If this parameter is set to 1, Aurora MySQL optimizes binary log replication based on the settings of the parameters aurora_binlog_read_buffer_size and aurora_binlog_replication_max_yield_seconds. If aurora_binlog_use_large_read_buffer is 0, Aurora MySQL ignores the values of the aurora_binlog_read_buffer_size and aurora_binlog_replication_max_yield_seconds parameters.

aurora_binlog_read_buffer_size

Binary log dump threads with larger read buffer minimize the number of read I/O operations by reading more events for each I/O. The parameter aurora_binlog_read_buffer_size sets the read buffer size. The large read buffer can reduce binary log contention for workloads that generate a large amount of binlog data.
Note
This parameter only has an effect when the cluster also has the setting `aurora_binlog_use_large_read_buffer=1`. Increasing the size of the read buffer doesn't affect the performance of binary log replication. Binary log dump threads don't wait for updating transactions to fill up the read buffer.

`aurora_binlog_replication_max_yield_seconds`

If your workload requires low transaction latency, and you can tolerate some replication lag, you can increase the `aurora_binlog_replication_max_yield_seconds` parameter. This parameter controls the maximum yield property of binary log replication in your cluster.

Note
This parameter only has an effect when the cluster also has the setting `aurora_binlog_use_large_read_buffer=1`.

Aurora MySQL recognizes any change to the `aurora_binlog_replication_max_yield_seconds` parameter value immediately. You don't need to restart the DB instance. However, when you turn on this setting, the dump thread only starts to yield when the current binlog file reaches its maximum size of 128 MB and is rotated to a new file.

Related parameters
Use the following DB cluster parameters to turn on the binlog optimization.

Binlog optimization parameters for Aurora MySQL version 2.04.5 and later

Enabling the max-yield mechanism for binary log replication

You can turn on the binary log replication max-yield optimization as follows. Doing so minimizes latency for transactions on the binlog source instance. However, you might experience higher replication lag.

To turn on the max-yield binlog optimization for an Aurora MySQL cluster

1. Create or edit a DB cluster parameter group using the following parameter settings:
   - aurora_binlog_use_large_read_buffer: turn on with a value of ON or 1.
   - aurora_binlog_replication_max_yield_seconds: specify a value greater than 0.
2. Associate the DB cluster parameter group with the Aurora MySQL cluster that works as the binlog source. To do so, follow the procedures in Working with DB parameter groups and DB cluster parameter groups (p. 335).
3. Confirm that the parameter change takes effect. To do so, run the following query on the binlog source instance.
Turning off the binary log replication max-yield optimization

You can turn off the binary log replication max-yield optimization as follows. Doing so minimizes replication lag. However, you might experience higher latency for transactions on the binlog source instance.

**To turn off the max-yield optimization for an Aurora MySQL cluster**

1. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `aurora_binlog_replication_max_yield_seconds` set to 0. For more information about setting configuration parameters using parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 335).
2. Confirm that the parameter change takes effect. To do so, run the following query on the binlog source instance.

```sql
SELECT @@aurora_binlog_replication_max_yield_seconds;
```

Your output should be similar to the following.

```
+-----------------------------------------------+
| @@aurora_binlog_replication_max_yield_seconds |
+-----------------------------------------------+
| 1                                              |
```

Turning off the large read buffer

You can turn off the entire large read buffer feature as follows.

**To turn off the large binary log read buffer for an Aurora MySQL cluster**

1. Reset the `aurora_binlog_use_large_read_buffer` to OFF or 0.

   Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `aurora_binlog_use_large_read_buffer` set to 0. For more information about setting configuration parameters using parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 335).

2. On the binlog source instance, run the following query.

```sql
SELECT @@aurora_binlog_use_large_read_buffer,
       @@aurora_binlog_replication_max_yield_seconds;
```
SELECT @@ aurora_binlog_use_large_read_buffer;

Your output should be similar to the following.

+---------------------------------------+
| @@aurora_binlog_use_large_read_buffer |
+---------------------------------------+
|                                     0 |
+---------------------------------------+

Synchronizing passwords between replication source and target

When you change user accounts and passwords on the replication source using SQL statements, those changes are replicated to the replication target automatically.

If you use the AWS Management Console, the AWS CLI, or the RDS API to change the master password on the replication source, those changes are not automatically replicated to the replication target. If you want to synchronize the master user and master password between the source and target systems, you must make the same change on the replication target yourself.

Using GTID-based replication for Aurora MySQL

Following, you can learn how to use global transaction identifiers (GTIDs) with binary log (binlog) replication between an Aurora MySQL cluster and an external source.

Note
For Aurora, you can only use this feature with Aurora MySQL clusters that use binlog replication to or from an external MySQL database. The other database might be an Amazon RDS MySQL instance, an on-premises MySQL database, or an Aurora DB cluster in a different AWS Region. To learn how to configure that kind of replication, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 897).

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see Replication with global transaction identifiers in the MySQL documentation for background.

GTID-based replication is supported for MySQL 5.7-compatible clusters in Aurora MySQL version 2.04 and higher. GTID-based replication isn't supported for MySQL 5.6-compatible clusters in Aurora MySQL version 1.

Topics
- Overview of global transaction identifiers (GTIDs) (p. 920)
- Parameters for GTID-based replication (p. 921)
- Configuring GTID-based replication for an Aurora MySQL cluster (p. 922)
- Disabling GTID-based replication for an Aurora MySQL DB cluster (p. 922)

Overview of global transaction identifiers (GTIDs)

Global transaction identifiers (GTIDs) are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

Note
When Aurora synchronizes data among the DB instances in a cluster, that replication mechanism doesn't involve the binary log (binlog). For Aurora MySQL, GTID-based replication only applies
when you also use binlog replication to replicate into or out of an Aurora MySQL DB cluster from an external MySQL-compatible database.

MySQL uses two different types of transactions for binlog replication:

- **GTID transactions** – Transactions that are identified by a GTID.
- **Anonymous transactions** – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You typically use GTID-based replication with Aurora when replicating from an external MySQL-compatible database into an Aurora cluster. You can set up this replication configuration as part of a migration from an on-premises or Amazon RDS database into Aurora MySQL. If the external database already uses GTIDs, enabling GTID-based replication for the Aurora cluster simplifies the replication process.

You configure GTID-based replication for an Aurora MySQL cluster by first setting the relevant configuration parameters in a DB cluster parameter group. You then associate that parameter group with the cluster.

### Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gtid_mode</td>
<td>OFF, OFF_PERMISSIVE, ON_PERMISSIVE, ON</td>
<td>OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated. OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated. ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated. ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.</td>
</tr>
<tr>
<td>enforce_gtid_consistency</td>
<td>OFF, ON, WARN</td>
<td>OFF allows transactions to violate GTID consistency. ON prevents transactions from violating GTID consistency. WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.</td>
</tr>
</tbody>
</table>

**Note**

In the AWS Management Console, the `gtid_mode` parameter appears as `gtid-mode`. 

921
For GTID-based replication, use these settings for the DB cluster parameter group for your Aurora MySQL DB cluster:

- **ON** and **ON_PERMISSIVE** apply only to outgoing replication from an RDS DB instance or Aurora MySQL cluster. Both of these values cause your RDS DB instance or Aurora DB cluster to use GTIDs for transactions that are replicated to an external database. **ON** requires that the external database also use GTID-based replication. **ON_PERMISSIVE** makes GTID-based replication optional on the external database.
- **OFF_PERMISSIVE**, if set, means that your RDS DB instances or Aurora DB cluster can accept incoming replication from an external database. It can do this whether the external database uses GTID-based replication or not.
- **OFF**, if set, means that your RDS DB instances or Aurora DB cluster only accept incoming replication from external databases that don't use GTID-based replication.

**Tip**

Incoming replication is the most common binlog replication scenario for Aurora MySQL clusters. For incoming replication, we recommend that you set the GTID mode to **OFF_PERMISSIVE**. That setting allows incoming replication from external databases regardless of the GTID settings at the replication source.

For more information about parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 335).

### Configuring GTID-based replication for an Aurora MySQL cluster

When GTID-based replication is enabled for an Aurora MySQL DB cluster, the GTID settings apply to both inbound and outbound binlog replication.

**To enable GTID-based replication for an Aurora MySQL cluster**

1. Create or edit a DB cluster parameter group using the following parameter settings:
   - `gtid_mode` – **ON** or **ON_PERMISSIVE**
   - `enforce_gtid_consistency` – **ON**
2. Associate the DB cluster parameter group with the Aurora MySQL cluster. To do so, follow the procedures in Working with DB parameter groups and DB cluster parameter groups (p. 335).
3. In Aurora MySQL version 3 and higher, optionally specify how to assign GTIDs to transactions that don't include them. To do so, call the stored procedure in `mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3 and higher)` (p. 1040).

### Disabling GTID-based replication for an Aurora MySQL DB cluster

You can disable GTID-based replication for an Aurora MySQL DB cluster. Doing so means that the Aurora cluster can't perform inbound or outbound binlog replication with external databases that use GTID-based replication.

**Note**

In the following procedure, `read replica` means the replication target in an Aurora configuration with binlog replication to or from an external database. It doesn't mean the read-only Aurora Replica DB instances. For example, when an Aurora cluster accepts incoming replication from an external source, the Aurora primary instance acts as the read replica for binlog replication.

For more details about the stored procedures mentioned in this section, see Aurora MySQL stored procedures (p. 1040).
To disable GTID-based replication for an Aurora MySQL DB cluster

1. On the Aurora primary instance, run the following procedure.

   ```
   CALL mysql.rds_set_master_auto_position(0);  \(\text{Aurora MySQL version 1 and 2}\)
   CALL mysql.rds_set_source_auto_position(0);  \(\text{Aurora MySQL version 3 and higher}\)
   ```

2. Reset the `gtid_mode` to `ON_PERMISSIVE`.
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `gtid_mode` set to `ON_PERMISSIVE`.
      
      For more information about setting configuration parameters using parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 335).
   b. Restart the Aurora MySQL DB cluster.

3. Reset the `gtid_mode` to `OFF_PERMISSIVE`:
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `gtid_mode` set to `OFF_PERMISSIVE`.
   b. Restart the Aurora MySQL DB cluster.

4. a. On the Aurora primary instance, run the `SHOW MASTER STATUS` command.
    
    Your output should be similar to the following.
    
    ```
    +----------------+-----------+
    | File           | Position  |
    +----------------+-----------+
    | mysql-bin-changelog.000031 | 107 |
    +----------------+-----------+
    ```
    
    Note the file and position in your output.
   
   b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

   ```
   SELECT MASTER_POS_WAIT('file', position);
   ```
   
   For example, if the file name is `mysql-bin-changelog.000031` and the position is 107, run the following statement.

   ```
   SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
   ```
   
   If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. When the query returns for all read replicas, go to the next step.

5. Reset the GTID parameters to disable GTID-based replication:
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has the following parameter settings:
      
      - `gtid_mode` – OFF
      - `enforce_gtid_consistency` – OFF
   b. Restart the Aurora MySQL DB cluster.

---

**Working with Aurora multi-master clusters**
Following, you can learn about Aurora multi-master clusters. In a multi-master cluster, all DB instances have read/write capability. Multi-master clusters have different availability characteristics, support for database features, and procedures for monitoring and troubleshooting than single-master clusters.

Topics
- Overview of Aurora multi-master clusters (p. 924)
- Creating an Aurora multi-master cluster (p. 929)
- Managing Aurora multi-master clusters (p. 934)
- Application considerations for Aurora multi-master clusters (p. 937)
- Performance considerations for Aurora multi-master clusters (p. 946)
- Approaches to Aurora multi-master clusters (p. 948)

Overview of Aurora multi-master clusters

Use the following background information to help you choose a multi-master or single-master cluster when you set up a new Aurora cluster. For you to make an informed choice, we recommend that you first understand how you plan to adapt your schema design and application logic to work best with a multi-master cluster.

For each new Amazon Aurora cluster, you can choose whether to create a single-master or multi-master cluster.

Most kinds of Aurora clusters are single-master clusters. For example, provisioned, Aurora Serverless, parallel query, and Global Database clusters are all single-master clusters. In a single-master cluster, a single DB instance performs all write operations and any other DB instances are read-only. If the writer DB instance becomes unavailable, a failover mechanism promotes one of the read-only instances to be the new writer.

In a multi-master cluster, all DB instances can perform write operations. The notions of a single read/write primary instance and multiple read-only Aurora Replicas don't apply. There isn't any failover when a writer DB instance becomes unavailable, because another writer DB instance is immediately available to take over the work of the failed instance. We refer to this type of availability as continuous availability, to distinguish it from the high availability (with brief downtime during failover) offered by a single-master cluster.

Multi-master clusters work differently in many ways from the other kinds of Aurora clusters, such as provisioned, Aurora Serverless, and parallel query clusters. With multi-master clusters, you consider different factors in areas such as high availability, monitoring, connection management, and database features. For example, in applications where you can't afford even brief downtime for database write operations, a multi-master cluster can help to avoid an outage when a writer instance becomes unavailable. The multi-master cluster doesn't use the failover mechanism, because it doesn't need to promote another DB instance to have read/write capability. With a multi-master cluster, you examine metrics related to DML throughput, latency, and deadlocks for all DB instances instead of a single primary instance.

Currently, multi-master clusters require Aurora MySQL version 1, which is compatible with MySQL 5.6. When specifying the DB engine version in the AWS Management Console, AWS CLI, or RDS API, choose 5.6.10a.

To create a multi-master cluster, you choose Multiple writers under Database features when creating the cluster. Doing so enables different behavior for replication among DB instances, availability, and performance than other kinds of Aurora clusters. This choice remains in effect for the life of the cluster. Make sure that you understand the specialized use cases that are appropriate for multi-master clusters.

Topics
Multi-master cluster terminology

You can understand the terminology about multi-master clusters by learning the following definitions. These terms are used throughout the documentation for multi-master clusters.

**Writer**

A DB instance that can perform write operations. In an Aurora multi-master cluster, all DB instances are writers. This is a significant difference from Aurora single-master clusters, where only one DB instance can act as a writer. With a single-master cluster, if the writer becomes unavailable, the failover mechanism promotes another DB instance to become the new writer. With a multi-master cluster, your application can redirect write operations from the failed DB instance to any other DB instance in the cluster.

**Multi-master**

An architecture for Aurora clusters where each DB instance can perform both read and write operations. Contrast this with *single-master*. Multi-master clusters are best suited for segmented workloads, such as for multitenant applications.

**Single-master**

The default architecture for Aurora clusters. A single DB instance (the primary instance) performs writes. All other DB instances (the Aurora Replicas) handle read-only query traffic. Contrast this with *multi-master*. This architecture is appropriate for general-purpose applications. In such applications, a single DB instance can handle all the data manipulation language (DML) and data definition language (DDL) statements. Scalability issues mostly involve SELECT queries.

**Write conflict**

A situation that occurs when different DB instances attempt to modify the same data page at the same time. Aurora reports a write conflict to your application as a deadlock error. This error condition causes the transaction to roll back. Your application must detect the error code and retry the transaction.

The main design consideration and performance tuning goal with Aurora multi-master clusters is to divide your write operations between DB instances in a way that minimizes write conflicts. That is why multi-master clusters are well-suited for sharded applications. For details about the write conflict mechanism, see *Conflict resolution for multi-master clusters* (p. 947).

**Sharding**

A particular class of segmented workloads. The data is physically divided into many partitions, tables, databases, or even separate clusters. The containers for specific portions of the data are known as *shards*. In an Aurora multi-master cluster, each shard is managed by a specific DB instance, and a DB instance can be responsible for multiple shards. A sharded schema design maps well to the way you manage connections in an Aurora multi-master cluster.

**Shard**

The unit of granularity within a sharded deployment. It might be a table, a set of related tables, a database, a partition, or even an entire cluster. With Aurora multi-master clusters, you can consolidate the data for a sharded application into a single Aurora shared storage volume, making the database continuously available and the data easy to manage. You decide which shards are
managed by each DB instance. You can change this mapping at any time, without physically reorganizing the data.

Resharding

Physically reorganizing sharded data so that different DB instances can handle specific tables or databases. You don’t need to physically reorganize data inside Aurora multi-master clusters in response to changing workload or DB instance failures. You can avoid resharding operations because all DB instances in a cluster can access all databases and tables through the shared storage volume.

Multitenant

A particular class of segmented workloads. The data for each customer, client, or user is kept in a separate table or database. This design ensures isolation and helps you to manage capacity and resources at the level of individual users.

