and parallelizing the I/O across the storage nodes. The amount of parallel I/O, filtering, and projection is independent of the number of DB instances in the Aurora cluster that runs the query.

Prerequisites
To use all features of parallel query requires an Aurora MySQL DB cluster that's running version 1.23 or 2.09 and higher. If you already have a cluster that you want to use with parallel query, you can upgrade it to a compatible version and turn on parallel query afterward. In that case, make sure to follow the upgrade procedure in Upgrade considerations for parallel query (p. 803) because the configuration setting names and default values are different in these newer versions.

You can also use parallel query with certain older Aurora MySQL versions that are compatible with MySQL 5.6: 1.22.2, 1.20.1, 1.19.6, and 5.6.10a. The parallel query support for these older versions is only available in certain AWS Regions. Those older versions have additional limitations, as described following. Using parallel query with an older Aurora MySQL version also requires creating a dedicated DB cluster with a special engine mode parameter that can't be changed later. For those reasons, we recommend using parallel query with Aurora MySQL 1.23 or 2.09 and higher where practical.

The DB instances in your cluster must be using the db.r* instance classes.

Make sure that the hash join optimization is turned on for your cluster. The procedure to do so is different depending on whether your cluster is running an Aurora MySQL version higher or lower than 1.23 or 2.09. To learn how, see Turning on hash join for parallel query clusters (p. 801).

To customize parameters such as aurora_parallel_query and aurora_disable_hash_join, you must have a custom parameter group that you use with your cluster. You can specify these parameters individually for each DB instance by using a DB parameter group. However, we recommend that you specify them in a DB cluster parameter group. That way, all DB instances in your cluster inherit the same settings for these parameters.

Limitations
The following limitations apply to the parallel query feature:

- You can't use parallel query with the db.t2 or db.t3 instance classes. This limitation applies even if you request parallel query using the aurora_pq_force SQL hint.
- Parallel query doesn't apply to tables using the COMPRESSED or REDUNDANT row formats. Use the COMPACT or DYNAMIC row formats for tables you plan to use with parallel query.
- Aurora uses a cost-based algorithm to determine whether to use the parallel query mechanism for each SQL statement. Using certain SQL constructs in a statement can prevent parallel query or make parallel query unlikely for that statement. For information about compatibility of SQL constructs with parallel query, see How parallel query works with SQL constructs (p. 811).
• Each Aurora DB instance can run only a certain number of parallel query sessions at one time. If a query has multiple parts that use parallel query, such as subqueries, joins, or UNION operators, those phases run in sequence. The statement only counts as a single parallel query session at any one time. You can monitor the number of active sessions using the parallel query status variables (p. 807). You can check the limit on concurrent sessions for a given DB instance by querying the status variable Aurora_pq_max_concurrent_requests.

• Parallel query is available in all AWS Regions that Aurora supports. For most AWS Regions, the minimum required Aurora MySQL version to use parallel query is 1.23 or 2.09. For more information, see Aurora parallel queries (p. 27).

• Aurora MySQL 1.22.2, 1.20.1, 1.19.6, and 5.6.10a only: Using parallel query with these older versions involves creating a new cluster, or restoring from an existing Aurora MySQL cluster snapshot.

• Aurora MySQL 1.22.2, 1.20.1, 1.19.6, and 5.6.10a only: Parallel query doesn't support AWS Identity and Access Management (IAM) database authentication.

Planning for a parallel query cluster

Planning for a DB cluster that has parallel query turned on requires making some choices. These include performing setup steps (either creating or restoring a full Aurora MySQL cluster) and deciding how broadly to turn on parallel query across your DB cluster.

Consider the following as part of planning:

• Which Aurora MySQL version do you plan to use for the cluster? Depending on your choice, you can use one of these ways to turn on parallel query for the cluster:

  If you use Aurora MySQL that's compatible with MySQL 5.7, you must choose Aurora MySQL 2.09 or higher. In this case, you always create a provisioned cluster. Then you turn on parallel query using the aurora_parallel_query parameter. We recommend this choice if you are starting with Aurora parallel query for the first time.

  If you use Aurora MySQL that's compatible with MySQL 5.6, you can choose version 1.23 or certain lower versions. With version 1.23 or higher, you create a provisioned cluster and then turn on parallel query using the aurora_parallel_query DB cluster parameter. With a version lower than 1.23, you choose the parallelquery engine mode when creating the cluster. In this case, parallel query is permanently turned on for the cluster. The parallelquery engine mode imposes limitations on interoperating with other kinds of Aurora MySQL clusters. If you have a choice, we recommend choosing version 1.23 or higher for Aurora MySQL with MySQL 5.6 compatibility.

  If you have an existing Aurora MySQL cluster that's running version 1.23 or higher, or 2.09 or higher, you don't have to create a new cluster to use parallel query. You can associate your cluster, or specific DB instances in the cluster, with a parameter group that has the aurora_parallel_query parameter turned on. By doing so, you can reduce the time and effort to set up the relevant data to use with parallel query.

• Plan for any large tables that you need to reorganize so that you can use parallel query when accessing them. You might need to create new versions of some large tables where parallel query is useful. For example, you might need to remove full-text search indexes. For details, see Creating schema objects to take advantage of parallel query (p. 804).

Checking Aurora MySQL version compatibility for parallel query

To check which Aurora MySQL versions are compatible with parallel query clusters, use the describe-db-engine-versions AWS CLI command and check the value of the SupportsParallelQuery field. The following code example shows how to check which combinations are available for parallel query clusters in a specified AWS Region. Make sure to specify the full --query parameter string on a single line.
Creating a parallel query cluster

The preceding commands produce output similar to the following. The output might vary depending on which Aurora MySQL versions are available in the specified AWS Region.

<table>
<thead>
<tr>
<th>Version</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.6.10a</td>
<td></td>
</tr>
<tr>

</tbody>
</table>

After you start using parallel query with a cluster, you can monitor performance and remove obstacles to parallel query usage. For those instructions, see Performance tuning for parallel query (p. 804).

Creating a DB cluster that works with parallel query

To create an Aurora MySQL cluster with parallel query, add new instances to it, or perform other administrative operations, you use the same AWS Management Console and AWS CLI techniques that you do with other Aurora MySQL clusters. You can create a new cluster to work with parallel query. You can also create a DB cluster to work with parallel query by restoring from a snapshot of a MySQL-compatible Aurora DB cluster. If you aren't familiar with the process for creating a new Aurora MySQL cluster, you can find background information and prerequisites in Creating an Amazon Aurora DB cluster (p. 127).

However, certain options are different:

- When you choose an Aurora MySQL engine version, we recommend that you choose the latest engine that is compatible with MySQL 5.7. Currently, Aurora MySQL 2.09 or higher, and certain Aurora MySQL versions that are compatible with MySQL 5.6 support parallel query. You have more flexibility to turn parallel query on and off, or use parallel query with existing clusters, if you use Aurora MySQL 1.23 or 2.09 and higher.
- Only for Aurora MySQL before version 1.23: When you create or restore the DB cluster, make sure to choose the `parallelquery` engine mode.

Whether you create a new cluster or restore from a snapshot, you use the same techniques to add new DB instances that you do with other Aurora MySQL clusters.
Creating a parallel query cluster using the console

You can create a new parallel query cluster with the console as described following.

To create a parallel query cluster with the AWS Management Console

1. Follow the general AWS Management Console procedure in Creating an Amazon Aurora DB cluster (p. 127).

2. On the Select engine screen, choose Aurora MySQL.

   For Engine version, choose Aurora MySQL 2.09 or higher, or Aurora MySQL 1.23 or higher if practical. With those versions, you have the fewest limitations on parallel query usage. Those versions also have the most flexibility to turn parallel query on or off at any time.

   If it isn't practical to use a recent Aurora MySQL version for this cluster, choose Show versions that support the parallel query feature. Doing so filters the Version menu to show only the specific Aurora MySQL versions that are compatible with parallel query.

3. (For older versions only) For Capacity type, choose Provisioned with Aurora parallel query enabled. The AWS Management Console only displays this choice when you select an Aurora MySQL version lower than 1.23. For Aurora MySQL 1.23 or 2.09 and higher, you don't need to make any special choice to make the cluster compatible with parallel query.

4. (For recent versions only) For Additional configuration, choose a parameter group that you created for DB cluster parameter group. Using such a custom parameter group is required for Aurora MySQL 1.23 or 2.09 or 3.1 and higher. In your DB cluster parameter group, specify the parameter settings `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF`. Doing so turns on parallel query for the cluster, and turns on the hash join optimization which works in combination with parallel query.

To verify that a new cluster can use parallel query

1. Create a cluster using the preceding technique.

2. (For Aurora MySQL version 2.09 and higher minor versions, or Aurora MySQL version 3) Check that the `aurora_parallel_query` configuration setting is true.

```
mysql> select @@aurora_parallel_query;
+-------------------------+
| @@aurora_parallel_query |
+-------------------------+
|                       1 |
+-------------------------+
```

3. (For Aurora MySQL version 2.09 and higher minor versions) Check that the `aurora_disable_hash_join` setting is false.

```
mysql> select @@aurora_disable_hash_join;
+----------------------------+
| @@aurora_disable_hash_join |
+----------------------------+
|                          0 |
+----------------------------+
```

4. (For older versions only) Check that the `aurora_pq_supported` configuration setting is true.

```
mysql> select @@aurora_pq_supported;
+-----------------------+
| @@aurora_pq_supported |
+-----------------------+
```

797
5. With some large tables and data-intensive queries, check the query plans to confirm that some of your queries are using the parallel query optimization. To do so, follow the procedure in Verifying which statements use parallel query (p. 804).

Creating a parallel query cluster using the CLI

You can create a new parallel query cluster with the CLI as described following.

To create a parallel query cluster with the AWS CLI

1. (Optional) Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the describe-db-engine-versions command and check the value of the SupportsParallelQuery field. For an example, see Checking Aurora MySQL version compatibility for parallel query (p. 795).

2. (Optional) Create a custom DB cluster parameter group with the settings aurora_parallel_query=ON and aurora_disable_hash_join=OFF. Use commands such as the following.

```bash
aws rds create-db-cluster-parameter-group --db-parameter-group-family aurora-mysql5.7
   --db-cluster-parameter-group-name pq-enabled-57-compatible
   --parameters
   ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name pq-enabled-57-compatible
   --parameters
   ParameterName=aurora_disable_hash_join,ParameterValue=OFF,ApplyMethod=pending-reboot
```

   If you perform this step, specify the option `--db-cluster-parameter-group-name my_cluster_parameter_group` in the subsequent create-db-cluster statement. Substitute the name of your own parameter group. If you omit this step, you create the parameter group and associate it with the cluster later, as described in Turning parallel query on and off (p. 800).

3. Follow the general AWS CLI procedure in Creating an Amazon Aurora DB cluster (p. 127).

4.Specify the following set of options:

   - For the `--engine` option, use aurora or aurora-mysql. These values produce parallel query clusters that are compatible with MySQL 5.6 or MySQL 5.7 respectively.
   - The value to use for the `--engine-mode` parameter depends on the engine version that you choose.

     - For Aurora MySQL 1.23 or higher, or 2.09 or higher, specify `--engine-mode provisioned`. You can also omit the `--engine-mode` parameter, because provisioned is the default. In these versions, you can turn parallel query on or off for the default kind of Aurora MySQL clusters, instead of creating clusters dedicated to always using parallel query.

     - Before Aurora MySQL 1.23, for the `--engine-mode` option, use parallelquery. The `--engine-mode` parameter applies to the `create-db-cluster` operation. Then the engine mode of the cluster is used automatically by subsequent `create-db-instance` operations.

   - For the `--db-cluster-parameter-group-name` option, specify the name of a DB cluster parameter group that you created and specified the parameter value aurora_parallel_query=ON. If you omit this option, you can create the cluster with a default parameter group and later modify it to use such a custom parameter group.
• For the `--engine-version` option, use an Aurora MySQL version that's compatible with parallel query. Use the procedure from Planning for a parallel query cluster (p. 795) to get a list of versions if necessary. If practical, use at least 1.23.0 or 2.09.0. These versions and all higher ones contain substantial enhancements to parallel query.

The following code example shows how. Substitute your own value for each of the environment variables such as `#CLUSTER_ID`.

```bash
aws rds create-db-cluster --db-cluster-identifier #CLUSTER_ID --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.09.0
    --master-username $MASTER_USER_ID --master-user-password $MASTER_USER_PW
    --db-cluster-parameter-group-name #CUSTOM_CLUSTER_PARAM_GROUP

aws rds create-db-cluster --db-cluster-identifier #CLUSTER_ID
    --engine aurora --engine-version 5.6.mysql_aurora.1.23.0
    --master-username $MASTER_USER_ID --master-user-password $MASTER_USER_PW
    --db-cluster-parameter-group-name #CUSTOM_CLUSTER_PARAM_GROUP

aws rds create-db-instance --db-instance-identifier ${INSTANCE_ID}-1
    --engine same_value_as_in_create_cluster_command
    --db-cluster-identifier #CLUSTER_ID --db-instance-class $INSTANCE_CLASS
```

5. Verify that a cluster you created or restored has the parallel query feature available.

For Aurora MySQL 1.23 and 2.09 or higher: Check that the `aurora_parallel_query` configuration setting exists. If this setting has the value 1, parallel query is ready for you to use. If this setting has the value 0, set it to 1 before you can use parallel query. Either way, the cluster is capable of performing parallel queries.

```
mysql> select @@aurora_parallel_query;
+------------------------+
| @@aurora_parallel_query|
+------------------------+
|                      1 |
+------------------------+
```

Before Aurora MySQL 1.23: Check that the `aurora_pq_supported` configuration setting is true.

```
mysql> select @@aurora_pq_supported;
+-----------------------+
| @@aurora_pq_supported |
+-----------------------+
|                     1 |
+-----------------------+
```

To restore a snapshot to a parallel query cluster with the AWS CLI

1. Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the `describe-db-engine-versions` command and check the value of the `SupportsParallelQuery` field. For an example, see Checking Aurora MySQL version compatibility for parallel query (p. 795). Decide which version to use for the restored cluster. If practical, choose Aurora MySQL 2.09.0 or higher for a MySQL 5.7-compatible cluster, or 1.23.0 or higher for a MySQL 5.6-compatible cluster.

2. Locate an Aurora MySQL-compatible cluster snapshot.

3. Follow the general AWS CLI procedure in Restoring from a DB cluster snapshot (p. 375).

4. The value to use for the `--engine-mode` parameter depends on the engine version that you choose.
For Aurora MySQL 1.23 or higher, or 2.09 or higher, specify `--engine-mode provisioned`. You can also omit the `--engine-mode` parameter, because provisioned is the default. In these versions, you can turn parallel query on or off for your Aurora MySQL clusters, instead of creating clusters dedicated to always using parallel query.

Before Aurora MySQL 1.23, specify `--engine-mode parallelquery`. The `--engine-mode` parameter applies to the `create-db-cluster` operation. Then the engine mode of the cluster is used automatically by subsequent `create-db-instance` operations.

```bash
aws rds restore-db-cluster-from-snapshot \
  --db-cluster-identifier mynewdbcluster \
  --snapshot-identifier mydbclustersnapshot \
  --engine aurora \
  --engine-mode parallelquery
```

5. Verify that a cluster you created or restored has the parallel query feature available. Use the same verification procedure as in Creating a parallel query cluster using the CLI (p. 798).

### Turning parallel query on and off

**Note**

When parallel query is turned on, Aurora MySQL determines whether to use it at runtime for each query. In the case of joins, unions, subqueries, and so on, Aurora MySQL determines whether to use parallel query at runtime for each query block. For details, see Verifying which statements use parallel query (p. 804) and How parallel query works with SQL constructs (p. 811).

**Aurora MySQL 1.23 and 2.09 or higher**

In Aurora MySQL 1.23 and 2.09 or higher, you can turn on and turn off parallel query dynamically at both the global and session level for a DB instance by using the `aurora_parallel_query` option. You can change the `aurora_parallel_query` setting in your DB cluster group to turn parallel query on or off by default.

```sql
mysql> select @@aurora_parallel_query;
+------------------------+
| @@aurora_parallel_query| 1 |
|------------------------|
```

To toggle the `aurora_parallel_query` parameter at the session level, use the standard methods to change a client configuration setting. For example, you can do so through the `mysql` command line or within a JDBC or ODBC application. The command on the standard MySQL client is `set session aurora_parallel_query = {'ON'/'OFF'}`). You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

You can permanently change the setting for the `aurora_parallel_query` parameter, either for a specific DB instance or for your whole cluster. If you specify the parameter value in a DB parameter group, that value only applies to specific DB instance in your cluster. If you specify the parameter value in a DB cluster parameter group, all DB instances in the cluster inherit the same setting. To toggle the `aurora_parallel_query` parameter, use the techniques for working with parameter groups, as described in Working with parameter groups (p. 215). Follow these steps:

1. Create a custom cluster parameter group (recommended) or a custom DB parameter group.
2. In this parameter group, update `parallel_query` to the value that you want.
3. Depending on whether you created a DB cluster parameter group or a DB parameter group, attach
the parameter group to your Aurora cluster or to the specific DB instances where you plan to use the
parallel query feature.

**Tip**
Because `aurora_parallel_query` is a dynamic parameter, it doesn't require a cluster
restart after changing this setting. However, any connections that were using parallel query
before toggling the option will continue to do so until the connection is closed, or the
instance is rebooted.

You can modify the parallel query parameter by using the `ModifyDBClusterParameterGroup` or
`ModifyDBParameterGroup` API operation or the AWS Management Console.

### Before Aurora MySQL 1.23

For these older versions, you can turn on and turn off parallel query dynamically at both the global
and session level for a DB instance by using the `aurora_pq` option. On clusters where the parallel query
feature is available, the parameter is turned on by default.

```sql
mysql> select @@aurora_pq;
+-------------+
| @@aurora_pq |
+-------------+
|           1 |
+-------------+
```

To toggle the `aurora_pq` parameter at the session level, for example through the `mysql` command
line or within a JDBC or ODBC application, use the standard methods to change a client configuration
setting. For example, the command on the standard MySQL client is `set session aurora_pq =
{"ON"/'OFF"}`. You can also add the session-level parameter to the JDBC configuration or within your
application code to turn on or turn off parallel query dynamically.

To toggle the `aurora_pq` parameter permanently, use the techniques for working with parameter
groups, as described in Working with parameter groups (p. 215). Follow these steps:

1. Create a custom cluster parameter group or DB instance parameter group. We recommend using a
   cluster parameter group, so that all DB instance in the cluster inherit the same settings.
2. In this parameter group, update `aurora_pq` to the value that you want.
3. Associate the custom cluster parameter group with the Aurora cluster where you plan to use the
   parallel query feature. Or, for a custom DB parameter group, associate it with one or more DB
   instances in the cluster.
4. Restart all the DB instances of the cluster.

You can modify the parallel query parameter by using the `ModifyDBClusterParameterGroup` or
`ModifyDBParameterGroup` API operation or the AWS Management Console.

**Note**
When parallel query is turned on, Aurora MySQL determines whether to use it at runtime
for each query. In the case of joins, unions, subqueries, and so on, Aurora MySQL determines
whether to use parallel query at runtime for each query block. For details, see Verifying
which statements use parallel query (p. 804) and How parallel query works with SQL
constructs (p. 811).

### Turning on hash join for parallel query clusters

Parallel query is typically used for the kinds of resource-intensive queries that benefit from the hash join
optimization. Thus, it's helpful to ensure that hash joins are turned on for clusters where you plan to
use parallel query. For information about how to use hash joins effectively, see Optimizing large Aurora MySQL join queries with hash joins (p. 946).

**Turning on and turning off parallel query using the console**

You can turn on or turn off parallel query at the DB instance level or the DB cluster level by working with parameter groups.

**To turn on or turn off parallel query for a DB cluster with the AWS Management Console**

1. Create a custom parameter group, as described in Working with parameter groups (p. 215).
2. For Aurora MySQL 1.23 and 2.09 or higher: Update `aurora_parallel_query` to 1 (turned on) or 0 (turned off). For clusters where the parallel query feature is available, `aurora_parallel_query` is turned off by default.

   For Aurora MySQL before 1.23: Update `aurora_pq` to 1 (turned on) or 0 (turned off). For clusters where the parallel query feature is available, `aurora_pq` is turned on by default.
3. If you use a custom cluster parameter group, attach it to the Aurora DB cluster where you plan to use the parallel query feature. If you use a custom DVB parameter group, attach it to one or more DB instances in the cluster. We recommend using a cluster parameter group. Doing so makes sure that all DB instances in the cluster have the same settings for parallel query and associated features such as hash join.

**Turning on and turning off parallel query using the CLI**

You can modify the parallel query parameter by using the `modify-db-cluster-parameter-group` or `modify-db-parameter-group` command. Choose the appropriate command depending on whether you specify the value of `aurora_parallel_query` through a DB cluster parameter group or a DB parameter group.

**To turn on or turn off parallel query for a DB cluster with the CLI**

- Modify the parallel query parameter by using the `modify-db-cluster-parameter-group` command. Use a command such as the following. Substitute the appropriate name for your own custom parameter group. Substitute either `ON` or `OFF` for the `ParameterValue` portion of the `--parameters` option.

```bash
# Aurora MySQL 1.23 or 2.09 and higher:
$ aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name cluster_param_group_name \
   --parameters ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot 
   { "DBClusterParameterGroupName": "cluster_param_group_name" }

# Before Aurora MySQL 1.23:
$ aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name cluster_param_group_name \
   --parameters ParameterName=aurora_pq,ParameterValue=ON,ApplyMethod=pending-reboot 
   { "DBClusterParameterGroupName": "cluster_param_group_name" }
```

You can also turn on or turn off parallel query at the session level, for example through the `mysql` command line or within a JDBC or ODBC application. To do so, use the standard methods to change a
Amazon Aurora User Guide for Aurora
Upgrading a parallel query cluster

client configuration setting. For example, the command on the standard MySQL client is `set session aurora_parallel_query = {'ON'/'OFF'}` for Aurora MySQL 1.23 or 2.09 and higher. Before Aurora MySQL 1.23, the command is `set session aurora_pq = {'ON'/'OFF'}`.

You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

**Upgrade considerations for parallel query**

Depending on the original and destination versions when you upgrade a parallel query cluster, you might find enhancements in the types of queries that parallel query can optimize. You might also find that you don't need to specify a special engine mode parameter for parallel query. The following sections explain the considerations when you upgrade a cluster that has parallel query turned on.

**Upgrading parallel query clusters to Aurora MySQL version 3**

Several SQL statements, clauses, and data types have new or improved parallel query support starting in Aurora MySQL version 3. When you upgrade from a release that's earlier than version 3, check whether additional queries can benefit from parallel query optimizations. For information about these parallel query enhancements, see Column data types (p. 814), Partitioned tables (p. 815), and Aggregate functions, GROUP BY clauses, and HAVING clauses (p. 816).

If you are upgrading a parallel query cluster from Aurora MySQL 2.08 or lower, also learn about changes in how to turn on parallel query. To do so, read Upgrading to Aurora MySQL 1.23 or 2.09 and higher (p. 803).

In Aurora MySQL version 3, the hash join optimization is turned on by default. The `aurora_disable_hash_join` configuration option from earlier versions isn't used.

**Upgrading to Aurora MySQL 1.23 or 2.09 and higher**

In Aurora MySQL 1.23 or 2.09 and higher, parallel query works for provisioned clusters and doesn't require the `parallelquery` engine mode parameter. Thus, you don't need to create a new cluster or restore from an existing snapshot to use parallel query with these versions. You can use the upgrade procedures described in Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 997) to upgrade your cluster to such a version. You can upgrade an older cluster regardless of whether it was a parallel query cluster or a provisioned cluster. To reduce the number of choices in the Engine version menu, you can choose Show versions that support the parallel query feature to filter the entries in that menu. Then choose Aurora MySQL 1.23 or 2.09 and higher.

After you upgrade an earlier parallel query cluster to Aurora MySQL 1.23 or 2.09 and higher, you turn on parallel query in the upgraded cluster. Parallel query is turned off by default in these versions, and the procedure for enabling it is different. The hash join optimization is also turned off by default and must be turned on separately. Thus, make sure that you turn on these settings again after the upgrade. For instructions on doing so, see Turning parallel query on and off (p. 800) and Turning on hash join for parallel query clusters (p. 801).

In particular, you turn on parallel query by using the configuration parameters `aurora_parallel_query=ON` and `aurora_disable_hash_join=OFF` instead of `aurora_pq_supported` and `aurora_pq`. The `aurora_pq_supported` and `aurora_pq` parameters are deprecated in the newer Aurora MySQL versions.

In the upgraded cluster, the `EngineMode` attribute has the value `provisioned` instead of `parallelquery`. To check whether parallel query is available for a specified engine version, now you check the value of the `SupportsParallelQuery` field in the output of the `describe-db-engine-versions` AWS CLI command. In earlier Aurora MySQL versions, you checked for the presence of `parallelquery` in the `SupportedEngineModes` list.
After you upgrade to Aurora MySQL 1.23 or 2.09 and higher, you can take advantage of the following features. These features aren’t available to parallel query clusters running older Aurora MySQL versions.

- Performance Insights. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 461).
- Backtracking. For more information, see Backtracking an Aurora DB cluster (p. 725).
- Stopping and starting the cluster. For more information, see Stopping and starting an Amazon Aurora DB cluster (p. 244).

Performance tuning for parallel query

To manage the performance of a workload with parallel query, make sure that parallel query is used for the queries where this optimization helps the most.

To do so, you can do the following:

- Make sure that your biggest tables are compatible with parallel query. You might change table properties or recreate some tables so that queries for those tables can take advantage of the parallel query optimization. To learn how, see Creating schema objects to take advantage of parallel query (p. 804).
- Monitor which queries use parallel query. To learn how, see Monitoring parallel query (p. 807).
- Verify that parallel query is being used for the most data-intensive and long-running queries, and with the right level of concurrency for your workload. To learn how, see Verifying which statements use parallel query (p. 804).
- Fine-tune your SQL code to turn on parallel query to apply to the queries that you expect. To learn how, see How parallel query works with SQL constructs (p. 811).

Creating schema objects to take advantage of parallel query

Before you create or modify tables that you plan to use for parallel query, make sure to familiarize yourself with the requirements described in Prerequisites (p. 794) and Limitations (p. 794).

Because parallel query requires tables to use the ROW_FORMAT=Compact or ROW_FORMAT=Dynamic setting, check your Aurora configuration settings for any changes to the INNODB_FILE_FORMAT configuration option. Issue the SHOW TABLE STATUS statement to confirm the row format for all the tables in a database.

Before changing your schema to turn on parallel query to work with more tables, make sure to test. Your tests should confirm if parallel query results in a net increase in performance for those tables. Also, make sure that the schema requirements for parallel query are otherwise compatible with your goals.

For example, before switching from ROW_FORMAT=Compressed to ROW_FORMAT=Compact or ROW_FORMAT=Dynamic, test the performance of workloads for the original and new tables. Also, consider other potential effects such as increased data volume.

Verifying which statements use parallel query

In typical operation, you don't need to perform any special actions to take advantage of parallel query. After a query meets the essential requirements for parallel query, the query optimizer automatically decides whether to use parallel query for each specific query.
If you run experiments in a development or test environment, you might find that parallel query isn't used because your tables are too small in number of rows or overall data volume. The data for the table might also be entirely in the buffer pool, especially for tables that you created recently to perform experiments.

As you monitor or tune cluster performance, make sure to decide whether parallel query is being used in the appropriate contexts. You might adjust the database schema, settings, SQL queries, or even the cluster topology and application connection settings to take advantage of this feature.

To check if a query is using parallel query, check the query plan (also known as the "explain plan") by running the EXPLAIN statement. For examples of how SQL statements, clauses, and expressions affect EXPLAIN output for parallel query, see How parallel query works with SQL constructs (p. 811).

The following example demonstrates the difference between a traditional query plan and a parallel query plan. This explain plan is from Query 3 from the TPC-H benchmark. Many of the sample queries throughout this section use the tables from the TPC-H dataset. You can get the table definitions, queries, and the dbgen program that generates sample data from the TPC-h website.

```
EXPLAIN SELECT l_orderkey, 
    sum(l_extendedprice * (1 - l_discount)) AS revenue, 
    o_orderdate, 
    o_shippriority 
FROM customer, 
    orders, 
    lineitem 
WHERE c_mktsegment = 'AUTOMOBILE' 
AND c_custkey = o_custkey 
AND l_orderkey = o_orderkey 
AND o_orderdate < date '1995-03-13' 
AND l_shipdate > date '1995-03-13' 
GROUP BY l_orderkey, 
    o_orderdate, 
    o_shippriority 
ORDER BY revenue DESC, 
    o_orderdate LIMIT 10;
```

By default, the query might have a plan like the following. If you don't see hash join used in the query plan, make sure that optimization is turned on first.

```
+----+-------------+----------+------------+------+---------------+------+---------+------+
| id | select_type | table    | partitions | type | possible_keys | key  | key_len | ref  |
| rows | filtered | Extra |
+----+-------------+----------+------------+------+---------------+------+---------+------+
|  1 | SIMPLE      | customer | NULL       | ALL  | NULL          | NULL | NULL    | NULL |
| 1480234 |    10.00 | Using where; Using temporary; Using filesort | |
|  1 | SIMPLE      | orders   | NULL       | ALL  | NULL          | NULL | NULL    | NULL |
| 14875240 |     3.33 | Using where; Using join buffer (Block Nested Loop) | |
|  1 | SIMPLE      | lineitem | NULL       | ALL  | NULL          | NULL | NULL    | NULL |
| 59270573 |     3.33 | Using where; Using join buffer (Block Nested Loop) | |
```

You can turn on hash join at the session level by issuing the following statement. Afterwards, try the EXPLAIN statement again.

```
# For Aurora MySQL version 3:
SET optimizer_switch='block_nested_loop=on';
```
# For Aurora MySQL version 2.09 and higher:

```sql
SET optimizer_switch='hash_join=on';
```

For information about how to use hash joins effectively, see Optimizing large Aurora MySQL join queries with hash joins (p. 946).

With hash join turned on but parallel query turned off, the query might have a plan like the following, which uses hash join but not parallel query.

```
+----+-------------+----------+...+-----------
+-----------------------------------------------------------------+
| id | select_type | table    |...| rows      | Extra                  |
+----+-------------+----------+...+-----------
+-----------------------------------------------------------------+
|  1 | SIMPLE      | customer |...|   5798330 | Using where; Using index; Using temporary; Using filesort       |
|  1 | SIMPLE      | orders   |...| 154545408 | Using where; Using join buffer (Hash Join Outer table orders)   |
|  1 | SIMPLE      | lineitem |...| 606119300 | Using where; Using join buffer (Hash Join Outer table lineitem) |
+----+-------------+----------+...+-----------
```

After parallel query is turned on, two steps in this query plan can use the parallel query optimization, as shown under the `Extra` column in the `EXPLAIN` output. The I/O-intensive and CPU-intensive processing for those steps is pushed down to the storage layer.

```
+----+...+
| id |...| Extra                  |
+----+...+
+----+...+
|  1 |...| Using where; Using index; Using temporary; Using filesort |
|  1 |...| Using where; Using join buffer (Hash Join Outer table orders); Using parallel query (4 columns, 1 filters, 1 exprs; 0 extra) |
|  1 |...| Using where; Using join buffer (Hash Join Outer table lineitem); Using parallel query (4 columns, 1 filters, 1 exprs; 0 extra) |
+----+...
```

For information about how to interpret `EXPLAIN` output for a parallel query and the parts of SQL statements that parallel query can apply to, see How parallel query works with SQL constructs (p. 811).

The following example output shows the results of running the preceding query on a db.r4.2xlarge instance with a cold buffer pool. The query runs substantially faster when using parallel query.

### Note
Because timings depend on many environmental factors, your results might be different. Always conduct your own performance tests to confirm the findings with your own environment, workload, and so on.

```
-- Without parallel query
+------------+-------------+-------------+----------------+
| l_orderkey | revenue     | o_orderdate | o_shippriority |
+------------+-------------+-------------+----------------+
```

806
Many of the sample queries throughout this section use the tables from this TPC-H dataset, particularly the `PART` table, which has 20 million rows and the following definition.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>

Experiment with your workload to get a sense of whether individual SQL statements can take advantage of parallel query. Then use the following monitoring techniques to help verify how often parallel query is used in real workloads over time. For real workloads, extra factors such as concurrency limits apply.

### Monitoring parallel query

If your Aurora MySQL cluster uses parallel query, you might see an increase in `VolumeReadIOPS` values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

In addition to the Amazon CloudWatch metrics described in Viewing metrics in the Amazon RDS console (p. 449), Aurora provides other global status variables. You can use these global status variables to help monitor parallel query execution. They can give you insights into why the optimizer might use or not use parallel query in a given situation. To access these variables, you can use the `SHOW GLOBAL STATUS` command. You can also find these variables listed following.

A parallel query session isn't necessarily a one-to-one mapping with the queries performed by the database. For example, suppose that your query plan has two steps that use parallel query. In that case, the query involves two parallel sessions and the counters for requests attempted and requests successful are incremented by two.

When you experiment with parallel query by issuing `EXPLAIN` statements, expect to see increases in the counters designated as "not chosen" even though the queries aren't actually running. When you work with parallel query in production, you can check if the "not chosen" counters are increasing faster than you expect. At this point, you can adjust so that parallel query runs for the queries that you expect. To do...
so, you can change your cluster settings, query mix, DB instances where parallel query is turned on, and so on.

These counters are tracked at the DB instance level. When you connect to a different endpoint, you might see different metrics because each DB instance runs its own set of parallel queries. You might also see different metrics when the reader endpoint connects to a different DB instance for each session.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora_pq_request_attempted</td>
<td>The number of parallel query sessions requested. This value might represent more than one session per query, depending on SQL constructs such as subqueries and joins.</td>
</tr>
<tr>
<td>Aurora_pq_request_executed</td>
<td>The number of parallel query sessions run successfully.</td>
</tr>
<tr>
<td>Aurora_pq_request_failed</td>
<td>The number of parallel query sessions that returned an error to the client. In some cases, a request for a parallel query might fail, for example due to a problem in the storage layer. In these cases, the query part that failed is retried using the nonparallel query mechanism. If the retried query also fails, an error is returned to the client and this counter is incremented.</td>
</tr>
<tr>
<td>Aurora_pq_pages_pushed_down</td>
<td>The number of data pages (each with a fixed size of 16 KiB) where parallel query avoided a network transmission to the head node.</td>
</tr>
<tr>
<td>Aurora_pq_bytes_returned</td>
<td>The number of bytes for the tuple data structures transmitted to the head node during parallel queries. Divide by 16,384 to compare against Aurora_pq_pages_pushed_down.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen</td>
<td>The number of times parallel query wasn't chosen to satisfy a query. This value is the sum of several other more granular counters. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_below_min_rows</td>
<td>The number of times parallel query wasn't chosen due to the number of rows in the table. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_small_table</td>
<td>The number of times parallel query wasn't chosen due to the overall size of the table, as determined by number of rows and average row length. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
</tbody>
</table>
| Aurora_pq_request_not_chosen_high_buffer_pool_pct| The number of times parallel query wasn't chosen because a high percentage of the table data (currently, greater than 95 percent) was already in the buffer pool. In these cases, the optimizer determines that reading the data from the buffer pool is more efficient. An EXPLAIN statement can
increment this counter even though the query isn't actually performed.

<tr>
<td><strong>Aurora_pq_request_not_chosen_long_trx</strong></td>
<td>The number of parallel query requests that used the nonparallel query processing path, due to the query being started inside a long-running transaction. An <strong>EXPLAIN</strong> statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td><strong>Aurora_pq_request_not_chosen_unsupported_access</strong></td>
<td>The number of parallel query requests that use the nonparallel query processing path because the <strong>WHERE</strong> clause doesn't meet the criteria for parallel query. This result can occur if the query doesn't require a data-intensive scan, or if the query is a <strong>DELETE</strong> or <strong>UPDATE</strong> statement.</td>
</tr>
<tr>
<td><strong>Aurora_pq_request_not_chosen_column_bit</strong></td>
<td>The number of parallel query requests that use the nonparallel query processing path because of an unsupported data type in the list of projected columns.</td>
</tr>
<tr>
<td><strong>Aurora_pq_request_not_chosen_column_geometry</strong></td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table has columns with the <strong>GEOMETRY</strong> data type. For information about Aurora MySQL versions that remove this limitation, see Upgrading parallel query clusters to Aurora MySQL version 3 (p. 803).</td>
</tr>
</tbody>
</table>
### Aurora_pq_request_not_chosen_column_lob
The number of parallel query requests that use the nonparallel query processing path because the table has columns with a LOB data type, or VARCHAR columns that are stored externally due to the declared length. For information about Aurora MySQL versions that remove this limitation, see [Upgrading parallel query clusters to Aurora MySQL version 3](p. 803).

### Aurora_pq_request_not_chosen_column_virtual
The number of parallel query requests that use the nonparallel query processing path because the table contains a virtual column.

### Aurora_pq_request_not_chosen_custom_charset
The number of parallel query requests that use the nonparallel query processing path because the table has columns with a custom character set.

### Aurora_pq_request_not_chosen_fast_ddl
The number of parallel query requests that use the nonparallel query processing path because the table is currently being altered by a fast DDL ALTER statement.

### Aurora_pq_request_not_chosen_full_text_index
The number of parallel query requests that use the nonparallel query processing path because the table has full-text indexes.

### Aurora_pq_request_not_chosen_index_hint
The number of parallel query requests that use the nonparallel query processing path because the query includes an index hint.

### Aurora_pq_request_not_chosen_innodb_table_format
The number of parallel query requests that use the nonparallel query processing path because the table uses an unsupported InnoDB row format. Aurora parallel query only applies to the COMPACT, REDUNDANT, and DYNAMIC row formats.

### Aurora_pq_request_not_chosen_no_where_clause
The number of parallel query requests that use the nonparallel query processing path because the query doesn't include any WHERE clause.

### Aurora_pq_request_not_chosen_range_scan
The number of parallel query requests that use the nonparallel query processing path because the query uses a range scan on an index.

### Aurora_pq_request_not_chosen_row_length_too_long
The number of parallel query requests that use the nonparallel query processing path because the total combined length of all the columns is too long.

### Aurora_pq_request_not_chosen_temporary_table
The number of parallel query requests that use the nonparallel query processing path because the query refers to temporary tables that use the unsupported MyISAM or memory table types.
How parallel query works with SQL constructs

In the following section, you can find more detail about why particular SQL statements use or don’t use parallel query. This section also details how Aurora MySQL features interact with parallel query. This information can help you diagnose performance issues for a cluster that uses parallel query or understand how parallel query applies for your particular workload.

The decision to use parallel query relies on many factors that occur at the moment that the statement runs. Thus, parallel query might be used for certain queries always, never, or only under certain conditions.

Tip
When you view these examples in HTML, you can use the Copy widget in the upper-right corner of each code listing to copy the SQL code to try yourself. Using the Copy widget avoids copying the extra characters around the mysql> prompt and --> continuation lines.

EXPLAIN statement

As shown in examples throughout this section, the EXPLAIN statement indicates whether each stage of a query is currently eligible for parallel query. It also indicates which aspects of a query can be pushed down to the storage layer. The most important items in the query plan are the following:

- A value other than NULL for the key column suggests that the query can be performed efficiently using index lookups, and parallel query is unlikely.
- A small value for the rows column (a value not in the millions) suggests that the query isn't accessing enough data to make parallel query worthwhile. This means that parallel query is unlikely.
- The Extra column shows you if parallel query is expected to be used. This output looks like the following example.

Using parallel query (A columns, B filters, C exprs; D extra)

The columns number represents how many columns are referred to in the query block.

The filters number represents the number of WHERE predicates representing a simple comparison of a column value to a constant. The comparison can be for equality, inequality, or a range. Aurora can parallelize these kinds of predicates most effectively.

The exprs number represents the number of expressions such as function calls, operators, or other expressions that can also be parallelized, though not as effectively as a filter condition.

The extra number represents how many expressions can't be pushed down and are performed by the head node.

For example, consider the following EXPLAIN output.

```
mysql> explain select p_name, p_mfgr from part
    -> where p_brand is not null
    -> and upper(p_type) is not null
    -> and round(p_retailprice) is not null;
+----+-------------+-------+...+----------
+----------------------------------------------------------------------------+
| id | select_type | table |...| rows     | Extra                      |
+----+-------------+-------+...+----------+
+----------------------------------------------------------------------------+
|  1 | SIMPLE      | part  |...| 20427936 | Using where; Using parallel query (5 columns, 1 filters, 2 exprs; 0 extra) |
+----------------------------------------------------------------------------+
```

The information from the Extra column shows that five columns are extracted from each row to evaluate the query conditions and construct the result set. One WHERE predicate involves a filter, that is, a column that is directly tested in the WHERE clause. Two WHERE clauses require evaluating more complicated expressions, in this case involving function calls. The 0 extra field confirms that all the operations in the WHERE clause are pushed down to the storage layer as part of parallel query processing.

In cases where parallel query isn't chosen, you can typically deduce the reason from the other columns of the EXPLAIN output. For example, the rows value might be too small, or the possible_keys column might indicate that the query can use an index lookup instead of a data-intensive scan. The following example shows a query where the optimizer can estimate that the query will scan only a small number of rows. It does so based on the characteristics of the primary key. In this case, parallel query isn't required.
The output showing whether parallel query will be used takes into account all available factors at the moment that the EXPLAIN statement is run. The optimizer might make a different choice when the query is actually run, if the situation changed in the meantime. For example, EXPLAIN might report that a statement will use parallel query. But when the query is actually run later, it might not use parallel query based on the conditions then. Such conditions can include several other parallel queries running concurrently. They can also include rows being deleted from the table, a new index being created, too much time passing within an open transaction, and so on.

**WHERE clause**

For a query to use the parallel query optimization, it must include a WHERE clause.

The parallel query optimization speeds up many kinds of expressions used in the WHERE clause:

- Simple comparisons of a column value to a constant, known as filters. These comparisons benefit the most from being pushed down to the storage layer. The number of filter expressions in a query is reported in the EXPLAIN output.
- Other kinds of expressions in the WHERE clause are also pushed down to the storage layer where possible. The number of such expressions in a query is reported in the EXPLAIN output. These expressions can be function calls, LIKE operators, CASE expressions, and so on.
- Certain functions and operators aren't currently pushed down by parallel query. The number of such expressions in a query is reported as the extra counter in the EXPLAIN output. The rest of the query can still use parallel query.
- While expressions in the select list aren't pushed down, queries containing such functions can still benefit from reduced network traffic for the intermediate results of parallel queries. For example, queries that call aggregation functions in the select list can benefit from parallel query, even though the aggregation functions aren't pushed down.

For example, the following query does a full-table scan and processes all the values for the P_BRAND column. However, it doesn't use parallel query because the query doesn't include any WHERE clause.

```sql
mysql> explain select count(*), p_brand from part group by p_brand;
+----+-------------+-------+------+---------------+------+---------+------+----------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>SIMPLE</td>
<td>part</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>20427936</td>
</tr>
</tbody>
</table>
Using temporary; Using filesort |
```

In contrast, the following query includes WHERE predicates that filter the results, so parallel query can be applied:

```sql
mysql> explain select count(*), p_brand from part where p_partkey between 1 and 100;
+----+-------------+-------+-------+---------------+---------+---------+------+------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>part</td>
<td>range</td>
<td>PRIMARY</td>
<td>PRIMARY</td>
<td>4</td>
<td>NULL</td>
<td>99</td>
</tr>
</tbody>
</table>
Using where; Using index |
```
If the optimizer estimates that the number of returned rows for a query block is small, parallel query isn't used for that query block. The following example shows a case where a greater-than operator on the primary key column applies to millions of rows, which causes parallel query to be used. The converse less-than test is estimated to apply to only a few rows and doesn't use parallel query.

mysql> explain select count(*) from part where p_partkey > 10;
+----+...+-------+--------------------------+
| id |...| rows  | Extra                     |
+----+...+-------+--------------------------+
|  1 |...| 20427936 | Using where; Using parallel query (1 columns, 1 filters, 0 exprs; 0 extra) |
+----+...+-------+--------------------------+

mysql> explain select count(*) from part where p_partkey < 10;
+----+...+-----+--------------------------+
| id |...| rows | Extra                    |
+----+...+-----+--------------------------+
|  1 |...|    9 | Using where; Using index |
+----+...+-----+--------------------------+

Data definition language (DDL)

Before Aurora MySQL version 3, parallel query is only available for tables for which no fast data definition language (DDL) operations are pending. In Aurora MySQL version 3, you can use parallel query on a table at the same time as an instant DDL operation. Instant DDL in Aurora MySQL version 3 replaces the fast DDL feature in Aurora MySQL versions 1 and 2. For information about instant DDL, see Instant DDL (Aurora MySQL version 3) (p. 742).

Column data types

In Aurora MySQL version 3, parallel query can work with tables containing columns with data types TEXT, BLOB, JSON, and GEOMETRY. It can also work with VARCHAR and CHAR columns with a maximum declared length longer than 768 bytes. If your query refers to any columns containing such large object types, the additional work to retrieve them does add some overhead to query processing. In that case, check if the query can omit the references to those columns. If not, run benchmarks to confirm if such queries are faster with parallel query turned on or turned off.

Before Aurora MySQL version 3, parallel query has these limitations for large object types:
In these earlier versions, TEXT, BLOB, JSON, and GEOMETRY data types aren't supported with parallel query. A query that refers to any columns of these types can't use parallel query.

In these earlier versions, variable-length columns (VARCHAR and CHAR data types) are compatible with parallel query up to a maximum declared length of 768 bytes. A query that refers to any columns of the types declared with a longer maximum length can't use parallel query. For columns that use multibyte character sets, the byte limit takes into account the maximum number of bytes in the character set. For example, for the character set utf8mb4 (which has a maximum character length of 4 bytes), a VARCHAR(192) column is compatible with parallel query but a VARCHAR(193) column isn’t.

**Partitioned tables**

You can use partitioned tables with parallel query in Aurora MySQL version 3. Because partitioned tables are represented internally as multiple smaller tables, a query that uses parallel query on a nonpartitioned table might not use parallel query on an identical partitioned table. Aurora MySQL considers whether each partition is large enough to qualify for the parallel query optimization, instead of evaluating the size of the entire table. Check whether the Aurora_pq_request_not_chosen_small_table status variable is incremented if a query on a partitioned table doesn’t use parallel query when you expect it to.

For example, consider one table partitioned with PARTITION BY HASH (column) PARTITIONS 2 and another table partitioned with PARTITION BY HASH (column) PARTITIONS 10. In the table with two partitions, the partitions are five times as large as the table with ten partitions. Thus, parallel query is more likely to be used for queries against the table with fewer partitions. In the following example, the table PART_BIG_PARTITIONS has two partitions and PART_SMALL_PARTITIONS has ten partitions. With identical data, parallel query is more likely to be used for the table with fewer big partitions.

```
mysql> explain select count(*), p_brand from part_big_partitions where p_name is not null
-> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000 group
by p_brand;

| id | select_type | table               | partitions | Extra
|----|-------------|---------------------+------------|---------------------------------------------------|
|  1 | SIMPLE      | part_big_partitions | p0,p1      | Using where; Using temporary; Using parallel query (4 columns, 1 filters, 1 exprs; 0 extra; 1 group-bys, 1 aggrs) |

mysql> explain select count(*), p_brand from part_small_partitions where p_name is not null
-> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000 group
by p_brand;

| id | select_type | table               | partitions | Extra
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>part_small_partitions</td>
<td>p0,p1,p2,p3,p4,p5,p6,p7,p8,p9</td>
<td>Using where; Using temporary</td>
</tr>
</tbody>
</table>
```
Aggregate functions, GROUP BY clauses, and HAVING clauses

Queries involving aggregate functions are often good candidates for parallel query, because they involve scanning large numbers of rows within large tables.

In Aurora MySQL 3, parallel query can optimize aggregate function calls in the select list and the HAVING clause.

Before Aurora MySQL 3, aggregate function calls in the select list or the HAVING clause aren't pushed down to the storage layer. However, parallel query can still improve the performance of such queries with aggregate functions. It does so by first extracting column values from the raw data pages in parallel at the storage layer. It then transmits those values back to the head node in a compact tuple format instead of as entire data pages. As always, the query requires at least one WHERE predicate for parallel query to be activated.

The following simple examples illustrate the kinds of aggregate queries that can benefit from parallel query. They do so by returning intermediate results in compact form to the head node, filtering nonmatching rows from the intermediate results, or both.

```
mysql> explain select sql_no_cache count(distinct p_brand) from part where p_mfgr = 'Manufacturer#5';
+----+...+----------------------------------------------------------------------------+
| id |...| Extra                                                                      |
+----+...+----------------------------------------------------------------------------+
|  1 |...| Using where; Using parallel query (2 columns, 1 filters, 0 exprs; 0 extra) |
+----+...+----------------------------------------------------------------------------+

mysql> explain select sql_no_cache p_mfgr from part where p_retailprice > 1000 group by p_mfgr having count(*) > 100;
+----+...+-------------------------------------------------------------------------------------------------------------+
| id |...| Extra                                                                 |
|  1 |...| Using where; Using temporary; Using filesort; Using parallel query (3 columns, 0 filters, 1 exprs; 0 extra) |
+----+...+-------------------------------------------------------------------------------------------------------------+
```

Function calls in WHERE clause

Aurora can apply the parallel query optimization to calls to most built-in functions in the WHERE clause. Parallelizing these function calls offloads some CPU work from the head node. Evaluating the predicate functions in parallel during the earliest query stage helps Aurora minimize the amount of data transmitted and processed during later stages.

Currently, the parallelization doesn't apply to function calls in the select list. Those functions are evaluated by the head node, even if identical function calls appear in the WHERE clause. The original values from relevant columns are included in the tuples transmitted from the storage nodes back to the head node. The head node performs any transformations such as UPPER, CONCATENATE, and so on to produce the final values for the result set.

In the following example, parallel query parallelizes the call to LOWER because it appears in the WHERE clause. Parallel query doesn't affect the calls to SUBSTR and UPPER because they appear in the select list.

```
mysql> explain select sql_no_cache distinct substr(upper(p_name),1,5) from part
     -> where lower(p_name) like '%cornflower%' or lower(p_name) like '%goldenrod%';
+----+...+-------------------------------------------------------------------------------------------------------------+
| id |...| Extra                                                                 |
+----+...+-------------------------------------------------------------------------------------------------------------+
```
The same considerations apply to other expressions, such as *CASE* expressions or *LIKE* operators. For example, the following example shows that parallel query evaluates the *CASE* expression and *LIKE* operators in the *WHERE* clause.

```sql
mysql> explain select p_mfgr, p_retailprice from part
    > where p_retailprice > case p_mfgr
    >   when 'Manufacturer#1' then 1000
    >   when 'Manufacturer#2' then 1200
    >   else 950
    > end
    > and p_name like '%vanilla%'
    > group by p_retailprice;
```

The first example following shows that an equality comparison against the primary key column can be performed efficiently without parallel query. The second example following shows that a similar comparison against an unindexed column requires scanning millions of rows and therefore can benefit from parallel query.

```sql
mysql> explain select * from part where p_partkey = 10;
```

**LIMIT clause**

Currently, parallel query isn't used for any query block that includes a *LIMIT* clause. Parallel query might still be used for earlier query phases with *GROUP by*, *ORDER BY*, or joins.

**Comparison operators**

The optimizer estimates how many rows to scan to evaluate comparison operators, and determines whether to use parallel query based on that estimate.

The first example following shows that an equality comparison against the primary key column can be performed efficiently without parallel query. The second example following shows that a similar comparison against an unindexed column requires scanning millions of rows and therefore can benefit from parallel query.
The same considerations apply for not-equals tests and for range comparisons such as less than, greater than or equal to, or BETWEEN. The optimizer estimates the number of rows to scan, and determines whether parallel query is worthwhile based on the overall volume of I/O.

### Joins

Join queries with large tables typically involve data-intensive operations that benefit from the parallel query optimization. The comparisons of column values between multiple tables (that is, the join predicates themselves) currently aren’t parallelized. However, parallel query can push down some of the internal processing for other join phases, such as constructing the Bloom filter during a hash join. Parallel query can apply to join queries even without a WHERE clause. Therefore, a join query is an exception to the rule that a WHERE clause is required to use parallel query.

Each phase of join processing is evaluated to check if it is eligible for parallel query. If more than one phase can use parallel query, these phases are performed in sequence. Thus, each join query counts as a single parallel query session in terms of concurrency limits.

For example, when a join query includes WHERE predicates to filter the rows from one of the joined tables, that filtering option can use parallel query. As another example, suppose that a join query uses the hash join mechanism, for example to join a big table with a small table. In this case, the table scan to produce the Bloom filter data structure might be able to use parallel query.

**Note**

Parallel query is typically used for the kinds of resource-intensive queries that benefit from the hash join optimization. The method for turning on the hash join optimization depends on the Aurora MySQL version. For details for each version, see Turning on hash join for parallel query clusters (p. 801). For information about how to use hash joins effectively, see Optimizing large Aurora MySQL join queries with hash joins (p. 946).
For a join query that uses the nested loop mechanism, the outermost nested loop block might use parallel query. The use of parallel query depends on the same factors as usual, such as the presence of additional filter conditions in the `WHERE` clause.

```
mysql> -- Nested loop join with extra filter conditions can use parallel query.
mysql> explain select count(*) from part, partsupp where p_partkey != ps_partkey and p_name
   is not null and ps_availqty > 0;
+----+-------------+----------+...+----------
| id | select_type | table    |...| rows     | Extra
|    | SIMPLE      | part     |...| 20427936 | Using where; Using parallel query (2 columns, 1 filters, 0 exprs; 0 extra) |
| 2 | UNION       | partsupp |...| 20427936 | Using where; Using join buffer (Block Nested Loop) |
```

**Subqueries**

The outer query block and inner subquery block might each use parallel query, or not. Whether they do is based on the usual characteristics of the table, `WHERE` clause, and so on, for each block. For example, the following query uses parallel query for the subquery block but not the outer block.

```
mysql> explain select count(*) from part where
   --> p_partkey < (select max(p_partkey) from part where p_name like '%vanilla%');
+----+----------------+...+----------
| id | select_type    |...| rows     | Extra
| 2 | SUBQUERY       |...| 20427936 | Using where; Using parallel query (2 columns, 0 filters, 1 exprs; 0 extra) |
```

Currently, correlated subqueries can't use the parallel query optimization.

**UNION**

Each query block in a `UNION` query can use parallel query, or not, based on the usual characteristics of the table, `WHERE` clause, and so on, for each part of the `UNION`.

```
mysql> explain select p_partkey from part where p_name like '%choco_ate%'
   --> union select p_partkey from part where p_name like '%vanilla%';
+----+----------------+...+----------
| id | select_type    |...| rows     | Extra
| 1 | PRIMARY        |...| 20427936 | Using where; Using parallel query (2 columns, 0 filters, 1 exprs; 0 extra) |
| 2 | UNION          |...| 20427936 | Using where; Using parallel query (2 columns, 0 filters, 1 exprs; 0 extra) |
```
Parallel query and SQL constructs

| NULL | UNION RESULT | <union1,2> |...| NULL | Using temporary
|...|...|...|...|...|...|

Note
Each UNION clause within the query is run sequentially. Even if the query includes multiple stages that all use parallel query, it only runs a single parallel query at any one time. Therefore, even a complex multistage query only counts as 1 toward the limit of concurrent parallel queries.

Views
The optimizer rewrites any query using a view as a longer query using the underlying tables. Thus, parallel query works the same whether table references are views or real tables. All the same considerations about whether to use parallel query for a query, and which parts are pushed down, apply to the final rewritten query.

For example, the following query plan shows a view definition that usually doesn’t use parallel query. When the view is queried with additional WHERE clauses, Aurora MySQL uses parallel query.

```
mysql> create view part_view as select * from part;
mysql> explain select count(*) from part_view where p_partkey is not null;
```

```
+----+...+----------+
| id |...| rows     | Extra     |
|...|...|----------|-----------|
|  1 |...| 20427936 | Using where; Using parallel query (1 columns, 0 filters, 0 exprs; 1 extra) |
```

Data manipulation language (DML) statements
The INSERT statement can use parallel query for the SELECT phase of processing, if the SELECT part meets the other conditions for parallel query.

```
mysql> create table part_subset like part;
mysql> explain insert into part_subset select * from part where p_mfgr = 'Manufacturer#1';
```

```
+----+...+----------+
| id |...| rows     | Extra     |
|...|...|----------|-----------|
|  1 |...| 20427936 | Using where; Using parallel query (9 columns, 1 filters, 0 exprs; 0 extra) |
```

Note
Typically, after an INSERT statement, the data for the newly inserted rows is in the buffer pool. Therefore, a table might not be eligible for parallel query immediately after inserting a large number of rows. Later, after the data is evicted from the buffer pool during normal operation, queries against the table might begin using parallel query again.

The CREATE TABLE AS SELECT statement doesn’t use parallel query, even if the SELECT portion of the statement would otherwise be eligible for parallel query. The DDL aspect of this statement makes
Parallel query and SQL constructs

Parallel query is never used for DELETE or UPDATE statements, regardless of the size of the table and predicates in the WHERE clause.

Transactions and locking

You can use all the isolation levels on the Aurora primary instance.

On Aurora reader DB instances, parallel query applies to statements performed under the REPEATABLE READ isolation level. Aurora MySQL versions 1.23 and 2.09 or higher can also use the READ COMMITTED isolation level on reader DB instances. REPEATABLE READ is the default isolation level for Aurora reader DB instances. To use READ COMMITTED isolation level on reader DB instances requires setting the `aurora_read_replica_read_committed` configuration option at the session level. The READ COMMITTED isolation level for reader instances complies with SQL standard behavior. However, the isolation is less strict on reader instances than when queries use READ COMMITTED isolation level on the writer instance.

For more information about Aurora isolation levels, especially the differences in READ COMMITTED between writer and reader instances, see Aurora MySQL isolation levels (p. 979).

After a big transaction is finished, the table statistics might be stale. Such stale statistics might require an ANALYZE TABLE statement before Aurora can accurately estimate the number of rows. A large-scale DML statement might also bring a substantial portion of the table data into the buffer pool. Having this data in the buffer pool can lead to parallel query being chosen less frequently for that table until the data is evicted from the pool.

When your session is inside a long-running transaction (by default, 10 minutes), further queries inside that session don’t use parallel query. A timeout can also occur during a single long-running query. This type of timeout might happen if the query runs for longer than the maximum interval (currently 10 minutes) before the parallel query processing starts.

You can reduce the chance of starting long-running transactions accidentally by setting `autocommit=1` in mysql sessions where you perform ad hoc (one-time) queries. Even a SELECT statement against a table begins a transaction by creating a read view. A read view is a consistent set of data for subsequent queries that remains until the transaction is committed. Be aware of this restriction also when using JDBC or ODBC applications with Aurora, because such applications might run with the autocommit setting turned off.

The following example shows how, with the autocommit setting turned off, running a query against a table creates a read view that implicitly begins a transaction. Queries that are run shortly afterward can still use parallel query. However, after a pause of several minutes, queries are no longer eligible for parallel query. Ending the transaction with COMMIT or ROLLBACK restores parallel query eligibility.

```
mysql> set autocommit=0;

mysql> explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
```
To see how many times queries weren't eligible for parallel query because they were inside long-running transactions, check the status variable `Aurora_pq_request_not_chosen_long_trx`.

```
mysql> show global status like '%pq%trx%';
+---------------------------------------+-------+
| Variable_name                         | Value |
+---------------------------------------+-------+
| Aurora_pq_request_not_chosen_long_trx | 4     |
+-------------------------------+-------+
```

Any SELECT statement that acquires locks, such as the SELECT FOR UPDATE or SELECT LOCK IN SHARE MODE syntax, can't use parallel query.

Parallel query can work for a table that is locked by a LOCK TABLES statement.

```
mysql> explain select o_orderpriority, o_shippriority from orders where o_clerk = 'Clerk#000095055';
+----+...+-----------+-------------+
| id |...| rows      | Extra       |
+----+...+-----------+-------------+
|  1 |...| 154545408 | Using where; Using parallel query (3 columns, 1 filters, 0 exprs; 0 extra) |
+----+...+-----------+-------------+
```
B-tree indexes

The statistics gathered by the `ANALYZE TABLE` statement help the optimizer to decide when to use parallel query or index lookups, based on the characteristics of the data for each column. Keep statistics current by running `ANALYZE TABLE` after DML operations that make substantial changes to the data within a table.

If index lookups can perform a query efficiently without a data-intensive scan, Aurora might use index lookups. Doing so avoids the overhead of parallel query processing. There are also concurrency limits on the number of parallel queries that can run simultaneously on any Aurora DB cluster. Make sure to use best practices for indexing your tables, so that your most frequent and most highly concurrent queries use index lookups.

Full-text search (FTS) indexes

Currently, parallel query isn’t used for tables that contain a full-text search index, regardless of whether the query refers to such indexed columns or uses the `MATCH` operator.

Virtual columns

Currently, parallel query isn’t used for tables that contain a virtual column, regardless of whether the query refers to any virtual columns.

Built-in caching mechanisms

Aurora includes built-in caching mechanisms, namely the buffer pool and the query cache. The Aurora optimizer chooses between these caching mechanisms and parallel query depending on which one is most effective for a particular query.

When a parallel query filters rows and transforms and extracts column values, data is transmitted back to the head node as tuples rather than as data pages. Therefore, running a parallel query doesn’t add any pages to the buffer pool, or evict pages that are already in the buffer pool.

Aurora checks the number of pages of table data that are present in the buffer pool, and what proportion of the table data that number represents. Aurora uses that information to determine whether it is more efficient to use parallel query (and bypass the data in the buffer pool). Alternatively, Aurora might use the nonparallel query processing path, which uses data cached in the buffer pool. Which pages are cached and how data-intensive queries affect caching and eviction depends on configuration settings related to the buffer pool. Therefore, it can be hard to predict whether any particular query uses parallel query, because the choice depends on the ever-changing data within the buffer pool.

Also, Aurora imposes concurrency limits on parallel queries. Because not every query uses parallel query, tables that are accessed by multiple queries simultaneously typically have a substantial portion of their data in the buffer pool. Therefore, Aurora often doesn’t choose these tables for parallel queries.

When you run a sequence of nonparallel queries on the same table, the first query might be slow due to the data not being in the buffer pool. Then the second and subsequent queries are much faster because the buffer pool is now "warmed up". Parallel queries typically show consistent performance from the very first query against the table. When conducting performance tests, benchmark the nonparallel
queries with both a cold and a warm buffer pool. In some cases, the results with a warm buffer pool can compare well to parallel query times. In these cases, consider factors such as the frequency of queries against that table. Also consider whether it is worthwhile to keep the data for that table in the buffer pool.

The query cache avoids rerunning a query when an identical query is submitted and the underlying table data hasn't changed. Queries optimized by parallel query feature can go into the query cache, effectively making them instantaneous when run again.

**Note**

When conducting performance comparisons, the query cache can produce artificially low timing numbers. Therefore, in benchmark-like situations, you can use the `sql_no_cache` hint. This hint prevents the result from being served from the query cache, even if the same query had been run previously. The hint comes immediately after the `SELECT` statement in a query. Many parallel query examples in this topic include this hint, to make query times comparable between versions of the query for which parallel query is turned on and turned off. Make sure that you remove this hint from your source when you move to production use of parallel query.

**MyISAM temporary tables**

The parallel query optimization only applies to InnoDB tables. Because Aurora MySQL uses MyISAM behind the scenes for temporary tables, internal query phases involving temporary tables never use parallel query. These query phases are indicated by `Using temporary` in the EXPLAIN output.

**Using Advanced Auditing with an Amazon Aurora MySQL DB cluster**

You can use the high-performance Advanced Auditing feature in Amazon Aurora MySQL to audit database activity. To do so, you enable the collection of audit logs by setting several DB cluster parameters. When Advanced Auditing is enabled, you can use it to log any combination of supported events.

You can view or download the audit logs to review the audit information for one DB instance at a time. To do so, you can use the procedures in Monitoring Amazon Aurora log files (p. 597).

**Tip**

For an Aurora DB cluster containing multiple DB instances, you might find it more convenient to examine the audit logs for all instances in the cluster. To do so, you can use CloudWatch Logs. You can turn on a setting at the cluster level to publish the Aurora MySQL audit log data to a log group in CloudWatch. Then you can view, filter, and search the audit logs through the CloudWatch interface. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 925).

**Enabling Advanced Auditing**

Use the parameters described in this section to enable and configure Advanced Auditing for your DB cluster.

Use the `server_audit_logging` parameter to enable or disable Advanced Auditing.

Use the `server_audit_events` parameter to specify what events to log.

Use the `server_audit_incl_users` and `server_audit_excl_users` parameters to specify who gets audited. By default, all users are audited. For details about how these parameters work when one or
both are left empty, or the same user names are specified in both, see server_audit_incl_users (p. 826) and server_audit_excl_users (p. 826).

Configure Advanced Auditing by setting these parameters in the parameter group used by your DB cluster. You can use the procedure shown in Modifying parameters in a DB parameter group (p. 231) to modify DB cluster parameters using the AWS Management Console. You can use the modify-db-cluster-parameter-group AWS CLI command or the ModifyDBClusterParameterGroup Amazon RDS API operation to modify DB cluster parameters programmatically.

Modifying these parameters doesn't require a DB cluster restart when the parameter group is already associated with your cluster. When you associate the parameter group with the cluster for the first time, a cluster restart is required.

Topics
• server_audit_logging (p. 825)
• server_audit_events (p. 825)
• server_audit_incl_users (p. 826)
• server_audit_excl_users (p. 826)

server_audit_logging
Enables or disables Advanced Auditing. This parameter defaults to OFF; set it to ON to enable Advanced Auditing.

No audit data appears in the logs unless you also define one or more types of events to audit using the server_audit_events parameter.

To confirm that audit data is logged for a DB instance, check that some log files for that instance have names of the form audit/audit.log.<other_identifying_information>. To see the names of the log files, follow the procedure in Viewing and listing database log files (p. 597).

server_audit_events
Contains the comma-delimited list of events to log. Events must be specified in all caps, and there should be no white space between the list elements, for example: CONNECT, QUERY_DDL. This parameter defaults to an empty string.

You can log any combination of the following events:

• CONNECT – Logs both successful and failed connections and also disconnections. This event includes user information.
• QUERY – Logs all queries in plain text, including queries that fail due to syntax or permission errors.
  Tip
  With this event type turned on, the audit data includes information about the continuous monitoring and health-checking information that Aurora does automatically. If you are only interested in particular kinds of operations, you can use the more specific kinds of events. You can also use the CloudWatch interface to search in the logs for events related to specific databases, tables, or users.
• QUERY_DCL – Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).
• QUERY_DDL – Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).
• QUERY_DML – Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT).
- **TABLE** – Logs the tables that were affected by query execution.

**server_audit_incl_users**

Contains the comma-delimited list of user names for users whose activity is logged. There should be no white space between the list elements, for example: user_3, user_4. This parameter defaults to an empty string. The maximum length is 1024 characters. Specified user names must match corresponding values in the User column of the mysql.user table. For more information about user names, see the MySQL documentation.

If `server_audit_incl_users` and `server_audit_excl_users` are both empty (the default), all users are audited.

If you add users to `server_audit_incl_users` and leave `server_audit_excl_users` empty, then only those users are audited.

If you add users to `server_audit_excl_users` and leave `server_audit_incl_users` empty, then all users are audited, except for those listed in `server_audit_excl_users`.

If you add the same users to both `server_audit_excl_users` and `server_audit_incl_users`, then those users are audited. When the same user is listed in both settings, `server_audit_incl_users` is given higher priority.