Bring-your-own-shard (BYOS)

A situation where you already have a database schema and associated applications that use sharding. You can transfer such deployments relatively easily to Aurora multi-master clusters. In this case, you can devote your effort to investigating the Aurora benefits such as server consolidation and high availability. You don’t need to create new application logic to handle multiple connections for write requests.

Global read-after-write (GRAW)

A setting that introduces synchronization so that any read operations always see the most current state of the data. By default, the data seen by a read operation in a multi-master cluster is subject to replication lag, typically a few milliseconds. During this brief interval, a query on one DB instance might retrieve stale data if the same data is modified at the same time by a different DB instance. To enable this setting, change `aurora_mm_session_consistency_level` from its default setting of `INSTANCE_RAW` to `REGIONAL_RAW`. Doing so ensures cluster-wide consistency for read operations regardless of the DB instances that perform the reads and writes. For details on GRAW mode, see Consistency model for multi-master clusters (p. 939).

Multi-master cluster architecture

Multi-master clusters have a different architecture than other kinds of Aurora clusters. In multi-master clusters, all DB instances have read/write capability. Other kinds of Aurora clusters have a single dedicated DB instance that performs all write operations, while all other DB instances are read-only and handle only SELECT queries. Multi-master clusters don’t have a primary instance or read-only Aurora Replicas.

Your application controls which write requests are handled by which DB instance. Thus, with a multi-master cluster, you connect to individual instance endpoints to issue DML and DDL statements. That’s different than other kinds of Aurora clusters, where you typically direct all write operations to the single cluster endpoint and all read operations to the single reader endpoint.

The underlying storage for Aurora multi-master clusters is similar to storage for single-master clusters. Your data is still stored in a highly reliable, shared storage volume that grows automatically. The core difference lies in the number and type of DB instances. In multi-master clusters, there are $N$ read/write nodes. Currently, the maximum for $N$ is 4.

Multi-master clusters have no dedicated read-only nodes. Thus, the Aurora procedures and guidelines about Aurora Replicas don’t apply to multi-master clusters. You can temporarily make a DB instance read-only to place read and write workloads on different DB instances. To do so, see Using instance read-only mode (p. 945).

Multi-master cluster nodes are connected using low-latency and low-lag Aurora replication. Multi-master clusters use all-to-all peer-to-peer replication. Replication works directly between writers. Every writer replicates its changes to all other writers.
DB instances in a multi-master cluster handle restart and recovery independently. If a writer restarts, there is no requirement for other writers to also restart. For details, see High availability considerations for Aurora multi-master clusters (p. 936).

Multi-master clusters keep track of all changes to data within all database instances. The unit of measurement is the data page, which has a fixed size of 16 KB. These changes include modifications to table data, secondary indexes, and system tables. Changes can also result from Aurora internal housekeeping tasks. Aurora ensures consistency between the multiple physical copies that Aurora keeps for each data page in the shared storage volume, and in memory on the DB instances.

If two DB instances attempt to modify the same data page at almost the same instant, a write conflict occurs. The earliest change request is approved using a quorum voting mechanism. That change is saved to permanent storage. The DB instance whose change isn't approved rolls back the entire transaction containing the attempted change. Rolling back the transaction ensures that data is kept in a consistent state, and applications always see a predictable view of the data. Your application can detect the deadlock condition and retry the entire transaction.

For details about how to minimize write conflicts and associated performance overhead, see Conflict resolution for multi-master clusters (p. 947).

Recommended workloads for multi-master clusters

Multi-master clusters work best with certain kinds of workloads.

Active-passive workloads

With an active-passive workload, you perform all read and write operations on one DB instance at a time. You hold any other DB instances in the Aurora cluster in reserve. If the original active DB instance becomes unavailable, you immediately switch all read and write operations to the other DB instance. With this configuration, you minimize any downtime for write operations. The other DB instance can take over all processing for your application without performing a failover.

Active-active workloads

With an active-active workload, you perform read and write operations to all the DB instances at the same time. In this configuration, you typically segment the workload so that the different DB instances don't modify the same underlying data at the same time. Doing so minimizes the chance for write conflicts.

Multi-master clusters work well with application logic that's designed for a segmented workload. In this type of workload, you divide write operations by database instance, database, table, or table partition. For example, you can run multiple applications on the same cluster, each assigned to a specific DB instance. Alternatively, you can run an application that uses multiple small tables, such as one table for each user of an online service. Ideally, you design your schema so that write operations for different DB instances don't perform simultaneous updates to overlapping rows within the same tables. Sharded applications are one example of this kind of architecture.

For examples of designs for active-active workloads, see Using a multi-master cluster for a sharded database (p. 948).

Advantages of multi-master clusters

You can take advantage of the following benefits with Aurora multi-master clusters:

- Multi-master clusters improve Aurora's already high availability. You can restart a read/write DB instance without causing other DB instances in the cluster to restart. There is no failover process and associated delay when a read/write DB instance becomes unavailable.
- Multi-master clusters are well-suited to sharded or multitenant applications. As you manage the data, you can avoid complex resharding operations. You might be able to consolidate sharded applications
with a smaller number of clusters or DB instances. For details, see Using a multi-master cluster for a sharded database (p. 948).

- Aurora detects write conflicts immediately, not when the transaction commits. For details about the write conflict mechanism, see Conflict resolution for multi-master clusters (p. 947).

### Limitations of multi-master clusters

**Note**

Aurora multi-master clusters are highly specialized for continuous availability use cases. Thus, such clusters might not be generally applicable to all workloads. Your requirements for performance, scalability, and availability might be satisfied by using a larger DB instance class with an Aurora single-master cluster. If so, consider using a provisioned or Aurora Serverless cluster.

### AWS and Aurora limitations

The following limitations currently apply to the AWS and Aurora features that you can use with multi-master clusters:

- Currently, you can have a maximum of four DB instances in a multi-master cluster.
- Currently, all DB instances in a multi-master cluster must be in the same AWS Region.
- You can't enable cross-Region replicas from multi-master clusters.
- Multi-master clusters are available in the following AWS Regions:
  - US East (N. Virginia) Region
  - US East (Ohio) Region
  - US West (Oregon) Region
  - Asia Pacific (Mumbai) Region
  - Asia Pacific (Seoul) Region
  - Asia Pacific (Tokyo) Region
  - Europe (Frankfurt) Region
  - Europe (Ireland) Region
- The Stop action isn't available for multi-master clusters.
- The Aurora survivable page cache, also known as the survivable buffer pool, isn't supported for multi-master clusters.
- A multi-master cluster doesn't do any load balancing for connections. Your application must implement its own connection management logic to distribute read and write operations among multiple DB instance endpoints. Typically, in a bring-your-own-shard (BYOS) application, you already have logic to map each shard to a specific connection. To learn how to adapt the connection management logic in your application, see Connection management for multi-master clusters (p. 938).
- Multi-master clusters have some processing and network overhead for coordination between DB instances. This overhead has the following consequences for write-intensive and read-intensive applications:
  - Throughput benefits are most obvious on busy clusters with multiple concurrent write operations. In many cases, a traditional Aurora cluster with a single primary instance can handle the write traffic for a cluster. In these cases, the benefits of multi-master clusters are mostly for high availability rather than performance.
  - Single-query performance is generally lower than for an equivalent single-master cluster.
- You can't take a snapshot created on a single-master cluster and restore it on a multi-master cluster, or the opposite. Instead, to transfer all data from one kind of cluster to the other, use a logical dump produced by a tool such as AWS Database Migration Service (AWS DMS) or the mysqldump command.
• You can't use the parallel query, Aurora Serverless, or Global Database features on a multi-master cluster.

The multi-master aspect is a permanent choice for a cluster. You can't switch an existing Aurora cluster between a multi-master cluster and another kind such as Aurora Serverless or parallel query.

• The zero-downtime patching (ZDP) and zero-downtime restart (ZDR) features aren't available for multi-master clusters.

• Integration with other AWS services such as AWS Lambda, Amazon S3, and AWS Identity and Access Management isn't available for multi-master clusters.

• The Performance Insights feature isn't available for multi-master clusters.

• You can't clone a multi-master cluster.

• You can't enable the backtrack feature for multi-master clusters.

Database engine limitations

The following limitations apply to the database engine features that you can use with a multi-master cluster:

• You can't perform binary log (binlog) replication to or from a multi-master cluster. This limitation means you also can't use global transaction ID (GTID) replication in a multi-master cluster.

• The event scheduler isn't available for multi-master clusters.

• The hash join optimization isn't enabled on multi-master clusters.

• The query cache isn't available on multi-master clusters.

• You can't use certain SQL language features on multi-master clusters. For the full list of SQL differences, and instructions about adapting your SQL code to address these limitations, see SQL considerations for multi-master clusters (p. 937).

Creating an Aurora multi-master cluster

You choose the multi-master or single-master architecture at the time you create an Aurora cluster. The following procedures show where to make the multi-master choice. If you haven't created any Aurora clusters before, you can learn the general procedure in Creating an Amazon Aurora DB cluster (p. 124).

Console

To create an Aurora multi-master cluster from the AWS Management Console, you make the following choices. On the first screen, you select an Aurora cluster:
You also choose MySQL 5.6 compatibility and location **Regional**: 

**Edition**

- Amazon Aurora with MySQL compatibility
- Amazon Aurora with PostgreSQL compatibility

**DB engine version**

**Aurora MySQL 1.21.0 (Compatible with MySQL 5.6)**

Select engine version Aurora MySQL 1.21.0 (Compatible with MySQL 5.6) to use create parallel query, multiple writers, serverless, or global databases.

**Database location**

- **Regional**
  You provision your Aurora database in a single region.
- **Global**
  You can provision your Aurora database in multiple regions. Writes in the primary have typical latency of <1 sec to secondary regions.

On the second screen, choose **Multiple writers** under **Database features**.
Fill in the other settings for the cluster. This part of the procedure is the same as the general procedure for creating an Aurora cluster in Creating a DB cluster (p. 125).

After you create the multi-master cluster, add two DB instances to it by following the procedure in Adding Aurora Replicas to a DB cluster (p. 388). Use the same AWS instance class for all DB instances within the multi-master cluster.

After you create the multi-master cluster and associated DB instances, you see the cluster in the AWS Management Console Databases page as follows. All DB instances show the role Writer.
AWS CLI

To create a multi-master cluster with the AWS CLI, run the `create-db-cluster` AWS CLI command and include the option `--engine_mode=multimaster`.

The following command shows the syntax for creating an Aurora cluster with multi-master replication. For the general procedure to create an Aurora cluster, see Creating a DB cluster (p. 125).

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora 
--engine-version 5.6.10a --master-username user-name --master-user-password password 
--db-subnet-group-name my_subnet_group --vpc-security-group-ids my_vpc_id 
--engine-mode multimaster
```

For Windows:

```
aws rds create-db-cluster --db-cluster-identifier sample-cluster --engine aurora ^
--engine-version 5.6.10a --master-username user-name --master-user-password password ^
--db-subnet-group-name my_subnet_group --vpc-security-group-ids my_vpc_id ^
--engine-mode multimaster
```

After you create the multi-master cluster, add a second DB instance to it by following the procedure in Adding Aurora Replicas to a DB cluster (p. 388). Use the same AWS instance class for all DB instances within the multi-master cluster.
RDS API

To create a multi-master cluster with the RDS API, run the `CreateDBCluster` operation. Specify the value `multimaster` for the `EngineMode` parameter. For the general procedure to create an Aurora cluster, see Creating a DB cluster (p. 125).

After you create the multi-master cluster, add two DB instances to it by following the procedure in Adding Aurora Replicas to a DB cluster (p. 388). Use the same AWS instance class for all DB instances within the multi-master cluster.

Adding a DB instance to a multi-master cluster

You need more than one DB instance to see the benefits of a multi-master cluster. After you create the first instance, you can create other DB instances, up to a maximum of four DB instances, using the procedures from Adding Aurora Replicas to a DB cluster (p. 388). The difference for multi-master clusters is that the new DB instances all have read/write capability instead of being read-only Aurora Replicas. Use the same AWS instance class for all DB instances within the multi-master cluster.

Managing Aurora multi-master clusters

You do most management and administration for Aurora multi-master clusters the same way as for other kinds of Aurora clusters. The following sections explain the differences and unique features of multi-master clusters for administration and management.

Topics
- Monitoring an Aurora multi-master cluster (p. 934)
- Data ingestion performance for multi-master clusters (p. 935)
- Exporting data from a multi-master cluster (p. 935)
- High availability considerations for Aurora multi-master clusters (p. 936)
- Replication between multi-master clusters and other clusters (p. 936)
- Upgrading a multi-master cluster (p. 936)

Monitoring an Aurora multi-master cluster

Most of the monitoring and diagnostic features supported by MySQL and Aurora single-master clusters are also supported for multi-master clusters:

- MySQL error logs, general logs and slow query logs.
- MySQL built-in diagnostic features such as SHOW commands, status variables, InnoDB runtime status tables, and so on.
- Advanced Auditing.
- CloudWatch metrics.
- Enhanced Monitoring.

Aurora multi-master clusters don't currently support the following monitoring features:

- Performance Insights.
Data ingestion performance for multi-master clusters

One best practice for DML operations on a multi-master cluster is to keep transactions small and brief. Also, route write operations for a particular table or database to a specific DB instance. Doing a bulk import might require relaxing the guidance for transaction size. However, you can still distribute the write operations to minimize the chance of write conflicts.

To distribute the write workload from a bulk import

1. Issue a separate `mysqldump` command for each database, table, or other object in your schema. Store the results of each `mysqldump` in a file whose name reflects the object being dumped. As an alternative, you can use a specialized dump and import tool that can automatically dump multiple tables in parallel, such as `mydumper`.

2. Run a separate `mysql` session for each data file, connecting to the appropriate instance endpoint that handles the corresponding schema object. Again, as an alternative, you can use a specialized parallel import command, such as `myloader`.

3. Run the import sessions in parallel across the DB instances in the multi-master cluster, instead of waiting for each to finish before starting the next.

You can use the following techniques to import data into an Aurora multi-master cluster:

- You can import logical (SQL-format) dumps from other MySQL-compatible servers to Aurora multi-master clusters, if the statements don't use any features that aren't supported in Aurora. For example, a logical dump from a table containing MySQL Full-Text Search (FTS) indexes doesn't work because the FTS feature is not supported on multi-master clusters.

- You can use managed services such as DMS to migrate data into an Aurora multi-master cluster.

- For migrations into an Aurora multi-master cluster from a server that isn't compatible with MySQL, follow existing instructions for heterogeneous Aurora migrations.

- Aurora multi-master clusters can produce MySQL-compatible logical dumps in SQL format. Any migration tool (for example, AWS DMS) that can understand such format can consume data dumps from Aurora multi-master clusters.

- Aurora doesn't support binary logging with the multi-master cluster as the binlog master or worker. You can't use binlog-based CDC tools with multi-master clusters.

- When migrating from non-MySQL-compatible servers, you can replicate into a multi-master cluster using the continuous change data capture (CDC) feature of AWS DMS. That type of replication transmits SQL statements to the destination cluster, thus the restriction on binlog replication doesn't apply.

For a detailed discussion of migration techniques and recommendations, see the Amazon Aurora migration handbook AWS whitepaper. Some of the migration methods listed in the handbook might not apply to Aurora multi-master clusters, but the document is a great overall source of knowledge about Aurora migration topics.

Exporting data from a multi-master cluster

You can save a snapshot of a multi-master cluster and restore it to another multi-master cluster. Currently, you can't restore a multi-master cluster snapshot into a single-master cluster.

To migrate data from a multi-master cluster to a single-master cluster, use a logical dump and restore with a tool such as `mysqldump`.

You can't use a multi-master cluster as the source or destination for binary log replication.
High availability considerations for Aurora multi-master clusters

In an Aurora multi-master cluster, any DB instance can restart without causing any other instance to restart. This behavior provides a higher level of availability for read/write and read-only connections than for Aurora single-master clusters. We refer to this availability level as continuous availability. In multi-master clusters, there is no downtime for write availability when a writer DB instance fails. Multi-master clusters don't use the failover mechanism, because all cluster instances are writable. If a DB instance fails in a multi-master cluster, your application can redirect the workload towards the remaining healthy instances.

In a single-master cluster, restarting the primary instance makes write operations unavailable until the failover mechanism promotes a new primary instance. Read-only operations also experience a brief downtime because all the Aurora Replicas in the cluster restart.

To minimize downtime for applications in a multi-master cluster, implement frequent SQL-level health checks. If a DB instance in a multi-master cluster becomes unavailable, you can decide what to do based on the expected length of the outage and the urgency of write operations in the workload. If you expect the outage to be brief and the write operations aren't urgent, you can wait for the DB instance to recover before resuming the workload that is normally handled by that DB instance. Alternatively, you can redirect that workload to a different DB instance. The underlying data remains available at all time to all DB instances in the cluster. The highly distributed Aurora storage volume keeps the data continuously available even in the unlikely event of a failure affecting an entire AZ. For information about the timing considerations for switching write operations away from an unavailable DB instance, see Using a multi-master cluster as an active standby (p. 949).

Replication between multi-master clusters and other clusters

Multi-master clusters don't support incoming or outgoing binary log replication.

Upgrading a multi-master cluster

Aurora multi-master clusters use the same version numbering scheme, with major and minor version numbers, as other kinds of Aurora clusters. However, the Enable auto minor version upgrade setting doesn't apply for multi-master clusters.

When you upgrade an Aurora multi-master cluster, typically the upgrade procedure moves the database engine from the current version to the next higher version. If you upgrade to an Aurora version that increments the version number by more than one, the upgrade uses a multi-step approach. Each DB instance is upgraded to the next higher version, then the next one after that, and so on until it reaches the specified upgrade version.

The approach is different depending on whether there are any backwards-incompatible changes between the old and new versions. For example, updates to the system schema are considered backwards-incompatible changes. You can check whether a specific version contains any backwards-incompatible changes by consulting the release notes.

If there aren't any incompatible changes between the old and new versions, each DB instance is upgraded and restarted individually. The upgrades are staggered so that the overall cluster doesn't experience any downtime. At least one DB instance is available at any time during the upgrade process.

If there are incompatible changes between the old and new versions, Aurora performs the upgrade in offline mode. All cluster nodes are upgraded and restarted at the same time. The cluster experiences some downtime, to avoid an older engine writing to newer system tables.

Zero-downtime patching (ZDP) isn't currently supported for Aurora multi-master clusters.
Application considerations for Aurora multi-master clusters

Following, you can learn any changes that might be required in your applications due to differences in feature support or behavior between multi-master and single-master clusters.

Topics

- SQL considerations for multi-master clusters (p. 937)
- Connection management for multi-master clusters (p. 938)
- Consistency model for multi-master clusters (p. 939)
- Multi-master clusters and transactions (p. 940)
- Write conflicts and deadlocks in multi-master clusters (p. 940)
- Multi-master clusters and locking reads (p. 941)
- Performing DDL operations on a multi-master cluster (p. 942)
- Using autoincrement columns (p. 943)
- Multi-master clusters feature reference (p. 944)

SQL considerations for multi-master clusters

The following are the major limitations that apply to the SQL language features you can use with a multi-master cluster:

- In a multi-master cluster, you can't use certain settings or column types that change the row layout. You can't enable the innodb_large_prefix configuration option. You can't use the column types MEDIUMTEXT, MEDIUMBLOB, LONGTEXT, or LONGBLOB.
- You can't use the CASCADE clause with any foreign key columns in a multi-master cluster.
- Multi-master clusters can't contain any tables with full-text search (FTS) indexes. Such tables can't be created on or imported into multi-master clusters.
- DDL works differently on multi-master and single-master clusters. For example, the fast DDL mechanism isn't available for multi-master clusters. You can't write to a table in a multi-master cluster while the table is undergoing DDL. For full details on DDL differences, see Performing DDL operations on a multi-master cluster (p. 942).
- You can't use the SERIALIZABLE transaction isolation level on multi-master clusters. On Aurora single-master clusters, you can use this isolation level on the primary instance.
- Autoincrement columns are handled using the auto_increment_increment and auto_increment_offset parameters. Parameter values are predetermined and not configurable. The parameter auto_increment_increment is set to 16, which is the maximum number of instances in any Aurora cluster. However, multi-master clusters currently have a lower limit on the number of DB instances. For details, see Using autoincrement columns (p. 943).

When adapting an application for an Aurora multi-master cluster, approach that activity the same as a migration. You might have to stop using certain SQL features, and change your application logic for other SQL features:

- In your CREATE TABLE statements, change any columns defined as MEDIUMTEXT, MEDIUMBLOB, LONGTEXT, or LONGBLOB to shorter types that don't require off-page storage.
- In your CREATE TABLE statements, remove the CASCADE clause from any foreign key declarations. Add application logic if necessary to emulate the CASCADE effects through INSERT or DELETE statements.
• Remove any use of InnoDB fulltext search (FTS) indexes. Check your source code for \texttt{MATCH()} operators in \texttt{SELECT} statements, and \texttt{FULLTEXT} keywords in DDL statements. Check if any table names from the \texttt{INFORMATION_SCHEMA.INNODB_SYS_TABLES} system table contain the string \texttt{FTS_}.

• Check the frequency of DDL operations such as \texttt{CREATE TABLE} and \texttt{DROP TABLE} in your application. Because DDL operations have more overhead in multi-master clusters, avoid running many small DDL statements. For example, look for opportunities to create needed tables ahead of time. For information about DDL differences with multi-master clusters, see Performing DDL operations on a multi-master cluster (p. 942).

• Examine your use of autoincrement columns. The sequences of values for autoincrement columns are different for multi-master clusters than other kinds of Aurora clusters. Check for the \texttt{AUTO_INCREMENT} keyword in DDL statements, the function name \texttt{last_insert_id()} in \texttt{SELECT} statements, and the name \texttt{innodb_autoinc_lock_mode} in your custom configuration settings. For details about the differences and how to handle them, see Using autoincrement columns (p. 943).

• Check your code for the \texttt{SERIALIZABLE} keyword. You can't use this transaction isolation level with a multi-master cluster.

### Connection management for multi-master clusters

The main connectivity consideration for multi-master clusters is the number and type of the available DNS endpoints. With multi-master clusters, you often use the instance endpoints, which you rarely use in other kinds of Aurora clusters.

Aurora multi-master clusters have the following kinds of endpoints:

#### Cluster endpoint

This type of endpoint always points to a DB instance with read/write capability. Each multi-master cluster has one cluster endpoint.

Because applications in multi-master clusters typically include logic to manage connections to specific DB instances, you rarely need to use this endpoint. It's mostly useful for connecting to a multi-master cluster to perform administration.

You can also connect to this endpoint to examine the cluster topology when you don't know the status of the DB instances in the cluster. To learn that procedure, see Describing cluster topology (p. 945).

#### DB instance endpoint

This type of endpoint connects to specific named DB instances. For Aurora multi-master clusters, your application typically uses the DB instance endpoints for all or nearly all connections. You decide which DB instance to use for each SQL statement based on the mapping between your shards and the DB instances in the cluster. Each DB instance has one such endpoint. Thus the multi-master cluster has one or more of these endpoints, and the number changes as DB instances are added to or removed from a multi-master cluster.

The way you use DB instance endpoints is different between single-master and multi-master clusters. For single-master clusters, you typically don't use this endpoint often.

#### Custom endpoint

This type of endpoint is optional. You can create one or more custom endpoints to group together DB instances for a specific purpose. When you connect to the endpoint, Aurora returns the IP address of a different DB instance each time. In multi-master clusters, you typically use custom endpoints to designate a set of DB instances to use mostly for read operations. We recommend not using custom endpoints with multi-master clusters to load-balance write operations, because doing so increases the chance of write conflicts.
Multi-master clusters don't have reader endpoints. Where practical, issue SELECT queries using the same DB instance endpoint that normally writes to the same table. Doing so makes more effective use of cached data from the buffer pool, and avoids potential issues with stale data due to replication lag within the cluster. If you don't locate SELECT statements on the same DB instances that write to the same tables, and you require strict read after write guarantee for certain queries, consider running those queries using the global read-after-write (GRAW) mechanism described in Consistency model for multi-master clusters (p. 939).

For general best practices of Aurora and MySQL connection management, see the Amazon Aurora migration handbook AWS whitepaper.

For information about how to emulate read-only DB instances in multi-master DB clusters, see Using instance read-only mode (p. 945).

Follow these guidelines when creating custom DNS endpoints and designing drivers and connectors for Aurora multi-master clusters:

- For DDL, DML, and DCL statements, don't use endpoints or connection routing techniques that operate in round-robin or random fashion.
- Avoid long-running write queries and long write transactions unless these transactions are guaranteed not to conflict with other write traffic in the cluster.
- Prefer to use autocommitted transactions. Where practical, avoid autocommit=0 settings at global or session level. When you use a database connector or database framework for your programming language, check that autocommit is turned on for applications that use the connector or framework. If needed, add COMMIT statements at logical points throughout your code to ensure that transactions are brief.
- When global read consistency or read-after-write guarantee is required, follow recommendations for global read-after-write (GRAW) described in Consistency model for multi-master clusters (p. 939).
- Use the cluster endpoint for DDL and DCL statements where practical. The cluster endpoint helps to minimize the dependency on the hostnames of the individual DB instances. You don't need to divide DDL and DCL statements by table or database, as you do with DML statements.

Consistency model for multi-master clusters

Aurora multi-master clusters support a global read-after-write (GRAW) mode that is configurable at the session level. This setting introduces extra synchronization to create a consistent read view for each query. That way, queries always see the very latest data. By default, the replication lag in a multi-master cluster means that a DB instance might see old data for a few milliseconds after the data was updated. Enable this feature if your application depends on queries seeing the latest data changes made by any other DB instance, even if the query has to wait as a result.

**Note**

Replication lag doesn't affect your query results if you write and then read the data using the same DB instance. Thus, the GRAW feature applies mainly to applications that issue multiple concurrent write operations through different DB instances.

When using the GRAW mode, don't enable it for all queries by default. Globally consistent reads are noticeably slower than local reads. Therefore, use GRAW selectively for queries that require it.

Be aware of these considerations for using GRAW:

- GRAW involves performance overhead due to the cost of establishing a cluster-wide consistent read view. The transaction must first determine a cluster-wide consistent point in time, then replication must catch up to that time. The total delay depends on the workload, but it's typically in the range of tens of milliseconds.
- You can't change GRAW mode within a transaction.
• When using GRAW without explicit transactions, each individual query incurs the performance overhead of establishing a globally consistent read view.
• With GRAW enabled, the performance penalty applies to both reads and writes.
• When you use GRAW with explicit transactions, the overhead of establishing a globally consistent view applies once for each transaction, when the transaction starts. Queries performed later in the transaction are as fast as if run without GRAW. If multiple successive statements can all use the same read view, you can wrap them in a single transaction for a better overall performance. That way, the penalty is only paid once per transaction instead of per query.

Multi-master clusters and transactions

Standard Aurora MySQL guidance applies to Aurora multi-master clusters. The Aurora MySQL database engine is optimized for short-lived SQL statements. These are the types of statements typically associated with online transaction processing (OLTP) applications.

In particular, make your write transactions as short as possible. Doing so reduces the window of opportunity for write conflicts. The conflict resolution mechanism is optimistic, meaning that it performs best when write conflicts are rare. The tradeoff is that when conflicts occur, they incur substantial overhead.

There are certain workloads that benefit from large transactions. For example, bulk data imports are significantly faster when run using multi-megabyte transactions rather than single-statement transactions. If you observe an unacceptable number of conflicts while running such workloads, consider the following options:
• Reduce transaction size.
• Reschedule or rearrange batch jobs so that they don't overlap and don't provoke conflicts with other workloads. If practical, reschedule the batch jobs so that they run during off-peak hours.
• Refactor the batch jobs so that they run on the same writer instance as the other transactions causing conflicts. When conflicting transactions are run on the same instance, the transactional engine manages access to the rows. In that case, storage-level write conflicts don't occur.

Write conflicts and deadlocks in multi-master clusters

One important performance aspect for multi-master clusters is the frequency of write conflicts. When such a problem condition occurs in the Aurora storage subsystem, your application receives a deadlock error and performs the usual error handling for deadlock conditions. Aurora uses a lock-free optimistic algorithm that performs best when such conflicts are rare.

In a multi-master cluster, all the DB instances can write to the shared storage volume. For every data page you modify, Aurora automatically distributes several copies across multiple Availability Zones (AZs). A write conflict can occur when multiple DB instances try to modify the same data page within a very short time. The Aurora storage subsystem detects that the changes overlap and performs conflict resolution before finalizing the write operation.

Aurora detects write conflicts at the level of the physical data pages, which have a fixed size of 16 KiB. Thus, a conflict can occur even for changes that affect different rows, if the rows are both within the same data page.

When conflicts do occur, the cleanup operation requires extra work to undo the changes from one of the DB instances. From the point of view of your application, the transaction that caused the conflict encounters a deadlock and Aurora rolls back that whole transaction. Your application receives error code 1213.

Undoing the transaction might require modifying many other data pages whose changes were already applied to the Aurora storage subsystem. Depending on how much data was changed by the transaction,
undoing it might involve substantial overhead. Therefore, minimizing the potential for write conflicts is a crucial design consideration for an Aurora multi-master cluster.

Some conflicts result from changes that you initiate. These changes include SQL statements, transactions, and transaction rollbacks. You can minimize these kinds of conflicts through your schema design and the connection management logic in your application.

Other conflicts happen because of simultaneous changes from both a SQL statement and an internal server thread. These conflicts are hard to predict because they depend on internal server activity that you might not be aware of. The two major kinds of internal activity that cause these conflicts are garbage collection (known as purge), and transaction rollbacks performed automatically by Aurora. For example, Aurora performs rollbacks automatically during crash recovery or if a client connection is lost.

A transaction rollback physically reverts page changes that were already made. A rollback produces page changes just like the original transaction does. A rollback takes time, potentially several times as long as the original transaction. While the rollback is proceeding, the changes it produces can come into conflict with your transactions.

Garbage collection has to do with multi-version concurrency control (MVCC), which is the concurrency control method used by the Aurora MySQL transactional engine. With MVCC, data mutations create new row versions, and the database keeps multiple versions of rows to achieve transaction isolation while permitting concurrent access to data. Row versions are removed (purged) when they're no longer needed. Here again, the process of purging produces page changes, which might conflict with your transactions. Depending on the workload, the database can develop a purge lag: a queue of changes waiting to be garbage collected. If the lag grows substantially, the database might need a considerable amount of time to complete the purge, even if you stop submitting SQL statements.

If an internal server thread encounters a write conflict, Aurora retries automatically. In contrast, your application must handle the retry logic for any transactions that encounter conflicts.

When multiple transactions from the same DB instance cause these kinds of overlapping changes, Aurora uses the standard transaction concurrency rules. For example, if two transactions on the same DB instance modify the same row, one of them waits. If the wait is longer than the configured timeout (innodb_lock_wait_timeout, by default 50 seconds), the waiting transaction aborts with a "Lock wait timeout exceeded" message.

### Multi-master clusters and locking reads

Aurora multi-master clusters support locking reads in the following forms.