Connect and disconnect events aren't affected by this variable; they are always logged if specified. A user is logged even if that user is also specified in the `server_audit_excl_users` parameter, because `server_audit_incl_users` has higher priority.

**server_audit_excl_users**

Contains the comma-delimited list of user names for users whose activity isn't logged. There should be no white space between the list elements, for example: rdsadmin, user_1, user_2. This parameter defaults to an empty string. The maximum length is 1024 characters. Specified user names must match corresponding values in the User column of the mysql.user table. For more information about user names, see the MySQL documentation.

If `server_audit_incl_users` and `server_audit_excl_users` are both empty (the default), all users are audited.

If you add users to `server_audit_excl_users` and leave `server_audit_incl_users` empty, then only those users that you list in `server_audit_excl_users` are not audited, and all other users are.

If you add the same users to both `server_audit_excl_users` and `server_audit_incl_users`, then those users are audited. When the same user is listed in both settings, `server_audit_incl_users` is given higher priority.

Connect and disconnect events aren't affected by this variable; they are always logged if specified. A user is logged if that user is also specified in the `server_audit_incl_users` parameter, because that setting has higher priority than `server_audit_excl_users`.

**Viewing audit logs**

You can view and download the audit logs by using the console. On the **Databases** page, choose the DB instance to show its details, then scroll to the **Logs** section. The audit logs produced by the Advanced Auditing feature have names of the form `audit/audit.log.<other_identifying_information>`.

To download a log file, choose that file in the **Logs** section and then choose **Download**.
Audit log details

Log files are represented as comma-separated variable (CSV) files in UTF-8 format. The audit log is stored separately on the local (ephemeral) storage of each instance. Each Aurora instance distributes writes across four log files at a time. The maximum size of the logs is 100 MB in aggregate. When this non-configurable limit is reached, Aurora rotates the files and generates four new files.

**Tip**

Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.

To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see Monitoring Amazon Aurora with Database Activity Streams (p. 619).

The audit log files include the following comma-delimited information in rows, in the specified order:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>The Unix time stamp for the logged event with microsecond precision.</td>
</tr>
<tr>
<td>serverhost</td>
<td>The name of the instance that the event is logged for.</td>
</tr>
<tr>
<td>username</td>
<td>The connected user name of the user.</td>
</tr>
<tr>
<td>host</td>
<td>The host that the user connected from.</td>
</tr>
<tr>
<td>connectionid</td>
<td>The connection ID number for the logged operation.</td>
</tr>
<tr>
<td>queryid</td>
<td>The query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines are added.</td>
</tr>
<tr>
<td>operation</td>
<td>The recorded action type. Possible values are: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, and DROP.</td>
</tr>
<tr>
<td>database</td>
<td>The active database, as set by the USE command.</td>
</tr>
<tr>
<td>object</td>
<td>For QUERY events, this value indicates the query that the database performed. For TABLE events, it indicates the table name.</td>
</tr>
<tr>
<td>retcode</td>
<td>The return code of the logged operation.</td>
</tr>
</tbody>
</table>

Single-master replication with Amazon Aurora MySQL

The Aurora MySQL replication features are key to the high availability and performance of your cluster. Aurora makes it easy to create or resize clusters with up to 15 Aurora Replicas.

All the replicas work from the same underlying data. If some database instances go offline, others remain available to continue processing queries or to take over as the writer if needed. Aurora automatically
spreads your read-only connections across multiple database instances, helping an Aurora cluster to support query-intensive workloads.

Following, you can find information about how Aurora MySQL replication works and how to fine-tune replication settings for best availability and performance.

**Note**
Following, you can learn about replication features for Aurora clusters using single-master replication. This kind of cluster is the default for Aurora. For information about Aurora multi-master clusters, see Working with Aurora multi-master clusters (p. 868).

**Topics**
- Using Aurora Replicas (p. 828)
- Replication options for Amazon Aurora MySQL (p. 829)
- Performance considerations for Amazon Aurora MySQL replication (p. 829)
- Zero-downtime restart (ZDR) for Amazon Aurora MySQL (p. 830)
- Monitoring Amazon Aurora MySQL replication (p. 831)
- Replicating Amazon Aurora MySQL DB clusters across AWS Regions (p. 832)
- Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 842)
- Using GTID-based replication for Amazon Aurora MySQL (p. 864)

**Using Aurora Replicas**

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an AWS Region. Although the DB cluster volume is made up of multiple copies of the data for the DB cluster, the data in the cluster volume is represented as a single, logical volume to the primary instance and to Aurora Replicas in the DB cluster. For more information about Aurora Replicas, see Aurora Replicas (p. 73).

Aurora Replicas work well for read scaling because they are fully dedicated to read operations on your cluster volume. Write operations are managed by the primary instance. Because the cluster volume is shared among all instances in your Aurora MySQL DB cluster, no additional work is required to replicate a copy of the data for each Aurora Replica. In contrast, MySQL read replicas must replay, on a single thread, all write operations from the source DB instance to their local data store. This limitation can affect the ability of MySQL read replicas to support large volumes of read traffic.

With Aurora MySQL, when an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

**Important**
Aurora Replicas for Aurora MySQL always use the REPEATABLE READ default transaction isolation level for operations on InnoDB tables. You can use the SET TRANSACTION ISOLATION LEVEL command to change the transaction level only for the primary instance of an Aurora MySQL DB cluster. This restriction avoids user-level locks on Aurora Replicas, and allows Aurora Replicas to scale to support thousands of active user connections while still keeping replica lag to a minimum.

**Note**
DDL statements that run on the primary instance might interrupt database connections on the associated Aurora Replicas. If an Aurora Replica connection is actively using a database object,
such as a table, and that object is modified on the primary instance using a DDL statement, the
Aurora Replica connection is interrupted.

Note
The China (Ningxia) Region does not support cross-Region read replicas.

Replication options for Amazon Aurora MySQL

You can set up replication between any of the following options:

• Two Aurora MySQL DB clusters in different AWS Regions, by creating a cross-Region read replica of an
  Aurora MySQL DB cluster.

  For more information, see Replicating Amazon Aurora MySQL DB clusters across AWS
  Regions (p. 832).

• Two Aurora MySQL DB clusters in the same AWS Region, by using MySQL binary log (binlog)
  replication.

  For more information, see Replication between Aurora and MySQL or between Aurora and another
  Aurora DB cluster (binary log replication) (p. 842).

• An RDS for MySQL DB instance as the source and an Aurora MySQL DB cluster, by creating an Aurora
  read replica of an RDS for MySQL DB instance.

  You can use this approach to bring existing and ongoing data changes into Aurora MySQL during
  migration to Aurora. For more information, see Migrating data from a MySQL DB instance to an
  Amazon Aurora MySQL DB cluster by using a DB snapshot (p. 706).

  You can also use this approach to increase the scalability of read queries for your data. You do so by
  querying the data using one or more DB instances within a read-only Aurora MySQL cluster. For more
  information, see Using Amazon Aurora to scale reads for your MySQL database (p. 855).

• An Aurora MySQL DB cluster in one AWS Region and up to five Aurora read-only Aurora MySQL DB
  clusters in different Regions, by creating an Aurora global database.

  You can use an Aurora global database to support applications with a world-wide footprint. The
  primary Aurora MySQL DB cluster has a Writer instance and up to 15 Aurora Replicas. The read-only
  secondary Aurora MySQL DB clusters can each be made up of as many as 16 Aurora Replicas. For more
  information, see Using Amazon Aurora global databases (p. 151).

  Note
  Rebooting the primary instance of an Amazon Aurora DB cluster also automatically reboots the
  Aurora Replicas for that DB cluster, to re-establish an entry point that guarantees read/write
  consistency across the DB cluster.

Performance considerations for Amazon Aurora
MySQL replication

The following features help you to fine-tune the performance of Aurora MySQL replication.

Starting in Aurora MySQL 1.17.4, the replica log compression feature automatically reduces network
bandwidth for replication messages. Because each message is transmitted to all Aurora Replicas, the
benefits are greater for larger clusters. This feature involves some CPU overhead on the writer node to
perform the compression. Thus, the feature is only available on the 8xlarge and 16xlarge instance
classes, which have high CPU capacity. It is enabled by default on these instance classes. You can control
this feature by turning off the aurora_enable_replica_log_compression parameter. For example,
you might turn off replica log compression for larger instance classes if your writer node is near its
maximum CPU capacity.
Starting in Aurora MySQL 1.17.4, the binlog filtering feature automatically reduces network bandwidth for replication messages. Because the Aurora Replicas don't use the binlog information that is included in the replication messages, that data is omitted from the messages sent to those nodes. You control this feature by changing the `aurora_enable_repl_bin_log_filtering` parameter. This parameter is on by default. Because this optimization is intended to be transparent, you might turn off this setting only during diagnosis or troubleshooting for issues related to replication. For example, you can do so to match the behavior of an older Aurora MySQL cluster where this feature was not available.

**Zero-downtime restart (ZDR) for Amazon Aurora MySQL**

The zero-downtime restart (ZDR) feature can preserve some or all of the active connections to DB instances during certain kinds of restarts. ZDR applies to restarts that Aurora performs automatically to resolve error conditions, for example when a replica begins to lag too far behind the source.

**Important**
The ZDR mechanism operates on a best-effort basis. The Aurora MySQL versions, instance classes, error conditions, compatible SQL operations, and other factors that determine where ZDR applies are subject to change at any time.

In Aurora MySQL 1.* versions where ZDR is available, you turn on this feature by turning on the `aurora_enable_zdr` parameter in the cluster parameter group. ZDR for Aurora MySQL 2.* requires version 2.10 and higher. ZDR is available in all minor versions of Aurora MySQL 3.*. In Aurora MySQL version 2 and 3, the ZDR mechanism is turned on by default and Aurora doesn't use the `aurora_enable_zdr` parameter.

Aurora reports on the **Events** page activities related to zero-downtime restart. Aurora records an event when it attempts a restart using the ZDR mechanism. This event states why Aurora performs the restart. Then Aurora records another event when the restart finishes. This final event reports how long the process took, and how many connections were preserved or dropped during the restart. You can consult the database error log to see more details about what happened during the restart.

Although connections remain intact following a successful ZDR operation, some variables and features are reinitialized. The following kinds of information aren't preserved through a restart caused by zero-downtime restart:

- Global variables. Aurora restores session variables, but it doesn't restore global variables after the restart.
- Status variables. In particular, the uptime value reported by the engine status is reset.
- `LAST_INSERT_ID`.
- In-memory auto_increment state for tables. The in-memory auto-increment state is reinitialized. For more information about auto-increment values, see MySQL Reference Manual.
- Diagnostic information from INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables. This diagnostic information also appears in the output of commands such as `SHOW PROFILE` and `SHOW PROFILES`.

The following table shows the versions, instance roles, instance classes, and other circumstances that determine whether Aurora can use the ZDR mechanism when restarting DB instances in your cluster:

<table>
<thead>
<tr>
<th>Aurora MySQL version</th>
<th>Does ZDR apply to the writer?</th>
<th>Does ZDR apply to readers?</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td>No</td>
<td>No</td>
<td>ZDR isn't available for these versions.</td>
</tr>
</tbody>
</table>
## Monitoring Amazon Aurora MySQL replication

Read scaling and high availability depend on minimal lag time. You can monitor how far an Aurora Replica is lagging behind the primary instance of your Aurora MySQL DB cluster by monitoring the Amazon CloudWatch `AuroraReplicaLag` metric. The `AuroraReplicaLag` metric is recorded in each Aurora Replica.

The primary DB instance also records the `AuroraReplicaLagMaximum` and `AuroraReplicaLag` Amazon CloudWatch metrics. The `AuroraReplicaLagMaximum` metric records the maximum amount of lag between the primary DB instance and each Aurora Replica in the DB cluster. The `AuroraReplicaLag` metric records the minimum amount of lag between the primary DB instance and each Aurora Replica in the DB cluster.

If you need the most current value for Aurora Replica lag, you can query the `recrystallisations` table on the primary instance in your Aurora MySQL DB cluster and check the value in the `Replica_lag_in_msec` column. This column value is provided to Amazon CloudWatch as the value for

<table>
<thead>
<tr>
<th>Aurora MySQL version</th>
<th>Does ZDR apply to the writer?</th>
<th>Does ZDR apply to readers?</th>
<th>Notes</th>
</tr>
</thead>
</table>
| version 1.*, 1.17.3 and lower | No | Yes | In these Aurora MySQL versions, the following conditions apply to the ZDR mechanism:  
- Aurora doesn't use the ZDR mechanism if binary logging is turned on for the DB instance.  
- Aurora rolls back any transactions that are in progress on active connections. Your application must retry the transactions.  
- Aurora cancels any connections that use TLS/SSL, temporary tables, table locks, or user locks. |
| Aurora MySQL version 1.*, 1.17.4 and higher | No | No | ZDR isn't available for these versions. The `aurora_enable_zdr` parameter isn't available in the default cluster parameter group for Aurora MySQL version 2. |
| Aurora MySQL version 2.*, before 2.10.0 | Yes | Yes | The ZDR mechanism is always enabled.  
In these Aurora MySQL versions, the following conditions apply to the ZDR mechanism:  
- Aurora rolls back any transactions that are in progress on active connections. Your application must retry the transactions.  
- Aurora cancels any connections that use TLS/SSL, temporary tables, table locks, or user locks. |
| Aurora MySQL version 2.*, 2.10.0 and higher | Yes | Yes | The ZDR mechanism is always enabled.  
The same conditions apply as in Aurora MySQL version 2.10. ZDR applies to all instance classes. |
| Aurora MySQL version 3.* | Yes | Yes | The ZDR mechanism is always enabled.  
The same conditions apply as in Aurora MySQL version 2.10. ZDR applies to all instance classes. |
the AuroraReplicaLag metric. The Aurora Replica lag is also recorded on each Aurora Replica in the INFORMATION_SCHEMA.REPLICA_HOST_STATUS table in your Aurora MySQL DB cluster.

For more information on monitoring RDS instances and CloudWatch metrics, see Monitoring metrics in an Amazon Aurora cluster (p. 427).

Replicating Amazon Aurora MySQL DB clusters across AWS Regions

You can create an Amazon Aurora MySQL DB cluster as a read replica in a different AWS Region than the source DB cluster. Taking this approach can improve your disaster recovery capabilities, let you scale read operations into an AWS Region that is closer to your users, and make it easier to migrate from one AWS Region to another.

You can create read replicas of both encrypted and unencrypted DB clusters. The read replica must be encrypted if the source DB cluster is encrypted.

For each source DB cluster, you can have up to five cross-Region DB clusters that are read replicas.

**Note**

As an alternative to cross-Region read replicas, you can scale read operations with minimal lag time by using an Aurora global database. An Aurora global database has a primary Aurora DB cluster in one AWS Region and up to five secondary read-only DB clusters in different Regions. Each secondary DB cluster can include up to 16 (rather than 15) Aurora Replicas. Replication from the primary DB cluster to all secondaries is handled by the Aurora storage layer rather than by the database engine, so lag time for replicating changes is minimal—typically, less than 1 second. Keeping the database engine out of the replication process means that the database engine is dedicated to processing workloads. It also means that you don't need to configure or manage Aurora MySQL's binlog (binary logging) replication. To learn more, see Using Amazon Aurora global databases (p. 151).

When you create an Aurora MySQL DB cluster read replica in another AWS Region, you should be aware of the following:

- Both your source DB cluster and your cross-Region read replica DB cluster can have up to 15 Aurora Replicas, along with the primary instance for the DB cluster. By using this functionality, you can scale read operations for both your source AWS Region and your replication target AWS Region.
- In a cross-Region scenario, there is more lag time between the source DB cluster and the read replica due to the longer network channels between AWS Regions.
- Data transferred for cross-Region replication incurs Amazon RDS data transfer charges. The following cross-Region replication actions generate charges for the data transferred out of the source AWS Region:
  - When you create the read replica, Amazon RDS takes a snapshot of the source cluster and transfers the snapshot to the AWS Region that holds the read replica.
  - For each data modification made in the source databases, Amazon RDS transfers data from the source region to the AWS Region that holds the read replica.

For more information about Amazon RDS data transfer pricing, see Amazon Aurora pricing.

- You can run multiple concurrent create or delete actions for read replicas that reference the same source DB cluster. However, you must stay within the limit of five read replicas for each source DB cluster.
- For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB cluster. If you scale the source DB cluster, you should also scale the read replicas.
Before you begin

Before you can create an Aurora MySQL DB cluster that is a cross-Region read replica, you must turn on binary logging on your source Aurora MySQL DB cluster. Cross-region replication for Aurora MySQL uses MySQL binary replication to replay changes on the cross-Region read replica DB cluster.

To turn on binary logging on an Aurora MySQL DB cluster, update the `binlog_format` parameter for your source DB cluster. The `binlog_format` parameter is a cluster-level parameter that is in the default cluster parameter group. If your DB cluster uses the default DB cluster parameter group, create a new DB cluster parameter group to modify `binlog_format` settings. We recommend that you set the `binlog_format` to `MIXED`. However, you can also set `binlog_format` to `ROW` or `STATEMENT` if you need a specific binlog format. Reboot your Aurora DB cluster for the change to take effect.

For more information about using binary logging with Aurora MySQL, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 842). For more information about modifying Aurora MySQL configuration parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 217) and Working with parameter groups (p. 215).

Creating an Amazon Aurora MySQL DB cluster that is a cross-Region read replica

You can create an Aurora DB cluster that is a cross-Region read replica by using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. You can create cross-Region read replicas from both encrypted and unencrypted DB clusters.

When you create a cross-Region read replica for Aurora MySQL by using the AWS Management Console, Amazon RDS creates a DB cluster in the target AWS Region, and then automatically creates a DB instance that is the primary instance for that DB cluster.

When you create a cross-Region read replica using the AWS CLI or RDS API, you first create the DB cluster in the target AWS Region and wait for it to become active. Once it is active, you then create a DB instance that is the primary instance for that DB cluster.

Replication begins when the primary instance of the read replica DB cluster becomes available.

Use the following procedures to create a cross-Region read replica from an Aurora MySQL DB cluster. These procedures work for creating read replicas from either encrypted or unencrypted DB clusters.

Console

To create an Aurora MySQL DB cluster that is a cross-Region read replica with the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top-right corner of the AWS Management Console, select the AWS Region that hosts your source DB cluster.
3. In the navigation pane, choose Databases.
4. Choose the DB cluster for which you want to create a cross-Region read replica.
5. For **Actions**, choose **Create cross-Region read replica**.
6. On the **Create cross region read replica** page, choose the option settings for your cross-Region read replica DB cluster, as described in the following table.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Destination region</strong></td>
<td>Choose the AWS Region to host the new cross-Region read replica DB cluster.</td>
</tr>
<tr>
<td><strong>Destination DB subnet group</strong></td>
<td>Choose the DB subnet group to use for the cross-Region read replica DB cluster.</td>
</tr>
<tr>
<td><strong>Publicly accessible</strong></td>
<td>Choose <strong>Yes</strong> to give the cross-Region read replica DB cluster a public IP address; otherwise, select <strong>No</strong>.</td>
</tr>
<tr>
<td><strong>Encryption</strong></td>
<td>Select <strong>Enable Encryption</strong> to turn on encryption at rest for this DB cluster. For more information, see Encrypting Amazon Aurora resources (p. 1638).</td>
</tr>
<tr>
<td><strong>AWS KMS key</strong></td>
<td>Only available if <strong>Encryption</strong> is set to <strong>Enable Encryption</strong>. Select the AWS KMS key to use for encrypting this DB cluster. For more information, see Encrypting Amazon Aurora resources (p. 1638).</td>
</tr>
<tr>
<td><strong>DB instance class</strong></td>
<td>Choose a DB instance class that defines the processing and memory requirements for the primary instance in the DB cluster. For more information about DB instance class options, see Aurora DB instance classes (p. 56).</td>
</tr>
<tr>
<td><strong>Multi-AZ deployment</strong></td>
<td>Choose <strong>Yes</strong> to create a read replica of the new DB cluster in another Availability Zone in the target AWS Region for failover support. For more information about multiple Availability Zones, see Regions and Availability Zones (p. 11).</td>
</tr>
<tr>
<td><strong>Read replica source</strong></td>
<td>Choose the source DB cluster to create a cross-Region read replica for.</td>
</tr>
<tr>
<td><strong>DB instance identifier</strong></td>
<td>Type a name for the primary instance in your cross-Region read replica DB cluster. This identifier is used in the endpoint address for the primary instance of the new DB cluster.</td>
</tr>
</tbody>
</table>

The DB instance identifier has the following constraints:

- It must contain from 1 to 63 alphanumeric characters or hyphens.
- Its first character must be a letter.
- It cannot end with a hyphen or contain two consecutive hyphens.
- It must be unique for all DB instances for each AWS account, for each AWS Region.

Because the cross-Region read replica DB cluster is created from a snapshot of the source DB cluster, the master user name and master password for the read
<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>replica are the same as the master user name and master password for the source DB cluster.</td>
<td></td>
</tr>
</tbody>
</table>
| DB cluster identifier  | Type a name for your cross-Region read replica DB cluster that is unique for your account in the target AWS Region for your replica. This identifier is used in the cluster endpoint address for your DB cluster. For information on the cluster endpoint, see Amazon Aurora connection management (p. 35).  
The DB cluster identifier has the following constraints:  
  - It must contain from 1 to 63 alphanumeric characters or hyphens.  
  - Its first character must be a letter.  
  - It cannot end with a hyphen or contain two consecutive hyphens.  
  - It must be unique for all DB clusters for each AWS account, for each AWS Region. |
<p>| Priority                | Choose a failover priority for the primary instance of the new DB cluster. This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. If you don't select a value, the default is tier-1. For more information, see Fault tolerance for an Aurora DB cluster (p. 72). |
| Database port           | Specify the port for applications and utilities to use to access the database. Aurora DB clusters default to the default MySQL port, 3306. Firewalls at some companies block connections to this port. If your company firewall blocks the default port, choose another port for the new DB cluster. |
| Enhanced monitoring     | Choose Enable enhanced monitoring to turn on gathering metrics in real time for the operating system that your DB cluster runs on. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 518). |
| Monitoring Role         | Only available if Enhanced Monitoring is set to Enable enhanced monitoring. Choose the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose Default to have RDS create a role for you named rds-monitoring-role. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 518). |
| Granularity             | Only available if Enhanced Monitoring is set to Enable enhanced monitoring. Set the interval, in seconds, between when metrics are collected for your DB cluster. |</p>
<table>

<td>engine updates for Amazon Aurora MySQL (p. 991).</td>
</tr>
</tbody>
</table>

7. Choose **Create** to create your cross-Region read replica for Aurora.

**AWS CLI**

**To create an Aurora MySQL DB cluster that is a cross-Region read replica with the CLI**

1. Call the AWS CLI `create-db-cluster` command in the AWS Region where you want to create the read replica DB cluster. Include the `--replication-source-identifier` option and specify the Amazon Resource Name (ARN) of the source DB cluster to create a read replica for.

   For cross-Region replication where the DB cluster identified by `--replication-source-identifier` is encrypted, specify the `--kms-key-id` option and the `--storage-encrypted` option.

   **Note**
   
   You can set up cross-Region replication from an unencrypted DB cluster to an encrypted read replica by specifying `--storage-encrypted` and providing a value for `--kms-key-id`.

   You can't specify the `--master-username` and `--master-user-password` parameters. Those values are taken from the source DB cluster.

   The following code example creates a read replica in the us-east-1 Region from an unencrypted DB cluster snapshot in the us-west-2 Region. The command is called in the us-east-1 Region.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-cluster \
   --db-cluster-identifier sample-replica-cluster \
   --engine aurora \
   ```

   For Windows:

   ```bash
   aws rds create-db-cluster ^
   --db-cluster-identifier sample-replica-cluster ^
   --engine aurora ^
   ```

   The following code example creates a read replica in the us-east-1 Region from an encrypted DB cluster snapshot in the us-west-2 Region. The command is called in the us-east-1 Region.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-cluster \
   --db-cluster-identifier sample-replica-cluster \
   --engine aurora \
   --storage-encrypted
   ```
Replicating Amazon Aurora MySQL DB clusters across AWS Regions

--kms-key-id my-us-east-1-key
--storage-encrypted

For Windows:

aws rds create-db-cluster ^
  --db-cluster-identifier sample-replica-cluster ^
  --engine aurora ^
  --kms-key-id my-us-east-1-key ^
  --storage-encrypted

The --source-region option is required for cross-Region replication between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, where the DB cluster identified by --replication-source-identifier is encrypted. For --source-region, specify the AWS Region of the source DB cluster.

If --source-region isn't specified, specify a --pre-signed-url value. A presigned URL is a URL that contains a Signature Version 4 signed request for the create-db-cluster command that is called in the source AWS Region. To learn more about the pre-signed-url option, see create-db-cluster in the AWS CLI Command Reference.

2. Check that the DB cluster has become available to use by using the AWS CLI describe-db-clusters command, as shown in the following example.

aws rds describe-db-clusters --db-cluster-identifier sample-replica-cluster

When the describe-db-clusters results show a status of available, create the primary instance for the DB cluster so that replication can begin. To do so, use the AWS CLI create-db-instance command as shown in the following example.

For Linux, macOS, or Unix:

aws rds create-db-instance \
  --db-cluster-identifier sample-replica-cluster \
  --db-instance-class db.r3.large \
  --db-instance-identifier sample-replica-instance \
  --engine aurora

For Windows:

aws rds create-db-instance ^
  --db-cluster-identifier sample-replica-cluster ^
  --db-instance-class db.r3.large ^
  --db-instance-identifier sample-replica-instance ^
  --engine aurora

When the DB instance is created and available, replication begins. You can determine if the DB instance is available by calling the AWS CLI describe-db-instances command.
RDS API

To create an Aurora MySQL DB cluster that is a cross-Region read replica with the API

1. Call the RDS API `CreateDBCluster` operation in the AWS Region where you want to create the read replica DB cluster. Include the `ReplicationSourceIdentifier` parameter and specify the Amazon Resource Name (ARN) of the source DB cluster to create a read replica for.

For cross-Region replication where the DB cluster identified by `ReplicationSourceIdentifier` is encrypted, specify the `KmsKeyId` parameter and set the `StorageEncrypted` parameter to `true`.

**Note**
You can set up cross-Region replication from an unencrypted DB cluster to an encrypted read replica by specifying `StorageEncrypted` as `true` and providing a value for `KmsKeyId`. In this case, you don't need to specify `PreSignedUrl`.

You don't need to include the `MasterUsername` and `MasterUserPassword` parameters, because those values are taken from the source DB cluster.

The following code example creates a read replica in the us-east-1 Region from an unencrypted DB cluster snapshot in the us-west-2 Region. The action is called in the us-east-1 Region.

```plaintext
https://rds.us-east-1.amazonaws.com/?Action=CreateDBCluster
&DBClusterIdentifier=sample-replica-cluster
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T001547Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=a04c831a0b54b5e4cd36a90dcb95f5fab7185eb3b5ebe9a70a4e95790c8b7
```

The following code example creates a read replica in the us-east-1 Region from an encrypted DB cluster snapshot in the us-west-2 Region. The action is called in the us-east-1 Region.

```plaintext
https://rds.us-east-1.amazonaws.com/?Action=CreateDBCluster
&KmsKeyId=my-us-east-1-key
&StorageEncrypted=true
&PreSignedUrl=https%253A%252F%252Fus-east-1.us-west-2.amazonaws.com%252Fservices%252Frds%252F2014-10-31%252Famz-request%252Fs3%252Furl
&ReplicationSourceIdentifier=arn%253Aaws%253Ards%253Aus-west-2%253A123456789012%253Acluster%253Asample-master-cluster
&DBClusterIdentifier=sample-replica-cluster
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20161117T215409Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=255a0f17b4e717d3b67fadb163c3ec26573b882c03a65523522cf890a67fca613
```
For cross-Region replication between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, where the DB cluster identified by `ReplicationSourceIdentifier` is encrypted, also specify the `PreSignedUrl` parameter. The presigned URL must be a valid request for the `CreateDBCluster` API operation that can be performed in the source AWS Region that contains the encrypted DB cluster to be replicated. The KMS key identifier is used to encrypt the read replica, and must be a KMS key valid for the destination AWS Region. To automatically rather than manually generate a presigned URL, use the AWS CLI `create-db-cluster` command with the `--source-region` option instead.

2. Check that the DB cluster has become available to use by using the RDS API `DescribeDBClusters` operation, as shown in the following example:

```
https://rds.us-east-1.amazonaws.com/
?Action=DescribeDBClusters
&DBClusterIdentifier=sample-replica-cluster
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIAI4QKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T002223Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=84c2e4f8f8ba7c557ac5d820711e34c6e45f835be8a6b7c50f329a7f45f426
```

When `DescribeDBClusters` results show a status of `available`, create the primary instance for the DB cluster so that replication can begin. To do so, use the RDS API `CreateDBInstance` action as shown in the following example:

```
https://rds.us-east-1.amazonaws.com/
?Action=CreateDBInstance
&DBClusterIdentifier=sample-replica-cluster
&DBInstanceClass=db.r3.large
&DBInstanceIdentifier=sample-replica-instance
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIAI4QKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T003808Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=125fe575959f5bbcebd53f265f90719757a805b7a16378d4a593875f8c6b
```

When the DB instance is created and available, replication begins. You can determine if the DB instance is available by calling the AWS CLI `DescribeDBInstances` command.
**Viewing Amazon Aurora MySQL cross-Region replicas**

You can view the cross-Region replication relationships for your Amazon Aurora MySQL DB clusters by calling the `describe-db-clusters` AWS CLI command or the `DescribeDBClusters` RDS API operation. In the response, refer to the `ReadReplicaIdentifiers` field for the DB cluster identifiers of any cross-Region read replica DB clusters. Refer to the `ReplicationSourceIdentifier` element for the ARN of the source DB cluster that is the replication source.

**Promoting a read replica to be a DB cluster**

You can promote an Aurora MySQL read replica to a standalone DB cluster. When you promote an Aurora MySQL read replica, its DB instances are rebooted before they become available.

Typically, you promote an Aurora MySQL read replica to a standalone DB cluster as a data recovery scheme if the source DB cluster fails.

To do this, first create a read replica and then monitor the source DB cluster for failures. In the event of a failure, do the following:

1. Promote the read replica.
2. Direct database traffic to the promoted DB cluster.
3. Create a replacement read replica with the promoted DB cluster as its source.

When you promote a read replica, the read replica becomes a standalone Aurora DB cluster. The promotion process can take several minutes or longer to complete, depending on the size of the read replica. After you promote the read replica to a new DB cluster, it's just like any other DB cluster. For example, you can create read replicas from it and perform point-in-time restore operations. You can also create Aurora Replicas for the DB cluster.

Because the promoted DB cluster is no longer a read replica, you can't use it as a replication target.

The following steps show the general process for promoting a read replica to a DB cluster:

1. Stop any transactions from being written to the read replica source DB cluster, and then wait for all updates to be made to the read replica. Database updates occur on the read replica after they have occurred on the source DB cluster, and this replication lag can vary significantly. Use the `ReplicaLag` metric to determine when all updates have been made to the read replica. The `ReplicaLag` metric records the amount of time a read replica DB instance lags behind the source DB instance. When the `ReplicaLag` metric reaches 0, the read replica has caught up to the source DB instance.

2. Promote the read replica by using the `Promote` option on the Amazon RDS console, the AWS CLI command `promote-read-replica-db-cluster`, or the `PromoteReadReplicaDBCluster` Amazon RDS API operation.

   You choose an Aurora MySQL DB instance to promote the read replica. After the read replica is promoted, the Aurora MySQL DB cluster is promoted to a standalone DB cluster. The DB instance with the highest failover priority is promoted to the primary DB instance for the DB cluster. The other DB instances become Aurora Replicas.

   **Note**
   The promotion process takes a few minutes to complete. When you promote a read replica, replication is stopped and the DB instances are rebooted. When the reboot is complete, the read replica is available as a new DB cluster.
To promote an Aurora MySQL read replica to a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. On the console, choose Instances.
   The **Instances** pane appears.
3. In the **Instances** pane, choose the read replica that you want to promote.
   The read replicas appear as Aurora MySQL DB instances.
4. For **Actions**, choose Promote read replica.
5. On the acknowledgment page, choose Promote read replica.

AWS CLI

To promote a read replica to a DB cluster, use the AWS CLI **`promote-read-replica-db-cluster`** command.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds promote-read-replica-db-cluster \
  --db-cluster-identifier mydbcluster
```

For Windows:

```bash
aws rds promote-read-replica-db-cluster ^
  --db-cluster-identifier mydbcluster
```

RDS API

To promote a read replica to a DB cluster, call **`PromoteReadReplicaDBCluster`**.

Troubleshooting Amazon Aurora MySQL cross Region replicas

Following you can find a list of common error messages that you might encounter when creating an Amazon Aurora cross-Region read replica, and how to resolve the specified errors.

**Source cluster [DB cluster ARN] doesn't have binlogs enabled**

To resolve this issue, turn on binary logging on the source DB cluster. For more information, see Before you begin (p. 833).

**Source cluster [DB cluster ARN] doesn't have cluster parameter group in sync on writer**

You receive this error if you have updated the **binlog_format** DB cluster parameter, but have not rebooted the primary instance for the DB cluster. Reboot the primary instance (that is, the writer) for the DB cluster and try again.

**Source cluster [DB cluster ARN] already has a read replica in this region**

You can have up to five cross-Region DB clusters that are read replicas for each source DB cluster in any AWS Region. If you already have the maximum number of read replicas for a DB cluster in a particular
AWS Region, you must delete an existing one before you can create a new cross-Region DB cluster in that Region.

DB cluster [DB cluster ARN] requires a database engine upgrade for cross-Region replication support

To resolve this issue, upgrade the database engine version for all of the instances in the source DB cluster to the most recent database engine version, and then try creating a cross-Region read replica DB again.

Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)

Because Amazon Aurora MySQL is compatible with MySQL, you can set up replication between a MySQL database and an Amazon Aurora MySQL DB cluster. This type of replication uses the MySQL binary log replication, also referred to as binlog replication. If you use binary log replication with Aurora, we recommend that your MySQL database run MySQL version 5.5 or later. You can set up replication where your Aurora MySQL DB cluster is the replication source or the replica. You can replicate with an Amazon RDS MySQL DB instance, a MySQL database external to Amazon RDS, or another Aurora MySQL DB cluster.

Note
You can’t use binlog replication to or from certain kinds of Aurora clusters. In particular, binlog replication isn’t available for Aurora Serverless v1 and multi-master clusters. If the SHOW MASTER STATUS and SHOW SLAVE STATUS (Aurora MySQL version 1 and 2) or SHOW REPLICA STATUS (Aurora MySQL version 3) statement returns no output, check that the cluster you’re using is one that supports binlog replication.

You can also replicate with an RDS for MySQL DB instance or Aurora MySQL DB cluster in another AWS Region. When you’re performing replication across AWS Regions, make sure that your DB clusters and DB instances are publicly accessible. If the Aurora MySQL DB clusters are in private subnets in your VPC, use VPC peering between the AWS Regions. For more information, see A DB cluster in a VPC accessed by an EC2 instance in a different VPC (p. 1740).

If you want to configure replication between an Aurora MySQL DB cluster and an Aurora MySQL DB cluster in another region, you can create an Aurora MySQL DB cluster as a read replica in a different AWS Region than the source DB cluster. For more information, see Replicating Amazon Aurora MySQL DB clusters across AWS Regions (p. 832).

With Aurora MySQL 2.04 and higher, you can replicate between Aurora MySQL and an external source or target that uses global transaction identifiers (GTIDs) for replication. Ensure that the GTID-related parameters in the Aurora MySQL DB cluster have settings that are compatible with the GTID status of the external database. To learn how to do this, see Using GTID-based replication for Amazon Aurora MySQL (p. 864). In Aurora MySQL version 3.01 and higher, you can choose how to assign GTIDs to transactions that are replicated from a source that doesn’t use GTIDs. For information about the stored procedure that controls that setting, see mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3 and higher) (p. 985).

Warning
When you replicate between Aurora MySQL and MySQL, ensure that you use only InnoDB tables. If you have MyISAM tables that you want to replicate, you can convert them to InnoDB before setting up replication with the following command.

```sql
alter table <schema>.<table_name> engine=innodb, algorithm=copy;
```

Setting up MySQL replication with Aurora MySQL involves the following steps, which are discussed in detail in this topic:
1. Turn on binary logging on the replication source (p. 843)
2. Retain binary logs on the replication source until no longer needed (p. 846)
3. Create a snapshot of your replication source (p. 848)
4. Load the snapshot into your replica target (p. 849)
5. Create a replication user on your replication source (p. 851)
6. Turn on replication on your replica target (p. 851)
7. Monitor your replica (p. 853)

**Setting up replication with MySQL or another Aurora DB cluster**

To set up Aurora replication with MySQL, take the following steps.

**1. Turn on binary logging on the replication source**

Find instructions on how to turn on binary logging on the replication source for your database engine following.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
</table>
| Aurora          | **To turn on binary logging on an Aurora MySQL DB cluster**  
Set the binlog_format parameter to ROW, STATEMENT, or MIXED. MIXED is recommended unless you have a need for a specific binlog format. The binlog_format parameter is a cluster-level parameter that is in the default cluster parameter group. If you're changing the binlog_format parameter from OFF to another value, then you need to reboot your Aurora DB cluster for the change to take effect.  
For more information, see Amazon Aurora DB cluster and DB instance parameters (p. 217) and Working with parameter groups (p. 215). |
| RDS for MySQL   | **To turn on binary logging on an Amazon RDS DB instance**  
You can't turn on binary logging directly for an Amazon RDS DB instance, but you can turn it on by doing one of the following:  
- Turn on automated backups for the DB instance. You can turn on automated backups when you create a DB instance, or you can turn on backups by modifying an existing DB instance. For more information, see Creating a DB instance in the Amazon RDS User Guide.  
- Create a read replica for the DB instance. For more information, see Working with read replicas in the Amazon RDS User Guide. |
| MySQL (external) | **To set up encrypted replication**  
To replicate data securely with Aurora MySQL version 5.6, you can use encrypted replication.  
Currently, encrypted replication with an external MySQL database is only supported for Aurora MySQL version 5.6.  
**Note**  
If you don't need to use encrypted replication, you can skip these steps. |
The following are prerequisites for using encrypted replication:

- Secure Sockets Layer (SSL) must be enabled on the external MySQL source database.
- A client key and client certificate must be prepared for the Aurora MySQL DB cluster.

During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

1. Ensure that you are prepared for encrypted replication:

- If you don't have SSL enabled on the external MySQL source database and don't have a client key and client certificate prepared, turn on SSL on the MySQL database server and generate the required client key and client certificate.
- If SSL is enabled on the external source, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key that you used to configure SSL on the external MySQL source database.

For more information, see [Creating SSL certificates and keys using openssl](https://dev.mysql.com/doc/openssl/html/index.html) in the MySQL documentation.

You need the certificate authority certificate, the client key, and the client certificate.

2. Connect to the Aurora MySQL DB cluster as the master user using SSL.

   For information about connecting to an Aurora MySQL DB cluster with SSL, see [Using SSL/TLS with Aurora MySQL DB clusters](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-ssl.html) (p. 683).

3. Run the `mysql.rds_import_binlog_ssl_material` stored procedure to import the SSL information into the Aurora MySQL DB cluster.

   For the `ssl_material_value` parameter, insert the information from the .pem format files for the Aurora MySQL DB cluster in the correct JSON payload.

   The following example imports SSL information into an Aurora MySQL DB cluster.

   ```sql
   call mysql.rds_import_binlog_ssl_material(
   '{"ssl_ca":"-----BEGIN CERTIFICATE-----
   AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqF3maAhDFcvBS706

|                 | "---END RSA PRIVATE KEY---\n"\});

For more information, see mysql_rds_import_binlog_ssl_material and Using SSL/TLS with Aurora MySQL DB clusters (p. 683).

Note
After running the procedure, the secrets are stored in files. To erase the files later, you can run the mysql_rds_remove_binlog_ssl_material stored procedure.

To turn on binary logging on an external MySQL database

1. From a command shell, stop the mysql service.

   ```
sudo service mysqld stop
   
2. Edit the my.cnf file (this file is usually under /etc).

   ```
   sudo vi /etc/my.cnf
   ```

Add the log_bin and server_id options to the [mysqld] section. The log_bin option provides a file name identifier for binary log files. The server_id option provides a unique identifier for the server in source-replica relationships.

If encrypted replication isn't required, ensure that the external MySQL database is started with binlogs enabled and SSL is turned off.

The following are the relevant entries in the /etc/my.cnf file for unencrypted data.

```
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
sync_binlog=1
```

If encrypted replication is required, ensure that the external MySQL database is started with SSL and binlogs enabled.

The entries in the /etc/my.cnf file include the .pem file locations for the MySQL database server.

```
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
```
Amazon Aurora User Guide for Aurora
Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)

### Database engine | Instructions
---|---
Aurora | To retain binary logs on an Aurora MySQL DB cluster

You do not have access to the binlog files for an Aurora MySQL DB cluster. As a result, you must choose a time frame to retain the binlog files on your replication source long enough to ensure that the changes have been applied to your replica before the binlog

---

2. Retain binary logs on the replication source until no longer needed

When you use MySQL binary log replication, Amazon RDS doesn't manage the replication process. As a result, you need to ensure that the binlog files on your replication source are retained until after the changes have been applied to the replica. This maintenance helps you to restore your source database in the event of a failure.

Use the following instructions to retain binary logs for your database engine.

---

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora</td>
<td>To retain binary logs on an Aurora MySQL DB cluster</td>
</tr>
</tbody>
</table>

Additionally, the sql_mode option for your MySQL DB instance must be set to 0, or must not be included in your my.cnf file.

While connected to the external MySQL database, record the external MySQL database's binary log position.

```
mysql> SHOW MASTER STATUS;
```

Your output should be similar to the following:

```
+------------------+-+------------------------+------------------+-+
| File             | Position | Binlog_Do_DB | Binlog_Ignore_DB | Executed_Gtid_Set |
+------------------+-+------------------------+------------------+-+
| mysql-bin.000031 | 107      |              |                  |                  |
|                  |          |              |                  |                  |
+------------------+-+------------------------+------------------+-+
1 row in set (0.00 sec)
```

For more information, see Setting the replication source configuration in the MySQL documentation.

3. Start the mysql service.

```
sudo service mysqld start
```
<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>You can retain binlog files on an Aurora MySQL DB cluster for up to 90 days. If you are setting up replication with a MySQL database or RDS for MySQL DB instance as the replica, and the database that you are creating a replica for is very large, choose a large time frame to retain binlog files until the initial copy of the database to the replica is complete and the replica lag has reached 0. To set the binary log retention time frame, use the <code>mysql_rds_set_configuration</code> procedure and specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster. The maximum value for Aurora MySQL version 1 is 2160 (90 days). The maximum value for Aurora MySQL version 2 and 3 is 168 (7 days). The following example sets the retention period for binlog files to 6 days:</td>
</tr>
<tr>
<td>MySQL (external)</td>
<td>To retain binary logs on an external MySQL database Because binlog files on an external MySQL database are not managed by Amazon RDS, they are retained until you delete them. After replication has been started, you can verify that changes have been applied to your replica by running the <code>SHOW SLAVE STATUS</code> (Aurora MySQL version 1 and 2) or <code>SHOW REPLICA STATUS</code> (Aurora MySQL version 3) command on your replica and checking the <code>Seconds behind master</code> field. If the <code>Seconds behind master</code> field is 0, then there is no replica lag. When there is no replica lag, you can delete old binlog files.</td>
</tr>
<tr>
<td>RDS for MySQL</td>
<td>To retain binary logs on an Amazon RDS DB instance You can retain binary log files on an Amazon RDS DB instance by setting the binlog retention hours just as with an Aurora MySQL DB cluster, described in the previous row. You can also retain binlog files on an Amazon RDS DB instance by creating a read replica for the DB instance. This read replica is temporary and solely for the purpose of retaining binlog files. After the read replica has been created, call the <code>mysql_rds_stop_replication</code> procedure on the read replica. While replication is stopped, Amazon RDS doesn't delete any of the binlog files on the replication source. After you have set up replication with your permanent replica, you can delete the read replica when the replica lag (Seconds behind master field) between your replication source and your permanent replica reaches 0.</td>
</tr>
</tbody>
</table>

After replication has been started, you can verify that changes have been applied to your replica by running the `SHOW SLAVE STATUS` (Aurora MySQL version 1 and 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command on your replica and checking the `Seconds behind master` field. If the `Seconds behind master` field is 0, then there is no replica lag. When there is no replica lag, you can delete old binlog files.
3. Create a snapshot of your replication source

You use a snapshot of your replication source to load a baseline copy of your data onto your replica and then start replicating from that point on.

Use the following instructions to create a snapshot of your replication source for your database engine.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora</td>
<td><strong>To create a snapshot of an Aurora MySQL DB cluster</strong></td>
</tr>
<tr>
<td></td>
<td>1. Create a DB cluster snapshot of your Amazon Aurora DB cluster. For more information, see [Creating a DB cluster snapshot](p. 373).</td>
</tr>
<tr>
<td></td>
<td>2. Create a new Aurora DB cluster by restoring from the DB cluster snapshot that you just created. Be sure to retain the same DB parameter group for your restored DB cluster as your original DB cluster. Doing this ensures that the copy of your DB cluster has binary logging enabled. For more information, see [Restoring from a DB cluster snapshot](p. 375).</td>
</tr>
<tr>
<td></td>
<td>3. In the console, choose <strong>Databases</strong> and choose the primary instance (writer) for your restored Aurora DB cluster to show its details. Scroll to <strong>Recent Events</strong>. An event message shows that includes the binlog file name and position. The event message is in the following format.</td>
</tr>
<tr>
<td></td>
<td>Binlog position from crash recovery is <strong>binlog-file-name binlog-position</strong></td>
</tr>
<tr>
<td></td>
<td>Save the binlog file name and position values for when you start replication.</td>
</tr>
<tr>
<td></td>
<td>You can also get the binlog file name and position by calling the describe-events command from the AWS CLI. The following shows an example describe-events command with example output.</td>
</tr>
<tr>
<td></td>
<td>PROMPT&gt; aws rds describe-events</td>
</tr>
<tr>
<td></td>
<td>```json</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;Events&quot;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;EventCategories&quot;: [],</td>
</tr>
<tr>
<td></td>
<td>&quot;SourceType&quot;: &quot;db-instance&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;Date&quot;: &quot;2016-10-28T19:43:46.862Z&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;Message&quot;: &quot;Binlog position from crash recovery is mysql-bin-changelog.000003 4278&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;SourceIdentifier&quot;: &quot;sample-restored-instance&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>You can also get the binlog file name and position by checking the MySQL error log for the last MySQL binlog file position.</td>
</tr>
</tbody>
</table>
|                 | 4. If your replica target is an Aurora DB cluster owned by another AWS account, an external MySQL database, or an RDS for MySQL DB instance, then you can't load the data from an Amazon Aurora DB cluster snapshot. Instead, create a dump of your Amazon Aurora DB cluster by connecting to your DB cluster using a MySQL client and issuing the mysqldump command. Be sure to run the mysqldump command against
<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDS for MySQL</td>
<td>To create a snapshot of an Amazon RDS DB instance</td>
</tr>
<tr>
<td>MySQL (external)</td>
<td>To create a snapshot of an external MySQL database</td>
</tr>
</tbody>
</table>

5. When you have finished creating the dump of your data from the newly created Aurora DB cluster, delete that DB cluster as it is no longer needed.

4. Load the snapshot into your replica target

If you plan to load data from a dump of a MySQL database that is external to Amazon RDS, then you might want to create an EC2 instance to copy the dump files to, and then load the data into your DB cluster or DB instance from that EC2 instance. Using this approach, you can compress the dump file(s) before copying them to the EC2 instance in order to reduce the network costs associated with...
copying data to Amazon RDS. You can also encrypt the dump file or files to secure the data as it is being transferred across the network.

Use the following instructions to load the snapshot of your replication source into your replica target for your database engine.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Aurora</strong></td>
<td><strong>To load a snapshot into an Aurora MySQL DB cluster</strong></td>
</tr>
<tr>
<td></td>
<td>• If the snapshot of your replication source is a DB cluster snapshot, then you can restore from the DB cluster snapshot to create a new Aurora MySQL DB cluster as your replica target. For more information, see Restoring from a DB cluster snapshot (p. 375).</td>
</tr>
<tr>
<td></td>
<td>• If the snapshot of your replication source is a DB snapshot, then you can migrate the data from your DB snapshot into a new Aurora MySQL DB cluster. For more information, see Migrating data to an Amazon Aurora DB cluster (p. 242).</td>
</tr>
<tr>
<td></td>
<td>• If the snapshot of your replication source is the output from the <code>mysqldump</code> command, then follow these steps:</td>
</tr>
<tr>
<td></td>
<td>1. Copy the output of the <code>mysqldump</code> command from your replication source to a location that can also connect to your Aurora MySQL DB cluster.</td>
</tr>
<tr>
<td></td>
<td>2. Connect to your Aurora MySQL DB cluster using the <code>mysql</code> command. The following is an example.</td>
</tr>
<tr>
<td></td>
<td>PROMPT&gt; mysql -h <code>&lt;host_name&gt;</code> -port=3306 -u <code>&lt;db_master_user&gt;</code> -p</td>
</tr>
<tr>
<td></td>
<td>3. At the <code>mysql</code> prompt, run the <code>source</code> command and pass it the name of your database dump file to load the data into the Aurora MySQL DB cluster, for example:</td>
</tr>
<tr>
<td></td>
<td><code>mysql&gt; source backup.sql;</code></td>
</tr>
<tr>
<td><strong>RDS for MySQL</strong></td>
<td><strong>To load a snapshot into an Amazon RDS DB instance</strong></td>
</tr>
<tr>
<td></td>
<td>1. Copy the output of the <code>mysqldump</code> command from your replication source to a location that can also connect to your MySQL DB instance.</td>
</tr>
<tr>
<td></td>
<td>2. Connect to your MySQL DB instance using the <code>mysql</code> command. The following is an example.</td>
</tr>
<tr>
<td></td>
<td>PROMPT&gt; mysql -h <code>&lt;host_name&gt;</code> -port=3306 -u <code>&lt;db_master_user&gt;</code> -p</td>
</tr>
<tr>
<td></td>
<td>3. At the <code>mysql</code> prompt, run the <code>source</code> command and pass it the name of your database dump file to load the data into the MySQL DB instance, for example:</td>
</tr>
<tr>
<td></td>
<td><code>mysql&gt; source backup.sql;</code></td>
</tr>
<tr>
<td><strong>MySQL (external)</strong></td>
<td><strong>To load a snapshot into an external MySQL database</strong></td>
</tr>
<tr>
<td></td>
<td>You cannot load a DB snapshot or a DB cluster snapshot into an external MySQL database. Instead, you must use the output from the <code>mysqldump</code> command.</td>
</tr>
<tr>
<td></td>
<td>1. Copy the output of the <code>mysqldump</code> command from your replication source to a location that can also connect to your MySQL database.</td>
</tr>
<tr>
<td></td>
<td>2. Connect to your MySQL database using the <code>mysql</code> command. The following is an example.</td>
</tr>
</tbody>
</table>
5. Create a replication user on your replication source

Create a user ID on the source that is used solely for replication. The following is an example.

```
mysql> CREATE USER 'repl_user'@'<domain_name>' IDENTIFIED BY '<password>';
```

The user requires the REPLICATION CLIENT and REPLICATION SLAVE privileges. Grant these privileges to the user.

If you need to use encrypted replication, require SSL connections for the replication user. For example, you can use one of the following statement to require SSL connections on the user account repl_user.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'<domain_name>';
GRANT USAGE ON *.* TO 'repl_user'@'<domain_name>' REQUIRE SSL;
```

Note

If REQUIRE SSL isn't included, the replication connection might silently fall back to an unencrypted connection.

6. Turn on replication on your replica target

Before you turn on replication, we recommend that you take a manual snapshot of the Aurora MySQL DB cluster or RDS for MySQL DB instance replica target. If a problem arises and you need to re-establish replication with the DB cluster or DB instance replica target, you can restore the DB cluster or DB instance from this snapshot instead of having to import the data into your replica target again.

Use the following instructions to turn on replication for your database engine.

### Database engine Instructions

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td><strong>To turn on replication from an Aurora MySQL DB cluster</strong></td>
</tr>
<tr>
<td></td>
<td>1. If your DB cluster replica target was created from a DB cluster snapshot, then connect to the DB cluster replica target and issue the <code>SHOW MASTER STATUS</code> command. Retrieve the current binary log file name from the <code>File</code> field and the log file position from the <code>Position</code> field.</td>
</tr>
<tr>
<td></td>
<td>If your DB cluster replica target was created from a DB snapshot, then you need the binlog file and binlog position that are the starting place for replication. You retrieved these values from the <code>SHOW SLAVE STATUS</code> (Aurora MySQL version 1 and 2) or <code>SHOW SLAVE</code> (Aurora MySQL version 3) command.</td>
</tr>
</tbody>
</table>
### Database engine

<table>
<thead>
<tr>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>REPLICA STATUS</strong> (Aurora MySQL version 3) command when you created the snapshot of your replication source.</td>
</tr>
</tbody>
</table>

2. Connect to the DB cluster and issue the `mysql_rds_set_external_master` (Aurora MySQL version 1 and 2), `mysql_rds_set_external_source` (Aurora MySQL version 3 and higher) and `mysql_rds_start_replication` procedures to start replication with your replication source using the binary log file name and location from the previous step. The following is an example.

For Aurora MySQL version 1 and 2:
```sql
CALL mysql.rds_set_external_master ('mydbinstance.123456789012.us-east-1.rds.amazonaws.com', 3306, 'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);
```

For Aurora MySQL version 3 and higher:
```sql
CALL mysql.rds_set_external_source ('mydbinstance.123456789012.us-east-1.rds.amazonaws.com', 3306, 'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);
```

For all versions:
```sql
CALL mysql.rds_start_replication;
```

To use SSL encryption, set the final value to 1 instead of 0.

### RDS for MySQL

**To turn on replication from an Amazon RDS DB instance**

1. If your DB instance replica target was created from a DB snapshot, then you need the binlog file and binlog position that are the starting place for replication. You retrieved these values from the `SHOW SLAVE STATUS` (Aurora MySQL version 1 and 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command when you created the snapshot of your replication source.

2. Connect to the DB instance and issue the `mysql_rds_set_external_master` and `mysql_rds_start_replication` procedures to start replication with your replication source using the binary log file name and location from the previous step. The following is an example.

For Aurora MySQL version 1 and 2:
```sql
CALL mysql.rds_set_external_master ('mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com', 3306, 'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);
```

For Aurora MySQL version 3 and higher:
```sql
CALL mysql.rds_set_external_source ('mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com', 3306, 'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);
```

For all versions:
```sql
CALL mysql.rds_start_replication;
```

To use SSL encryption, set the final value to 1 instead of 0.
### MySQL (external)

**To turn on replication from an external MySQL database**

1. Retrieve the binlog file and binlog position that are the starting place for replication. You retrieved these values from the `SHOW SLAVE STATUS` (Aurora MySQL version 1 and 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command when you created the snapshot of your replication source. If your external MySQL replica target was populated from the output of the `mysqldump` command with the `--master-data=2` option, then the binlog file and binlog position are included in the output. The following is an example.

   ```
   -- Position to start replication or point-in-time recovery from
   --
   -- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031',
   -- MASTER_LOG_POS=107;
   ```

2. Connect to the external MySQL replica target, and issue `CHANGE MASTER TO` and `START SLAVE` (Aurora MySQL version 1 and 2) or `START REPLICA` (Aurora MySQL version 3) to start replication with your replication source using the binary log file name and location from the previous step, for example:

   ```
   CHANGE MASTER TO
   MASTER_HOST = 'mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com',
   MASTER_PORT = 3306,
   MASTER_USER = 'repl_user',
   MASTER_PASSWORD = '<password>',
   MASTER_LOG_FILE = 'mysql-bin-changelog.000031',
   MASTER_LOG_POS = 107;
   -- And one of these statements depending on your engine version:
   START SLAVE; -- Aurora MySQL version 1 and 2
   START REPLICA; -- Aurora MySQL version 3
   ```

If replication fails, it can result in a large increase in unintentional I/O on the replica, which can degrade performance. If replication fails or is no longer needed, you can run the `mysql.rds_reset_external_master` stored procedure to remove the replication configuration.

### 7. Monitor your replica

When you set up MySQL replication with an Aurora MySQL DB cluster, you must monitor failover events for the Aurora MySQL DB cluster when it is the replica target. If a failover occurs, then the DB cluster that is your replica target might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification (p. 572).

You can also monitor how far the replica target is behind the replication source by connecting to the replica target and running the `SHOW SLAVE STATUS` (Aurora MySQL version 1 and 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command. In the command output, the `Seconds Behind Master` field tells you how far the replica target is behind the source.
### Stopping replication between Aurora and MySQL or between Aurora and another Aurora DB cluster

To stop binary log replication with a MySQL DB instance, external MySQL database, or another Aurora DB cluster, follow these steps, discussed in detail following in this topic.

1. **Stop binary log replication on the replica target** (p. 854)
2. **Turn off binary logging on the replication source** (p. 854)

#### 1. Stop binary log replication on the replica target

Find instructions on how to stop binary log replication for your database engine following.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
</table>
| Aurora          | **To stop binary log replication on an Aurora MySQL DB cluster replica target**  
|                 | Connect to the Aurora DB cluster that is the replica target, and call the `mysql_rds_stop_replication` procedure. |
| RDS for MySQL   | **To stop binary log replication on an Amazon RDS DB instance**  
|                 | Connect to the RDS DB instance that is the replica target and call the `mysql_rds_stop_replication` procedure. The `mysql.rds_stop_replication` procedure is only available for MySQL versions 5.5 and later, 5.6 and later, and 5.7 and later. |
| MySQL (external)| **To stop binary log replication on an external MySQL database**  
|                 | Connect to the MySQL database and call the `STOP REPLICATION` command. |

#### 2. Turn off binary logging on the replication source

Find instructions on how to turn off binary logging on the replication source for your database engine following.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
</table>
| Aurora          | **To turn off binary logging on an Amazon Aurora DB cluster**  
|                 | 1. Connect to the Aurora DB cluster that is the replication source, and set the binary log retention time frame to 0. To set the binary log retention time frame, use the `mysql_rds_set_configuration` procedure and specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, in this case 0, as shown in the following example.  
|                 |     CALL mysql.rds_set_configuration('binlog retention hours', 0);  
|                 | 2. Set the `binlog_format` parameter to `OFF` on the replication source. The `binlog_format` parameter is a cluster-level parameter that is in the default cluster parameter group.  
|                 |     After you have changed the `binlog_format` parameter value, reboot your DB cluster for the change to take effect. |

**Amazon Aurora** | For more information, see [Amazon Aurora DB cluster and DB instance parameters](#) and [Modifying parameters in a DB parameter group](#).
**RDS for MySQL** | **To turn off binary logging on an Amazon RDS DB instance**
You can’t turn off binary logging directly for an Amazon RDS DB instance, but you can turn it off by doing the following:
1. Turn off automated backups for the DB instance. You can turn off automated backups by modifying an existing DB instance and setting the **Backup Retention Period** to 0. For more information, see [Modifying an Amazon RDS DB instance](#) and *[Working with backups](#)* in the **Amazon Relational Database Service User Guide**.
2. Delete all read replicas for the DB instance. For more information, see *[Working with read replicas of MariaDB, MySQL, and PostgreSQL DB instances](#)* in the **Amazon Relational Database Service User Guide**.
**MySQL (external)** | **To turn off binary logging on an external MySQL database**
Connect to the MySQL database and call the **STOP REPLICATION** command.
1. From a command shell, stop the `mysqld` service,
   ```bash
   sudo service mysqld stop
   ```
2. Edit the `my.cnf` file (this file is usually under `/etc`).
   ```bash
   sudo vi /etc/my.cnf
   ```
   Delete the `log_bin` and `server_id` options from the `[mysqld]` section.
   For more information, see *[Setting the replication source configuration](#)* in the MySQL documentation.
3. Start the `mysql` service.
   ```bash
   sudo service mysqld start
   ```

### Using Amazon Aurora to scale reads for your MySQL database

You can use Amazon Aurora with your MySQL DB instance to take advantage of the read scaling capabilities of Amazon Aurora and expand the read workload for your MySQL DB instance. To use Aurora to read scale your MySQL DB instance, create an Amazon Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance. This applies to an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS.

For information on creating an Amazon Aurora DB cluster, see *[Creating an Amazon Aurora DB cluster](#)*.

When you set up replication between your MySQL DB instance and your Amazon Aurora DB cluster, be sure to follow these guidelines:
• Use the Amazon Aurora DB cluster endpoint address when you reference your Amazon Aurora MySQL DB cluster. If a failover occurs, then the Aurora Replica that is promoted to the primary instance for the Aurora MySQL DB cluster continues to use the DB cluster endpoint address.

• Maintain the binlogs on your writer instance until you have verified that they have been applied to the Aurora Replica. This maintenance ensures that you can restore your writer instance in the event of a failure.

**Important**
When using self-managed replication, you're responsible for monitoring and resolving any replication issues that may occur. For more information, see Diagnosing and resolving lag between read replicas (p. 1765).

**Note**
The permissions required to start replication on an Amazon Aurora MySQL DB cluster are restricted and not available to your Amazon RDS master user. Because of this, you must use the Amazon RDS `mysql_rds_set_external_master` and `mysql_rds_start_replication` procedures to set up replication between your Amazon Aurora MySQL DB cluster and your MySQL DB instance.

### Start replication between an external source instance and a MySQL DB instance on Amazon RDS

1. Make the source MySQL DB instance read-only:
   ```sql
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Run the `SHOW MASTER STATUS` command on the source MySQL DB instance to determine the binlog location. You receive output similar to the following example:
   ```
   File                        Position
   ------------------------------------
   mysql-bin-changelog.000031      107
   ------------------------------------
   ```

3. Copy the database from the external MySQL DB instance to the Amazon Aurora MySQL DB cluster using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to a MySQL or MariaDB DB instance with reduced downtime in the Amazon Relational Database Service User Guide.

For Linux, macOS, or Unix:
   ```
   mysqldump --databases <database_name> --single-transaction --compress --order-by-primary -u <local_user> -p <local_password> | mysql --host aurora_cluster_endpoint_address --port 3306 -u <RDS_user_name> -p <RDS_password>
   ```

For Windows:
   ```
   mysqldump ^
   --databases <database_name> ^
   --single-transaction ^
   ```
Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)

```
--compress ^
--order-by-primary ^
-u <local_user> ^
-p <local_password> | mysql ^
--host aurora_cluster_endpoint_address ^
--port 3306 ^
-u <RDS_user_name> ^
-p <RDS_password>
```

**Note**

Make sure that there is not a space between the `-p` option and the entered password.

Use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command to specify the hostname, user name, port, and password to connect to your Aurora DB cluster. The host name is the DNS name from the Amazon Aurora DB cluster endpoint, for example, `mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the cluster details in the Amazon RDS Management Console.

4. Make the source MySQL DB instance writeable again:

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see [Backing up a source or replica by making it read only](https://mysql.com/doc/) in the MySQL documentation.

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the source MySQL database to the VPC security group for the Amazon Aurora DB cluster. For more information on modifying a VPC security group, see [Security groups for your VPC](https://aws.amazon.com/rds/vpc-user-guide/) in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Amazon Aurora DB cluster, so that it can communicate with your source MySQL instance. To find the IP address of the Amazon Aurora DB cluster, use the `host` command.

```
host <aurora_endpoint_address>
```

The host name is the DNS name from the Amazon Aurora DB cluster endpoint.

6. Using the client of your choice, connect to the external MySQL instance and create a MySQL user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```sql
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY '<password>';
```

7. For the external MySQL instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```sql
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY '<password>';
```

8. Take a manual snapshot of the Aurora MySQL DB cluster to be the read replica before setting up replication. If you need to reestablish replication with the DB cluster as a read replica, you can restore the Aurora MySQL DB cluster from this snapshot instead of having to import the data from your MySQL DB instance into a new Aurora MySQL DB cluster.

9. Make the Amazon Aurora DB cluster the replica. Connect to the Amazon Aurora DB cluster as the master user and identify the source MySQL database as the replication master by using the
mysql_rds_set_external_master procedure. Use the master log file name and master log position that you determined in Step 2. The following is an example.

For Aurora MySQL version 1 and 2:
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);

For Aurora MySQL version 3 and higher:
CALL mysql.rds_set_external_source ('mymasterserver.mydomain.com', 3306, 'repl_user', '<password>', 'mysql-bin-changelog.000031', 107, 0);

10. On the Amazon Aurora DB cluster, issue the mysql_rds_start_replication procedure to start replication.

CALL mysql.rds_start_replication;

After you have established replication between your source MySQL DB instance and your Amazon Aurora DB cluster, you can add Aurora Replicas to your Amazon Aurora DB cluster. You can then connect to the Aurora Replicas to read scale your data. For information on creating an Aurora Replica, see Adding Aurora Replicas to a DB cluster (p. 270).

Optimizing binary log replication

Following, you can learn how to optimize binary log replication performance and troubleshoot related issues in Aurora MySQL.

Tip
This discussion presumes that you are familiar with the MySQL binary log replication mechanism and how it works. For background information, see Replication Implementation in the MySQL documentation.

Multithreaded binary log replication (Aurora MySQL version 3 and higher)

With multithreaded binary log replication, a SQL thread reads events from the relay log and queues them up for SQL worker threads to apply. The SQL worker threads are managed by a coordinator thread. The binary log events are applied in parallel when possible.

When an Aurora MySQL instance is configured to use binary log replication, by default the replica instance uses single-threaded replication. To enable multithreaded replication, you update the replica_parallel_workers parameter to a value greater than zero in your custom parameter group.

The following configuration options help you to fine-tune multithreaded replication. For usage information, see Replication and Binary Logging Options and Variables in the MySQL Reference Manual.

Optimal configuration depends on several factors. For example, performance for binary log replication is influenced by your database workload characteristics and the DB instance class the replica is running on. Thus, we recommend that you thoroughly test all changes to these configuration parameters before applying new parameter settings to a production instance.

• replica_parallel_workers
• replica_parallel_type
• replica_preserve_commit_order
• binlog_transaction_dependency_tracking
• binlog_transaction_dependency_history_size
• binlog_group_commit_sync_delay
• binlog_group_commit_sync_no_delay_count
Optimizing binlog replication (Aurora MySQL 2.10 and higher)

In Aurora MySQL 2.10 and higher, Aurora automatically applies an optimization known as the binlog I/O cache to binary log replication. By caching the most recently committed binlog events, this optimization is designed to improve binlog dump thread performance while limiting the impact to foreground transactions on the binlog source instance.

**Note**
This memory used for this feature is independent of the MySQL binlog_cache setting. This feature doesn't apply to Aurora DB instances that use the `db.t2` and `db.t3` instance classes.

You don't need to adjust any configuration parameters to turn on this optimization. In particular, if you adjust the configuration parameter `aurora_binlog_replication_max_yield_seconds` to a nonzero value in earlier Aurora MySQL versions, set it back to zero for Aurora MySQL 2.10 and higher.

The status variables `aurora_binlog_io_cache_reads` and `aurora_binlog_io_cache_read_requests` are available in Aurora MySQL 2.10 and higher. These status variables help you to monitor how often the data is read from the binlog I/O cache.

- `aurora_binlog_io_cache_read_requests` shows the number of binlog I/O read requests from the cache.
- `aurora_binlog_io_cache_reads` shows the number of binlog I/O reads that retrieve information from the cache.

The following SQL query computes the percentage of binlog read requests that take advantage of the cached information. In this case, the closer the ratio is to 100, the better it is.