```sql
SELECT ... FOR UPDATE
SELECT ... LOCK IN SHARE MODE
```

For more information about locking reads, see the [MySQL reference manual](https://dev.mysql.com/doc/refman/8.0/en/locking-rows.html).

Locking read operations are supported on all nodes, but the lock scope is local to the node on which the command was run. A locking read performed on one writer doesn't prevent other writers from accessing or modifying the locked rows. Despite this limitation, you can still work with locking reads in use cases that guarantee strict workload scope separation between writers, such as in sharded or multitenant databases.

Consider the following guidelines:

- Remember that a node can always see its own changes immediately and without delay. When possible, you can colocate reads and writes on the same node to eliminate the GRAW requirement.
- If read-only queries must be run with globally consistent results, use GRAW.
- If read-only queries care about data visibility but not global consistency, use GRAW or introduce a timed wait before each read. For example, a single application thread might maintain connections C1 and C2 to two different nodes. The application writes on C1 and reads on C2. In such case, the
application can issue a read immediately using GRAW, or it can sleep before issuing a read. The sleep time should be equal to or longer than the replication lag (usually approximately 20–30 ms).

The read-after-write feature is controlled using the `aurora_mm_session_consistency_level` session variable. The valid values are `INSTANCE_RAW` for local consistency mode (default) and `REGIONAL_RAW` for cluster-wide consistency:

### Performing DDL operations on a multi-master cluster

The SQL data definition language (DDL) statements have special considerations for multi-master clusters. These statements sometimes cause substantial reorganization of the underlying data. Such large-scale changes potentially affect many data pages in the shared storage volume. The definitions of tables and other schema objects are held in the `INFORMATION_SCHEMA` tables. Aurora handles changes to those tables specially to avoid write conflicts when multiple DB instances run DDL statements at the same time.

For DDL statements, Aurora automatically delegates the statement processing to a special server process in the cluster. Because Aurora centralizes the changes to the `INFORMATION_SCHEMA` tables, this mechanism avoids the potential for write conflicts between DDL statements.

DDL operations prevent concurrent writes to that table. During a DDL operation on a table, all DB instances in the multi-master cluster are limited to read-only access to that table until the DDL statement finishes.

The following DDL behaviors are the same in Aurora single-master and multi-master clusters:

- A DDL performed on one DB instance causes other instances to terminate any connections actively using the table.
- Session-level temporary tables can be created on any node using the `MyISAM` or `MEMORY` storage engines.
- DDL operations on very large tables might fail if the DB instance doesn’t have sufficient local temporary storage.

Note the following DDL performance considerations in multi-master clusters:

- Try to avoid issuing large numbers of short DDL statements in your application. Create databases, tables, partitions, columns, and so on, in advance where practical. Replication overhead can impose significant performance overhead for simple DDL statements that are typically very quick. The statement doesn’t finish until the changes are replicated to all DB instances in the cluster. For example, multi-master clusters take longer than other Aurora clusters to create empty tables, drop tables, or drop schemas containing many tables.

  If you do need to perform a large set of DDL operations, you can reduce the network and coordination overhead by issuing the statements in parallel through multiple threads.

- Long-running DDL statements are less affected, because the replication delay is only a small fraction of the total time for the DDL statement.

- Performance of DDLs on session-level temporary tables should be roughly equivalent on Aurora single-master and multi-master clusters. Operations on temporary tables happen locally and are not subject to synchronous replication overhead.

### Using Percona online schema change with multi-master clusters

The `pt-online-schema-change` tool works with multi-master clusters. You can use it if your priority is to run table modifications in the most nonblocking manner. However, be aware of the write conflict implications of the schema change process.
At a high level, the `pt-online-schema-change` tool works as follows:

1. It creates a new, empty table with the desired structure.
2. It creates `DELETE`, `INSERT` and `UPDATE` triggers on the original table to redo any data changes on the original table on top of the new table.
3. It moves existing rows into the new table using small chunks while ongoing table changes are automatically handled using the triggers.
4. After all the data is moved, it drops the triggers and switches the tables by renaming them.

The potential contention point occurs while the data is being transferred to the new table. When the new table is initially created, it's completely empty and therefore can become a locking hot point. The same is true in other kinds of database systems. Because triggers are synchronous, the impact from the hot point can propagate back to your queries.

In multi-master clusters, the impact can be more visible. This visibility is because the new table not only provokes lock contention, but also increases the likelihood of write conflicts. The table initially has very few pages in it, which means that writes are highly localized and therefore prone to conflicts. After the table grows, writes should spread out and write conflicts should no longer be a problem.

You can use the online schema change tool with multi-master clusters. However, it might require more careful testing and its effects on the ongoing workload might be slightly more visible in the first minutes of the operation.

### Using autoincrement columns

Aurora multi-master clusters handle autoincrement columns using the existing configuration parameters `auto_increment_increment` and `auto_increment_offset`. For more information, see the MySQL reference manual.

Parameter values are predetermined and you can't change them. Specifically, the `auto_increment_increment` parameter is hardcoded to 16, which is the maximum number of DB instances in any kind of Aurora cluster.

Due to the hard-coded increment setting, autoincrement values are consumed much more quickly than in single-master clusters. This is true even if a given table is only ever modified by a single DB instance. For best results, always use a `BIGINT` data type instead of `INT` for your autoincrement columns.

In a multi-master cluster, your application logic must be prepared to tolerate autoincrement columns that have the following properties:

- The values are noncontiguous.
- The values might not start from 1 on an empty table.
- The values increase by increments greater than 1.
- The values are consumed significantly more quickly than in a single-master cluster.

The following example shows how the sequence of autoincrement values in a multi-master cluster can be different from what you might expect.

```sql
mysql> create table autoinc (id bigint not null auto_increment, s varchar(64), primary key (id));

mysql> insert into autoinc (s) values ('row 1'), ('row 2'), ('row 3');
Query OK, 3 rows affected (0.02 sec)

mysql> select * from autoinc order by id;
```

943
You can change the `AUTO_INCREMENT` table property. Using a nondefault value only works reliably if that value is larger than any of the primary key values already in the table. You can't use smaller values to fill in an empty interval in the table. If you do, the change takes effect either temporarily or not at all. This behavior is inherited from MySQL 5.6 and is not specific to the Aurora implementation.

## Multi-master clusters feature reference

Following, you can find a quick reference of the commands, procedures, and status variables specific to Aurora multi-master clusters.

### Using read-after-write

The read-after-write feature is controlled using the `aurora_mm_session_consistency_level` session variable. The valid values are `INSTANCE_RAW` for local consistency mode (default) and `REGIONAL_RAW` for cluster-wide consistency.

An example follows.

```sql
mysql> select @@aurora_mm_session_consistency_level;
+---------------------------------------+
| @@aurora_mm_session_consistency_level |
+---------------------------------------+
| INSTANCE_RAW                         |
+---------------------------------------+
1 row in set (0.01 sec)
mysql> set session aurora_mm_session_consistency_level = 'REGIONAL_RAW';
Query OK, 0 rows affected (0.00 sec)
mysql> select @@aurora_mm_session_consistency_level;
+---------------------------------------+
| @@aurora_mm_session_consistency_level |
+---------------------------------------+
| REGIONAL_RAW                         |
+---------------------------------------+
1 row in set (0.03 sec)
```

### Checking DB instance read-write mode

In multi-master clusters, all nodes operate in read/write mode. The `innodb_read_only` variable always returns zero. The following example shows that when you connect to any DB instance in a multi-master cluster, the DB instance reports that it has read/write capability.

```text
$ mysql -h mysql -A -h multi-master-instance-1.example123.us-east-1.rds.amazonaws.com
mysql> select @@innodb_read_only;
+--------------------+
| @@innodb_read_only |
+--------------------+
|                  0  |
+--------------------+
mysql> quit;
Bye
```
Checking the node name and role

You can check the name of the DB instance you're currently connected to by using the `aurora_server_id` status variable. The following example shows how.

```sql
mysql> select @@aurora_server_id;
+----------------------+
| @@aurora_server_id   |
+----------------------+
| mmr-demo-test-mm-3-1 |
+----------------------+
1 row in set (0.00 sec)
```

To find this information for all the DB instances in a multi-master cluster, see Describing cluster topology (p. 945).

Describing cluster topology

You can describe multi-master cluster topology by selecting from the `information_schema.replica_host_status` table. Multi-master clusters have the following differences from single-master clusters:

- The `has_primary` column identifies the role of the node. For multi-master clusters, this value is true for the DB instance that handles all DDL and DCL statements. Aurora forwards such requests to one of the DB instances in a multi-master cluster.
- The `replica_lag_in_milliseconds` column reports replication lag on all DB instances.
- The `last_reported_status` column reports the status of the DB instance. It can be Online, Recovery, or Offline.

An example follows.

```sql
mysql> select server_id, has_primary, replica_lag_in_milliseconds, last_reported_status
       -> from information_schema.replica_host_status;
+----------------------+-------------+-----------------------------+----------------------+
| server_id            | has_primary | replica_lag_in_milliseconds | last_reported_status |
| mmr-demo-test-mm-3-1 | true        | 37.302                      | Online               |
| mmr-demo-test-mm-3-2 | false       | 39.907                      | Online               |
+----------------------+-------------+-----------------------------+----------------------+
```

Using instance read-only mode

In Aurora multi-master clusters, you usually issue `SELECT` statements to the specific DB instance that performs write operations on the associated tables. Doing so avoids consistency issues due to replication lag and maximizes reuse for table and index data from the buffer pool.

If you need to run a query-intensive workload across multiple tables, you might designate one of more DB instances within a multi-master cluster as read-only.
To put an entire DB instance into read-only mode at runtime, call the `mysql.rds_set_read_only` stored procedure.

```
mysql> select @@read_only;
+-------------+
| @@read_only |
+-------------+
| 0           |
+-------------+
1 row in set (0.00 sec)
mysql> call mysql.rds_set_read_only(1);
Query OK, 0 rows affected (0.00 sec)
mysql> select @@read_only;
+-------------+
| @@read_only |
+-------------+
| 1           |
+-------------+
1 row in set (0.00 sec)
mysql> call mysql.rds_set_read_only(0);
Query OK, 0 rows affected (0.00 sec)
mysql> select @@read_only;
+-------------+
| @@read_only |
+-------------+
| 0           |
+-------------+
1 row in set (0.00 sec)
```

Calling the stored procedure is equivalent to running `SET GLOBAL read_only = 0|1`. That setting is runtime only and doesn't survive an engine restart. You can permanently set the DB instance to read-only by setting the `read_only` parameter to `true` in the parameter group for your DB instance.

**Performance considerations for Aurora multi-master clusters**

For both single-master and multi-master clusters, the Aurora engine is optimized for OLTP workloads. OLTP applications consist mostly of short-lived transactions with highly selective, random-access queries. You get the most advantage from Aurora with workloads that run many such operations concurrently.

Avoid running all the time at 100 percent utilization. Doing so lets Aurora keep up with internal maintenance work. To learn how to measure how busy a multi-master cluster is and how much maintenance work is needed, see Monitoring an Aurora multi-master cluster (p. 934).

**Topics**

- Query performance for multi-master clusters (p. 946)
- Conflict resolution for multi-master clusters (p. 947)
- Optimizing buffer pool and dictionary cache usage (p. 947)

**Query performance for multi-master clusters**

Multi-master clusters don't provide dedicated read-only nodes or read-only DNS endpoints, but it's possible to create groups of read-only DB instances and use them for the intended purpose. For more information, see Using instance read-only mode (p. 945).

You can use the following approaches to optimize query performance for a multi-master cluster:
Performance considerations

- Perform `SELECT` statements on the DB instance that handles the shard containing the associated table, database, or other schema objects involved in the query. This technique maximizes reuse of data in the buffer pool. It also avoids the same data being cached on more than one DB instance. For more details about this technique, see Optimizing buffer pool and dictionary cache usage (p. 947).
- If you need read/write workload isolation, designate one or more DB instances as read-only, as described in Using instance read-only mode (p. 945). You can direct read-only sessions to those DB instances by connecting to the corresponding instance endpoints, or by defining a custom endpoint that is associated with all the read-only instances.
- Spread read-only queries across all DB instances. This approach is the least efficient. Use one of the other approaches where practical, especially as you move from the development and test phase towards production.

Conflict resolution for multi-master clusters

Many best practices for multi-master clusters focus on reducing the chance of write conflicts. Resolving write conflicts involves network overhead. Your applications must also handle error conditions and retry transactions. Wherever possible, try to minimize these unwanted consequences:

- Wherever practical, make all changes to a particular table and its associated indexes using the same DB instance. If only one DB instance ever modifies a data page, changing that page cannot trigger any write conflicts. This access pattern is common in sharded or multitenant database deployments. Thus, it's relatively easy to switch such deployments to use multi-master clusters.
- A multi-master cluster doesn't have a reader endpoint. The reader endpoint load-balances incoming connections, freeing you from knowing which DB instance is handling a particular connection. In a multi-master cluster, managing connections involves being aware which DB instance is used for each connection. That way, modifications to a particular database or table can always be routed to the same DB instance.
- A write conflict for a small amount of data (one 16-KB page) can trigger a substantial amount of work to roll back the entire transaction. Thus, ideally you keep the transactions for a multi-master cluster relatively brief and small. This best practice for OLTP applications is especially important for Aurora multi-master clusters.

Conflicts are detected at page level. A conflict could occur because proposed changes from different DB instances modify different rows within the page. All page changes introduced in the system are subject to conflict detection. This rule applies regardless of whether the source is a user transaction or a server background process. It also applies whether the data page is from a table, secondary index, undo space, and so on.

You can divide the write operations so that each DB instance handles all write operations for a set of schema objects. In this case, all the changes to each data page are made by one specific instance.

Optimizing buffer pool and dictionary cache usage

Each DB instance in a multi-master cluster maintains separate in-memory buffers and caches such as the buffer pool, table handler cache, and table dictionary cache. For each DB instance, the contents and amount of turnover for the buffers and caches depends on the SQL statements processed by that instance.

Using memory efficiently can help the performance of multi-master clusters and reduce I/O cost. Use a sharded design to physically separate the data and write to each shard from a particular DB instance. Doing so makes the most efficient use of the buffer cache on each DB instance. Try to assign `SELECT` statements for a table to the same DB instance that performs write operations for that table. Doing so helps those queries to reuse the cached data on that DB instance. If you have a large number of tables or partitions, this technique also reduces the number of unique table handlers and dictionary objects held in memory by each DB instance.
Approaches to Aurora multi-master clusters

In the following sections, you can find approaches to take for particular deployments that are suitable for multi-master clusters. These approaches involve ways to divide the workload so that the DB instances perform write operations for portions of the data that don't overlap. Doing so minimizes the chances of write conflicts. Write conflicts are the main focus of performance tuning and troubleshooting for a multi-master cluster.

Topics
- Using a multi-master cluster for a sharded database (p. 948)
- Using a multi-master cluster without sharding (p. 948)
- Using a multi-master cluster as an active standby (p. 949)

Using a multi-master cluster for a sharded database

Sharding is a popular type of schema design that works well with Aurora multi-master clusters. In a sharded architecture, each DB instance is assigned to update a specific group of schema objects. That way, multiple DB instances can write to the same shared storage volume without conflicts from concurrent changes. Each DB instance can handle write operations for multiple shards. You can change the mapping of DB instances to shards at any time by updating your application configuration. You don't need to reorganize your database storage or reconfigure DB instances when you do so.

Applications that use a sharded schema design are good candidates to use with Aurora multi-master clusters. The way the data is physically divided in a sharded system helps to avoid write conflicts. You map each shard to a schema object such as a partition, a table, or a database. Your application directs all write operations for a particular shard to the appropriate DB instance.

Bring-your-own-shard (BYOS) describes a use case where you already have a sharded/partitioned database and an application capable of accessing it. The shards are already physically separated. Thus, you can easily move the workload to Aurora multi-master clusters without changing your schema design. The same simple migration path applies to multitenant databases, where each tenant uses a dedicated table, a set of tables, or an entire database.

You map shards or tenants to DB instances in a one-to-one or many-to-one fashion. Each DB instance handles one or more shards. The sharded design primarily applies to write operations. You can issue SELECT queries for any shard from any DB instance with equivalent performance.

Suppose you used a multi-master cluster for a sharded gaming application. You might distribute the work so that database updates are performed by specific DB instances, depending on the player's user name. Your application handles the logic of mapping each player to the appropriate DB instance and connecting to the endpoint for that instance. Each DB instance can handle write operations for many different shards. You can submit queries to any DB instance, because conflicts can only arise during write operations. You might designate one DB instance to perform all SELECT queries to minimize the overhead on the DB instances that perform write operations.

Suppose that as time goes on, one of the shards becomes much more active. To rebalance the workload, you can switch which DB instance is responsible for that shard. In a non-Aurora system, you might have to physically move the data to a different server. With an Aurora multi-master cluster, you can reshard like this by directing all write operations for the shard to some other DB instance that has unused compute capacity. The Aurora shared storage model avoids the need to physically reorganize the data.

Using a multi-master cluster without sharding

If your schema design doesn't subdivide the data into physically separate containers such as databases, tables, or partitions, you can still divide write operations such as DML statements among the DB instances in a multi-master cluster.
You might see some performance overhead, and your application might have to deal with occasional transaction rollbacks when write conflicts are treated as deadlock conditions. Write conflicts are more likely during write operations for small tables. If a table contains few data pages, rows from different parts of the primary key range might be in the same data page. This overlap might lead to write conflicts if those rows are changed simultaneously by different DB instances.

You should also minimize the number of secondary indexes in this case. When you make a change to indexed columns in a table, Aurora makes corresponding changes in the associated secondary indexes. A change to an index could cause a write conflict because the order and grouping of rows is different between a secondary index and the associated table.

Because you might still experience some write conflicts when using this technique, Amazon recommends using a different approach if practical. See if you can use an alternative database design that subdivides the data into different schema objects.

**Using a multi-master cluster as an active standby**

An *active standby* is a DB instance that is kept synchronized with another DB instance, and is ready to take over for it very quickly. This configuration helps with high availability in situations where a single DB instance can handle the full workload.

You can use multi-master clusters in an active standby configuration by directing all traffic, both read/write and read-only, to a single DB instance. If that DB instance becomes unavailable, your application must detect the problem and switch all connections to a different DB instance. In this case, Aurora doesn't perform any failover because the other DB instance is already available to accept read/write connections. By only writing to a single DB instance at any one time, you avoid write conflicts. Thus, you don't need to have a sharded database schema to use multi-master clusters in this way.

**Tip**

If your application can tolerate a brief pause, you can wait several seconds after a DB instance becomes unavailable before redirecting write traffic to another instance. When an instance becomes unavailable because of a restart, it becomes available again after approximately 10–20 seconds. If the instance can't restart quickly, Aurora might initiate recovery for that instance. When an instance is shut down, it performs some additional cleanup activities as part of the shutdown. If you begin writing to a different instance while the instance is restarting, undergoing recovery, or being shut down, you can encounter write conflicts. The conflicts can occur between SQL statements on the new instance, and recovery operations such as rollback and purge on the instance that was restarted or shut down.

**Integrating Amazon Aurora MySQL with other AWS services**

Amazon Aurora MySQL integrates with other AWS services so that you can extend your Aurora MySQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora MySQL DB cluster can use AWS services to do the following:

- Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. For more information, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 975).

- Load data from text or XML files stored in an Amazon Simple Storage Service (Amazon S3) bucket into your DB cluster using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` command. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 962).
• Save data to text files stored in an Amazon S3 bucket from your DB cluster using the `SELECT INTO OUTFILE S3` command. For more information, see Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 969).

• Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora replicas (p. 423).

• Perform sentiment analysis with Amazon Comprehend, or a wide variety of machine learning algorithms with SageMaker. For more information, see Using machine learning (ML) capabilities with Amazon Aurora (p. 438).

Aurora secures the ability to access other AWS services by using AWS Identity and Access Management (IAM). You grant permission to access other AWS services by creating an IAM role with the necessary permissions, and then associating the role with your DB cluster. For details and instructions on how to permit your Aurora MySQL DB cluster to access other AWS services on your behalf, see Authorizing Amazon Aurora MySQL to access other AWS services on your behalf (p. 950).

**Authorizing Amazon Aurora MySQL to access other AWS services on your behalf**

**Note**

Integration with other AWS services is available for Amazon Aurora MySQL version 1.8 and later. Some integration features are only available for later versions of Aurora MySQL. For more information on Aurora versions, see Database engine updates for Amazon Aurora MySQL (p. 1047).

For your Aurora MySQL DB cluster to access other services on your behalf, create and configure an AWS Identity and Access Management (IAM) role. This role authorizes database users in your DB cluster to access other AWS services. For more information, see Setting up IAM roles to access AWS services (p. 950).

You must also configure your Aurora DB cluster to allow outbound connections to the target AWS service. For more information, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 961).

If you do so, your database users can perform these actions using other AWS services:

• Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. Or, asynchronously invoke an AWS Lambda function using the `mysql.lambda_async` procedure. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).

• Load data from text or XML files stored in an Amazon S3 bucket into your DB cluster by using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 962).

• Save data from your DB cluster into text files stored in an Amazon S3 bucket by using the `SELECT INTO OUTFILE S3` statement. For more information, see Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 969).

• Export log data to Amazon CloudWatch Logs MySQL. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs (p. 982).

• Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora replicas (p. 423).

**Setting up IAM roles to access AWS services**

To permit your Aurora DB cluster to access another AWS service, do the following:
1. Create an IAM policy that grants permission to the AWS service. For more information, see:
   - Creating an IAM policy to access Amazon S3 resources (p. 951)
   - Creating an IAM policy to access AWS Lambda resources (p. 953)
   - Creating an IAM policy to access CloudWatch Logs resources (p. 954)
   - Creating an IAM policy to access AWS KMS resources (p. 955)
2. Create an IAM role and attach the policy that you created. For more information, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956).
3. Associate that IAM role with your Aurora DB cluster. For more information, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 957).

Creating an IAM policy to access Amazon S3 resources

Aurora can access Amazon S3 resources to either load data to or save data from an Aurora DB cluster. However, you must first create an IAM policy that provides the bucket and object permissions that allow Aurora to access Amazon S3.

The following table lists the Aurora features that can access an Amazon S3 bucket on your behalf, and the minimum required bucket and object permissions required by each feature.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Bucket permissions</th>
<th>Object permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOAD DATA FROM S3</td>
<td>ListBucket</td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObjectVersion</td>
</tr>
<tr>
<td>LOAD XML FROM S3</td>
<td>ListBucket</td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObjectVersion</td>
</tr>
<tr>
<td>SELECT INTO OUTFILE S3</td>
<td>ListBucket</td>
<td>AbortMultipartUpload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>DeleteObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ListMultipartUploadParts</td>
</tr>
<tr>
<td></td>
<td></td>
<td>PutObject</td>
</tr>
</tbody>
</table>

The following policy adds the permissions that might be required by Aurora to access an Amazon S3 bucket on your behalf.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowAuroraToExampleBucket",
         "Effect": "Allow",
         "Action": [
            "s3:PutObject",
            "s3:GetObject",
            "s3:AbortMultipartUpload",
            "s3:ListBucket",
            "s3:DeleteObject",
            "s3:GetObjectVersion",
            "s3:ListMultipartUploadParts"
         ]
      }
   ]
}
```
"Resource": [
  "arn:aws:s3:::example-bucket/*",
  "arn:aws:s3:::example-bucket"
]
}