```sql
mysql> SELECT
    (SELECT VARIABLE_VALUE FROM INFORMATION_SCHEMA.GLOBAL_STATUS
     WHERE VARIABLE_NAME='aurora_binlog_io_cache_reads')
/ (SELECT VARIABLE_VALUE FROM INFORMATION_SCHEMA.GLOBAL_STATUS
     WHERE VARIABLE_NAME='aurora_binlog_io_cache_read_requests') * 100
# binlog_io_cache_hit_ratio
| 99.99847949080622 |
```

The binlog I/O cache feature also includes new metrics related to the binlog dump threads. *Dump threads* are the threads that are created when new binlog replicas are connected to the binlog source instance.

The dump thread metrics are printed to the database log every 60 seconds with the prefix `Dump thread metrics`. The metrics include information for each binlog replica such as `Secondary_id`, `Secondary_uuid`, binlog file name, and the position that each replica is reading. The metrics also include `Bytes_behind_primary` representing the distance in bytes between replication source and replica. This metric measures the lag of the replica I/O thread. That figure is different from the lag of the replica SQL applier thread, which is represented by the `seconds_behind_master` metric on the binlog replica. You can determine whether binlog replicas are catching up to the source or falling behind by checking whether the distance decreases or increases.

Optimizing binlog replication (Aurora MySQL 2.04.5 through 2.09)

To optimize binary log replication for Aurora MySQL, you adjust the following cluster-level optimization parameters. These parameters help you to specify the right balance between latency on the binlog source instance and replication lag.
• **aurora_binlog_use_large_read_buffer**
• **aurora_binlog_read_buffer_size**
• **aurora_binlog_replication_max_yield_seconds**

**Note**
For MySQL 5.7-compatible clusters, you can use these parameters in Aurora MySQL version 2.04.5 through 2.09.*. In Aurora MySQL 2.10.0 and higher, these parameters are superseded by the binlog I/O cache optimization and you don't need to use them. For MySQL 5.6-compatible clusters, you can use these parameters in Aurora MySQL version 1.17.6 and later.

**Topics**
• Overview of the large read buffer and max-yield optimizations (p. 860)
• Related parameters (p. 861)
• Enabling the max-yield mechanism for binary log replication (p. 862)
• Turning off the binary log replication max-yield optimization (p. 863)
• Turning off the large read buffer (p. 863)

**Overview of the large read buffer and max-yield optimizations**
You might experience reduced binary log replication performance when the binary log dump thread accesses the Aurora cluster volume while the cluster processes a high number of transactions. You can use the parameters **aurora_binlog_use_large_read_buffer**, **aurora_binlog_replication_max_yield_seconds**, and **aurora_binlog_read_buffer_size** to help minimize this type of contention.

Suppose that you have a situation where **aurora_binlog_replication_max_yield_seconds** is set to greater than 0 and the current binlog file of the dump thread is active. In this case, the binary log dump thread waits up to a specified number of seconds for the current binlog file to be filled by transactions. This wait period avoids contention that can arise from replicating each binlog event individually. However, doing so increases the replica lag for binary log replicas. Those replicas can fall behind the source by the same number of seconds as the **aurora_binlog_replication_max_yield_seconds** setting.

The current binlog file means the binlog file that the dump thread is currently reading to perform replication. We consider that a binlog file is active when the binlog file is updating or open to be updated by incoming transactions. After Aurora MySQL fills up the active binlog file, MySQL creates and switches to a new binlog file. The old binlog file becomes inactive. It isn't updated by incoming transactions any longer.

**Note**
Before adjusting these parameters, measure your transaction latency and throughput over time. You might find that binary log replication performance is stable and has low latency even if there is occasional contention.

**aurora_binlog_use_large_read_buffer**
If this parameter is set to 1, Aurora MySQL optimizes binary log replication based on the settings of the parameters **aurora_binlog_read_buffer_size** and **aurora_binlog_replication_max_yield_seconds**. If **aurora_binlog_use_large_read_buffer** is 0, Aurora MySQL ignores the values of the **aurora_binlog_read_buffer_size** and **aurora_binlog_replication_max_yield_seconds** parameters.
aurora_binlog_read_buffer_size

Binary log dump threads with larger read buffer minimize the number of read I/O operations by reading more events for each I/O. The parameter `aurora_binlog_read_buffer_size` sets the read buffer size. The large read buffer can reduce binary log contention for workloads that generate a large amount of binlog data.

**Note**
This parameter only has an effect when the cluster also has the setting `aurora_binlog_use_large_read_buffer=1`. Increasing the size of the read buffer doesn't affect the performance of binary log replication. Binary log dump threads don't wait for updating transactions to fill up the read buffer.

`aurora_binlog_replication_max_yield_seconds`

If your workload requires low transaction latency, and you can tolerate some replication lag, you can increase the `aurora_binlog_replication_max_yield_seconds` parameter. This parameter controls the maximum yield property of binary log replication in your cluster.

**Note**
This parameter only has an effect when the cluster also has the setting `aurora_binlog_use_large_read_buffer=1`.

Aurora MySQL recognizes any change to the `aurora_binlog_replication_max_yield_seconds` parameter value immediately. You don't need to restart the DB instance. However, when you turn on this setting, the dump thread only starts to yield when the current binlog file reaches its maximum size of 128 MB and is rotated to a new file.

**Related parameters**

Use the following DB cluster parameters to turn on the binlog optimization.

### Enabling the max-yield mechanism for binary log replication

You can turn on the binary log replication max-yield optimization as follows. Doing so minimizes latency for transactions on the binlog source instance. However, you might experience higher replication lag.

**To turn on the max-yield binlog optimization for an Aurora MySQL cluster**

1. Create or edit a DB cluster parameter group using the following parameter settings:
   - aurora_binlog_use_large_read_buffer: turn on with a value of ON or 1.
• `aurora_binlog_replication_max_yield_seconds`: specify a value greater than 0.

2. Associate the DB cluster parameter group with the Aurora MySQL cluster that works as the binlog source. To do so, follow the procedures in Working with parameter groups (p. 215).

3. Confirm that the parameter change takes effect. To do so, run the following query on the binlog source instance.

```sql
SELECT @@aurora_binlog_use_large_read_buffer, @@aurora_binlog_replication_max_yield_seconds;
```

Your output should be similar to the following.

```
<table>
<thead>
<tr>
<th>@@aurora_binlog_use_large_read_buffer</th>
<th>@@aurora_binlog_replication_max_yield_seconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>45</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>-----------------------------------------------</td>
</tr>
</tbody>
</table>
```

### Turning off the binary log replication max-yield optimization

You can turn off the binary log replication max-yield optimization as follows. Doing so minimizes replication lag. However, you might experience higher latency for transactions on the binlog source instance.

**To turn off the max-yield optimization for an Aurora MySQL cluster**

1. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `aurora_binlog_replication_max_yield_seconds` set to 0. For more information about setting configuration replication parameters using parameter groups, see Working with parameter groups (p. 215).

2. Confirm that the parameter change takes effect. To do so, run the following query on the binlog source instance.

```sql
SELECT @@aurora_binlog_replication_max_yield_seconds;
```

Your output should be similar to the following.

```
<table>
<thead>
<tr>
<th>@@aurora_binlog_replication_max_yield_seconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
</tr>
</tbody>
</table>
```

### Turning off the large read buffer

You can turn off the entire large read buffer feature as follows.

**To turn off the large binary log read buffer for an Aurora MySQL cluster**

1. Reset the `aurora_binlog_use_large_read_buffer` to OFF or 0.
Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `aurora_binlog_use_large_read_buffer` set to 0. For more information about setting configuration parameters using parameter groups, see "Working with parameter groups (p. 215)."

2. On the binlog source instance, run the following query.

```
SELECT @@aurora_binlog_use_large_read_buffer;
```

Your output should be similar to the following.

```
+---------------------------------------+
<table>
<thead>
<tr>
<th>@@aurora_binlog_use_large_read_buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+---------------------------------------+
```

### Synchronizing passwords between replication source and target

When you change user accounts and passwords on the replication source using SQL statements, those changes are replicated to the replication target automatically.

If you use the AWS Management Console, the AWS CLI, or the RDS API to change the master password on the replication source, those changes are not automatically replicated to the replication target. If you want to synchronize the master user and master password between the source and target systems, you must make the same change on the replication target yourself.

### Using GTID-based replication for Amazon Aurora MySQL

Following, you can learn how to use global transaction identifiers (GTIDs) with binary log (binlog) replication between an Aurora MySQL cluster and an external source.

**Note**

For Aurora, you can use this feature only with Aurora MySQL clusters that use binlog replication to or from an external MySQL database. The other database might be an Amazon RDS MySQL instance, an on-premises MySQL database, or an Aurora DB cluster in a different AWS Region. To learn how to configure that kind of replication, see "Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 842)."

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see "Replication with global transaction identifiers" in the MySQL documentation for background.

GTID-based replication is supported for MySQL 5.7-compatible clusters in Aurora MySQL version 2.04 and higher. GTID-based replication isn't supported for MySQL 5.6-compatible clusters in Aurora MySQL version 1.

**Topics**

- Overview of global transaction identifiers (GTIDs) (p. 865)
- Parameters for GTID-based replication (p. 865)
- Configuring GTID-based replication for an Aurora MySQL cluster (p. 866)
- Disabling GTID-based replication for an Aurora MySQL DB cluster (p. 866)
Overview of global transaction identifiers (GTIDs)

*Global transaction identifiers (GTIDs)* are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

**Note**
When Aurora synchronizes data among the DB instances in a cluster, that replication mechanism doesn't involve the binary log (binlog). For Aurora MySQL, GTID-based replication only applies when you also use binlog replication to replicate into or out of an Aurora MySQL DB cluster from an external MySQL-compatible database.

MySQL uses two different types of transactions for binlog replication:

- **GTID transactions** – Transactions that are identified by a GTID.
- **Anonymous transactions** – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You typically use GTID-based replication with Aurora when replicating from an external MySQL-compatible database into an Aurora cluster. You can set up this replication configuration as part of a migration from an on-premises or Amazon RDS database into Aurora MySQL. If the external database already uses GTIDs, enabling GTID-based replication for the Aurora cluster simplifies the replication process.

You configure GTID-based replication for an Aurora MySQL cluster by first setting the relevant configuration parameters in a DB cluster parameter group. You then associate that parameter group with the cluster.

**Parameters for GTID-based replication**

Use the following parameters to configure GTID-based replication.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
</table>
| gtid_mode        | OFF, OFF_PERMISSIVE, ON_PERMISSIVE, ON | OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated.  
|                  |                               | OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated.  
|                  |                               | ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated.  
|                  |                               | ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.  |
| enforce_gtid     | OFF, ON, WARN               | OFF allows transactions to violate GTID consistency.  
|                  |                               | ON prevents transactions from violating GTID consistency.  |
### Using GTID-based replication

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WARN</td>
<td></td>
<td>WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.</td>
</tr>
</tbody>
</table>

#### Note
In the AWS Management Console, the `gtid_mode` parameter appears as `gtid-mode`.

For GTID-based replication, use these settings for the DB cluster parameter group for your Aurora MySQL DB cluster:

- **ON** and **ON_PERMISSIVE** apply only to outgoing replication from an Aurora MySQL cluster. Both of these values cause your Aurora DB cluster to use GTIDs for transactions that are replicated to an external database. **ON** requires that the external database also use GTID-based replication. **ON_PERMISSIVE** makes GTID-based replication optional on the external database.
- **OFF_PERMISSIVE**, if set, means that your Aurora DB cluster can accept incoming replication from an external database. It can do this whether the external database uses GTID-based replication or not.
- **OFF**, if set, means that your Aurora DB cluster only accepts incoming replication from external databases that don't use GTID-based replication.

#### Tip
Incoming replication is the most common binlog replication scenario for Aurora MySQL clusters. For incoming replication, we recommend that you set the GTID mode to **OFF_PERMISSIVE**. That setting allows incoming replication from external databases regardless of the GTID settings at the replication source.

For more information about parameter groups, see [Working with parameter groups](#) (p. 215).

### Configuring GTID-based replication for an Aurora MySQL cluster

When GTID-based replication is enabled for an Aurora MySQL DB cluster, the GTID settings apply to both inbound and outbound binlog replication.

**To enable GTID-based replication for an Aurora MySQL cluster**

1. Create or edit a DB cluster parameter group using the following parameter settings:
   - `gtid_mode` – **ON** or **ON_PERMISSIVE**
   - `enforce_gtid_consistency` – **ON**
2. Associate the DB cluster parameter group with the Aurora MySQL cluster. To do so, follow the procedures in [Working with parameter groups](#) (p. 215).
3. In Aurora MySQL version 3 and higher, optionally specify how to assign GTIDs to transactions that don't include them. To do so, call the stored procedure in `mysql.rds_assign_gtids_to_anonymous_transactions` (Aurora MySQL version 3 and higher) (p. 985).

### Disabling GTID-based replication for an Aurora MySQL DB cluster

You can disable GTID-based replication for an Aurora MySQL DB cluster. Doing so means that the Aurora cluster can't perform inbound or outbound binlog replication with external databases that use GTID-based replication.
### Note
In the following procedure, *read replica* means the replication target in an Aurora configuration with binlog replication to or from an external database. It doesn't mean the read-only Aurora Replica DB instances. For example, when an Aurora cluster accepts incoming replication from an external source, the Aurora primary instance acts as the read replica for binlog replication.

For more details about the stored procedures mentioned in this section, see [Aurora MySQL stored procedures](p. 985).

### To disable GTID-based replication for an Aurora MySQL DB cluster

1. On the Aurora primary instance, run the following procedure.

   ```sql
   CALL mysql.rds_set_master_auto_position(0); (Aurora MySQL version 1 and 2)  
   CALL mysql.rds_set_source_auto_position(0); (Aurora MySQL version 3 and higher)
   ```

2. Reset the `gtid_mode` to `ON_PERMISSIVE`.
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `gtid_mode` set to `ON_PERMISSIVE`.
      
      For more information about setting configuration parameters using parameter groups, see [Working with parameter groups](p. 215).
   b. Restart the Aurora MySQL DB cluster.

3. Reset the `gtid_mode` to `OFF_PERMISSIVE`:
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `gtid_mode` set to `OFF_PERMISSIVE`.
   b. Restart the Aurora MySQL DB cluster.

4. a. On the Aurora primary instance, run the `SHOW MASTER STATUS` command.

   Your output should be similar to the following.

   ```
   File                        Position
   ------------------------------------
   mysql-bin-changelog.000031      107
   ------------------------------------
   ```

   Note the file and position in your output.
   b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

   ```sql
   SELECT MASTER_POS_WAIT('file', position);  
   ```

   For example, if the file name is `mysql-bin-changelog.000031` and the position is 107, run the following statement.

   ```sql
   SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);  
   ```

   If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. When the query returns for all read replicas, go to the next step.

5. Reset the GTID parameters to disable GTID-based replication:
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has the following parameter settings:
• `gtid_mode` – OFF
  • `enforce_gtids_consistency` – OFF

b. Restart the Aurora MySQL DB cluster.

**Working with Aurora multi-master clusters**

**Important**

Amazon has announced an end-of-life policy for Amazon Aurora MySQL-Compatible Edition v1. For details about how long Aurora MySQL version 1 will remain available and how to migrate to a higher Aurora MySQL version, see Preparing for Amazon Aurora MySQL-Compatible Edition version 1 end of life (p. 995).

Following, you can learn about Aurora multi-master clusters. In a multi-master cluster, all DB instances have read/write capability. Multi-master clusters have different availability characteristics, support for database features, and procedures for monitoring and troubleshooting than single-master clusters.

**Topics**

- Overview of Aurora multi-master clusters (p. 868)
- Creating an Aurora multi-master cluster (p. 874)
- Managing Aurora multi-master clusters (p. 876)
- Application considerations for Aurora multi-master clusters (p. 879)
- Performance considerations for Aurora multi-master clusters (p. 888)
- Approaches to Aurora multi-master clusters (p. 890)

**Overview of Aurora multi-master clusters**

Use the following background information to help you choose a multi-master or single-master cluster when you set up a new Aurora cluster. For you to make an informed choice, we recommend that you first understand how you plan to adapt your schema design and application logic to work best with a multi-master cluster.

For each new Amazon Aurora cluster, you can choose whether to create a single-master or multi-master cluster.

Most kinds of Aurora clusters are single-master clusters. For example, provisioned, Aurora Serverless, parallel query, and Global Database clusters are all single-master clusters. In a single-master cluster, a single DB instance performs all write operations and any other DB instances are read-only. If the writer DB instance becomes unavailable, a failover mechanism promotes one of the read-only instances to be the new writer.

In a multi-master cluster, all DB instances can perform write operations. The notions of a single read/write primary instance and multiple read-only Aurora Replicas don't apply. There isn't any failover when a writer DB instance becomes unavailable, because another writer DB instance is immediately available to take over the work of the failed instance. We refer to this type of availability as continuous availability, to distinguish it from the high availability (with brief downtime during failover) offered by a single-master cluster.

Multi-master clusters work differently in many ways from the other kinds of Aurora clusters, such as provisioned, Aurora Serverless, and parallel query clusters. With multi-master clusters, you consider different factors in areas such as high availability, monitoring, connection management, and database features. For example, in applications where you can't afford even brief downtime for database write operations, a multi-master cluster can help to avoid an outage when a writer instance becomes
unavailable. The multi-master cluster doesn't use the failover mechanism, because it doesn't need to promote another DB instance to have read/write capability. With a multi-master cluster, you examine metrics related to DML throughput, latency, and deadlocks for all DB instances instead of a single primary instance.

Currently, multi-master clusters require Aurora MySQL version 1, which is compatible with MySQL 5.6. When specifying the DB engine version in the AWS Management Console, AWS CLI, or RDS API, choose 5.6.10a.

To create a multi-master cluster, you choose Multiple writers under Database features when creating the cluster. Doing so enables different behavior for replication among DB instances, availability, and performance than other kinds of Aurora clusters. This choice remains in effect for the life of the cluster. Make sure that you understand the specialized use cases that are appropriate for multi-master clusters.

Topics
- Multi-master cluster terminology (p. 869)
- Multi-master cluster architecture (p. 870)
- Recommended workloads for multi-master clusters (p. 871)
- Advantages of multi-master clusters (p. 872)
- Limitations of multi-master clusters (p. 872)
- Migrating from multi-master clusters (p. 873)

Multi-master cluster terminology

You can understand the terminology about multi-master clusters by learning the following definitions. These terms are used throughout the documentation for multi-master clusters.

Writer

A DB instance that can perform write operations. In an Aurora multi-master cluster, all DB instances are writers. This is a significant difference from Aurora single-master clusters, where only one DB instance can act as a writer. With a single-master cluster, if the writer becomes unavailable, the failover mechanism promotes another DB instance to become the new writer. With a multi-master cluster, your application can redirect write operations from the failed DB instance to any other DB instance in the cluster.

Multi-master

An architecture for Aurora clusters where each DB instance can perform both read and write operations. Contrast this with single-master. Multi-master clusters are best suited for segmented workloads, such as for multitenant applications.

Single-master

The default architecture for Aurora clusters. A single DB instance (the primary instance) performs writes. All other DB instances (the Aurora Replicas) handle read-only query traffic. Contrast this with multi-master. This architecture is appropriate for general-purpose applications. In such applications, a single DB instance can handle all the data manipulation language (DML) and data definition language (DDL) statements. Scalability issues mostly involve SELECT queries.

Write conflict

A situation that occurs when different DB instances attempt to modify the same data page at the same time. Aurora reports a write conflict to your application as a deadlock error. This error condition causes the transaction to roll back. Your application must detect the error code and retry the transaction.

The main design consideration and performance tuning goal with Aurora multi-master clusters is to divide your write operations between DB instances in a way that minimizes write conflicts. That
is why multi-master clusters are well-suited for sharded applications. For details about the write conflict mechanism, see Conflict resolution for multi-master clusters (p. 889).

**Sharding**

A particular class of segmented workloads. The data is physically divided into many partitions, tables, databases, or even separate clusters. The containers for specific portions of the data are known as shards. In an Aurora multi-master cluster, each shard is managed by a specific DB instance, and a DB instance can be responsible for multiple shards. A sharded schema design maps well to the way you manage connections in an Aurora multi-master cluster.

**Shard**

The unit of granularity within a sharded deployment. It might be a table, a set of related tables, a database, a partition, or even an entire cluster. With Aurora multi-master clusters, you can consolidate the data for a sharded application into a single Aurora shared storage volume, making the database continuously available and the data easy to manage. You decide which shards are managed by each DB instance. You can change this mapping at any time, without physically reorganizing the data.

**Resharding**

Physically reorganizing sharded data so that different DB instances can handle specific tables or databases. You don't need to physically reorganize data inside Aurora multi-master clusters in response to changing workload or DB instance failures. You can avoid resharding operations because all DB instances in a cluster can access all databases and tables through the shared storage volume.

**Multitenant**

A particular class of segmented workloads. The data for each customer, client, or user is kept in a separate table or database. This design ensures isolation and helps you to manage capacity and resources at the level of individual users.

**Bring-your-own-shard (BYOS)**

A situation where you already have a database schema and associated applications that use sharding. You can transfer such deployments relatively easily to Aurora multi-master clusters. In this case, you can devote your effort to investigating the Aurora benefits such as server consolidation and high availability. You don't need to create new application logic to handle multiple connections for write requests.

**Global read-after-write (GRAW)**

A setting that introduces synchronization so that any read operations always see the most current state of the data. By default, the data seen by a read operation in a multi-master cluster is subject to replication lag, typically a few milliseconds. During this brief interval, a query on one DB instance might retrieve stale data if the same data is modified at the same time by a different DB instance. To enable this setting, change `aurora_mm_session_consistency_level` from its default setting of `INSTANCE_RAW` to `REGIONAL_RAW`. Doing so ensures cluster-wide consistency for read operations regardless of the DB instances that perform the reads and writes. For details on GRAW mode, see Consistency model for multi-master clusters (p. 881).

**Multi-master cluster architecture**

Multi-master clusters have a different architecture than other kinds of Aurora clusters. In multi-master clusters, all DB instances have read/write capability. Other kinds of Aurora clusters have a single dedicated DB instance that performs all write operations, while all other DB instances are read-only and handle only SELECT queries. Multi-master clusters don't have a primary instance or read-only Aurora Replicas.

Your application controls which write requests are handled by which DB instance. Thus, with a multi-master cluster, you connect to individual instance endpoints to issue DML and DDL statements. That's
different than other kinds of Aurora clusters, where you typically direct all write operations to the single cluster endpoint and all read operations to the single reader endpoint.

The underlying storage for Aurora multi-master clusters is similar to storage for single-master clusters. Your data is still stored in a highly reliable, shared storage volume that grows automatically. The core difference lies in the number and type of DB instances. In multi-master clusters, there are \( N \) read/write nodes. Currently, the maximum for \( N \) is 4.

Multi-master clusters have no dedicated read-only nodes. Thus, the Aurora procedures and guidelines about Aurora Replicas don’t apply to multi-master clusters. You can temporarily make a DB instance read-only to place read and write workloads on different DB instances. To do so, see Using instance read-only mode (p. 888).

Multi-master cluster nodes are connected using low-latency and low-lag Aurora replication. Multi-master clusters use all-to-all peer-to-peer replication. Replication works directly between writers. Every writer replicates its changes to all other writers.

DB instances in a multi-master cluster handle restart and recovery independently. If a writer restarts, there is no requirement for other writers to also restart. For details, see High availability considerations for Aurora multi-master clusters (p. 878).

Multi-master clusters keep track of all changes to data within all database instances. The unit of measurement is the data page, which has a fixed size of 16 KB. These changes include modifications to table data, secondary indexes, and system tables. Changes can also result from Aurora internal housekeeping tasks. Aurora ensures consistency between the multiple physical copies that Aurora keeps for each data page in the shared storage volume, and in memory on the DB instances.

If two DB instances attempt to modify the same data page at almost the same instant, a write conflict occurs. The earliest change request is approved using a quorum voting mechanism. That change is saved to permanent storage. The DB instance whose change isn't approved rolls back the entire transaction containing the attempted change. Rolling back the transaction ensures that data is kept in a consistent state, and applications always see a predictable view of the data. Your application can detect the deadlock condition and retry the entire transaction.

For details about how to minimize write conflicts and associated performance overhead, see Conflict resolution for multi-master clusters (p. 889).

Recommended workloads for multi-master clusters

Multi-master clusters work best with certain kinds of workloads.

Active-passive workloads

With an active-passive workload, you perform all read and write operations on one DB instance at a time. You hold any other DB instances in the Aurora cluster in reserve. If the original active DB instance becomes unavailable, you immediately switch all read and write operations to the other DB instance. With this configuration, you minimize any downtime for write operations. The other DB instance can take over all processing for your application without performing a failover.

Active-active workloads

With an active-active workload, you perform read and write operations to all the DB instances at the same time. In this configuration, you typically segment the workload so that the different DB instances don't modify the same underlying data at the same time. Doing so minimizes the chance for write conflicts.

Multi-master clusters work well with application logic that's designed for a segmented workload. In this type of workload, you divide write operations by database instance, database, table, or table partition. For example, you can run multiple applications on the same cluster, each assigned to a specific DB instance. Alternatively, you can run an application that uses multiple small tables, such as one table for
each user of an online service. Ideally, you design your schema so that write operations for different DB instances don’t perform simultaneous updates to overlapping rows within the same tables. Sharded applications are one example of this kind of architecture.

For examples of designs for active-active workloads, see Using a multi-master cluster for a sharded database (p. 890).

Advantages of multi-master clusters

You can take advantage of the following benefits with Aurora multi-master clusters:

• Multi-master clusters improve Aurora's already high availability. You can restart a read/write DB instance without causing other DB instances in the cluster to restart. There is no failover process and associated delay when a read/write DB instance becomes unavailable.
• Multi-master clusters are well-suited to sharded or multitenant applications. As you manage the data, you can avoid complex resharding operations. You might be able to consolidate sharded applications with a smaller number of clusters or DB instances. For details, see Using a multi-master cluster for a sharded database (p. 890).
• Aurora detects write conflicts immediately, not when the transaction commits. For details about the write conflict mechanism, see Conflict resolution for multi-master clusters (p. 889).

Limitations of multi-master clusters

Note

Aurora multi-master clusters are only available for Amazon Aurora MySQL-Compatible Edition v1. Amazon has announced an end-of-life policy for this major Aurora MySQL version. For details about how long Aurora MySQL version 1 will remain available and how to migrate to a higher Aurora MySQL version, see Preparing for Amazon Aurora MySQL-Compatible Edition version 1 end of life (p. 995).

AWS and Aurora limitations

The following limitations currently apply to the AWS and Aurora features that you can use with multi-master clusters:

• Currently, you can have a maximum of four DB instances in a multi-master cluster.
• Currently, all DB instances in a multi-master cluster must be in the same AWS Region.
• You can't enable cross-Region replicas from multi-master clusters.
• Multi-master clusters are available in the following AWS Regions:
  • US East (N. Virginia) Region
  • US East (Ohio) Region
  • US West (Oregon) Region
  • Asia Pacific (Mumbai) Region
  • Asia Pacific (Seoul) Region
  • Asia Pacific (Tokyo) Region
  • Europe (Frankfurt) Region
  • Europe (Ireland) Region
• The Stop action isn’t available for multi-master clusters.
• The Aurora survivable page cache, also known as the survivable buffer pool, isn’t supported for multi-master clusters.
• A multi-master cluster doesn’t do any load balancing for connections. Your application must implement its own connection management logic to distribute read and write operations among multiple DB instance endpoints. Typically, in a bring-your-own-shard (BYOS) application,
you already have logic to map each shard to a specific connection. To learn how to adapt the connection management logic in your application, see Connection management for multi-master clusters (p. 880).

- Aurora multi-master clusters are highly specialized for continuous availability use cases. Thus, such clusters might not be generally applicable to all workloads. Your requirements for performance, scalability, and availability might be satisfied by using a larger DB instance class with an Aurora single-master cluster. If so, consider using a provisioned or Aurora Serverless cluster.

- Multi-master clusters have some processing and network overhead for coordination between DB instances. This overhead has the following consequences for write-intensive and read-intensive applications:
  - Throughput benefits are most obvious on busy clusters with multiple concurrent write operations. In many cases, a traditional Aurora cluster with a single primary instance can handle the write traffic for a cluster. In these cases, the benefits of multi-master clusters are mostly for high availability rather than performance.
  - Single-query performance is generally lower than for an equivalent single-master cluster.
  - You can't take a snapshot created on a single-master cluster and restore it on a multi-master cluster, or the opposite. Instead, to transfer all data from one kind of cluster to the other, use a logical dump produced by a tool such as AWS Database Migration Service (AWS DMS) or the `mysqldump` command.
  - When you restore a snapshot created on a multi-master cluster, make sure to include the `--engine-mode multimaster` option. If you don't use this option, you will receive an error.
  - You can't use the parallel query, Aurora Serverless, or Global Database features on a multi-master cluster.

The multi-master aspect is a permanent choice for a cluster. You can't switch an existing Aurora cluster between a multi-master cluster and another kind such as Aurora Serverless or parallel query.

- The zero-downtime patching (ZDP) and zero-downtime restart (ZDR) features aren't available for multi-master clusters.
- Integration with other AWS services such as AWS Lambda, Amazon S3, and AWS Identity and Access Management isn't available for multi-master clusters.
- The Performance Insights feature isn't available for multi-master clusters.
- You can't clone a multi-master cluster.
- You can't enable the backtrack feature for multi-master clusters.

### Database engine limitations

The following limitations apply to the database engine features that you can use with a multi-master cluster:

- You can't perform binary log (binlog) replication to or from a multi-master cluster. This limitation means you also can't use global transaction ID (GTID) replication in a multi-master cluster.
- The event scheduler isn't available for multi-master clusters.
- The hash join optimization isn't enabled on multi-master clusters.
- The query cache isn't available on multi-master clusters.
- You can't use certain SQL language features on multi-master clusters. For the full list of SQL differences, and instructions about adapting your SQL code to address these limitations, see SQL considerations for multi-master clusters (p. 879).

### Migrating from multi-master clusters

Migration from an Aurora multi-master cluster means changing back to an Aurora single-master DB cluster. Use a logical dump produced by a tool such as AWS Database Migration Service (AWS DMS) or the `mysqldump` command.
Creating an Aurora multi-master cluster

You choose the multi-master or single-master architecture at the time you create an Aurora cluster. The following procedures show where to make the multi-master choice. If you haven't created any Aurora clusters before, you can learn the general procedure in Creating an Amazon Aurora DB cluster (p. 127).

Console

Use the following procedure.

To create an Aurora multi-master cluster

1. For **Engine type**, choose Amazon Aurora.
3. Expand **Replication features**, then choose Multi-master.

For **Available versions**, the only version supported for multi-master clusters is **Aurora (MySQL 5.6) multimaster_10a**.

4. Fill in the other settings for the cluster. This part of the procedure is the same as the general procedure for creating an Aurora cluster in Creating a DB cluster (p. 131).
5. Choose **Create database**.

The multi-master cluster is created with one writer instance.
6. After you create the multi-master cluster, add a second writer instance to it by using the following procedure:
   a. On the Databases page, choose the multi-master cluster.
   b. For Actions, choose Add DB instance.
   c. Enter the DB instance identifier.
   d. Make other choices as needed, then choose Add DB instance.

AWS CLI

To create a multi-master cluster with the AWS CLI, run the create-db-cluster AWS CLI command and include the --engine-mode option with the value multimaster.
The following command shows the syntax for creating an Aurora cluster with multi-master replication. For the general procedure to create an Aurora cluster, see Creating a DB cluster (p. 131).

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora --engine-version 5.6.10a --master-username user-name --master-user-password password --db-subnet-group-name my_subnet_group --vpc-security-group-ids my_vpc_id --engine-mode multimaster
```

For Windows:

```bash
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora --engine-version 5.6.10a --master-username user-name --master-user-password password --db-subnet-group-name my_subnet_group --vpc-security-group-ids my_vpc_id --engine-mode multimaster
```

After you create the multi-master cluster, add a second DB instance to it by following the procedure in Adding Aurora Replicas to a DB cluster (p. 270).

**RDS API**

To create a multi-master cluster with the RDS API, run the `CreateDBCluster` operation. Specify the value `multimaster` for the `EngineMode` parameter. For the general procedure to create an Aurora cluster, see Creating a DB cluster (p. 131).

After you create the multi-master cluster, add two DB instances to it by following the procedure in Adding Aurora Replicas to a DB cluster (p. 270).

**Adding a DB instance to a multi-master cluster**

You need more than one DB instance to see the benefits of a multi-master cluster. After you create the first instance, you can create other DB instances, up to a maximum of four DB instances. The difference for multi-master clusters is that the new DB instances all have read/write capability instead of being read-only Aurora Replicas.

**Managing Aurora multi-master clusters**

You do most management and administration for Aurora multi-master clusters the same way as for other kinds of Aurora clusters. The following sections explain the differences and unique features of multi-master clusters for administration and management.

**Topics**

- Monitoring an Aurora multi-master cluster (p. 876)
- Data ingestion performance for multi-master clusters (p. 877)
- Exporting data from a multi-master cluster (p. 878)
- High availability considerations for Aurora multi-master clusters (p. 878)
- Replication between multi-master clusters and other clusters (p. 878)
- Upgrading a multi-master cluster (p. 878)

**Monitoring an Aurora multi-master cluster**

Most of the monitoring and diagnostic features supported by MySQL and Aurora single-master clusters are also supported for multi-master clusters:
• MySQL error logs, general logs and slow query logs.
• MySQL built-in diagnostic features such as SHOW commands, status variables, InnoDB runtime status tables, and so on.
• MySQL Performance Schema.
• Advanced Auditing.
• CloudWatch metrics.
• Enhanced Monitoring.

Aurora multi-master clusters don't currently support the following monitoring features:

• Performance Insights.

Data ingestion performance for multi-master clusters

One best practice for DML operations on a multi-master cluster is to keep transactions small and brief. Also, route write operations for a particular table or database to a specific DB instance. Doing a bulk import might require relaxing the guidance for transaction size. However, you can still distribute the write operations to minimize the chance of write conflicts.