Note
Make sure to include both entries for the Resource value. Aurora needs the permissions on both the bucket itself and all the objects inside the bucket. Based on your use case, you might not need to add all of the permissions in the sample policy. Also, other permissions might be required. For example, if your Amazon S3 bucket is encrypted, you need to add kms:Decrypt permissions.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access an Amazon S3 bucket on your behalf. To allow Aurora to access all of your Amazon S3 buckets, you can skip these steps and use either the AmazonS3ReadOnlyAccess or AmazonS3FullAccess predefined IAM policy instead of creating your own.

To create an IAM policy to grant access to your Amazon S3 resources

1. Open the IAM Management Console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose S3.
5. For Actions, choose Expand all, and then choose the bucket permissions and object permissions needed for the IAM policy.

Object permissions are permissions for object operations in Amazon S3, and need to be granted for objects in a bucket, not the bucket itself. For more information about permissions for object operations in Amazon S3, see Permissions for object operations.

6. Choose Resources, and choose Add ARN for bucket.
7. In the Add ARN(s) dialog box, provide the details about your resource, and choose Add.

Specify the Amazon S3 bucket to allow access to. For instance, if you want to allow Aurora to access the Amazon S3 bucket named example-bucket, then set the Amazon Resource Name (ARN) value to arn:aws:s3:::example-bucket.

8. If the object resource is listed, choose Add ARN for object.
9. In the Add ARN(s) dialog box, provide the details about your resource.

For the Amazon S3 bucket, specify the Amazon S3 bucket to allow access to. For the object, you can choose Any to grant permissions to any object in the bucket.

Note
You can set Amazon Resource Name (ARN) to a more specific ARN value in order to allow Aurora to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

10. (Optional) Choose Add ARN for bucket to add another Amazon S3 bucket to the policy, and repeat the previous steps for the bucket.

Note
You can repeat this to add corresponding bucket permission statements to your policy for each Amazon S3 bucket that you want Aurora to access. Optionally, you can also grant access to all buckets and objects in Amazon S3.

12. For Name, enter a name for your IAM policy, for example AllowAuroraToExampleBucket. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.

13. Choose Create policy.

14. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956).

Creating an IAM policy to access AWS Lambda resources

You can create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf.

The following policy adds the permissions required by Aurora to invoke an AWS Lambda function on your behalf.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowAuroraToExampleFunction",
         "Effect": "Allow",
         "Action": "lambda:InvokeFunction",
         "Resource": "arn:aws:lambda:<region>:<123456789012>:function:<example_function>"
      }
   ]
}
```

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf. To allow Aurora to invoke all of your AWS Lambda functions, you can skip these steps and use the predefined AWSLambdaRole policy instead of creating your own.

**To create an IAM policy to grant invoke to your AWS Lambda functions**

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose Lambda.
5. For Actions, choose Expand all, and then choose the AWS Lambda permissions needed for the IAM policy.
   
   Ensure that InvokeFunction is selected. It is the minimum required permission to enable Amazon Aurora to invoke an AWS Lambda function.

6. Choose Resources and choose Add ARN for function.
7. In the Add ARN(s) dialog box, provide the details about your resource.
   
   Specify the Lambda function to allow access to. For instance, if you want to allow Aurora to access a Lambda function named example_function, then set the ARN value to arn:aws:lambda:::function:example_function.
   
   For more information on how to define an access policy for AWS Lambda, see Authentication and access control for AWS Lambda.

8. Optionally, choose Add additional permissions to add another AWS Lambda function to the policy, and repeat the previous steps for the function.
Note
You can repeat this to add corresponding function permission statements to your policy for each AWS Lambda function that you want Aurora to access.

9. Choose **Review policy**.

10. Set **Name** to a name for your IAM policy, for example **AllowAuroraToExampleFunction**. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.

11. Choose **Create policy**.

12. Complete the steps in **Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956)**.

Creating an IAM policy to access CloudWatch Logs resources

Aurora can access CloudWatch Logs to export audit log data from an Aurora DB cluster. However, you must first create an IAM policy that provides the log group and log stream permissions that allow Aurora to access CloudWatch Logs.

The following policy adds the permissions required by Aurora to access Amazon CloudWatch Logs on your behalf, and the minimum required permissions to create log groups and export data.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogEvents",
      "Effect": "Allow",
      "Action": [
        "logs:GetLogEvents",
        "logs:PutLogEvents"
      ],
      "Resource": "arn:aws:logs:*:*:log-group:/aws/rds/*:log-stream:*"
    },
    {
      "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogGroupsAndStreams",
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogStream",
        "logs:DescribeLogStreams",
        "logs:PutRetentionPolicy",
        "logs:CreateLogGroup"
      ],
      "Resource": "arn:aws:logs:*:*:log-group:/aws/rds/*"
    }
  ]
}
```

You can modify the ARNs in the policy to restrict access to a specific AWS Region and account.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access CloudWatch Logs on your behalf. To allow Aurora full access to CloudWatch Logs, you can skip these steps and use the **CloudWatchLogsFullAccess** predefined IAM policy instead of creating your own. For more information, see **Using identity-based policies (IAM policies) for CloudWatch Logs** in the **Amazon CloudWatch User Guide**.

**To create an IAM policy to grant access to your CloudWatch Logs resources**

1. Open the **IAM console**.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose CloudWatch Logs.
5. For Actions, choose Expand all (on the right), and then choose the Amazon CloudWatch Logs permissions needed for the IAM policy.

   Ensure that the following permissions are selected:
   
   - CreateLogGroup
   - CreateLogStream
   - DescribeLogStreams
   - GetLogEvents
   - PutLogEvents
   - PutRetentionPolicy

6. Choose Resources and choose Add ARN for log-group.
7. In the Add ARN(s) dialog box, enter the following values:

   - Region – An AWS Region or *
   - Account – An account number or *
   - Log Group Name – /aws/rds/*

8. In the Add ARN(s) dialog box, choose Add.
10. In the Add ARN(s) dialog box, enter the following values:

    - Region – An AWS Region or *
    - Account – An account number or *
    - Log Group Name – /aws/rds/*
    - Log Stream Name – *

11. In the Add ARN(s) dialog box, choose Add.
13. Set Name to a name for your IAM policy, for example AmazonRDSCloudWatchLogs. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.
14. Choose Create policy.
15. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956).

Creating an IAM policy to access AWS KMS resources

Aurora can access the AWS KMS keys used for encrypting their database backups. However, you must first create an IAM policy that provides the permissions that allow Aurora to access KMS keys.

The following policy adds the permissions required by Aurora to access KMS keys on your behalf.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt"
```
You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access KMS keys on your behalf.

**To create an IAM policy to grant access to your KMS keys**

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose KMS.
5. For Actions, choose Write, and then choose Decrypt.
6. Choose Resources, and choose Add ARN.
7. In the Add ARN(s) dialog box, enter the following values:
   - Region – Type the AWS Region, such as us-west-2.
   - Account – Type the user account number.
   - Log Stream Name – Type the KMS key identifier.
8. In the Add ARN(s) dialog box, choose Add
10. Set Name to a name for your IAM policy, for example AmazonRDSKMSKey. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.
11. Choose Create policy.
12. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956).

**Creating an IAM role to allow Amazon Aurora to access AWS services**

After creating an IAM policy to allow Aurora to access AWS resources, you must create an IAM role and attach the IAM policy to the new IAM role.

To create an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.

**To create an IAM role to allow Amazon RDS to access AWS services**

1. Open the IAM console.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. Under AWS service, choose RDS.
5. Under Select your use case, choose RDS – Add Role to Database.
6. Choose Next: Permissions.
7. On the Attach permissions policies page, enter the name of your policy in the Search field.
8. When it appears in the list, select the policy that you defined earlier using the instructions in one of the following sections:
• Creating an IAM policy to access Amazon S3 resources (p. 951)
• Creating an IAM policy to access AWS Lambda resources (p. 953)
• Creating an IAM policy to access CloudWatch Logs resources (p. 954)
• Creating an IAM policy to access AWS KMS resources (p. 955)

9. Choose Next: Tags, and then choose Next: Review.

10. In Role name, enter a name for your IAM role, for example RDSLoadFromS3. You can also add an optional Role description value.

11. Choose Create Role.

12. Complete the steps in Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 957).

### Associating an IAM role with an Amazon Aurora MySQL DB cluster

To permit database users in an Amazon Aurora DB cluster to access other AWS services, you associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956) with that DB cluster.

**Note**

You can't associate an IAM role with an Aurora Serverless DB cluster. For more information, see Using Amazon Aurora Serverless v1 (p. 146).

To associate an IAM role with a DB cluster you do two things:

- Add the role to the list of associated roles for a DB cluster by using the RDS console, the add-role-to-db-cluster AWS CLI command, or the AddRoleToDBCluster RDS API operation.

  You can add a maximum of five IAM roles for each Aurora DB cluster.

- Set the cluster-level parameter for the related AWS service to the ARN for the associated IAM role.

The following table describes the cluster-level parameter names for the IAM roles used to access other AWS services.

<table>
<thead>
<tr>
<th>Cluster-level parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws_default_lambda_role</td>
<td>Used when invoking a Lambda function from your DB cluster.</td>
</tr>
<tr>
<td>aws_default_logs_role</td>
<td>This parameter is no longer required for exporting log data from your DB cluster to Amazon CloudWatch Logs. Aurora MySQL now uses a service-linked role for the required permissions. For more information about service-linked roles, see Using service-linked roles for Amazon Aurora (p. 1704).</td>
</tr>
<tr>
<td>aws_default_s3_role</td>
<td>Used when invoking the LOAD DATA FROM S3, LOAD XML FROM S3, or SELECT INTO OUTFILE S3 statement from your DB cluster. The IAM role specified in this parameter is used only if an IAM role isn't specified for aurora_load_from_s3_role or aurora_select_into_s3_role for the appropriate statement.</td>
</tr>
</tbody>
</table>
### Cluster-level parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aurora_load_from_s3_role</td>
<td>Used when invoking the LOAD DATA FROM S3 or LOAD XML FROM S3 statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in <code>aws_default_s3_role</code> is used. For earlier versions of Aurora, this parameter is not available.</td>
</tr>
<tr>
<td>aurora_select_into_s3_role</td>
<td>Used when invoking the SELECT INTO OUTFILE S3 statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in <code>aws_default_s3_role</code> is used. For earlier versions of Aurora, this parameter is not available.</td>
</tr>
</tbody>
</table>

To associate an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.

**To associate an IAM role with an Aurora DB cluster using the console**

2. Choose **Databases**.
3. Choose the name of the Aurora DB cluster that you want to associate an IAM role with to show its details.
4. On the **Connectivity & security** tab, in the Manage IAM roles section, choose the role to add under **Add IAM roles to this cluster**.

5. Choose **Add role**.
6. (Optional) To stop associating an IAM role with a DB cluster and remove the related permission, choose the role and choose **Delete**.
7. In the RDS console, choose **Parameter groups** in the navigation pane.

8. If you are already using a custom DB parameter group, you can select that group to use instead of creating a new DB cluster parameter group. If you are using the default DB cluster parameter group, create a new DB cluster parameter group, as described in the following steps:

   a. Choose **Create parameter group**.
   b. For **Parameter group family**, choose **aurora-mysql8.0** for an Aurora MySQL 8.0-compatible DB cluster, choose **aurora-mysql5.7** for an Aurora MySQL 5.7-compatible DB cluster, or choose **aurora5.6** for an Aurora MySQL 5.6-compatible DB cluster.
   c. For **Type**, choose **DB Cluster Parameter Group**.
   d. For **Group name**, type the name of your new DB cluster parameter group.
   e. For **Description**, type a description for your new DB cluster parameter group.

   ![Create parameter group]

   f. Choose **Create**.

9. On the **Parameter groups** page, select your DB cluster parameter group and choose **Edit** for **Parameter group actions**.

10. Set the appropriate cluster-level parameters to the related IAM role ARN values. For example, you can set just the **aws_default_s3_role** parameter to `arn:aws:iam::123456789012:role/AllowAuroraS3Role`.

11. Choose **Save changes**.

12. To change the DB cluster parameter group for your DB cluster, complete the following steps:

   a. Choose **Databases**, and then choose your Aurora DB cluster.
   b. Choose **Modify**.
   c. Scroll to **Database options** and set **DB cluster parameter group** to the DB cluster parameter group.
   d. Choose **Continue**.
   e. Verify your changes and then choose **Apply immediately**.
   f. Choose **Modify cluster**.
g. Choose **Databases**, and then choose the primary instance for your DB cluster.

h. For **Actions**, choose **Reboot**.

When the instance has rebooted, your IAM role is associated with your DB cluster.

For more information about cluster parameter groups, see *Aurora MySQL configuration parameters (p. 1007).*

### To associate an IAM role with a DB cluster by using the AWS CLI

1. Call the `add-role-to-db-cluster` command from the AWS CLI to add the ARNs for your IAM roles to the DB cluster, as shown following.

   ```shell
   PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws:iam::123456789012:role/AllowAuroraS3Role
   PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws:iam::123456789012:role/AllowAuroraLambdaRole
   ```

2. If you are using the default DB cluster parameter group, create a new DB cluster parameter group. If you are already using a custom DB parameter group, you can use that group instead of creating a new DB cluster parameter group.

   To create a new DB cluster parameter group, call the `create-db-cluster-parameter-group` command from the AWS CLI, as shown following.

   ```shell
   PROMPT> aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess
   --db-parameter-group-family aurora5.6 --description "Allow access to Amazon S3 and AWS Lambda"
   ```

   For an Aurora MySQL 5.7-compatible DB cluster, specify `aurora-mysql5.7` for `--db-parameter-group-family`. For an Aurora MySQL 8.0-compatible DB cluster, specify `aurora-mysql8.0` for `--db-parameter-group-family`.

3. Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group, as shown following.

   ```shell
   PROMPT> aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess
   --parameters
   "ParameterName=aws_default_s3_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraS3Role,method=pending-reboot"
   "ParameterName=aws_default_lambda_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraLambdaRole,method=pending-reboot"
   ```

4. Modify the DB cluster to use the new DB cluster parameter group and then reboot the cluster, as shown following.

   ```shell
   PROMPT> aws rds modify-db-cluster --db-cluster-identifier my-cluster --db-cluster-parameter-group-name AllowAWSAccess
   PROMPT> aws rds reboot-db-instance --db-instance-identifier my-cluster-primary
   ```

When the instance has rebooted, your IAM roles are associated with your DB cluster.

For more information about cluster parameter groups, see *Aurora MySQL configuration parameters (p. 1007).*
Enabling network communication from Amazon Aurora MySQL to other AWS services

To use certain other AWS services with Amazon Aurora, the network configuration of your Aurora DB cluster must allow outbound connections to endpoints for those services. The following operations require this network configuration.

- Invoking AWS Lambda functions. To learn about this feature, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Accessing files from Amazon S3. To learn about this feature, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 962) and Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 969).
- Accessing AWS KMS endpoints. AWS KMS access is required to use database activity streams with Aurora MySQL. To learn about this feature, see Monitoring Amazon Aurora using Database Activity Streams (p. 683).
- Accessing SageMaker endpoints. SageMaker access is required to use SageMaker machine learning with Aurora MySQL. To learn about this feature, see Using machine learning (ML) with Aurora MySQL (p. 985).

Aurora returns the following error messages if it can't connect to a service endpoint.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1871 (HY000)</td>
<td>S3 API returned error: Network Connection</td>
</tr>
<tr>
<td>1873 (HY000)</td>
<td>Lambda API returned error: Network Connection. Unable to connect to endpoint</td>
</tr>
<tr>
<td>1815 (HY000)</td>
<td>Internal error: Unable to initialize S3Stream</td>
</tr>
</tbody>
</table>

For database activity streams using Aurora MySQL, the activity stream stops functioning if the DB cluster can't access the AWS KMS endpoint. Aurora notifies you about this issue using RDS Events.

If you encounter these messages while using the corresponding AWS services, check if your Aurora DB cluster is public or private. If your Aurora DB cluster is private, you must configure it to enable connections.

For an Aurora DB cluster to be public, it must be marked as publicly accessible. If you look at the details for the DB cluster in the AWS Management Console, Publicly Accessible is Yes if this is the case. The DB cluster must also be in an Amazon VPC public subnet. For more information about publicly accessible DB instances, see Working with a DB instance in a VPC (p. 1708). For more information about public Amazon VPC subnets, see Your VPC and subnets.

If your Aurora DB cluster isn't publicly accessible and in a VPC public subnet, it is private. You might have a DB cluster that is private and want to use one of the features that requires this network configuration. If so, configure the cluster so that it can connect to Internet addresses through Network Address Translation (NAT). As an alternative for Amazon S3, Amazon SageMaker, and AWS Lambda, you can instead configure the VPC to have a VPC endpoint for the other service associated with the DB cluster's route table. For more information about configuring NAT in your VPC, see NAT gateways. For more information about configuring VPC endpoints, see VPC endpoints.

• Managing an Amazon Aurora DB cluster (p. 363)

Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket

You can use the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement to load data from files stored in an Amazon S3 bucket.

If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can't load data from a bucket that is encrypted with a customer managed key.

**Note**

Loading data into a table from text files in an Amazon S3 bucket is available for Amazon Aurora MySQL version 1.8 and later. For more information about Aurora MySQL versions, see [Database engine updates for Amazon Aurora MySQL](p. 1047).

This feature currently isn't available for Aurora Serverless clusters.

Giving Aurora access to Amazon S3

Before you can load data from an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

**To give Aurora MySQL access to Amazon S3**

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see [Creating an IAM policy to access Amazon S3 resources](p. 951).
2. Create an IAM role, and attach the IAM policy you created in [Creating an IAM policy to access Amazon S3 resources](p. 951) to the new IAM role. For instructions, see [Creating an IAM role to allow Amazon Aurora to access AWS services](p. 956).
3. Make sure the DB cluster is using a custom DB cluster parameter group. For more information about creating a custom DB cluster parameter group, see [Creating a DB cluster parameter group](p. 339).
4. Set either the `aurora_load_from_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_load_from_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database. Although only the primary cluster in an Aurora global database can load data, another cluster might be promoted by the failover mechanism and become the primary cluster.

For more information about DB cluster parameters, see [Amazon Aurora DB cluster and DB instance parameters](p. 337).
5. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services](p. 956) with the DB cluster. For an Aurora global database, associate the role with each Aurora cluster in the global database. For information about associating an IAM role with a DB cluster, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster](p. 957).
6. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services](p. 961).

For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.
Granting privileges to load data in Amazon Aurora MySQL

The database user that issues the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement must have a specific role or privilege to issue either statement. In Aurora MySQL version 3, you grant the `AWS_LOAD_S3_ACCESS` role. In Aurora MySQL version 1 or 2, you grant the `LOAD FROM S3` privilege.

The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```
GRANT AWS_LOAD_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

**Tip**
When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 730). You can also find more details in Using Roles in the MySQL Reference Manual.

Use the following statement for Aurora MySQL version 1 or 2:

```
GRANT LOAD FROM S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The `AWS_LOAD_S3_ACCESS` role and `LOAD FROM S3` privilege are specific to Amazon Aurora and are not available for MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora DB cluster as the replication master and a MySQL database as the replication client, then the `GRANT` statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL DB instance, use the `mysql_rds_skip_repl_error` procedure. To skip the error on an external MySQL database, use the `SET GLOBAL sql_slave_skip_counter` statement (Aurora MySQL version 1 and 2) or `SET GLOBAL sql_replica_skip_counter` statement (Aurora MySQL version 3).

Specifying a path to an Amazon S3 bucket

The syntax for specifying a path to files stored on an Amazon S3 bucket is as follows.

```
s3-region://bucket-name/file-name-or-prefix
```

The path includes the following values:

- `region` (optional) – The AWS Region that contains the Amazon S3 bucket to load from. This value is optional. If you don't specify a `region` value, then Aurora loads your file from Amazon S3 in the same region as your DB cluster.
- `bucket-name` – The name of the Amazon S3 bucket that contains the data to load. Object prefixes that identify a virtual folder path are supported.
- `file-name-or-prefix` – The name of the Amazon S3 text file or XML file, or a prefix that identifies one or more text or XML files to load. You can also specify a manifest file that identifies one or more text files to load. For more information about using a manifest file to load text files from Amazon S3, see Using a manifest to specify data files to load (p. 965).

LOAD DATA FROM S3

You can use the `LOAD DATA FROM S3` statement to load data from any text file format that is supported by the MySQL `LOAD DATA INFILE` statement, such as text data that is comma-delimited. Compressed files are not supported.
Syntax

```
LOAD DATA FROM S3 [FILE | PREFIX | MANIFEST] 'S3-URI'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[(FIELDS | COLUMNS)
  [TERMINATED BY 'string']
  [OPTIONALLY] ENCLOSED BY 'char'
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number {LINES | ROWS}]
[\((col_name_or_user_var,...)\]
[SET col_name = expr,...]
```

Parameters

Following, you can find a list of the required and optional parameters used by the `LOAD DATA FROM S3` statement. You can find more details about some of these parameters in `LOAD DATA INFILE syntax` in the MySQL documentation.

- **FILE | PREFIX | MANIFEST** – Identifies whether to load the data from a single file, from all files that match a given prefix, or from all files in a specified manifest. `FILE` is the default.
- **S3-URI** – Specifies the URI for a text or manifest file to load, or an Amazon S3 prefix to use. Specify the URI using the syntax described in Specifying a path to an Amazon S3 bucket (p. 963).
- **REPLACE | IGNORE** – Determines what action to take if an input row as the same unique key values as an existing row in the database table.
  - Specify `REPLACE` if you want the input row to replace the existing row in the table.
  - Specify `IGNORE` if you want to discard the input row.
- **INTO TABLE** – Identifies the name of the database table to load the input rows into.
- **PARTITION** – Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.
- **CHARACTER SET** – Identifies the character set of the data in the input file.
- **FIELDS | COLUMNS** – Identifies how the fields or columns in the input file are delimited. Fields are tab-delimited by default.
- **LINES** – Identifies how the lines in the input file are delimited. Lines are delimited by a newline character (`\n`) by default.
- **IGNORE number LINES | ROWS** – Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names, or `IGNORE 2 ROWS` to skip over the first two rows of data in the input file. If you also use `PREFIX`, `IGNORE` skips a certain number of lines or rows at the start of the first input file.
- **col_name_or_user_var, ...** – Specifies a comma-separated list of one or more column names or user variables that identify which columns to load by name. The name of a user variable used for this purpose must match the name of an element from the text file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of `table1`, and sets the value of the `table_column2` column in `table1` to the input value of the second column divided by 100.
LOAD DATA FROM S3 's3://mybucket/data.txt'
  INTO TABLE table1
  (column1, column2)
  SET table_column2 = @var1/100;

- **SET** – Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of table1 to the values in the first two columns from the input file, and then sets the value of the column3 in table1 to the current time stamp.

```
LOAD DATA FROM S3 's3://mybucket/data.txt'
  INTO TABLE table1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of SET assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you cannot use a subquery to select from the table that is being loaded.

You cannot use the **LOCAL** keyword of the LOAD DATA FROM S3 statement if you are loading data from an Amazon S3 bucket.

### Using a manifest to specify data files to load

You can use the LOAD DATA FROM S3 statement with the MANIFEST keyword to specify a manifest file in JSON format that lists the text files to be loaded into a table in your DB cluster. You must be using Aurora 1.11 or greater to use the MANIFEST keyword with the LOAD DATA FROM S3 statement.

The following JSON schema describes the format and content of a manifest file.

```json
{
  "$schema": "http://json-schema.org/draft-04/schema#",
  "additionalProperties": false,
  "definitions": {},
  "id": "Aurora_LoadFromS3_Manifest",
  "properties": {
    "entries": {
      "additionalItems": false,
      "id": "/properties/entries",
      "items": {
        "additionalProperties": false,
        "id": "/properties/entries/items",
        "properties": {
          "mandatory": {
            "default": "false",
            "id": "/properties/entries/items/properties/mandatory",
            "type": "boolean"
          },
          "url": {
            "id": "/properties/entries/items/properties/url",
            "maxLength": 1024,
            "minLength": 1,
            "type": "string"
          }
        }
      }
    },
    "required": ["url"],
```

965
Each URL in the manifest must specify a URL with the bucket name and full object path for the file, not just a prefix. You can use a manifest to load files from different buckets, different regions, or files that do not share the same prefix. If a region is not specified in the URL, the region of the target Aurora DB cluster is used. The following example shows a manifest file that loads four files from different buckets.

```
{
  "entries": [
    {
      "url":"s3://aurora-bucket/2013-10-04-customerdata",
      "mandatory":true
    },
    {
      "url":"s3-us-west-2://aurora-bucket-usw2/2013-10-05-customerdata",
      "mandatory":true
    },
    {
      "url":"s3://aurora-bucket/2013-10-04-customerdata",
      "mandatory":false
    },
    {
      "url":"s3://aurora-bucket/2013-10-05-customerdata"
    }
  ]
}
```

The optional mandatory flag specifies whether LOAD DATA FROM S3 should return an error if the file is not found. The mandatory flag defaults to false. Regardless of how mandatory is set, LOAD DATA FROM S3 terminates if no files are found.

Manifest files can have any extension. The following example runs the LOAD DATA FROM S3 statement with the manifest in the previous example, which is named `customer.manifest`.

```
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/customer.manifest'
  INTO TABLE CUSTOMER
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  (ID, FIRSTNAME, LASTNAME, EMAIL);
```

After the statement completes, an entry for each successfully loaded file is written to the `aurora_s3_load_history` table.

**Verifying loaded files using the aurora_s3_load_history table**

Every successful LOAD DATA FROM S3 statement updates the `aurora_s3_load_history` table in the `mysql` schema with an entry for each file that was loaded.

After you run the LOAD DATA FROM S3 statement, you can verify which files were loaded by querying the `aurora_s3_load_history` table. To see the files that were loaded from one iteration of the
statement, use the WHERE clause to filter the records on the Amazon S3 URI for the manifest file used in the statement. If you have used the same manifest file before, filter the results using the timestamp field.

```sql
select * from mysql.aurora_s3_load_history where load_prefix = 'S3_URI';
```

The following table describes the fields in the `aurora_s3_load_history` table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>load_prefix</td>
<td>The URI that was specified in the load statement. This URI can map to any of the following:</td>
</tr>
<tr>
<td></td>
<td>• A single data file for a LOAD DATA FROM S3 FILE statement</td>
</tr>
<tr>
<td></td>
<td>• An Amazon S3 prefix that maps to multiple data files for a LOAD DATA FROM S3 PRESENT statement</td>
</tr>
<tr>
<td></td>
<td>• A single manifest file that contains the names of files to be loaded for a LOAD DATA FROM S3 MANIFEST statement</td>
</tr>
<tr>
<td>file_name</td>
<td>The name of a file that was loaded into Aurora from Amazon S3 using the URI identified in the load_prefix field.</td>
</tr>
<tr>
<td>version_number</td>
<td>The version number of the file identified by the file_name field that was loaded, if the Amazon S3 bucket has a version number.</td>
</tr>
<tr>
<td>bytes_loaded</td>
<td>The size of the file loaded, in bytes.</td>
</tr>
<tr>
<td>load_timestamp</td>
<td>The timestamp when the LOAD DATA FROM S3 statement completed.</td>
</tr>
</tbody>
</table>

**Examples**

The following statement loads data from an Amazon S3 bucket that is in the same region as the Aurora DB cluster. The statement reads the comma-delimited data in the file `customerdata.txt` that is in the `dbbucket` Amazon S3 bucket, and then loads the data into the table `store-schema.customer-table`.