To distribute the write workload from a bulk import

1. Issue a separate `mysqldump` command for each database, table, or other object in your schema. Store the results of each `mysqldump` in a file whose name reflects the object being dumped. As an alternative, you can use a specialized dump and import tool that can automatically dump multiple tables in parallel, such as `mydumper`.
2. Run a separate `mysql` session for each data file, connecting to the appropriate instance endpoint that handles the corresponding schema object. Again, as an alternative, you can use a specialized parallel import command, such as `myloader`.
3. Run the import sessions in parallel across the DB instances in the multi-master cluster, instead of waiting for each to finish before starting the next.

You can use the following techniques to import data into an Aurora multi-master cluster:

• You can import logical (SQL-format) dumps from other MySQL-compatible servers to Aurora multi-master clusters, if the statements don’t use any features that aren’t supported in Aurora. For example, a logical dump from a table containing MySQL Full-Text Search (FTS) indexes doesn’t work because the FTS feature is not supported on multi-master clusters.
• You can use managed services such as DMS to migrate data into an Aurora multi-master cluster.
• For migrations into an Aurora multi-master cluster from a server that isn’t compatible with MySQL, follow existing instructions for heterogeneous Aurora migrations.
• Aurora multi-master clusters can produce MySQL-compatible logical dumps in SQL format. Any migration tool (for example, AWS DMS) that can understand such format can consume data dumps from Aurora multi-master clusters.
• Aurora doesn’t support binary logging with the multi-master cluster as the binlog master or worker. You can’t use binlog-based CDC tools with multi-master clusters.
• When migrating from non-MySQL-compatible servers, you can replicate into a multi-master cluster using the continuous change data capture (CDC) feature of AWS DMS. That type of replication transmits SQL statements to the destination cluster, thus the restriction on binlog replication doesn’t apply.

For a detailed discussion of migration techniques and recommendations, see the Amazon Aurora migration handbook AWS whitepaper. Some of the migration methods listed in the handbook might not
apply to Aurora multi-master clusters, but the document is a great overall source of knowledge about Aurora migration topics.

**Exporting data from a multi-master cluster**

You can save a snapshot of a multi-master cluster and restore it to another multi-master cluster. Currently, you can't restore a multi-master cluster snapshot into a single-master cluster.

To migrate data from a multi-master cluster to a single-master cluster, use a logical dump and restore with a tool such as `mysqldump`.

You can't use a multi-master cluster as the source or destination for binary log replication.

**High availability considerations for Aurora multi-master clusters**

In an Aurora multi-master cluster, any DB instance can restart without causing any other instance to restart. This behavior provides a higher level of availability for read/write and read-only connections than for Aurora single-master clusters. We refer to this availability level as *continuous availability*. In multi-master clusters, there is no downtime for write availability when a writer DB instance fails. Multi-master clusters don't use the failover mechanism, because all cluster instances are writable. If a DB instance fails in a multi-master cluster, your application can redirect the workload towards the remaining healthy instances.

In a single-master cluster, restarting the primary instance makes write operations unavailable until the failover mechanism promotes a new primary instance. Read-only operations also experience a brief downtime because all the Aurora Replicas in the cluster restart.

To minimize downtime for applications in a multi-master cluster, implement frequent SQL-level health checks. If a DB instance in a multi-master cluster becomes unavailable, you can decide what to do based on the expected length of the outage and the urgency of write operations in the workload. If you expect the outage to be brief and the write operations aren't urgent, you can wait for the DB instance to recover before resuming the workload that is normally handled by that DB instance. Alternatively, you can redirect that workload to a different DB instance. The underlying data remains available at all time to all DB instances in the cluster. The highly distributed Aurora storage volume keeps the data continuously available even in the unlikely event of a failure affecting an entire AZ. For information about the timing considerations for switching write operations away from an unavailable DB instance, see *Using a multi-master cluster as an active standby* (p. 891).

**Replication between multi-master clusters and other clusters**

Multi-master clusters don't support incoming or outgoing binary log replication.

**Upgrading a multi-master cluster**

Aurora multi-master clusters use the same version numbering scheme, with major and minor version numbers, as other kinds of Aurora clusters. However, the *Enable auto minor version upgrade* setting doesn't apply for multi-master clusters.

When you upgrade an Aurora multi-master cluster, typically the upgrade procedure moves the database engine from the current version to the next higher version. If you upgrade to an Aurora version that increments the version number by more than one, the upgrade uses a multi-step approach. Each DB instance is upgraded to the next higher version, then the next one after that, and so on until it reaches the specified upgrade version.

The approach is different depending on whether there are any backwards-incompatible changes between the old and new versions. For example, updates to the system schema are considered
backwards-incompatible changes. You can check whether a specific version contains any backwards-incompatible changes by consulting the release notes.

If there aren't any incompatible changes between the old and new versions, each DB instance is upgraded and restarted individually. The upgrades are staggered so that the overall cluster doesn't experience any downtime. At least one DB instance is available at any time during the upgrade process.

If there are incompatible changes between the old and new versions, Aurora performs the upgrade in offline mode. All cluster nodes are upgraded and restarted at the same time. The cluster experiences some downtime, to avoid an older engine writing to newer system tables.

Zero-downtime patching (ZDP) isn't currently supported for Aurora multi-master clusters.

Application considerations for Aurora multi-master clusters

Following, you can learn any changes that might be required in your applications due to differences in feature support or behavior between multi-master and single-master clusters.

Topics
- SQL considerations for multi-master clusters (p. 879)
- Connection management for multi-master clusters (p. 880)
- Consistency model for multi-master clusters (p. 881)
- Multi-master clusters and transactions (p. 882)
- Write conflicts and deadlocks in multi-master clusters (p. 882)
- Multi-master clusters and locking reads (p. 883)
- Performing DDL operations on a multi-master cluster (p. 884)
- Using autoincrement columns (p. 885)
- Multi-master clusters feature reference (p. 886)

SQL considerations for multi-master clusters

The following are the major limitations that apply to the SQL language features you can use with a multi-master cluster:

- In a multi-master cluster, you can't use certain settings or column types that change the row layout. You can't enable the innodb_large_prefix configuration option. You can't use the column types MEDIUMTEXT, MEDIUMBLOB, LONGTEXT, or LONGBLOB.
- You can't use the CASCADE clause with any foreign key columns in a multi-master cluster.
- Multi-master clusters can't contain any tables with full-text search (FTS) indexes. Such tables can't be created on or imported into multi-master clusters.
- DDL works differently on multi-master and single-master clusters. For example, the fast DDL mechanism isn't available for multi-master clusters. You can't write to a table in a multi-master cluster while the table is undergoing DDL. For full details on DDL differences, see Performing DDL operations on a multi-master cluster (p. 884).
- You can't use the SERIALIZABLE transaction isolation level on multi-master clusters. On Aurora single-master clusters, you can use this isolation level on the primary instance.
- Autoincrement columns are handled using the auto_increment_increment and auto_increment_offset parameters. Parameter values are predetermined and not configurable. The parameter auto_increment_increment is set to 16, which is the maximum number of
instances in any Aurora cluster. However, multi-master clusters currently have a lower limit on the number of DB instances. For details, see Using autoincrement columns (p. 885).

When adapting an application for an Aurora multi-master cluster, approach that activity the same as a migration. You might have to stop using certain SQL features, and change your application logic for other SQL features:

- In your `CREATE TABLE` statements, change any columns defined as `MEDIUMTEXT`, `MEDIUMBLOB`, `LONGTEXT`, or `LONGBLOB` to shorter types that don't require off-page storage.
- In your `CREATE TABLE` statements, remove the `CASCADE` clause from any foreign key declarations. Add application logic if necessary to emulate the `CASCADE` effects through `INSERT` or `DELETE` statements.
- Remove any use of InnoDB fulltext search (FTS) indexes. Check your source code for `MATCH()` operators in `SELECT` statements, and `FULLTEXT` keywords in DDL statements. Check if any table names from the `INFORMATION_SCHEMA.INNODB_SYS_TABLES` system table contain the string `FTS_`.
- Check the frequency of DDL operations such as `CREATE TABLE` and `DROP TABLE` in your application. Because DDL operations have more overhead in multi-master clusters, avoid running many small DDL statements. For example, look for opportunities to create needed tables ahead of time. For information about DDL differences with multi-master clusters, see Performing DDL operations on a multi-master cluster (p. 884).
- Examine your use of autoincrement columns. The sequences of values for autoincrement columns are different for multi-master clusters than other kinds of Aurora clusters. Check for the `AUTO_INCREMENT` keyword in DDL statements, the function name `last_insert_id()` in `SELECT` statements, and the name `innodb_autoinc_lock_mode` in your custom configuration settings. For details about the differences and how to handle them, see Using autoincrement columns (p. 885).
- Check your code for the `SERIALIZABLE` keyword. You can't use this transaction isolation level with a multi-master cluster.

**Connection management for multi-master clusters**

The main connectivity consideration for multi-master clusters is the number and type of the available DNS endpoints. With multi-master clusters, you often use the instance endpoints, which you rarely use in other kinds of Aurora clusters.

Aurora multi-master clusters have the following kinds of endpoints:

**Cluster endpoint**

This type of endpoint always points to a DB instance with read/write capability. Each multi-master cluster has one cluster endpoint.

Because applications in multi-master clusters typically include logic to manage connections to specific DB instances, you rarely need to use this endpoint. It's mostly useful for connecting to a multi-master cluster to perform administration.

You can also connect to this endpoint to examine the cluster topology when you don't know the status of the DB instances in the cluster. To learn that procedure, see Describing cluster topology (p. 887).

**DB instance endpoint**

This type of endpoint connects to specific named DB instances. For Aurora multi-master clusters, your application typically uses the DB instance endpoints for all or nearly all connections. You decide which DB instance to use for each SQL statement based on the mapping between your shards and the DB instances in the cluster. Each DB instance has one such endpoint. Thus the multi-master cluster has one or more of these endpoints, and the number changes as DB instances are added to or removed from a multi-master cluster.
The way you use DB instance endpoints is different between single-master and multi-master clusters. For single-master clusters, you typically don’t use this endpoint often.

Custom endpoint

This type of endpoint is optional. You can create one or more custom endpoints to group together DB instances for a specific purpose. When you connect to the endpoint, Aurora returns the IP address of a different DB instance each time. In multi-master clusters, you typically use custom endpoints to designate a set of DB instances to use mostly for read operations. We recommend not using custom endpoints with multi-master clusters to load-balance write operations, because doing so increases the chance of write conflicts.

Multi-master clusters don’t have reader endpoints. Where practical, issue `SELECT` queries using the same DB instance endpoint that normally writes to the same table. Doing so makes more effective use of cached data from the buffer pool, and avoids potential issues with stale data due to replication lag within the cluster. If you don’t locate `SELECT` statements on the same DB instances that write to the same tables, and you require strict read after write guarantee for certain queries, consider running those queries using the global read-after-write (GRAW) mechanism described in Consistency model for multi-master clusters (p. 881).

For general best practices of Aurora and MySQL connection management, see the Amazon Aurora migration handbook AWS whitepaper.

For information about how to emulate read-only DB instances in multi-master DB clusters, see Using instance read-only mode (p. 888).

Follow these guidelines when creating custom DNS endpoints and designing drivers and connectors for Aurora multi-master clusters:

- For DDL, DML, and DCL statements, don’t use endpoints or connection routing techniques that operate in round-robin or random fashion.
- Avoid long-running write queries and long write transactions unless these transactions are guaranteed not to conflict with other write traffic in the cluster.
- Prefer to use autocommitted transactions. Where practical, avoid `autocommit=0` settings at global or session level. When you use a database connector or database framework for your programming language, check that `autocommit` is turned on for applications that use the connector or framework. If needed, add `COMMIT` statements at logical points throughout your code to ensure that transactions are brief.
- When global read consistency or read-after-write guarantee is required, follow recommendations for global read-after-write (GRAW) described in Consistency model for multi-master clusters (p. 881).
- Use the cluster endpoint for DDL and DCL statements where practical. The cluster endpoint helps to minimize the dependency on the hostnames of the individual DB instances. You don’t need to divide DDL and DCL statements by table or database, as you do with DML statements.

Consistency model for multi-master clusters

Aurora multi-master clusters support a global read-after-write (GRAW) mode that is configurable at the session level. This setting introduces extra synchronization to create a consistent read view for each query. That way, queries always see the very latest data. By default, the replication lag in a multi-master cluster means that a DB instance might see old data for a few milliseconds after the data was updated. Enable this feature if your application depends on queries seeing the latest data changes made by any other DB instance, even if the query has to wait as a result.

**Note**

Replication lag doesn’t affect your query results if you write and then read the data using the same DB instance. Thus, the GRAW feature applies mainly to applications that issue multiple concurrent write operations through different DB instances.
When using the GRAW mode, don’t enable it for all queries by default. Globally consistent reads are noticeably slower than local reads. Therefore, use GRAW selectively for queries that require it.

Be aware of these considerations for using GRAW:

- GRAW involves performance overhead due to the cost of establishing a cluster-wide consistent read view. The transaction must first determine a cluster-wide consistent point in time, then replication must catch up to that time. The total delay depends on the workload, but it’s typically in the range of tens of milliseconds.
- You can’t change GRAW mode within a transaction.
- When using GRAW without explicit transactions, each individual query incurs the performance overhead of establishing a globally consistent read view.
- With GRAW enabled, the performance penalty applies to both reads and writes.
- When you use GRAW with explicit transactions, the overhead of establishing a globally consistent view applies once for each transaction, when the transaction starts. Queries performed later in the transaction are as fast as if run without GRAW. If multiple successive statements can all use the same read view, you can wrap them in a single transaction for a better overall performance. That way, the penalty is only paid once per transaction instead of per query.

Multi-master clusters and transactions

Standard Aurora MySQL guidance applies to Aurora multi-master clusters. The Aurora MySQL database engine is optimized for short-lived SQL statements. These are the types of statements typically associated with online transaction processing (OLTP) applications.

In particular, make your write transactions as short as possible. Doing so reduces the window of opportunity for write conflicts. The conflict resolution mechanism is optimistic, meaning that it performs best when write conflicts are rare. The tradeoff is that when conflicts occur, they incur substantial overhead.

There are certain workloads that benefit from large transactions. For example, bulk data imports are significantly faster when run using multi-megabyte transactions rather than single-statement transactions. If you observe an unacceptable number of conflicts while running such workloads, consider the following options:

- Reduce transaction size.
- Reschedule or rearrange batch jobs so that they don’t overlap and don’t provoke conflicts with other workloads. If practical, reschedule the batch jobs so that they run during off-peak hours.
- Refactor the batch jobs so that they run on the same writer instance as the other transactions causing conflicts. When conflicting transactions are run on the same instance, the transactional engine manages access to the rows. In that case, storage-level write conflicts don’t occur.

Write conflicts and deadlocks in multi-master clusters

One important performance aspect for multi-master clusters is the frequency of write conflicts. When such a problem condition occurs in the Aurora storage subsystem, your application receives a deadlock error and performs the usual error handling for deadlock conditions. Aurora uses a lock-free optimistic algorithm that performs best when such conflicts are rare.

In a multi-master cluster, all the DB instances can write to the shared storage volume. For every data page you modify, Aurora automatically distributes several copies across multiple Availability Zones (AZs). A write conflict can occur when multiple DB instances try to modify the same data page within a very short time. The Aurora storage subsystem detects that the changes overlap and performs conflict resolution before finalizing the write operation.
Aurora detects write conflicts at the level of the physical data pages, which have a fixed size of 16 KiB. Thus, a conflict can occur even for changes that affect different rows, if the rows are both within the same data page.

When conflicts do occur, the cleanup operation requires extra work to undo the changes from one of the DB instances. From the point of view of your application, the transaction that caused the conflict encounters a deadlock and Aurora rolls back that whole transaction. Your application receives error code 1213.

Undoing the transaction might require modifying many other data pages whose changes were already applied to the Aurora storage subsystem. Depending on how much data was changed by the transaction, undoing it might involve substantial overhead. Therefore, minimizing the potential for write conflicts is a crucial design consideration for an Aurora multi-master cluster.

Some conflicts result from changes that you initiate. These changes include SQL statements, transactions, and transaction rollbacks. You can minimize these kinds of conflicts through your schema design and the connection management logic in your application.

Other conflicts happen because of simultaneous changes from both a SQL statement and an internal server thread. These conflicts are hard to predict because they depend on internal server activity that you might not be aware of. The two major kinds of internal activity that cause these conflicts are garbage collection (known as purge), and transaction rollbacks performed automatically by Aurora. For example, Aurora performs rollbacks automatically during crash recovery or if a client connection is lost.

A transaction rollback physically reverts page changes that were already made. A rollback produces page changes just like the original transaction does. A rollback takes time, potentially several times as long as the original transaction. While the rollback is proceeding, the changes it produces can come into conflict with your transactions.

Garbage collection has to do with multi-version concurrency control (MVCC), which is the concurrency control method used by the Aurora MySQL transactional engine. With MVCC, data mutations create new row versions, and the database keeps multiple versions of rows to achieve transaction isolation while permitting concurrent access to data. Row versions are removed (purged) when they're no longer needed. Here again, the process of purging produces page changes, which might conflict with your transactions. Depending on the workload, the database can develop a purge lag: a queue of changes waiting to be garbage collected. If the lag grows substantially, the database might need a considerable amount of time to complete the purge, even if you stop submitting SQL statements.

If an internal server thread encounters a write conflict, Aurora retries automatically. In contrast, your application must handle the retry logic for any transactions that encounter conflicts.

When multiple transactions from the same DB instance cause these kinds of overlapping changes, Aurora uses the standard transaction concurrency rules. For example, if two transactions on the same DB instance modify the same row, one of them waits. If the wait is longer than the configured timeout (innodb_lock_wait_timeout, by default 50 seconds), the waiting transaction aborts with a "Lock wait timeout exceeded" message.

**Multi-master clusters and locking reads**

Aurora multi-master clusters support locking reads in the following forms.

<table>
<thead>
<tr>
<th>SELECT ... FOR UPDATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT ... LOCK IN SHARE MODE</td>
</tr>
</tbody>
</table>

For more information about locking reads, see the MySQL reference manual.

Locking read operations are supported on all nodes, but the lock scope is local to the node on which the command was run. A locking read performed on one writer doesn't prevent other writers from accessing
or modifying the locked rows. Despite this limitation, you can still work with locking reads in use cases that guarantee strict workload scope separation between writers, such as in sharded or multitenant databases.

Consider the following guidelines:

- Remember that a node can always see its own changes immediately and without delay. When possible, you can colocate reads and writes on the same node to eliminate the GRAW requirement.
- If read-only queries must be run with globally consistent results, use GRAW.
- If read-only queries care about data visibility but not global consistency, use GRAW or introduce a timed wait before each read. For example, a single application thread might maintain connections C1 and C2 to two different nodes. The application writes on C1 and reads on C2. In such case, the application can issue a read immediately using GRAW, or it can sleep before issuing a read. The sleep time should be equal to or longer than the replication lag (usually approximately 20–30 ms).

The read-after-write feature is controlled using the `aurora_mm_session_consistency_level` session variable. The valid values are `INSTANCE_RAW` for local consistency mode (default) and `REGIONAL_RAW` for cluster-wide consistency:

**Performing DDL operations on a multi-master cluster**

The SQL data definition language (DDL) statements have special considerations for multi-master clusters. These statements sometimes cause substantial reorganization of the underlying data. Such large-scale changes potentially affect many data pages in the shared storage volume. The definitions of tables and other schema objects are held in the `INFORMATION_SCHEMA` tables. Aurora handles changes to those tables specially to avoid write conflicts when multiple DB instances run DDL statements at the same time.

For DDL statements, Aurora automatically delegates the statement processing to a special server process in the cluster. Because Aurora centralizes the changes to the `INFORMATION_SCHEMA` tables, this mechanism avoids the potential for write conflicts between DDL statements.

DDL operations prevent concurrent writes to that table. During a DDL operation on a table, all DB instances in the multi-master cluster are limited to read-only access to that table until the DDL statement finishes.

The following DDL behaviors are the same in Aurora single-master and multi-master clusters:

- A DDL performed on one DB instance causes other instances to terminate any connections actively using the table.
- Session-level temporary tables can be created on any node using the `MyISAM` or `MEMORY` storage engines.
- DDL operations on very large tables might fail if the DB instance doesn’t have sufficient local temporary storage.

Note the following DDL performance considerations in multi-master clusters:

- Try to avoid issuing large numbers of short DDL statements in your application. Create databases, tables, partitions, columns, and so on, in advance where practical. Replication overhead can impose significant performance overhead for simple DDL statements that are typically very quick. The statement doesn’t finish until the changes are replicated to all DB instances in the cluster. For example, multi-master clusters take longer than other Aurora clusters to create empty tables, drop tables, or drop schemas containing many tables.

If you do need to perform a large set of DDL operations, you can reduce the network and coordination overhead by issuing the statements in parallel through multiple threads.
• Long-running DDL statements are less affected, because the replication delay is only a small fraction of the total time for the DDL statement.
• Performance of DDLs on session-level temporary tables should be roughly equivalent on Aurora single-master and multi-master clusters. Operations on temporary tables happen locally and are not subject to synchronous replication overhead.

Using Percona online schema change with multi-master clusters

The pt-online-schema-change tool works with multi-master clusters. You can use it if your priority is to run table modifications in the most nonblocking manner. However, be aware of the write conflict implications of the schema change process.

At a high level, the pt-online-schema-change tool works as follows:

1. It creates a new, empty table with the desired structure.
2. It creates DELETE, INSERT and UPDATE triggers on the original table to redo any data changes on the original table on top of the new table.
3. It moves existing rows into the new table using small chunks while ongoing table changes are automatically handled using the triggers.
4. After all the data is moved, it drops the triggers and switches the tables by renaming them.

The potential contention point occurs while the data is being transferred to the new table. When the new table is initially created, it’s completely empty and therefore can become a locking hot point. The same is true in other kinds of database systems. Because triggers are synchronous, the impact from the hot point can propagate back to your queries.

In multi-master clusters, the impact can be more visible. This visibility is because the new table not only provokes lock contention, but also increases the likelihood of write conflicts. The table initially has very few pages in it, which means that writes are highly localized and therefore prone to conflicts. After the table grows, writes should spread out and write conflicts should no longer be a problem.

You can use the online schema change tool with multi-master clusters. However, it might require more careful testing and its effects on the ongoing workload might be slightly more visible in the first minutes of the operation.

Using autoincrement columns

Aurora multi-master clusters handle autoincrement columns using the existing configuration parameters auto_increment_increment and auto_increment_offset. For more information, see the MySQL reference manual.

Parameter values are predetermined and you can’t change them. Specifically, the auto_increment_increment parameter is hardcoded to 16, which is the maximum number of DB instances in any kind of Aurora cluster.

Due to the hard-coded increment setting, autoincrement values are consumed much more quickly than in single-master clusters. This is true even if a given table is only ever modified by a single DB instance. For best results, always use a BIGINT data type instead of INT for your autoincrement columns.

In a multi-master cluster, your application logic must be prepared to tolerate autoincrement columns that have the following properties:

• The values are noncontiguous.
• The values might not start from 1 on an empty table.
• The values increase by increments greater than 1.
• The values are consumed significantly more quickly than in a single-master cluster.
The following example shows how the sequence of autoincrement values in a multi-master cluster can be different from what you might expect.

```sql
mysql> create table autoinc (id bigint not null auto_increment, s varchar(64), primary key (id));
```

```sql
mysql> insert into autoinc (s) values ('row 1'), ('row 2'), ('row 3');
Query OK, 3 rows affected (0.02 sec)
```

```sql
mysql> select * from autoinc order by id;
+----+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>s</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>row 1</td>
</tr>
<tr>
<td>18</td>
<td>row 2</td>
</tr>
<tr>
<td>34</td>
<td>row 3</td>
</tr>
</tbody>
</table>
+----+-------+
3 rows in set (0.00 sec)
```

You can change the `AUTO_INCREMENT` table property. Using a nondefault value only works reliably if that value is larger than any of the primary key values already in the table. You can't use smaller values to fill in an empty interval in the table. If you do, the change takes effect either temporarily or not at all. This behavior is inherited from MySQL 5.6 and is not specific to the Aurora implementation.

**Multi-master clusters feature reference**

Following, you can find a quick reference of the commands, procedures, and status variables specific to Aurora multi-master clusters.

**Using read-after-write**

The read-after-write feature is controlled using the `aurora_mm_session_consistency_level` session variable. The valid values are `INSTANCE_RAW` for local consistency mode (default) and `REGIONAL_RAW` for cluster-wide consistency.

An example follows.

```sql
mysql> select @@aurora_mm_session_consistency_level;
+---------------------------------------+
<table>
<thead>
<tr>
<th>@@aurora_mm_session_consistency_level</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSTANCE_RAW</td>
</tr>
</tbody>
</table>
+---------------------------------------+
1 row in set (0.01 sec)
```

```sql
mysql> set session aurora_mm_session_consistency_level = 'REGIONAL_RAW';
Query OK, 0 rows affected (0.00 sec)
```

```sql
mysql> select @@aurora_mm_session_consistency_level;
+---------------------------------------+
<table>
<thead>
<tr>
<th>@@aurora_mm_session_consistency_level</th>
</tr>
</thead>
<tbody>
<tr>
<td>REGIONAL_RAW</td>
</tr>
</tbody>
</table>
+---------------------------------------+
1 row in set (0.03 sec)
```

**Checking DB instance read-write mode**

In multi-master clusters, all nodes operate in read/write mode. The `innodb_read_only` variable always returns zero. The following example shows that when you connect to any DB instance in a multi-master cluster, the DB instance reports that it has read/write capability.
Checking the node name and role

You can check the name of the DB instance you're currently connected to by using the `aurora_server_id` status variable. The following example shows how.

```
mysql> select @@aurora_server_id;
+----------------------+
| @@aurora_server_id   |
+----------------------+
| mmr-demo-test-mm-3-1 |
+----------------------+
1 row in set (0.00 sec)
```

To find this information for all the DB instances in a multi-master cluster, see Describing cluster topology (p. 887).

Describing cluster topology

You can describe multi-master cluster topology by selecting from the `information_schema.replica_host_status` table. Multi-master clusters have the following differences from single-master clusters:

- The `has_primary` column identifies the role of the node. For multi-master clusters, this value is true for the DB instance that handles all DDL and DCL statements. Aurora forwards such requests to one of the DB instances in a multi-master cluster.
- The `replica_lag_in_milliseconds` column reports replication lag on all DB instances.
- The `last_reported_status` column reports the status of the DB instance. It can be `Online`, `Recovery`, or `Offline`.

An example follows.

```
mysql> select server_id, has_primary, replica_lag_in_milliseconds, last_reported_status
    > from information_schema.replica_host_status;
+----------------------+-------------+-----------------------------+----------------------+
| server_id            | has_primary | replica_lag_in_milliseconds | last_reported_status |
| mmr-demo-test-mm-3-1 | true        | 37.302                      | Online               |
| mmr-demo-test-mm-3-2 | false       | 39.907                      | Online               |
+----------------------+-------------+-----------------------------+----------------------+
```
Using instance read-only mode

In Aurora multi-master clusters, you usually issue `SELECT` statements to the specific DB instance that performs write operations on the associated tables. Doing so avoids consistency issues due to replication lag and maximizes reuse for table and index data from the buffer pool.

If you need to run a query-intensive workload across multiple tables, you might designate one of more DB instances within a multi-master cluster as read-only.

To put an entire DB instance into read-only mode at runtime, call the `mysql.rds_set_read_only` stored procedure.

```sql
mysql> select @@read_only;
+-------------+
| @@read_only |
+-------------+
| 0           |
+-------------+
1 row in set (0.00 sec)

mysql> call mysql.rds_set_read_only(1);
Query OK, 0 rows affected (0.00 sec)

mysql> select @@read_only;
+-------------+
| @@read_only |
+-------------+
| 1           |
+-------------+
1 row in set (0.00 sec)

mysql> call mysql.rds_set_read_only(0);
Query OK, 0 rows affected (0.00 sec)

mysql> select @@read_only;
+-------------+
| @@read_only |
+-------------+
| 0           |
+-------------+
1 row in set (0.00 sec)
```

Calling the stored procedure is equivalent to running `SET GLOBAL read_only = 0|1`. That setting is runtime only and doesn’t survive an engine restart. You can permanently set the DB instance to read-only by setting the `read_only` parameter to `true` in the parameter group for your DB instance.

Performance considerations for Aurora multi-master clusters

For both single-master and multi-master clusters, the Aurora engine is optimized for OLTP workloads. OLTP applications consist mostly of short-lived transactions with highly selective, random-access queries. You get the most advantage from Aurora with workloads that run many such operations concurrently.

Avoid running all the time at 100 percent utilization. Doing so lets Aurora keep up with internal maintenance work. To learn how to measure how busy a multi-master cluster is and how much maintenance work is needed, see Monitoring an Aurora multi-master cluster (p. 876).

Topics

- Query performance for multi-master clusters (p. 889)
- Conflict resolution for multi-master clusters (p. 889)
- Optimizing buffer pool and dictionary cache usage (p. 889)
Query performance for multi-master clusters

Multi-master clusters don't provide dedicated read-only nodes or read-only DNS endpoints, but it's possible to create groups of read-only DB instances and use them for the intended purpose. For more information, see Using instance read-only mode (p. 888).

You can use the following approaches to optimize query performance for a multi-master cluster:

- Perform `SELECT` statements on the DB instance that handles the shard containing the associated table, database, or other schema objects involved in the query. This technique maximizes reuse of data in the buffer pool. It also avoids the same data being cached on more than one DB instance. For more details about this technique, see Optimizing buffer pool and dictionary cache usage (p. 889).
- If you need read/write workload isolation, designate one or more DB instances as read-only, as described in Using instance read-only mode (p. 888). You can direct read-only sessions to those DB instances by connecting to the corresponding instance endpoints, or by defining a custom endpoint that is associated with all the read-only instances.
- Spread read-only queries across all DB instances. This approach is the least efficient. Use one of the other approaches where practical, especially as you move from the development and test phase towards production.

Conflict resolution for multi-master clusters

Many best practices for multi-master clusters focus on reducing the chance of write conflicts. Resolving write conflicts involves network overhead. Your applications must also handle error conditions and retry transactions. Wherever possible, try to minimize these unwanted consequences:

- Wherever practical, make all changes to a particular table and its associated indexes using the same DB instance. If only one DB instance ever modifies a data page, changing that page cannot trigger any write conflicts. This access pattern is common in sharded or multitenant database deployments. Thus, it's relatively easy to switch such deployments to use multi-master clusters.
- A multi-master cluster doesn't have a reader endpoint. The reader endpoint load-balances incoming connections, freeing you from knowing which DB instance is handling a particular connection. In a multi-master cluster, managing connections involves being aware which DB instance is used for each connection. That way, modifications to a particular database or table can always be routed to the same DB instance.
- A write conflict for a small amount of data (one 16-KB page) can trigger a substantial amount of work to roll back the entire transaction. Thus, ideally you keep the transactions for a multi-master cluster relatively brief and small. This best practice for OLTP applications is especially important for Aurora multi-master clusters.

Conflicts are detected at page level. A conflict could occur because proposed changes from different DB instances modify different rows within the page. All page changes introduced in the system are subject to conflict detection. This rule applies regardless of whether the source is a user transaction or a server background process. It also applies whether the data page is from a table, secondary index, undo space, and so on.

You can divide the write operations so that each DB instance handles all write operations for a set of schema objects. In this case, all the changes to each data page are made by one specific instance.

Optimizing buffer pool and dictionary cache usage

Each DB instance in a multi-master cluster maintains separate in-memory buffers and caches such as the buffer pool, table handler cache, and table dictionary cache. For each DB instance, the contents and amount of turnover for the buffers and caches depends on the SQL statements processed by that instance.
Using memory efficiently can help the performance of multi-master clusters and reduce I/O cost. Use a sharded design to physically separate the data and write to each shard from a particular DB instance. Doing so makes the most efficient use of the buffer cache on each DB instance. Try to assign `SELECT` statements for a table to the same DB instance that performs write operations for that table. Doing so helps those queries to reuse the cached data on that DB instance. If you have a large number of tables or partitions, this technique also reduces the number of unique table handlers and dictionary objects held in memory by each DB instance.

### Approaches to Aurora multi-master clusters

In the following sections, you can find approaches to take for particular deployments that are suitable for multi-master clusters. These approaches involve ways to divide the workload so that the DB instances perform write operations for portions of the data that don't overlap. Doing so minimizes the chances of write conflicts. Write conflicts are the main focus of performance tuning and troubleshooting for a multi-master cluster.

### Topics
- Using a multi-master cluster for a sharded database (p. 890)
- Using a multi-master cluster without sharding (p. 891)
- Using a multi-master cluster as an active standby (p. 891)

### Using a multi-master cluster for a sharded database

Sharding is a popular type of schema design that works well with Aurora multi-master clusters. In a sharded architecture, each DB instance is assigned to update a specific group of schema objects. That way, multiple DB instances can write to the same shared storage volume without conflicts from concurrent changes. Each DB instance can handle write operations for multiple shards. You can change the mapping of DB instances to shards at any time by updating your application configuration. You don't need to reorganize your database storage or reconfigure DB instances when you do so.

Applications that use a sharded schema design are good candidates to use with Aurora multi-master clusters. The way the data is physically divided in a sharded system helps to avoid write conflicts. You map each shard to a schema object such as a partition, a table, or a database. Your application directs all write operations for a particular shard to the appropriate DB instance.

Bring-your-own-shard (BYOS) describes a use case where you already have a sharded/partitioned database and an application capable of accessing it. The shards are already physically separated. Thus, you can easily move the workload to Aurora multi-master clusters without changing your schema design. The same simple migration path applies to multitenant databases, where each tenant uses a dedicated table, a set of tables, or an entire database.