```
LOAD DATA FROM S3 's3://dbbucket/customerdata.csv'
INTO TABLE store-schema.customer-table
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
(ID, FIRSTNAME, LASTNAME, ADDRESS, EMAIL, PHONE);
```

The following statement loads data from an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement reads the comma-delimited data from all files that match the `employee-data` object prefix in the `my-data` Amazon S3 bucket in the `us-west-2` region, and then loads the data into the `employees` table.

```
LOAD DATA FROM S3 PREFIX 's3-us-west-2://my-data/employee_data'
INTO TABLE employees
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
(ID, FIRSTNAME, LASTNAME, EMAIL, SALARY);
```

The following statement loads data from the files specified in a JSON manifest file named `q1_sales.json` into the `sales` table.

967
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/q1_sales.json'
INTO TABLE sales
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
(MONTH, STORE, GROSS, NET);

LOAD XML FROM S3

You can use the `LOAD XML FROM S3` statement to load data from XML files stored on an Amazon S3 bucket in one of three different XML formats:

- Column names as attributes of a `<row>` element. The attribute value identifies the contents of the table field.

```
<row column1="value1" column2="value2" .../>
```

- Column names as child elements of a `<row>` element. The value of the child element identifies the contents of the table field.

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names in the `name` attribute of `<field>` elements in a `<row>` element. The value of the `<field>` element identifies the contents of the table field.

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

Syntax

```
LOAD XML FROM S3 'S3-URI'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<element-name>']
[IGNORE number (LINES | ROWS)]
[(field_name_or_user_var,...)]
[SET col_name = expr,...]
```

Parameters

Following, you can find a list of the required and optional parameters used by the `LOAD DATA FROM S3` statement. You can find more details about some of these parameters in `LOAD XML syntax` in the MySQL documentation.

- **FILE | PREFIX** – Identifies whether to load the data from a single file, or from all files that match a given prefix. FILE is the default.

- **REPLACE | IGNORE** – Determines what action to take if an input row as the same unique key values as an existing row in the database table.
  - Specify REPLACE if you want the input row to replace the existing row in the table.
• Specify `IGNORE` if you want to discard the input row. `IGNORE` is the default.

• `INTO TABLE` – Identifies the name of the database table to load the input rows into.

• `PARTITION` – Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.

• `CHARACTER SET` – Identifies the character set of the data in the input file.

• `ROWS IDENTIFIED BY` – Identifies the element name that identifies a row in the input file. The default is `<row>`.

• `IGNORE number LINES | ROWS` – Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use `IGNORE 1 LINES` to skip over the first line in the text file, or `IGNORE 2 ROWS` to skip over the first two rows of data in the input XML.

• `field_name_or_user_var, ...` – Specifies a comma-separated list of one or more XML element names or user variables that identify which elements to load by name. The name of a user variable used for this purpose must match the name of an element from the XML file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of `table1`, and sets the value of the `table_column2` column in `table1` to the input value of the second column divided by 100.

```sql
LOAD XML FROM S3 's3://mybucket/data.xml'
INTO TABLE table1
(column1, @var1)
SET table_column2 = @var1/100;
```

• `SET` – Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of `table1` to the values in the first two columns from the input file, and then sets the value of the `column3` in `table1` to the current time stamp.

```sql
LOAD XML FROM S3 's3://mybucket/data.xml'
INTO TABLE table1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of `SET` assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you cannot use a subquery to select from the table that is being loaded.

• Migrating data to an Amazon Aurora DB cluster (p. 362)

Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket
You can use the `SELECT INTO OUTFILE S3` statement to query data from an Amazon Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. You can use this functionality to skip bringing the data down to the client first, and then copying it from the client to Amazon S3. The `LOAD DATA FROM S3` statement can use the files created by this statement to load data into an Aurora DB cluster. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 962).

If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can't save data to a bucket that is encrypted with a customer managed key.

This feature currently isn't available for Aurora Serverless clusters.

**Note**
You can save DB cluster snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB snapshot data to Amazon S3 (p. 514).

**Giving Aurora MySQL access to Amazon S3**

Before you can save data into an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

**To give Aurora MySQL access to Amazon S3**

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see Creating an IAM policy to access Amazon S3 resources (p. 951).

2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access Amazon S3 resources (p. 951) to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956).

3. Set either the `aurora_select_into_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_select_into_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`.

   If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database.

   For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 337).

4. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956) with the DB cluster.

   For an Aurora global database, associate the role with each Aurora cluster in the global database.

   For information about associating an IAM role with a DB cluster, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 957).

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 961).

   For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.
Granting privileges to save data in Aurora MySQL

The database user that issues the `SELECT INTO OUTFILE S3` statement must have a specific role or privilege. In Aurora MySQL version 3, you grant the `AWS_SELECT_S3_ACCESS` role. In Aurora MySQL version 1 or 2, you grant the `SELECT INTO S3` privilege. The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```
GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

**Tip**

When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 730). You can also find more details in Using Roles in the MySQL Reference Manual.

Use the following statement for Aurora MySQL version 1 or 2:

```
GRANT SELECT INTO S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The `AWS_SELECT_S3_ACCESS` role and `SELECT INTO S3` privilege are specific to Amazon Aurora MySQL and are not available for MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora MySQL DB cluster as the replication master and a MySQL database as the replication client, then the `GRANT` statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL DB instance, use the `mysql_rds_skip_repl_error` procedure. To skip the error on an external MySQL database, use the `SET GLOBAL sql_slave_skip_counter` statement (Aurora MySQL version 1 and 2) or `SET GLOBAL sql_replica_skip_counter` statement (Aurora MySQL version 3).

Specifying a path to an Amazon S3 bucket

The syntax for specifying a path to store the data and manifest files on an Amazon S3 bucket is similar to that used in the `LOAD DATA FROM S3 PREFIX` statement, as shown following.

```
#3-region://bucket-name/file-prefix
```

The path includes the following values:

- `region` (optional) – The AWS Region that contains the Amazon S3 bucket to save the data into. This value is optional. If you don't specify a `region` value, then Aurora saves your files into Amazon S3 in the same region as your DB cluster.
- `bucket-name` – The name of the Amazon S3 bucket to save the data into. Object prefixes that identify a virtual folder path are supported.
- `file-prefix` – The Amazon S3 object prefix that identifies the files to be saved in Amazon S3.

The data files created by the `SELECT INTO OUTFILE S3` statement use the following path, in which `00000` represents a 5-digit, zero-based integer number.

```
#3-region://bucket-name/file-prefix.part_00000
```

For example, suppose that a `SELECT INTO OUTFILE S3` statement specifies `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files. The specified Amazon S3 bucket contains the following data files.
Creating a manifest to list data files

You can use the `SELECT INTO OUTFILE S3` statement with the `MANIFEST ON` option to create a manifest file in JSON format that lists the text files created by the statement. The `LOAD DATA FROM S3` statement can use the manifest file to load the data files back into an Aurora MySQL DB cluster. For more information about using a manifest to load data files from Amazon S3 into an Aurora MySQL DB cluster, see Using a manifest to specify data files to load (p. 965).

The data files included in the manifest created by the `SELECT INTO OUTFILE S3` statement are listed in the order that they're created by the statement. For example, suppose that a `SELECT INTO OUTFILE S3` statement specified `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files and a manifest file. The specified Amazon S3 bucket contains a manifest file named `s3-us-west-2://bucket/prefix.manifest`, that contains the following information.

```json
{
  "entries": [
    {
      "url": "s3-us-west-2://bucket/prefix.part_00000"
    },
    {
      "url": "s3-us-west-2://bucket/prefix.part_00001"
    },
    {
      "url": "s3-us-west-2://bucket/prefix.part_00002"
    }
  ]
}
```

**SELECT INTO OUTFILE S3**

You can use the `SELECT INTO OUTFILE S3` statement to query data from a DB cluster and save it directly into delimited text files stored in an Amazon S3 bucket. Compressed files are not supported. Encrypted files are supported starting in Aurora MySQL 2.09.0.

**Syntax**

```
SELECT
[ ALL | DISTINCT | DISTINCTROW ]
[ HIGH_PRIORITY ]
[ STRAIGHT_JOIN ]
[ SQL_SMALL_RESULT ] [ SQL_BIG_RESULT ] [ SQL_BUFFER_RESULT ]
[ SQL_CACHE | SQL_NO_CACHE ] [ SQL_CALC_FOUND_ROWS ]
select_expr [ , select_expr ... ]
FROM table_references
[ PARTITION partition_list ]
[ WHERE where_condition ]
[ GROUP BY { col_name | expr | position }]
[ ASC | DESC ], ... [ WITH ROLLUP ]
[ HAVING where_condition ]
[ ORDER BY { col_name | expr | position }]
[ ASC | DESC ], ... ]
[ LIMIT { [offset,] row_count | row_count OFFSET offset }]
[ PROCEDURE procedure_name(argument_list) ]
INTO OUTFILE S3 's3_uri'
[ CHARACTER SET charset_name ]
```
Saving data into text files in Amazon S3

Parameters

Following, you can find a list of the required and optional parameters used by the `SELECT INTO OUTFILE S3` statement that are specific to Aurora.

- **s3-uri** – Specifies the URI for an Amazon S3 prefix to use. Specify the URI using the syntax described in Specifying a path to an Amazon S3 bucket (p. 971).

- **FORMAT {CSV|TEXT} [HEADER]** – Optionally saves the data in CSV format. This syntax is available in Aurora MySQL version 2.07.0 and later.

  The TEXT option is the default and produces the existing MySQL export format.

  The CSV option produces comma-separated data values. The CSV format follows the specification in RFC-4180. If you specify the optional keyword HEADER, the output file contains one header line. The labels in the header line correspond to the column names from the SELECT statement. You can use the CSV files for training data models for use with AWS ML services. For more information about using exported Aurora data with AWS ML services, see Exporting data to Amazon S3 for SageMaker model training (p. 991).

- **MANIFEST {ON | OFF}** – Indicates whether a manifest file is created in Amazon S3. The manifest file is a JavaScript Object Notation (JSON) file that can be used to load data into an Aurora DB cluster with the `LOAD DATA FROM S3 MANIFEST` statement. For more information about `LOAD DATA FROM S3 MANIFEST`, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 962).

  If MANIFEST ON is specified in the query, the manifest file is created in Amazon S3 after all data files have been created and uploaded. The manifest file is created using the following path:

  ```
s3-region://bucket-name/file-prefix.manifest
  ```

  For more information about the format of the manifest file’s contents, see Creating a manifest to list data files (p. 972).

- **OVERWRITE {ON | OFF}** – Indicates whether existing files in the specified Amazon S3 bucket are overwritten. If OVERWRITE ON is specified, existing files that match the file prefix in the URI specified in s3-uri are overwritten. Otherwise, an error occurs.

You can find more details about other parameters in SELECT syntax and LOAD DATA INFILE syntax, in the MySQL documentation.

Considerations

The number of files written to the Amazon S3 bucket depends on the amount of data selected by the `SELECT INTO OUTFILE S3` statement and the file size threshold for Aurora MySQL. The default
file size threshold is 6 gigabytes (GB). If the data selected by the statement is less than the file size threshold, a single file is created; otherwise, multiple files are created. Other considerations for files created by this statement include the following:

- Aurora MySQL guarantees that rows in data files are not split across file boundaries. For multiple files, the size of every data file except the last is typically close to the file size threshold. However, occasionally staying under the file size threshold results in a row being split across two data files. In this case, Aurora MySQL creates a data file that keeps the row intact, but might be larger than the file size threshold.

- Because each SELECT statement in Aurora MySQL runs as an atomic transaction, a SELECT INTO OUTFILE S3 statement that selects a large data set might run for some time. If the statement fails for any reason, you might need to start over and issue the statement again. If the statement fails, however, files already uploaded to Amazon S3 remain in the specified Amazon S3 bucket. You can use another statement to upload the remaining data instead of starting over again.

- If the amount of data to be selected is large (more than 25 GB), we recommend that you use multiple SELECT INTO OUTFILE S3 statements to save the data to Amazon S3. Each statement should select a different portion of the data to be saved, and also specify a different file_prefix in the s3-uri parameter to use when saving the data files. Partitioning the data to be selected with multiple statements makes it easier to recover from an error in one statement. If an error occurs for one statement, only a portion of data needs to be re-selected and uploaded to Amazon S3. Using multiple statements also helps to avoid a single long-running transaction, which can improve performance.

- If multiple SELECT INTO OUTFILE S3 statements that use the same file_prefix in the s3-uri parameter run in parallel to select data into Amazon S3, the behavior is undefined.

- Metadata, such as table schema or file metadata, is not uploaded by Aurora MySQL to Amazon S3.

- In some cases, you might re-run a SELECT INTO OUTFILE S3 query, such as to recover from a failure. In these cases, you must either remove any existing data files in the Amazon S3 bucket with the same file prefix specified in s3-uri, or include OVERWRITE ON in the SELECT INTO OUTFILE S3 query.

The SELECT INTO OUTFILE S3 statement returns a typical MySQL error number and response on success or failure. If you don't have access to the MySQL error number and response, the easiest way to determine when it's done is by specifying MANIFEST ON in the statement. The manifest file is the last file written by the statement. In other words, if you have a manifest file, the statement has completed.

Currently, there's no way to directly monitor the progress of the SELECT INTO OUTFILE S3 statement while it runs. However, suppose that you're writing a large amount of data from Aurora MySQL to Amazon S3 using this statement, and you know the size of the data selected by the statement. In this case, you can estimate progress by monitoring the creation of data files in Amazon S3.

To do so, you can use the fact that a data file is created in the specified Amazon S3 bucket for about every 6 GB of data selected by the statement. Divide the size of the data selected by 6 GB to get the estimated number of data files to create. You can then estimate the progress of the statement by monitoring the number of files uploaded to Amazon S3 while the statement runs.

**Examples**

The following statement selects all of the data in the employees table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character. The statement returns an error if files that match the sample_employee_data file prefix exist in the specified Amazon S3 bucket.

```sql
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/sample_employee_data' FIELDS TERMINATED BY ',',
```
The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character, and also a manifest file. The statement returns an error if files that match the `sample_employee_data` file prefix exist in the specified Amazon S3 bucket.

```sql
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/sample_employee_data'
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  MANIFEST ON;
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character. The statement overwrites any existing files that match the `sample_employee_data` file prefix in the specified Amazon S3 bucket.

```sql
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/sample_employee_data'
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  OVERWRITE ON;
```

The following statement selects all of the data in the `employees` table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character, and also a manifest file. The statement overwrites any existing files that match the `sample_employee_data` file prefix in the specified Amazon S3 bucket.

```sql
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/sample_employee_data'
  FIELDS TERMINATED BY ','
  LINES TERMINATED BY '\n'
  MANIFEST ON
  OVERWRITE ON;
```

Invoking a Lambda function from an Amazon Aurora MySQL DB cluster

You can invoke an AWS Lambda function from an Amazon Aurora MySQL-Compatible Edition DB cluster with the native function `lambda_sync` or `lambda_async`. Before invoking a Lambda function from an
Aurora MySQL, the Aurora DB cluster must have access to Lambda. For details about granting access to Aurora MySQL, see Giving Aurora access to Lambda (p. 976). For information about the `lambda_sync` and `lambda_async` stored functions, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).

You can also call an AWS Lambda function by using a stored procedure. However, using a stored procedure is deprecated. We strongly recommend using an Aurora MySQL native function if you are using one of the following Aurora MySQL versions:

- Aurora MySQL version 1.16 and later, for MySQL 5.6-compatible clusters.
- Aurora MySQL version 2.06 and later, for MySQL 5.7-compatible clusters.
- Aurora MySQL version 3.01 and higher, for MySQL 8.0-compatible clusters. The stored procedure is not available in Aurora MySQL version 3.

**Topics**

- Giving Aurora access to Lambda (p. 976)
- Invoking a Lambda function with an Aurora MySQL native function (p. 977)
- Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated) (p. 979)

**Giving Aurora access to Lambda**

Before you can invoke Lambda functions from an Aurora MySQL DB cluster, make sure to first give your cluster permission to access Lambda.