You map shards or tenants to DB instances in a one-to-one or many-to-one fashion. Each DB instance handles one or more shards. The sharded design primarily applies to write operations. You can issue `SELECT` queries for any shard from any DB instance with equivalent performance.

Suppose you used a multi-master cluster for a sharded gaming application. You might distribute the work so that database updates are performed by specific DB instances, depending on the player's username. Your application handles the logic of mapping each player to the appropriate DB instance and connecting to the endpoint for that instance. Each DB instance can handle write operations for many different shards. You can submit queries to any DB instance, because conflicts can only arise during write operations. You might designate one DB instance to perform all `SELECT` queries to minimize the overhead on the DB instances that perform write operations.

Suppose that as time goes on, one of the shards becomes much more active. To rebalance the workload, you can switch which DB instance is responsible for that shard. In a non-Aurora system, you might have to physically move the data to a different server. With an Aurora multi-master cluster, you can reshard
like this by directing all write operations for the shard to some other DB instance that has unused compute capacity. The Aurora shared storage model avoids the need to physically reorganize the data.

**Using a multi-master cluster without sharding**

If your schema design doesn’t subdivide the data into physically separate containers such as databases, tables, or partitions, you can still divide write operations such as DML statements among the DB instances in a multi-master cluster.

You might see some performance overhead, and your application might have to deal with occasional transaction rollbacks when write conflicts are treated as deadlock conditions. Write conflicts are more likely during write operations for small tables. If a table contains few data pages, rows from different parts of the primary key range might be in the same data page. This overlap might lead to write conflicts if those rows are changed simultaneously by different DB instances.

You should also minimize the number of secondary indexes in this case. When you make a change to indexed columns in a table, Aurora makes corresponding changes in the associated secondary indexes. A change to an index could cause a write conflict because the order and grouping of rows is different between a secondary index and the associated table.

Because you might still experience some write conflicts when using this technique, Amazon recommends using a different approach if practical. See if you can use an alternative database design that subdivides the data into different schema objects.

**Using a multi-master cluster as an active standby**

An *active standby* is a DB instance that is kept synchronized with another DB instance, and is ready to take over for it very quickly. This configuration helps with high availability in situations where a single DB instance can handle the full workload.

You can use multi-master clusters in an active standby configuration by directing all traffic, both read/write and read-only, to a single DB instance. If that DB instance becomes unavailable, your application must detect the problem and switch all connections to a different DB instance. In this case, Aurora doesn’t perform any failover because the other DB instance is already available to accept read/write connections. By only writing to a single DB instance at any one time, you avoid write conflicts. Thus, you don’t need to have a sharded database schema to use multi-master clusters in this way.

**Tip**

If your application can tolerate a brief pause, you can wait several seconds after a DB instance becomes unavailable before redirecting write traffic to another instance. When an instance becomes unavailable because of a restart, it becomes available again after approximately 10–20 seconds. If the instance can’t restart quickly, Aurora might initiate recovery for that instance. When an instance is shut down, it performs some additional cleanup activities as part of the shutdown. If you begin writing to a different instance while the instance is restarting, undergoing recovery, or being shut down, you can encounter write conflicts. The conflicts can occur between SQL statements on the new instance, and recovery operations such as rollback and purge on the instance that was restarted or shut down.

### Integrating Amazon Aurora MySQL with other AWS services

Amazon Aurora MySQL integrates with other AWS services so that you can extend your Aurora MySQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora MySQL DB cluster can use AWS services to do the following:
• Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. For more information, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 918).

• Load data from text or XML files stored in an Amazon Simple Storage Service (Amazon S3) bucket into your DB cluster using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` command. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 904).

• Save data to text files stored in an Amazon S3 bucket from your DB cluster using the `SELECT INTO OUTFILE S3` command. For more information, see Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 912).

• Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora replicas (p. 305).

• Perform sentiment analysis with Amazon Comprehend, or a wide variety of machine learning algorithms with SageMaker. For more information, see Using machine learning (ML) capabilities with Amazon Aurora (p. 320).

Aurora secures the ability to access other AWS services by using AWS Identity and Access Management (IAM). You grant permission to access other AWS services by creating an IAM role with the necessary permissions, and then associating the role with your DB cluster. For details and instructions on how to permit your Aurora MySQL DB cluster to access other AWS services on your behalf, see Authorizing Amazon Aurora MySQL to access other AWS services on your behalf (p. 892).

**Authorizing Amazon Aurora MySQL to access other AWS services on your behalf**

**Note**
Integration with other AWS services is available for Amazon Aurora MySQL version 1.8 and later. Some integration features are only available for later versions of Aurora MySQL. For more information on Aurora versions, see Database engine updates for Amazon Aurora MySQL (p. 991).

For your Aurora MySQL DB cluster to access other services on your behalf, create and configure an AWS Identity and Access Management (IAM) role. This role authorizes database users in your DB cluster to access other AWS services. For more information, see Setting up IAM roles to access AWS services (p. 893).

You must also configure your Aurora DB cluster to allow outbound connections to the target AWS service. For more information, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 903).

If you do so, your database users can perform these actions using other AWS services:

• Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. Or, asynchronously invoke an AWS Lambda function using the `mysql.lambda_async` procedure. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 919).

• Load data from text or XML files stored in an Amazon S3 bucket into your DB cluster by using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 904).

• Save data from your DB cluster into text files stored in an Amazon S3 bucket by using the `SELECT INTO OUTFILE S3` statement. For more information, see Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 912).

• Export log data to Amazon CloudWatch Logs MySQL. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 925).
• Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora replicas (p. 305).

Setting up IAM roles to access AWS services

To permit your Aurora DB cluster to access another AWS service, do the following:

1. Create an IAM policy that grants permission to the AWS service. For more information, see:
   • Creating an IAM policy to access Amazon S3 resources (p. 893)
   • Creating an IAM policy to access AWS Lambda resources (p. 895)
   • Creating an IAM policy to access CloudWatch Logs resources (p. 896)
   • Creating an IAM policy to access AWS KMS resources (p. 897)
2. Create an IAM role and attach the policy that you created. For more information, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898).
3. Associate that IAM role with your Aurora DB cluster. For more information, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 899).

Creating an IAM policy to access Amazon S3 resources

Aurora can access Amazon S3 resources to either load data to or save data from an Aurora DB cluster. However, you must first create an IAM policy that provides the bucket and object permissions that allow Aurora to access Amazon S3.

The following table lists the Aurora features that can access an Amazon S3 bucket on your behalf, and the minimum required bucket and object permissions required by each feature.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Bucket permissions</th>
<th>Object permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOAD DATA FROM S3</td>
<td>ListBucket</td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObjectVersion</td>
</tr>
<tr>
<td>LOAD XML FROM S3</td>
<td>ListBucket</td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObjectVersion</td>
</tr>
<tr>
<td>SELECT INTO OUTFILE S3</td>
<td>ListBucket</td>
<td>AbortMultipartUpload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>DeleteObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ListMultipartUploadParts</td>
</tr>
<tr>
<td></td>
<td></td>
<td>PutObject</td>
</tr>
</tbody>
</table>

The following policy adds the permissions that might be required by Aurora to access an Amazon S3 bucket on your behalf.

```json
{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "AllowAuroraToExampleBucket",
```

893

"Effect": "Allow",
"Action": [
  "s3:PutObject",
  "s3:GetObject",
  "s3:AbortMultipartUpload",
  "s3:ListBucket",
  "s3:DeleteObject",
  "s3:GetObjectVersion",
  "s3:ListMultipartUploadParts"
],
"Resource": [
  "arn:aws:s3:::example-bucket/*",
  "arn:aws:s3:::example-bucket"
]
}

**Note**

Make sure to include both entries for the Resource value. Aurora needs the permissions on both the bucket itself and all the objects inside the bucket. Based on your use case, you might not need to add all of the permissions in the sample policy. Also, other permissions might be required. For example, if your Amazon S3 bucket is encrypted, you need to add kms:Decrypt permissions.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access an Amazon S3 bucket on your behalf. To allow Aurora to access all of your Amazon S3 buckets, you can skip these steps and use either the AmazonS3ReadOnlyAccess or AmazonS3FullAccess predefined IAM policy instead of creating your own.

**To create an IAM policy to grant access to your Amazon S3 resources**

1. Open the IAM Management Console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose S3.
5. For Actions, choose Expand all, and then choose the bucket permissions and object permissions needed for the IAM policy.

Object permissions are permissions for object operations in Amazon S3, and need to be granted for objects in a bucket, not the bucket itself. For more information about permissions for object operations in Amazon S3, see Permissions for object operations.

6. Choose Resources, and choose Add ARN for bucket.
7. In the Add ARN(s) dialog box, provide the details about your resource, and choose Add.

Specify the Amazon S3 bucket to allow access to. For instance, if you want to allow Aurora to access the Amazon S3 bucket named example-bucket, then set the Amazon Resource Name (ARN) value to arn:aws:s3:::example-bucket.

8. If the object resource is listed, choose Add ARN for object.
9. In the Add ARN(s) dialog box, provide the details about your resource.

For the Amazon S3 bucket, specify the Amazon S3 bucket to allow access to. For the object, you can choose Any to grant permissions to any object in the bucket.

**Note**

You can set Amazon Resource Name (ARN) to a more specific ARN value in order to allow Aurora to access only specific files or folders in an Amazon S3 bucket. For more information
about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

10. (Optional) Choose **Add ARN** for **bucket** to add another Amazon S3 bucket to the policy, and repeat the previous steps for the bucket.

**Note**
You can repeat this to add corresponding bucket permission statements to your policy for each Amazon S3 bucket that you want Aurora to access. Optionally, you can also grant access to all buckets and objects in Amazon S3.

11. Choose **Review policy**.
12. For **Name**, enter a name for your IAM policy, for example `AllowAuroraToExampleBucket`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
13. Choose **Create policy**.
14. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898).

### Creating an IAM policy to access AWS Lambda resources

You can create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf.

The following policy adds the permissions required by Aurora to invoke an AWS Lambda function on your behalf.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAuroraToExampleFunction",
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:<region>:<123456789012>:function:<example_function>"
    }
  ]
}
```

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf. To allow Aurora to invoke all of your AWS Lambda functions, you can skip these steps and use the predefined `AWSLambdaRole` policy instead of creating your own.

**To create an IAM policy to grant invoke to your AWS Lambda functions**

1. Open the **IAM console**.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **Lambda**.
5. For **Actions**, choose **Expand all**, and then choose the AWS Lambda permissions needed for the IAM policy.

   Ensure that **InvokeFunction** is selected. It is the minimum required permission to enable Amazon Aurora to invoke an AWS Lambda function.
6. Choose **Resources** and choose **Add ARN for function**.
7. In the **Add ARN(s)** dialog box, provide the details about your resource.

   Specify the Lambda function to allow access to. For instance, if you want to allow Aurora to access a Lambda function named `example_function`, then set the ARN value to `arn:aws:lambda:::function:example_function`.

   For more information on how to define an access policy for AWS Lambda, see [Authentication and access control for AWS Lambda](#).

8. Optionally, choose **Add additional permissions** to add another AWS Lambda function to the policy, and repeat the previous steps for the function.

   **Note**
   
   You can repeat this to add corresponding function permission statements to your policy for each AWS Lambda function that you want Aurora to access.

9. Choose **Review policy**.

10. Set **Name** to a name for your IAM policy, for example `AllowAuroraToExampleFunction`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.

11. Choose **Create policy**.

12. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access AWS services](#) (p. 898).

### Creating an IAM policy to access CloudWatch Logs resources

Aurora can access CloudWatch Logs to export audit log data from an Aurora DB cluster. However, you must first create an IAM policy that provides the log group and log stream permissions that allow Aurora to access CloudWatch Logs.

The following policy adds the permissions required by Aurora to access Amazon CloudWatch Logs on your behalf, and the minimum required permissions to create log groups and export data.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogEvents",
            "Effect": "Allow",
            "Action": [  
                "logs:GetLogEvents",
                "logs:PutLogEvents"
            ],
            "Resource": "arn:aws:logs::*:*:log-group:/aws/rds/*:log-stream:*"
        },
        {
            "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogGroupsAndStreams",
            "Effect": "Allow",
            "Action": [  
                "logs:CreateLogStream",
                "logs:DescribeLogStreams",
                "logs:PutRetentionPolicy",
                "logs:CreateLogGroup"
            ],
            "Resource": "arn:aws:logs::*:*:log-group:/aws/rds/*"
        }
    ]
}
```

You can modify the ARNs in the policy to restrict access to a specific AWS Region and account.
You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access CloudWatch Logs on your behalf. To allow Aurora full access to CloudWatch Logs, you can skip these steps and use the `CloudWatchLogsFullAccess` predefined IAM policy instead of creating your own. For more information, see Using identity-based policies (IAM policies) for CloudWatch Logs in the Amazon CloudWatch User Guide.

**To create an IAM policy to grant access to your CloudWatch Logs resources**

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose CloudWatch Logs.
5. For Actions, choose Expand all (on the right), and then choose the Amazon CloudWatch Logs permissions needed for the IAM policy.

   Ensure that the following permissions are selected:
   - CreateLogGroup
   - CreateLogStream
   - DescribeLogStreams
   - GetLogEvents
   - PutLogEvents
   - PutRetentionPolicy

6. Choose Resources and choose Add ARN for log-group.
7. In the Add ARN(s) dialog box, enter the following values:
   - Region – An AWS Region or *
   - Account – An account number or *
   - Log Group Name – /aws/rds/*
8. In the Add ARN(s) dialog box, choose Add.
10. In the Add ARN(s) dialog box, enter the following values:
     - Region – An AWS Region or *
     - Account – An account number or *
     - Log Group Name – /aws/rds/*
     - Log Stream Name – *
11. In the Add ARN(s) dialog box, choose Add.
13. Set Name to a name for your IAM policy, for example `AmazonRDSCloudWatchLogs`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.
14. Choose Create policy.
15. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898).

**Creating an IAM policy to access AWS KMS resources**

Aurora can access the AWS KMS keys used for encrypting their database backups. However, you must first create an IAM policy that provides the permissions that allow Aurora to access KMS keys.

The following policy adds the permissions required by Aurora to access KMS keys on your behalf.
You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access KMS keys on your behalf.

**To create an IAM policy to grant access to your KMS keys**

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose KMS.
5. For Actions, choose Write, and then choose Decrypt.
6. Choose Resources, and choose Add ARN.
7. In the Add ARN(s) dialog box, enter the following values:
   - Region – Type the AWS Region, such as us-west-2.
   - Account – Type the user account number.
   - Log Stream Name – Type the KMS key identifier.
8. In the Add ARN(s) dialog box, choose Add.
10. Set Name to a name for your IAM policy, for example AmazonRDSKMSKey. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.
11. Choose Create policy.
12. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898).

**Creating an IAM role to allow Amazon Aurora to access AWS services**

After creating an IAM policy to allow Aurora to access AWS resources, you must create an IAM role and attach the IAM policy to the new IAM role.

To create an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.

**To create an IAM role to allow Amazon RDS to access AWS services**

1. Open the IAM console.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. Under AWS service, choose RDS.
5. Under Select your use case, choose RDS – Add Role to Database.
6. Choose Next.
7. On the **Permissions policies** page, enter the name of your policy in the **Search** field.
8. When it appears in the list, select the policy that you defined earlier using the instructions in one of the following sections:
   - Creating an IAM policy to access Amazon S3 resources (p. 893)
   - Creating an IAM policy to access AWS Lambda resources (p. 895)
   - Creating an IAM policy to access CloudWatch Logs resources (p. 896)
   - Creating an IAM policy to access AWS KMS resources (p. 897)
9. Choose **Next**.
10. In **Role name**, enter a name for your IAM role, for example `RDSLoadFromS3`. You can also add an optional **Description** value.
11. Choose **Create Role**.
12. Complete the steps in **Associating an IAM role with an Amazon Aurora MySQL DB cluster** (p. 899).

**Associating an IAM role with an Amazon Aurora MySQL DB cluster**

To permit database users in an Amazon Aurora DB cluster to access other AWS services, you associate the role that you created in **Creating an IAM role to allow Amazon Aurora to access AWS services** (p. 898) with that DB cluster.

---

**Note**

You can't associate an IAM role with an Aurora Serverless v1 DB cluster. For more information, see **Using Amazon Aurora Serverless v1** (p. 1542).

You can associate an IAM role with an Aurora Serverless v2 DB cluster.

---

To associate an IAM role with a DB cluster you do two things:

- Add the role to the list of associated roles for a DB cluster by using the RDS console, the `add-role-to-db-cluster` AWS CLI command, or the `AddRoleToDBCluster` RDS API operation.

You can add a maximum of five IAM roles for each Aurora DB cluster.

- Set the cluster-level parameter for the related AWS service to the ARN for the associated IAM role.

The following table describes the cluster-level parameter names for the IAM roles used to access other AWS services.

<table>
<thead>
<tr>
<th>Cluster-level parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aws_default_lambda_role</code></td>
<td>Used when invoking a Lambda function from your DB cluster.</td>
</tr>
<tr>
<td><code>aws_default_logs_role</code></td>
<td>This parameter is no longer required for exporting log data from your DB cluster to Amazon CloudWatch Logs. Aurora MySQL now uses a service-linked role for the required permissions. For more information about service-linked roles, see <strong>Using service-linked roles for Amazon Aurora</strong> (p. 1723).</td>
</tr>
<tr>
<td><code>aws_default_s3_role</code></td>
<td>Used when invoking the <code>LOAD DATA FROM S3</code>, <code>LOAD XML FROM S3</code>, or <code>SELECT INTO OUTFILE S3</code> statement from your DB cluster. The IAM role specified in this parameter is used if an IAM role isn't specified</td>
</tr>
</tbody>
</table>
Authorizing Aurora MySQL to access AWS services

<table>
<thead>
<tr>
<th>Cluster-level parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>for aurora_load_from_s3_role or aurora_select_into_s3_role for the appropriate statement. For Aurora MySQL version 3, the IAM role specified for this parameter is always used.</td>
</tr>
<tr>
<td>aurora_load_from_s3_role</td>
<td>Used when invoking the LOAD DATA FROM S3 or LOAD XML FROM S3 statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in aws_default_s3_role is used. For Aurora MySQL version 3, this parameter isn't available.</td>
</tr>
<tr>
<td>aurora_select_into_s3_role</td>
<td>Used when invoking the SELECT INTO OUTFILE S3 statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in aws_default_s3_role is used. For Aurora MySQL version 3, this parameter isn't available.</td>
</tr>
</tbody>
</table>

To associate an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.

**To associate an IAM role with an Aurora DB cluster using the console**

2. Choose **Databases**.
3. Choose the name of the Aurora DB cluster that you want to associate an IAM role with to show its details.
4. On the **Connectivity & security** tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this cluster.
5. Choose **Add role**.
6. (Optional) To stop associating an IAM role with a DB cluster and remove the related permission, choose the role and choose **Delete**.

7. In the RDS console, choose **Parameter groups** in the navigation pane.

8. If you are already using a custom DB parameter group, you can select that group to use instead of creating a new DB cluster parameter group. If you are using the default DB cluster parameter group, create a new DB cluster parameter group, as described in the following steps:

   a. Choose **Create parameter group**.
   b. For **Parameter group family**, choose `aurora-mysql8.0` for an Aurora MySQL 8.0-compatible DB cluster, choose `aurora-mysql5.7` for an Aurora MySQL 5.7-compatible DB cluster, or choose `aurora5.6` for an Aurora MySQL 5.6-compatible DB cluster.
   c. For **Type**, choose **DB Cluster Parameter Group**.
   d. For **Group name**, type the name of your new DB cluster parameter group.
   e. For **Description**, type a description for your new DB cluster parameter group.

   ![Create parameter group](image)

   f. Choose **Create**.

9. On the **Parameter groups** page, select your DB cluster parameter group and choose **Edit for Parameter group actions**.

10. Set the appropriate cluster-level parameters to the related IAM role ARN values. For example, you can set just the `aws_default_s3_role` parameter to `arn:aws:iam::123456789012:role/AllowAuroraS3Role`.

11. Choose **Save changes**.

12. To change the DB cluster parameter group for your DB cluster, complete the following steps:

   a. Choose **Databases**, and then choose your Aurora DB cluster.
   b. Choose **Modify**.
   c. Scroll to **Database options** and set **DB cluster parameter group** to the DB cluster parameter group.
   d. Choose **Continue**.
e. Verify your changes and then choose **Apply immediately**.

f. Choose **Modify cluster**.

g. Choose **Databases**, and then choose the primary instance for your DB cluster.

h. For **Actions**, choose **Reboot**.

When the instance has rebooted, your IAM role is associated with your DB cluster.

For more information about cluster parameter groups, see *Aurora MySQL configuration parameters* (p. 950).

**To associate an IAM role with a DB cluster by using the AWS CLI**

1. Call the `add-role-to-db-cluster` command from the AWS CLI to add the ARNs for your IAM roles to the DB cluster, as shown following.

   ```bash
   PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws:iam::123456789012:role/AllowAuroraS3Role
   PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws:iam::123456789012:role/AllowAuroraLambdaRole
   ```

2. If you are using the default DB cluster parameter group, create a new DB cluster parameter group. If you are already using a custom DB parameter group, you can use that group instead of creating a new DB cluster parameter group.

   To create a new DB cluster parameter group, call the `create-db-cluster-parameter-group` command from the AWS CLI, as shown following.

   ```bash
   PROMPT> aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess
                      --db-parameter-group-family aurora5.6 --description "Allow access to Amazon S3 and AWS Lambda"
   ```

   For an Aurora MySQL 5.7-compatible DB cluster, specify `aurora-mysql5.7` for `--db-parameter-group-family`. For an Aurora MySQL 8.0-compatible DB cluster, specify `aurora-mysql8.0` for `--db-parameter-group-family`.

3. Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group, as shown following.

   ```bash
   PROMPT> aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess
                        --parameters "ParameterName=aws_default_s3_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraS3Role,method=pending-reboot"
                      --parameters "ParameterName=aws_default_lambda_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraLambdaRole,method=pending-reboot"
   ```

4. Modify the DB cluster to use the new DB cluster parameter group and then reboot the cluster, as shown following.

   ```bash
   PROMPT> aws rds modify-db-cluster --db-cluster-identifier my-cluster --db-cluster-parameter-group-name AllowAWSAccess
   PROMPT> aws rds reboot-db-instance --db-instance-identifier my-cluster-primary
   ```

   When the instance has rebooted, your IAM roles are associated with your DB cluster.
Enabling network communication from Amazon Aurora MySQL to other AWS services

To use certain other AWS services with Amazon Aurora, the network configuration of your Aurora DB cluster must allow outbound connections to endpoints for those services. The following operations require this network configuration.

- Invoking AWS Lambda functions. To learn about this feature, see Invoking a Lambda function with an Aurora MySQL native function (p. 919).
- Accessing files from Amazon S3. To learn about this feature, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 904) and Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 912).
- Accessing AWS KMS endpoints. AWS KMS access is required to use database activity streams with Aurora MySQL. To learn about this feature, see Monitoring Amazon Aurora with Database Activity Streams (p. 619).
- Accessing SageMaker endpoints. SageMaker access is required to use SageMaker machine learning with Aurora MySQL. To learn about this feature, see Using machine learning (ML) with Aurora MySQL (p. 928).

Aurora returns the following error messages if it can't connect to a service endpoint.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR 1871 (HY000):</td>
<td>S3 API returned error: Network Connection</td>
</tr>
<tr>
<td>ERROR 1873 (HY000):</td>
<td>Lambda API returned error: Network Connection. Unable to connect to endpoint</td>
</tr>
<tr>
<td>ERROR 1815 (HY000):</td>
<td>Internal error: Unable to initialize S3Stream</td>
</tr>
</tbody>
</table>

For database activity streams using Aurora MySQL, the activity stream stops functioning if the DB cluster can't access the AWS KMS endpoint. Aurora notifies you about this issue using RDS Events.

If you encounter these messages while using the corresponding AWS services, check if your Aurora DB cluster is public or private. If your Aurora DB cluster is private, you must configure it to enable connections.

For an Aurora DB cluster to be public, it must be marked as publicly accessible. If you look at the details for the DB cluster in the AWS Management Console, Publicly Accessible is Yes if this is the case. The DB cluster must also be in an Amazon VPC public subnet. For more information about publicly accessible DB instances, see Working with a DB cluster in a VPC (p. 1728). For more information about public Amazon VPC subnets, see Your VPC and subnets.

If your Aurora DB cluster isn't publicly accessible and in a VPC public subnet, it is private. You might have a DB cluster that is private and want to use one of the features that requires this network configuration. If so, configure the cluster so that it can connect to Internet addresses through Network Address Translation (NAT). As an alternative for Amazon S3, Amazon SageMaker, and AWS Lambda, you can instead configure the VPC to have a VPC endpoint for the other service associated with the DB cluster's route table. For more information about configuring NAT in your VPC, see NAT gateways. For more information about configuring VPC endpoints, see VPC endpoints.
You might also have to open the ephemeral ports for your network access control lists (ACLs) in the outbound rules for your VPC security group. For more information on ephemeral ports for network ACLs, see Ephemeral ports in the Amazon Virtual Private Cloud User Guide.

- Integrating Aurora with other AWS services (p. 304)
- Managing an Amazon Aurora DB cluster (p. 243)

Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket

You can use the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement to load data from files stored in an Amazon S3 bucket.

If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can’t load data from a bucket that is encrypted with a customer managed key.

**Note**
Loading data into a table from text files in an Amazon S3 bucket is available for Amazon Aurora MySQL version 1.8 and later. For more information about Aurora MySQL versions, see Database engine updates for Amazon Aurora MySQL (p. 991).

This feature isn’t supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

Giving Aurora access to Amazon S3

Before you can load data from an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

**To give Aurora MySQL access to Amazon S3**

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see Creating an IAM policy to access Amazon S3 resources (p. 893).
2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access Amazon S3 resources (p. 893) to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898).
3. Make sure the DB cluster is using a custom DB cluster parameter group.

   For more information about creating a custom DB cluster parameter group, see Creating a DB cluster parameter group (p. 219).

4. For Aurora MySQL version 1 or 2, set either the `aurora_load_from_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn’t specified for `aurora_load_from_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

   For Aurora MySQL version 3, use `aws_default_s3_role`.

If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database. Although only the primary cluster in an Aurora global database can load data, another cluster might be promoted by the failover mechanism and become the primary cluster.

For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 217).
5. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898) with the DB cluster. For an Aurora global database, associate the role with each Aurora cluster in the global database. For information about associating an IAM role with a DB cluster, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 899).

6. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 903).

For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

**Granting privileges to load data in Amazon Aurora MySQL**

The database user that issues the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement must have a specific role or privilege to issue either statement. In Aurora MySQL version 3, you grant the `AWS_LOAD_S3_ACCESS` role. In Aurora MySQL version 1 or 2, you grant the `LOAD FROM S3` privilege.

The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```
GRANT AWS_LOAD_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

**Tip**

When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 664). You can also find more details in Using Roles in the MySQL Reference Manual.

This only applies to the current active session. When you reconnect, you have to run the `SET ROLE` statement again to grant privileges. For more information, see SET ROLE statement in the MySQL Reference Manual.

You can also use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don’t have to call the `SET ROLE` statement explicitly to activate a role. For more information, see `activate_all_roles_on_login` in the MySQL Reference Manual.

Use the following statement for Aurora MySQL version 1 or 2:

```
GRANT LOAD FROM S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The `AWS_LOAD_S3_ACCESS` role and `LOAD FROM S3` privilege are specific to Amazon Aurora and are not available for MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora DB cluster as the replication master and a MySQL database as the replication client, then the GRANT statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on a RDS for MySQL DB instance, use the `mysql_rds_skip_repl_error` procedure. To skip the error on an external MySQL database, use the `SET GLOBAL sql_slave_skip_counter` statement (Aurora MySQL version 1 and 2) or `SET GLOBAL sql_replica_skip_counter` statement (Aurora MySQL version 3).

**Specifying a path to an Amazon S3 bucket**

The syntax for specifying a path to files stored on an Amazon S3 bucket is as follows.

```s3-region://bucket-name/file-name-or-prefix```
The path includes the following values:

- **region** (optional) – The AWS Region that contains the Amazon S3 bucket to load from. This value is optional. If you don't specify a region value, then Aurora loads your file from Amazon S3 in the same region as your DB cluster.
- **bucket-name** – The name of the Amazon S3 bucket that contains the data to load. Object prefixes that identify a virtual folder path are supported.
- **file-name-or-prefix** – The name of the Amazon S3 text file or XML file, or a prefix that identifies one or more text or XML files to load. You can also specify a manifest file that identifies one or more text files to load. For more information about using a manifest file to load text files from Amazon S3, see Using a manifest to specify data files to load (p. 907).

**LOAD DATA FROM S3**

You can use the `LOAD DATA FROM S3` statement to load data from any text file format that is supported by the MySQL `LOAD DATA INFILE` statement, such as text data that is comma-delimited. Compressed files are not supported.

**Syntax**

```sql
LOAD DATA FROM S3 [FILE | PREFIX | MANIFEST] '"S3-URI'"
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name, ...)]
[CHARACTER SET charset_name]
[\{FIELDS | COLUMNS\]
\[TERMINATED BY 'string']
\[[OPTIONALLY] ENCLOSED BY 'char']
\[ESCAPED BY 'char']
]\[LINES
\[STARTING BY 'string']
\[TERMINATED BY 'string']
]\[IGNORE number {LINES | ROWS}]
\[(col_name_or_user_var, ...)]
[SET col_name = expr, ...]
```

**Parameters**

Following, you can find a list of the required and optional parameters used by the `LOAD DATA FROM S3` statement. You can find more details about some of these parameters in `LOAD DATA INFILE syntax` in the MySQL documentation.

- **FILE | PREFIX | MANIFEST** – Identifies whether to load the data from a single file, from all files that match a given prefix, or from all files in a specified manifest. `FILE` is the default.
- **S3-URI** – Specifies the URI for a text or manifest file to load, or an Amazon S3 prefix to use. Specify the URI using the syntax described in Specifying a path to an Amazon S3 bucket (p. 905).
- **REPLACE | IGNORE** – Determines what action to take if an input row as the same unique key values as an existing row in the database table.
  - Specify REPLACE if you want the input row to replace the existing row in the table.
  - Specify IGNORE if you want to discard the input row.
- **INTO TABLE** – Identifies the name of the database table to load the input rows into.
- **PARTITION** – Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.
• **CHARACTER SET** – Identifies the character set of the data in the input file.

• **FIELDS | COLUMNS** – Identifies how the fields or columns in the input file are delimited. Fields are tab-delimited by default.

• **LINES** – Identifies how the lines in the input file are delimited. Lines are delimited by a newline character (\n) by default.

• **IGNORE number LINES | ROWS** – Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use IGNORE 1 LINES to skip over an initial header line containing column names, or IGNORE 2 ROWS to skip over the first two rows of data in the input file. If you also use PREFIX, IGNORE skips a certain number of lines or rows at the start of the first input file.

• **col_name_or_user_var, ...** – Specifies a comma-separated list of one or more column names or user variables that identify which columns to load by name. The name of a user variable used for this purpose must match the name of an element from the text file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of table1, and sets the value of the table_column2 column in table1 to the input value of the second column divided by 100.

```
LOAD DATA FROM S3 's3://mybucket/data.txt'
    INTO TABLE table1
    (column1, @var1)
    SET table_column2 = @var1/100;
```

• **SET** – Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of table1 to the values in the first two columns from the input file, and then sets the value of the column3 in table1 to the current time stamp.

```
LOAD DATA FROM S3 's3://mybucket/data.txt'
    INTO TABLE table1
    (column1, column2)
    SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of SET assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you cannot use a subquery to select from the table that is being loaded.

You cannot use the LOCAL keyword of the LOAD DATA FROM S3 statement if you are loading data from an Amazon S3 bucket.

**Using a manifest to specify data files to load**

You can use the LOAD DATA FROM S3 statement with the MANIFEST keyword to specify a manifest file in JSON format that lists the text files to be loaded into a table in your DB cluster. You must be using Aurora 1.11 or greater to use the MANIFEST keyword with the LOAD DATA FROM S3 statement.

The following JSON schema describes the format and content of a manifest file.

```json
{
    "$schema": "http://json-schema.org/draft-04/schema#",
    "additionalProperties": false,
    "definitions": {},
    "id": "Aurora_LoadFromS3_Manifest",
    "properties": {
        "entries": {
            ...
        }
    }
}
```
Each `url` in the manifest must specify a URL with the bucket name and full object path for the file, not just a prefix. You can use a manifest to load files from different buckets, different regions, or files that do not share the same prefix. If a region is not specified in the URL, the region of the target Aurora DB cluster is used. The following example shows a manifest file that loads four files from different buckets.

```json
{
  "entries": [
    {
      "url": "s3://aurora-bucket/2013-10-04-customerdata",
      "mandatory": true
    },
    {
      "url": "s3-us-west-2://aurora-bucket-usw2/2013-10-05-customerdata",
      "mandatory": true
    },
    {
      "url": "s3://aurora-bucket/2013-10-04-customerdata",
      "mandatory": false
    },
    {
      "url": "s3://aurora-bucket/2013-10-05-customerdata"
    }
  ]
}
```

The optional `mandatory` flag specifies whether `LOAD DATA FROM S3` should return an error if the file is not found. The mandatory flag defaults to `false`. Regardless of how `mandatory` is set, `LOAD DATA FROM S3` terminates if no files are found.
Manifest files can have any extension. The following example runs the `LOAD DATA FROM S3` statement with the manifest in the previous example, which is named `customer.manifest`.

```sql
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/customer.manifest'
INTO TABLE CUSTOMER
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
(ID, FIRSTNAME, LASTNAME, EMAIL);
```

After the statement completes, an entry for each successfully loaded file is written to the `aurora_s3_load_history` table.

**Verifying loaded files using the `aurora_s3_load_history` table**

Every successful `LOAD DATA FROM S3` statement updates the `aurora_s3_load_history` table in the `mysql` schema with an entry for each file that was loaded.

After you run the `LOAD DATA FROM S3` statement, you can verify which files were loaded by querying the `aurora_s3_load_history` table. To see the files that were loaded from one iteration of the statement, use the `WHERE` clause to filter the records on the Amazon S3 URI for the manifest file used in the statement. If you have used the same manifest file before, filter the results using the `timestamp` field.

```sql
select * from mysql.aurora_s3_load_history where load_prefix = 'S3_URI';
```

The following table describes the fields in the `aurora_s3_load_history` table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>load_prefix</td>
<td>The URI that was specified in the load statement. This URI can map to any of the following:</td>
</tr>
<tr>
<td></td>
<td>• A single data file for a <code>LOAD DATA FROM S3 FILE</code> statement</td>
</tr>
<tr>
<td></td>
<td>• An Amazon S3 prefix that maps to multiple data files for a <code>LOAD DATA FROM S3 PREFIX</code> statement</td>
</tr>
<tr>
<td></td>
<td>• A single manifest file that contains the names of files to be loaded for a <code>LOAD DATA FROM S3 MANIFEST</code> statement</td>
</tr>
<tr>
<td>file_name</td>
<td>The name of a file that was loaded into Aurora from Amazon S3 using the URI identified in the <code>load_prefix</code> field.</td>
</tr>
<tr>
<td>version_number</td>
<td>The version number of the file identified by the <code>file_name</code> field that was loaded, if the Amazon S3 bucket has a version number.</td>
</tr>
<tr>
<td>bytes_loaded</td>
<td>The size of the file loaded, in bytes.</td>
</tr>
<tr>
<td>load_timestamp</td>
<td>The timestamp when the <code>LOAD DATA FROM S3</code> statement completed.</td>
</tr>
</tbody>
</table>

**Examples**

The following statement loads data from an Amazon S3 bucket that is in the same region as the Aurora DB cluster. The statement reads the comma-delimited data in the file `customerdata.txt` that is in the `dbbucket` Amazon S3 bucket, and then loads the data into the table `store-schema.customer-table`. 

909
LOAD DATA FROM S3 's3://dbbucket/customerdata.csv' INTO TABLE store-schema.customer-table FIELDS TERMINATED BY ',' LINES TERMINATED BY '
' (ID, FIRSTNAME, LASTNAME, ADDRESS, EMAIL, PHONE);

The following statement loads data from an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement reads the comma-delimited data from all files that match the employee-data object prefix in the my-data Amazon S3 bucket in the us-west-2 region, and then loads the data into the employees table.

LOAD DATA FROM S3 PREFIX 's3-us-west-2://my-data/employee_data' INTO TABLE employees FIELDS TERMINATED BY ',' LINES TERMINATED BY '
' (ID, FIRSTNAME, LASTNAME, EMAIL, SALARY);

The following statement loads data from the files specified in a JSON manifest file named q1_sales.json into the sales table.

LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/q1_sales.json' INTO TABLE sales FIELDS TERMINATED BY ',' LINES TERMINATED BY '
' (MONTH, STORE, GROSS, NET);

LOAD XML FROM S3

You can use the LOAD XML FROM S3 statement to load data from XML files stored on an Amazon S3 bucket in one of three different XML formats:

- Column names as attributes of a <row> element. The attribute value identifies the contents of the table field.

  <row column1="value1" column2="value2" .../>

- Column names as child elements of a <row> element. The value of the child element identifies the contents of the table field.

  <row>
    <column1>value1</column1>
    <column2>value2</column2>
  </row>

- Column names in the name attribute of <field> elements in a <row> element. The value of the <field> element identifies the contents of the table field.

  <row>
    <field name='column1'>value1</field>
    <field name='column2'>value2</field>
  </row>

Syntax

LOAD XML FROM S3 'S3-URI'
Parameters
Following, you can find a list of the required and optional parameters used by the \texttt{LOAD DATA FROM S3} statement. You can find more details about some of these parameters in \texttt{LOAD XML syntax} in the MySQL documentation.

- \texttt{FILE | PREFIX} – Identifies whether to load the data from a single file, or from all files that match a given prefix. \texttt{FILE} is the default.
- \texttt{REPLACE | IGNORE} – Determines what action to take if an input row as the same unique key values as an existing row in the database table.
  - Specify \texttt{REPLACE} if you want the input row to replace the existing row in the table.
  - Specify \texttt{IGNORE} if you want to discard the input row. \texttt{IGNORE} is the default.
- \texttt{INTO TABLE} – Identifies the name of the database table to load the input rows into.
- \texttt{PARTITION} – Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.
- \texttt{CHARACTER SET} – Identifies the character set of the data in the input file.
- \texttt{ROWS IDENTIFIED BY} – Identifies the element name that identifies a row in the input file. The default is \texttt{<row>}.
- \texttt{IGNORE number LINES | ROWS} – Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use \texttt{IGNORE 1 LINES} to skip over the first line in the text file, or \texttt{IGNORE 2 ROWS} to skip over the first two rows of data in the input XML.
- \texttt{field_name_or_user_var, …} – Specifies a comma-separated list of one or more XML element names or user variables that identify which elements to load by name. The name of a user variable used for this purpose must match the name of an element from the XML file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of \texttt{table1}, and sets the value of the \texttt{table_column2} column in \texttt{table1} to the input value of the second column divided by 100.

```sql
LOAD XML FROM S3 's3://mybucket/data.xml'
INTO TABLE table1
(column1, @var1)
SET table_column2 = @var1/100;
```

- \texttt{SET} – Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of \texttt{table1} to the values in the first two columns from the input file, and then sets the value of the \texttt{column3} in \texttt{table1} to the current time stamp.

```sql
LOAD XML FROM S3 's3://mybucket/data.xml'
INTO TABLE table1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```
You can use subqueries in the right side of \texttt{SET} assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you cannot use a subquery to select from the table that is being loaded.

**Related topics**

- Integrating Amazon Aurora MySQL with other AWS services (p. 891)
- Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 912)
- Managing an Amazon Aurora DB cluster (p. 243)
- Migrating data to an Amazon Aurora DB cluster (p. 242)

**Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket**

You can use the \texttt{SELECT INTO OUTFILE S3} statement to query data from an Amazon Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. You can use this functionality to skip bringing the data down to the client first, and then copying it from the client to Amazon S3. The \texttt{LOAD DATA FROM S3} statement can use the files created by this statement to load data into an Aurora DB cluster. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 904).

If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can't save data to a bucket that is encrypted with a customer managed key.

This feature currently isn't available for Aurora Serverless clusters.

**Note**

You can save DB cluster snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB cluster snapshot data to Amazon S3 (p. 396).

**Giving Aurora MySQL access to Amazon S3**

Before you can save data into an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

**To give Aurora MySQL access to Amazon S3**

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see Creating an IAM policy to access Amazon S3 resources (p. 893).

2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access Amazon S3 resources (p. 893) to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898).

3. For Aurora MySQL version 1 or 2, set either the \texttt{aurora_select_into_s3_role} or \texttt{aws_default_s3_role} DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for \texttt{aurora_select_into_s3_role}, Aurora uses the IAM role specified in \texttt{aws_default_s3_role}.

   For Aurora MySQL version 3, use \texttt{aws_default_s3_role}. 

---

912
If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database.

For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 217).

4. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898) with the DB cluster.

For an Aurora global database, associate the role with each Aurora cluster in the global database.

For information about associating an IAM role with a DB cluster, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 899).

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 903).

For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

**Granting privileges to save data in Aurora MySQL**

The database user that issues the `SELECT INTO OUTFILE S3` statement must have a specific role or privilege. In Aurora MySQL version 3, you grant the `AWS_SELECT_S3_ACCESS` role. In Aurora MySQL version 1 or 2, you grant the `SELECT INTO S3` privilege. The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```sql
GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

**Tip**

When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 664). You can also find more details in Using Roles in the MySQL Reference Manual.

This only applies to the current active session. When you reconnect, you have to run the `SET ROLE` statement again to grant privileges. For more information, see `SET ROLE` statement in the MySQL Reference Manual.

You can also use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see `activate_all_roles_on_login` in the MySQL Reference Manual.

Use the following statement for Aurora MySQL version 1 or 2:

```sql
GRANT SELECT INTO S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The `AWS_SELECT_S3_ACCESS` role and `SELECT INTO S3` privilege are specific to Amazon Aurora MySQL and are not available for MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora MySQL DB cluster as the replication master and a MySQL database as the replication client, then the `GRANT` statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL DB
instance, use the `mysql_rds_skip_repl_error` procedure. To skip the error on an external MySQL database, use the `SET GLOBAL sql_slave_skip_counter` statement (Aurora MySQL version 1 and 2) or `SET GLOBAL sql_replica_skip_counter` statement (Aurora MySQL version 3).

### Specifying a path to an Amazon S3 bucket

The syntax for specifying a path to store the data and manifest files on an Amazon S3 bucket is similar to that used in the `LOAD DATA FROM S3` statement, as shown following.

```sql
s3-region://bucket-name/file-prefix
```

The path includes the following values:

- **region** (optional) – The AWS Region that contains the Amazon S3 bucket to save the data into. This value is optional. If you don't specify a `region` value, then Aurora saves your files into Amazon S3 in the same region as your DB cluster.
- **bucket-name** – The name of the Amazon S3 bucket to save the data into. Object prefixes that identify a virtual folder path are supported.
- **file-prefix** – The Amazon S3 object prefix that identifies the files to be saved in Amazon S3.

The data files created by the `SELECT INTO OUTFILE S3` statement use the following path, in which `00000` represents a 5-digit, zero-based integer number.

```sql
s3-region://bucket-name/file-prefix.part_00000
```

For example, suppose that a `SELECT INTO OUTFILE S3` statement specifies `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files. The specified Amazon S3 bucket contains the following data files.

- `s3-us-west-2://bucket/prefix.part_00000`
- `s3-us-west-2://bucket/prefix.part_00001`
- `s3-us-west-2://bucket/prefix.part_00002`

### Creating a manifest to list data files

You can use the `SELECT INTO OUTFILE S3` statement with the `MANIFEST ON` option to create a manifest file in JSON format that lists the text files created by the statement. The `LOAD DATA FROM S3` statement can use the manifest file to load the data files back into an Aurora MySQL DB cluster. For more information about using a manifest to load data files from Amazon S3 into an Aurora MySQL DB cluster, see Using a manifest to specify data files to load (p. 907).

The data files included in the manifest created by the `SELECT INTO OUTFILE S3` statement are listed in the order that they're created by the statement. For example, suppose that a `SELECT INTO OUTFILE S3` statement specified `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files and a manifest file. The specified Amazon S3 bucket contains a manifest file named `s3-us-west-2://bucket/prefix.manifest`, that contains the following information.

```json
{
  "entries": [ 
    { "url":"s3-us-west-2://bucket/prefix.part_00000" },
    { 
```

914
SELECT INTO OUTFILE S3

You can use the `SELECT INTO OUTFILE S3` statement to query data from a DB cluster and save it directly into delimited text files stored in an Amazon S3 bucket. Compressed files are not supported. Encrypted files are supported starting in Aurora MySQL 2.09.0.

**Syntax**

```sql
SELECT
  [ALL | DISTINCT | DISTINCTROW]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [ , select_expr ...]
FROM table_references
[PARTITION partition_list]
WHERE where_condition
[GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
[HAVING where_condition]
[ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
[LIMIT { [row_count | row_count OFFSET offset] ]]
INTO OUTFILE S3 's3_uri'
[CHARACTER SET charset_name]
[export_options]
[MANIFEST {ON | OFF}]
[OVERWRITE {ON | OFF}]

export_options:
  [FORMAT {CSV|TEXT} [HEADER]]
  [(FIELDS | COLUMNS]
    [TERMINATED BY 'string']
    [[OPTIONALLY] ENCLOSED BY 'char']
    [ESCAPED BY 'char']
  )
  [LINES
    [STARTING BY 'string']
    [TERMINATED BY 'string']
  ]
```

**Parameters**

Following, you can find a list of the required and optional parameters used by the `SELECT INTO OUTFILE S3` statement that are specific to Aurora.

- **s3-uri** – Specifies the URI for an Amazon S3 prefix to use. Specify the URI using the syntax described in Specifying a path to an Amazon S3 bucket (p. 914).
- **FORMAT (CSV|TEXT) [HEADER]** – Optionally saves the data in CSV format. This syntax is available in Aurora MySQL version 2.07.0 and later.
  
  The TEXT option is the default and produces the existing MySQL export format.
The CSV option produces comma-separated data values. The CSV format follows the specification in RFC-4180. If you specify the optional keyword HEADER, the output file contains one header line. The labels in the header line correspond to the column names from the SELECT statement. You can use the CSV files for training data models for use with AWS ML services. For more information about using exported Aurora data with AWS ML services, see Exporting data to Amazon S3 for SageMaker model training (p. 934).

- **MANIFEST (ON | OFF)** – Indicates whether a manifest file is created in Amazon S3. The manifest file is a JavaScript Object Notation (JSON) file that can be used to load data into an Aurora DB cluster with the `LOAD DATA FROM S3 MANIFEST` statement. For more information about `LOAD DATA FROM S3 MANIFEST`, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 904).

  If `MANIFEST ON` is specified in the query, the manifest file is created in Amazon S3 after all data files have been created and uploaded. The manifest file is created using the following path:

  ```
  s3-region://bucket-name/file-prefix.manifest
  ```

  For more information about the format of the manifest file's contents, see Creating a manifest to list data files (p. 914).

- **OVERWRITE (ON | OFF)** – Indicates whether existing files in the specified Amazon S3 bucket are overwritten. If `OVERWRITE ON` is specified, existing files that match the file prefix in the URI specified in `s3-uri` are overwritten. Otherwise, an error occurs.

  You can find more details about other parameters in SELECT syntax and LOAD DATA INFILE syntax, in the MySQL documentation.

### Considerations

The number of files written to the Amazon S3 bucket depends on the amount of data selected by the `SELECT INTO OUTFILE S3` statement and the file size threshold for Aurora MySQL. The default file size threshold is 6 gigabytes (GB). If the data selected by the statement is less than the file size threshold, a single file is created; otherwise, multiple files are created. Other considerations for files created by this statement include the following:

- Aurora MySQL guarantees that rows in data files are not split across file boundaries. For multiple files, the size of every data file except the last is typically close to the file size threshold. However, occasionally staying under the file size threshold results in a row being split across two data files. In this case, Aurora MySQL creates a data file that keeps the row intact, but might be larger than the file size threshold.

- Because each `SELECT` statement in Aurora MySQL runs as an atomic transaction, a `SELECT INTO OUTFILE S3` statement that selects a large data set might run for some time. If the statement fails for any reason, you might need to start over and issue the statement again. If the statement fails, however, files already uploaded to Amazon S3 remain in the specified Amazon S3 bucket. You can use another statement to upload the remaining data instead of starting over again.

- If the amount of data to be selected is large (more than 25 GB), we recommend that you use multiple `SELECT INTO OUTFILE S3` statements to save the data to Amazon S3. Each statement should select a different portion of the data to be saved, and also specify a different `file_prefix` in the `s3-uri` parameter to use when saving the data files. Partitioning the data to be selected with multiple statements makes it easier to recover from an error in one statement. If an error occurs for one statement, only a portion of data needs to be re-selected and uploaded to Amazon S3. Using multiple statements also helps to avoid a single long-running transaction, which can improve performance.

- If multiple `SELECT INTO OUTFILE S3` statements that use the same `file_prefix` in the `s3-uri` parameter run in parallel to select data into Amazon S3, the behavior is undefined.

- Metadata, such as table schema or file metadata, is not uploaded by Aurora MySQL to Amazon S3.
• In some cases, you might re-run a `SELECT INTO OUTFILE S3` query, such as to recover from a failure. In these cases, you must either remove any existing data files in the Amazon S3 bucket with the same file prefix specified in `s3-uri`, or include `OVERWRITE ON` in the `SELECT INTO OUTFILE S3` query.

The `SELECT INTO OUTFILE S3` statement returns a typical MySQL error number and response on success or failure. If you don't have access to the MySQL error number and response, the easiest way to determine when it's done is by specifying `MANIFEST ON` in the statement. The manifest file is the last file written by the statement. In other words, if you have a manifest file, the statement has completed.

Currently, there's no way to directly monitor the progress of the `SELECT INTO OUTFILE S3` statement while it runs. However, suppose that you're writing a large amount of data from Aurora MySQL to Amazon S3 using this statement, and you know the size of the data selected by the statement. In this case, you can estimate progress by monitoring the creation of data files in Amazon S3.

To do so, you can use the fact that a data file is created in the specified Amazon S3 bucket for about every 6 GB of data selected by the statement. Divide the size of the data selected by 6 GB to get the estimated number of data files to create. You can then estimate the progress of the statement by monitoring the number of files uploaded to Amazon S3 while the statement runs.

**Examples**

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (`,`) character and each row is terminated by a newline (`\n`) character. The statement returns an error if files that match the `sample_employee_data` file prefix exist in the specified Amazon S3 bucket.

```sql
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/sample_employee_data'
    FIELDS TERMINATED BY ', '
    LINES TERMINATED BY '\n';
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (`,`) character and each row is terminated by a newline (`\n`) character, and also a manifest file. The statement returns an error if files that match the `sample_employee_data` file prefix exist in the specified Amazon S3 bucket.

```sql
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/sample_employee_data'
    FIELDS TERMINATED BY ', '
    LINES TERMINATED BY '\n'
    MANIFEST ON;
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement creates data files in which each field is terminated by a comma (`,`) character and each row is terminated by a newline (`\n`) character. The statement overwrites any existing files that match the `sample_employee_data` file prefix in the specified Amazon S3 bucket.

```sql
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/sample_employee_data'
    FIELDS TERMINATED BY ', '
    LINES TERMINATED BY '\n'
    OVERWRITE ON;
```
The following statement selects all of the data in the employees table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character, and also a manifest file. The statement overwrites any existing files that match the sample_employee_data file prefix in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/sample_employee_data'
    FIELDS TERMINATED BY ','
    LINES TERMINATED BY '\n'
    MANIFEST ON
    OVERWRITE ON;
```

Invoking a Lambda function from an Amazon Aurora MySQL DB cluster

You can invoke an AWS Lambda function from an Amazon Aurora MySQL-Compatible Edition DB cluster with the native function `lambda_sync` or `lambda_async`. Before invoking a Lambda function from an Aurora MySQL, the Aurora DB cluster must have access to Lambda. For details about granting access to Aurora MySQL, see Giving Aurora access to Lambda (p. 918). For information about the `lambda_sync` and `lambda_async` stored functions, see Invoking a Lambda function with an Aurora MySQL native function (p. 919).

You can also call an AWS Lambda function by using a stored procedure. However, using a stored procedure is deprecated. We strongly recommend using an Aurora MySQL native function if you are using one of the following Aurora MySQL versions:

- Aurora MySQL version 1.16 and later, for MySQL 5.6-compatible clusters.
- Aurora MySQL version 2.06 and later, for MySQL 5.7-compatible clusters.
- Aurora MySQL version 3.01 and higher, for MySQL 8.0-compatible clusters. The stored procedure is not available in Aurora MySQL version 3.

Topics

- Giving Aurora access to Lambda (p. 918)
- Invoking a Lambda function with an Aurora MySQL native function (p. 919)
- Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated) (p. 922)

Giving Aurora access to Lambda

Before you can invoke Lambda functions from an Aurora MySQL DB cluster, make sure to first give your cluster permission to access Lambda.
To give Aurora MySQL access to Lambda

1. Create an AWS Identity and Access Management (IAM) policy that provides the permissions that allow your Aurora MySQL DB cluster to invoke Lambda functions. For instructions, see Creating an IAM policy to access AWS Lambda resources (p. 895).

2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access AWS Lambda resources (p. 895) to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898).

3. Set the `aws_default_lambda_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role.

   If the cluster is part of an Aurora global database, apply the same setting for each Aurora cluster in the global database.

   For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 217).

4. To permit database users in an Aurora MySQL DB cluster to invoke Lambda functions, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 898) with the DB cluster. For information about associating an IAM role with a DB cluster, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 899).

   If the cluster is part of an Aurora global database, associate the role with each Aurora cluster in the global database.

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Lambda. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 903).

   If the cluster is part of an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

Invoking a Lambda function with an Aurora MySQL native function

Note
You can call the native functions `lambda_sync` and `lambda_async` when you use Aurora MySQL version 1.16 and later, Aurora MySQL 2.06 and later, or Aurora MySQL version 3.01 and higher. For more information about Aurora MySQL versions, see Database engine updates for Amazon Aurora MySQL (p. 991).

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the native functions `lambda_sync` and `lambda_async`. This approach can be useful when you want to integrate your database running on Aurora MySQL with other AWS services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

Working with native functions to invoke a Lambda function

The `lambda_sync` and `lambda_async` functions are built-in, native functions that invoke a Lambda function synchronously or asynchronously. When you must know the result of the Lambda function before moving on to another action, use the synchronous function `lambda_sync`. When you don’t need to know the result of the Lambda function before moving on to another action, use the asynchronous function `lambda_async`.

In Aurora MySQL version 3, the user invoking a native function must be granted the `AWS_LAMBDA_ACCESS` role. To grant this role to a user, connect to the DB instance as the administrative user, and run the following statement.
You can revoke this role by running the following statement.

```
REVOKE AWS_LAMBDA_ACCESS FROM user@domain-or-ip-address
```

**Tip**
When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 664). You can also find more details in Using Roles in the MySQL Reference Manual.

This only applies to the current active session. When you reconnect, you have to run the `SET ROLE` statement again to grant privileges. For more information, see SET ROLE statement in the MySQL Reference Manual.

You can also use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see `activate_all_roles_on_login` in the MySQL Reference Manual.

In Aurora MySQL version 1 and 2, the user invoking a native function must be granted the **INVOKE LAMBDA** privilege. To grant this privilege to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT INVOKE LAMBDA ON *.* TO user@domain-or-ip-address
```

You can revoke this privilege by running the following statement.

```
REVOKE INVOKE LAMBDA ON *.* FROM user@domain-or-ip-address
```

### Syntax for the `lambda_sync` function

You invoke the `lambda_sync` function synchronously with the RequestResponse invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```
lambda_sync ( 
    lambda_function_ARN,
    JSON_payload
)
```

**Note**
You can use triggers to call Lambda on data-modifying statements. Remember that triggers are not run once per SQL statement, but once per row modified, one row at a time. When a trigger runs, the process is synchronous. The data-modifying statement only returns when the trigger completes.

Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. INSERT, UPDATE, and DELETE triggers are activated per row. A write-heavy workload on a table with INSERT, UPDATE, or DELETE triggers results in a large number of calls to your AWS Lambda function.

### Parameters for the `lambda_sync` function

The `lambda_sync` function has the following parameters.
**lambda_function_ARN**

The Amazon Resource Name (ARN) of the Lambda function to invoke.

**JSON_payload**

The payload for the invoked Lambda function, in JSON format.

**Note**

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL versions 1 and 2 don't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

**Example for the lambda_sync function**

The following query based on `lambda_sync` invokes the Lambda function `BasicTestLambda` synchronously using the function ARN. The payload for the function is `{"operation": "ping"}`.

```sql
SELECT lambda_sync(  
    'arn:aws:lambda:us-east-1:868710585169:function:BasicTestLambda',  
    '{"operation": "ping"}');
```

**Syntax for the lambda_async function**

You invoke the `lambda_async` function asynchronously with the Event invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```sql
lambda_async (  
    lambda_function_ARN,  
    JSON_payload
)
```

**Parameters for the lambda_async function**

The `lambda_async` function has the following parameters.

**lambda_function_ARN**

The Amazon Resource Name (ARN) of the Lambda function to invoke.

**JSON_payload**

The payload for the invoked Lambda function, in JSON format.

**Note**

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL versions 1 and 2 don't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

**Example for the lambda_async function**

The following query based on `lambda_async` invokes the Lambda function `BasicTestLambda` asynchronously using the function ARN. The payload for the function is `{"operation": "ping"}`.

```sql
SELECT lambda_async(  
    'arn:aws:lambda:us-east-1:868710585169:function:BasicTestLambda',
```
Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated)

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the `mysql.lambda_async` procedure. This approach can be useful when you want to integrate your database running on Aurora MySQL with other AWS services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

Aurora MySQL version considerations

Starting in Aurora MySQL version 1.8 and Aurora MySQL version 2.06, you can use the native function method instead of these stored procedures to invoke a Lambda function. For more information about the native functions, see Working with native functions to invoke a Lambda function (p. 919).

Starting with Amazon Aurora version 1.16 and 2.06, the stored procedure `mysql.lambda_async` is no longer supported. If you are using an Aurora version that's higher than 1.16 or 2.06, we strongly recommend that you work with native Lambda functions instead. In Aurora MySQL version 3, the stored procedure isn't available.

Working with the `mysql.lambda_async` procedure to invoke a Lambda function (deprecated)

The `mysql.lambda_async` procedure is a built-in stored procedure that invokes a Lambda function asynchronously. To use this procedure, your database user must have `EXECUTE` privilege on the `mysql.lambda_async` stored procedure.

Syntax

The `mysql.lambda_async` procedure has the following syntax.

```
CALL mysql.lambda_async (  
    lambda_function_ARN,  
    lambda_function_input  
)
```

Parameters

The `mysql.lambda_async` procedure has the following parameters.

`lambda_function_ARN`  
The Amazon Resource Name (ARN) of the Lambda function to invoke.

`lambda_function_input`  
The input string, in JSON format, for the invoked Lambda function.

Examples

As a best practice, we recommend that you wrap calls to the `mysql.lambda.async` procedure in a stored procedure that can be called from different sources such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier to invoke Lambda functions.
Note
Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. INSERT, UPDATE, and DELETE triggers are activated per row. A write-heavy workload on a table with INSERT, UPDATE, or DELETE triggers results in a large number of calls to your AWS Lambda function.

Although calls to the mysql.lambda_async procedure are asynchronous, triggers are synchronous. A statement that results in a large number of trigger activations doesn’t wait for the call to the AWS Lambda function to complete, but it does wait for the triggers to complete before returning control to the client.

Example: Invoke an AWS Lambda function to send email

The following example creates a stored procedure that you can call in your database code to send an email using a Lambda function.

AWS Lambda Function

```python
import boto3
ses = boto3.client('ses')
def SES_send_email(event, context):
    return ses.send_email(
        Source=event['email_from'],
        Destination={
            'ToAddresses': [
                event['email_to'],
            ],
        },
        Message={
            'Subject': {
                'Data': event['email_subject']
            },
            'Body': {
                'Text': {
                    'Data': event['email_body']
                }
            }
        }
    )
```

Stored Procedure

```sql
DROP PROCEDURE IF EXISTS SES_send_email;
DELIMITER ;
CREATE PROCEDURE SES_send_email(IN email_from VARCHAR(255),
                            IN email_to VARCHAR(255),
                            IN subject VARCHAR(255),
                            IN body TEXT) LANGUAGE SQL
BEGIN
CALL mysql.lambda_async(
    CONCAT('"email_to": "', email_to,
    '" , "email_from": "', email_from,
    '" , "email_subject": "', subject,
    '" , "email_body": "', body, '"')
);
END
;`
```
Amazon Aurora User Guide for Aurora
Invoking a Lambda function from Aurora MySQL
DELIMITER ;

Call the Stored Procedure to Invoke the AWS Lambda Function
mysql> call SES_send_email('example_from@amazon.com', 'example_to@amazon.com', 'Email
subject', 'Email content');

Example Example: Invoke an AWS Lambda function to publish an event from a trigger
The following example creates a stored procedure that publishes an event by using Amazon SNS. The
code calls the procedure from a trigger when a row is added to a table.
AWS Lambda Function
import boto3
sns = boto3.client('sns')
def SNS_publish_message(event, context):
return sns.publish(
Message=event['message'],
Subject=event['subject'],
MessageStructure='string'
)

Stored Procedure
DROP PROCEDURE IF EXISTS SNS_Publish_Message;
DELIMITER ;;
CREATE PROCEDURE SNS_Publish_Message (IN subject VARCHAR(255),
IN message TEXT) LANGUAGE SQL
BEGIN
CONCAT('{ "subject" : "', subject,
'", "message" : "', message, '" }')
);
END
;;
DELIMITER ;

Table
CREATE TABLE 'Customer_Feedback' (
'id' int(11) NOT NULL AUTO_INCREMENT,
'customer_name' varchar(255) NOT NULL,
'customer_feedback' varchar(1024) NOT NULL,
PRIMARY KEY ('id')
) ENGINE=InnoDB DEFAULT CHARSET=utf8;

Trigger
DELIMITER ;;
CREATE TRIGGER TR_Customer_Feedback_AI
AFTER INSERT ON Customer_Feedback
FOR EACH ROW

Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs

You can configure your Aurora MySQL DB cluster to publish general, slow, audit, and error log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

To publish logs to CloudWatch Logs, the respective logs must be enabled. Error logs are enabled by default, but you must enable the other types of logs explicitly. For information about enabling logs in MySQL, see Selecting general query and slow query log output destinations in the MySQL documentation. For more information about enabling Aurora MySQL audit logs, see Enabling Advanced Auditing (p. 824).

Note

Be aware of the following:

- You can't publish logs to CloudWatch Logs for the China (Ningxia) region.
- If exporting log data is disabled, Aurora doesn't delete existing log groups or log streams. If exporting log data is disabled, existing log data remains available in CloudWatch Logs, depending on log retention, and you still incur charges for stored audit log data. You can delete log streams and log groups using the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API.
- An alternative way to publish audit logs to CloudWatch Logs is by enabling advanced auditing and setting the cluster-level DB parameter `server_audit_logs_upload` to 1. The default for the `server_audit_logs_upload` parameter is 0. If you use this alternative method, you must have an IAM role to access CloudWatch Logs and set the `aws_default_logs_role` cluster-level parameter to the ARN for this role. For information about creating the role, see Setting up IAM roles to access AWS services (p. 893). However, if you have the `AWSServiceRoleForRDSServiceLinkedRole` role, it provides access to CloudWatch Logs and overrides any custom-defined roles. For information about creating the role, see Using service-linked roles for Amazon Aurora (p. 1723).
- If you don't want to export audit logs to CloudWatch Logs, make sure that all methods of exporting audit logs are disabled. These methods are the AWS Management Console, the AWS CLI, the RDS API, and the `server_audit_logs_upload` parameter.
- The procedure is slightly different for Aurora Serverless v1 clusters than for clusters with provisioned or Aurora Serverless v2 instances. Aurora Serverless v1 clusters automatically upload all the kinds of logs that you enable through the configuration parameters. Therefore, you turn on or turn off log upload for Serverless clusters by turning different log types on and off in the DB cluster parameter group. You don't modify the settings of the cluster itself.
through the AWS Management Console, AWS CLI, or RDS API. For information about turning on and off MySQL logs for Aurora Serverless v1 clusters, see Parameter groups for Aurora Serverless v1 (p. 1553).

Console

You can publish Aurora MySQL logs for provisioned clusters to CloudWatch Logs with the console.

To publish Aurora MySQL logs from the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora MySQL DB cluster that you want to publish the log data for.
4. Choose Modify.
5. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
6. Choose Continue, and then choose Modify DB Cluster on the summary page.

AWS CLI

You can publish Aurora MySQL logs for provisioned clusters with the AWS CLI. To do so, you run the modify-db-cluster AWS CLI command with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--cloudwatch-logs-export-configuration`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs by running one of the following AWS CLI commands:

- `create-db-cluster`
- `restore-db-cluster-from-s3`
- `restore-db-cluster-from-snapshot`
- `restore-db-cluster-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--engine`—The database engine.
- `--enable-cloudwatch-logs-exports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the AWS CLI command that you run.

Example

The following command modifies an existing Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
```
Publishing Aurora MySQL logs to CloudWatch Logs

--db-cluster-identifier mydbcluster \
--cloudwatch-logs-export-configuration '{"EnableLogTypes": ["error","general","slowquery","audit"]}"

For Windows:

```bash
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["error","general","slowquery","audit"]}"
```

**Example**

The following command creates an Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

**For Linux, macOS, or Unix:**

```bash
aws rds create-db-cluster \
    --db-cluster-identifier mydbcluster \
    --engine aurora \
    --enable-cloudwatch-logs-exports '["error","general","slowquery","audit"]'
```

**For Windows:**

```bash
aws rds create-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --engine aurora ^
    --enable-cloudwatch-logs-exports '["error","general","slowquery","audit"]'
```

**RDS API**

You can publish Aurora MySQL logs for provisioned clusters with the RDS API. To do so, you run the `ModifyDBCluster` operation with the following options:

- **DBClusterIdentifier**—The DB cluster identifier.
- **CloudwatchLogsExportConfiguration**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs with the RDS API by running one of the following RDS API operations:

- **CreateDBCluster**
- **RestoreDBClusterFromS3**
- **RestoreDBClusterFromSnapshot**
- **RestoreDBClusterToPointInTime**

Run the RDS API operation with the following parameters:

- **DBClusterIdentifier**—The DB cluster identifier.
- **Engine**—The database engine.
• EnableCloudwatchLogsExports—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the AWS CLI command that you run.

**Monitoring log events in Amazon CloudWatch**

After enabling Aurora MySQL log events, you can monitor the events in Amazon CloudWatch Logs. A new log group is automatically created for the Aurora DB cluster under the following prefix, in which `cluster-name` represents the DB cluster name, and `log_type` represents the log type.

```
/aws/rds/cluster/cluster-name/log_type
```

For example, if you configure the export function to include the slow query log for a DB cluster named `mydbcluster`, slow query data is stored in the `/aws/rds/cluster/mydbcluster/slowquery` log group.

The events from all instances in your cluster are pushed to a log group using different log streams. The behavior depends on which of the following conditions is true:

• A log group with the specified name exists.
  
  Aurora uses the existing log group to export log data for the cluster. To create log groups with predefined log retention periods, metric filters, and customer access, you can use automated configuration, such as AWS CloudFormation.

• A log group with the specified name doesn't exist.
  
  When a matching log entry is detected in the log file for the instance, Aurora MySQL creates a new log group in CloudWatch Logs automatically. The log group uses the default log retention period of *Never Expire*.