**To give Aurora MySQL access to Lambda**

1. Create an AWS Identity and Access Management (IAM) policy that provides the permissions that allow your Aurora MySQL DB cluster to invoke Lambda functions. For instructions, see Creating an IAM policy to access AWS Lambda resources (p. 953).

2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access AWS Lambda resources (p. 953) to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956).

3. Set the `aws_default_lambda_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role.

   If the cluster is part of an Aurora global database, apply the same setting for each Aurora cluster in the global database.

   For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters (p. 337).

4. To permit database users in an Aurora MySQL DB cluster to invoke Lambda functions, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956) with the DB cluster. For information about associating an IAM role with a DB cluster, see Associating an IAM role with an Amazon Aurora MySQL DB cluster (p. 957).

   If the cluster is part of an Aurora global database, associate the role with each Aurora cluster in the global database.

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Lambda. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 961).

   If the cluster is part of an Aurora global database, enable outbound connections for each Aurora cluster in the global database.
Invoking a Lambda function with an Aurora MySQL native function

You can call the native functions `lambda_sync` and `lambda_async` when you use Aurora MySQL version 1.16 and later, Aurora MySQL 2.06 and later, or Aurora MySQL version 3.01 and higher. For more information about Aurora MySQL versions, see Database engine updates for Amazon Aurora MySQL (p. 1047).

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the native functions `lambda_sync` and `lambda_async`. This approach can be useful when you want to integrate your database running on Aurora MySQL with other AWS services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

Working with native functions to invoke a Lambda function

The `lambda_sync` and `lambda_async` functions are built-in, native functions that invoke a Lambda function synchronously or asynchronously. When you must know the result of the Lambda function before moving on to another action, use the synchronous function `lambda_sync`. When you don't need to know the result of the Lambda function before moving on to another action, use the asynchronous function `lambda_async`.

In Aurora MySQL version 3, the user invoking a native function must be granted the `AWS_LAMBDA_ACCESS` role. To grant this role to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT AWS_LAMBDA_ACCESS TO user@domain-or-ip-address
```

You can revoke this role by running the following statement.

```
REVOKE AWS_LAMBDA_ACCESS FROM user@domain-or-ip-address
```

Tip
When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 730). You can also find more details in Using Roles in the MySQL Reference Manual.

In Aurora MySQL version 1 and 2, the user invoking a native function must be granted the `INVOKE_LAMBDA` privilege. To grant this privilege to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT INVOKE LAMBDA ON *.* TO user@domain-or-ip-address
```

You can revoke this privilege by running the following statement.

```
REVOKE INVOKE LAMBDA ON *.* FROM user@domain-or-ip-address
```

Syntax for the `lambda_sync` function

You invoke the `lambda_sync` function synchronously with the `RequestResponse` invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```
lambda_sync()
```
You can use triggers to call Lambda on data-modifying statements. Remember that triggers are not run once per SQL statement, but once per row modified, one row at a time. When a trigger runs, the process is synchronous. The data-modifying statement only returns when the trigger completes.

Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. INSERT, UPDATE, and DELETE triggers are activated per row. A write-heavy workload on a table with INSERT, UPDATE, or DELETE triggers results in a large number of calls to your AWS Lambda function.

**Parameters for the `lambda_sync` function**

The `lambda_sync` function has the following parameters.

- `lambda_function_ARN`
  - The Amazon Resource Name (ARN) of the Lambda function to invoke.
- `JSON_payload`
  - The payload for the invoked Lambda function, in JSON format.

**Note**

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL versions 1 and 2 don't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

**Example for the `lambda_sync` function**

The following query based on `lambda_sync` invokes the Lambda function `BasicTestLambda` synchronously using the function ARN. The payload for the function is `{"operation": "ping"}`.

```sql
SELECT lambda_sync(
    'arn:aws:lambda:us-east-1:868710585169:function:BasicTestLambda',
    '"operation": "ping"');
```

**Syntax for the `lambda_async` function**

You invoke the `lambda_async` function asynchronously with the Event invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```
lambda_async (  
    lambda_function_ARN,  
    JSON_payload  
)
```

**Parameters for the `lambda_async` function**

The `lambda_async` function has the following parameters.

- `lambda_function_ARN`
  - The Amazon Resource Name (ARN) of the Lambda function to invoke.
- `JSON_payload`
  - The payload for the invoked Lambda function, in JSON format.
Note

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL versions 1 and 2 don't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

Example for the lambda_async function

The following query based on lambda_async invokes the Lambda function BasicTestLambda asynchronously using the function ARN. The payload for the function is {"operation": "ping"}.

```sql
SELECT lambda_async(
   'arn:aws:lambda:us-east-1:868710585169:function:BasicTestLambda',
   '{"operation": "ping"}');
```

Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated)

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the mysql.lambda_async procedure. This approach can be useful when you want to integrate your database running on Aurora MySQL with other AWS services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

Aurora MySQL version considerations

Starting in Aurora MySQL version 1.8 and Aurora MySQL version 2.06, you can use the native function method instead of these stored procedures to invoke a Lambda function. For more information about the native functions, see Working with native functions to invoke a Lambda function (p. 977).

Starting with Amazon Aurora version 1.16 and 2.06, the stored procedure mysql.lambda_async is no longer supported. If you are using an Aurora version that's higher than 1.16 or 2.06, we strongly recommend that you work with native Lambda functions instead. In Aurora MySQL version 3, the stored procedure isn't available.

Working with the mysql.lambda_async procedure to invoke a Lambda function (deprecated)

The mysql.lambda_async procedure is a built-in stored procedure that invokes a Lambda function asynchronously. To use this procedure, your database user must have EXECUTE privilege on the mysql.lambda_async stored procedure.

Syntax

The mysql.lambda_async procedure has the following syntax.

```sql
CALL mysql.lambda_async (  
   lambda_function_ARN,  
   lambda_function_input
)
```

Parameters

The mysql.lambda_async procedure has the following parameters.

`lambda_function_ARN`

The Amazon Resource Name (ARN) of the Lambda function to invoke.
**lambda_function_input**

The input string, in JSON format, for the invoked Lambda function.

**Examples**

As a best practice, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure that can be called from different sources such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier to invoke Lambda functions.

**Note**

Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. INSERT, UPDATE, and DELETE triggers are activated per row. A write-heavy workload on a table with INSERT, UPDATE, or DELETE triggers results in a large number of calls to your AWS Lambda function.

Although calls to the `mysql.lambda_async` procedure are asynchronous, triggers are synchronous. A statement that results in a large number of trigger activations doesn't wait for the call to the AWS Lambda function to complete, but it does wait for the triggers to complete before returning control to the client.

**Example Example: Invoke an AWS Lambda function to send email**

The following example creates a stored procedure that you can call in your database code to send an email using a Lambda function.

**AWS Lambda Function**

```python
import boto3

ses = boto3.client('ses')

def SES_send_email(event, context):
    return ses.send_email(
        Source=event['email_from'],
        Destination={
            'ToAddresses': [
                event['email_to'],
            ],
        },
        Message={
            'Subject': { 'Data': event['email_subject'] },
            'Body': { 'Text': { 'Data': event['email_body'] } },
        }
    )
```

**Stored Procedure**

```sql
DROP PROCEDURE IF EXISTS SES_send_email;
DELIMITER ;;
CREATE PROCEDURE SES_send_email(IN email_from VARCHAR(255),
                                 IN email_to VARCHAR(255),
                                 IN subject VARCHAR(255),
                                 IN body TEXT) LANGUAGE SQL
BEGIN
```
    CONCAT({"email_to" : ", email_to,
    "email_from" : ", email_from,
    "email_subject" : ", subject,
    ", email_body" : ", body, "'});
END
;
DELIMITER ;

Call the Stored Procedure to Invoke the AWS Lambda Function

mysql> call SES_send_email('example_from@amazon.com', 'example_to@amazon.com', 'Email subject', 'Email content');

Example Example: Invoke an AWS Lambda function to publish an event from a trigger

The following example creates a stored procedure that publishes an event by using Amazon SNS. The code calls the procedure from a trigger when a row is added to a table.

AWS Lambda Function

```python
import boto3
sns = boto3.client('sns')
def SNS_publish_message(event, context):
    return sns.publish(
        Message=event['message'],
        Subject=event['subject'],
        MessageStructure='string'
    )
```

Stored Procedure

```sql
DROP PROCEDURE IF EXISTS SNS_Publish_Message;
DELIMITER ;;
CREATE PROCEDURE SNS_Publish_Message (IN subject VARCHAR(255),
IN message TEXT) LANGUAGE SQL
BEGIN
        CONCAT({"subject" : "", subject,
        ", message" : "", message, " "}'))
END
;;
DELIMITER ;
```

Table

```sql
CREATE TABLE 'Customer_Feedback' (  
    'id' int(11) NOT NULL AUTO_INCREMENT,  
    'customer_name' varchar(255) NOT NULL,  
    'customer_feedback' varchar(1024) NOT NULL,  
    PRIMARY KEY ('id')
) ENGINE=InnoDB DEFAULT CHARSET=utf8;
```
Trigger

DELIMITER ;;
CREATE TRIGGER TR_Customer_Feedback_AI
AFTER INSERT ON Customer_Feedback
FOR EACH ROW
BEGIN
    SELECT CONCAT('New customer feedback from ', NEW.customer_name), NEW.customer_feedback
    INTO @subject, @feedback;
    CALL SNS_Publish_Message(@subject, @feedback);
END
;;
DELIMITER ;

Insert a Row into the Table to Trigger the Notification

mysql> insert into Customer_Feedback (customer_name, customer_feedback) VALUES ('Sample Customer', 'Good job guys!');

Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs

You can configure your Aurora MySQL DB cluster to publish general, slow, audit, and error log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

To publish logs to CloudWatch Logs, the respective logs must be enabled. Error logs are enabled by default, but you must enable the other types of logs explicitly. For information about enabling logs in MySQL, see Selecting general query and slow query log output destinations in the MySQL documentation. For more information about enabling Aurora MySQL audit logs, see Enabling Advanced Auditing (p. 881).

**Note**

Be aware of the following:

- You can't publish logs to CloudWatch Logs for the China (Ningxia) region.
- If exporting log data is disabled, Aurora doesn't delete existing log groups or log streams. If exporting log data is disabled, existing log data remains available in CloudWatch Logs, depending on log retention, and you still incur charges for stored audit log data. You can delete log streams and log groups using the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API.
- An alternative way to publish audit logs to CloudWatch Logs is by enabling advanced auditing and setting the cluster-level DB parameter server_audit_logs_upload to 1. The default for the server_audit_logs_upload parameter is 0.

If you use this alternative method, you must have an IAM role to access CloudWatch Logs and set the aws_default_logs_role cluster-level parameter to the ARN for this role. For information about creating the role, see Setting up IAM roles to access AWS services (p. 950). However, if you have the AWSServiceRoleForRDS service-linked role, it provides access to CloudWatch Logs and overrides any custom-defined roles. For information service-linked roles for Amazon RDS, see Using service-linked roles for Amazon Aurora (p. 1704).

- If you don't want to export audit logs to CloudWatch Logs, make sure that all methods of exporting audit logs are disabled. These methods are the AWS Management Console, the AWS CLI, the RDS API, and the server_audit_logs_upload parameter.
• The procedure is slightly different for Aurora Serverless clusters than for provisioned clusters. Serverless clusters automatically upload all the kinds of logs that you enable through the configuration parameters. Therefore, you enable or disable log upload for Serverless clusters by turning different log types on and off in the DB cluster parameter group. You don't modify the settings of the cluster itself through the AWS Management Console, AWS CLI, or RDS API. For information about enabling MySQL logs for Serverless clusters, see Parameter groups and Aurora Serverless v1 (p. 155).

Console

You can publish Aurora MySQL logs for provisioned clusters to CloudWatch Logs with the console.

To publish Aurora MySQL logs from the console
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Aurora MySQL DB cluster that you want to publish the log data for.
4. Choose Modify.
5. In the Log exports section, choose the logs that you want to start publishing to CloudWatch Logs.
6. Choose Continue, and then choose Modify DB Cluster on the summary page.

AWS CLI

You can publish Aurora MySQL logs for provisioned clusters with the AWS CLI. To do so, you run the modify-db-cluster AWS CLI command with the following options:

• --db-cluster-identifier—The DB cluster identifier.
• --cloudwatch-logs-export-configuration—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs by running one of the following AWS CLI commands:

• create-db-cluster
• restore-db-cluster-from-s3
• restore-db-cluster-from-snapshot
• restore-db-cluster-to-point-in-time

Run one of these AWS CLI commands with the following options:

• --db-cluster-identifier—The DB cluster identifier.
• --engine—The database engine.
• --enable-cloudwatch-logs-exports—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the AWS CLI command that you run.

Example

The following command modifies an existing Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:
aws rds modify-db-cluster \
   --db-cluster-identifier mydbcluster \
   --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["error","general","slowquery","audit"]}'

For Windows:

aws rds modify-db-cluster ^
   --db-cluster-identifier mydbcluster ^
   --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["error","general","slowquery","audit"]}'

Example

The following command creates an Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

aws rds create-db-cluster \
   --db-cluster-identifier mydbcluster \
   --engine aurora \
   --enable-cloudwatch-logs-exports '["error","general","slowquery","audit"]'

For Windows:

aws rds create-db-cluster ^
   --db-cluster-identifier mydbcluster ^
   --engine aurora ^
   --enable-cloudwatch-logs-exports '["error","general","slowquery","audit"]'

RDS API

You can publish Aurora MySQL logs for provisioned clusters with the RDS API. To do so, you run the ModifyDBCluster operation with the following options:

- `DBClusterIdentifier`—The DB cluster identifier.
- `CloudwatchLogsExportConfiguration`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs with the RDS API by running one of the following RDS API operations:

- `CreateDBCluster`
- `RestoreDBClusterFromS3`
- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`

Run the RDS API operation with the following parameters:

- `DBClusterIdentifier`—The DB cluster identifier.
• Engine—The database engine.
• EnableCloudwatchLogsExports—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the AWS CLI command that you run.

Monitoring log events in Amazon CloudWatch

After enabling Aurora MySQL log events, you can monitor the events in Amazon CloudWatch Logs. A new log group is automatically created for the Aurora DB cluster under the following prefix, in which cluster-name represents the DB cluster name, and log_type represents the log type.

/aws/rds/cluster/cluster-name/log_type

For example, if you configure the export function to include the slow query log for a DB cluster named mydbcluster, slow query data is stored in the /aws/rds/cluster/mydbcluster/slowquery log group.

The events from all instances in your cluster are pushed to a log group using different log streams. The behavior depends on which of the following conditions is true:

• A log group with the specified name exists.

  Aurora uses the existing log group to export log data for the cluster. To create log groups with predefined log retention periods, metric filters, and customer access, you can use automated configuration, such as AWS CloudFormation.

• A log group with the specified name doesn't exist.

  When a matching log entry is detected in the log file for the instance, Aurora MySQL creates a new log group in CloudWatch Logs automatically. The log group uses the default log retention period of Never Expire.

  To change the log retention period, use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information about changing log retention periods in CloudWatch Logs, see Change log data retention in CloudWatch Logs.

To search for information within the log events for a DB cluster, use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information about searching and filtering log data, see Searching and filtering log data.

Using machine learning (ML) with Aurora MySQL

With Aurora machine learning, you can add machine learning–based predictions to database applications using the SQL language. Aurora machine learning uses a highly optimized integration between the Aurora database and the AWS machine learning (ML) services SageMaker and Amazon Comprehend.

Benefits of Aurora machine learning include the following:

• You can add ML–based predictions to your existing database applications. You don't need to build custom integrations or learn separate tools. You can embed machine learning processing directly into your SQL query as calls to stored functions.

• The ML integration is a fast way to enable ML services to work with transactional data. You don't have to move the data out of the database to perform the machine learning operations. You don't have to convert or reimport the results of the machine learning operations to use them in your database application.
AWS ML Services are managed services that are set up and run in their own production environments. Currently, Aurora machine learning integrates with Amazon Comprehend for sentiment analysis and SageMaker for a wide variety of ML algorithms.

For details about using Aurora and Amazon Comprehend together, see Using Amazon Comprehend for sentiment detection (p. 994). For general information about Amazon Comprehend, see Amazon Comprehend.

For details about using Aurora and SageMaker together, see Using SageMaker to run your own ML models (p. 992). For general information about SageMaker, see SageMaker.

### Prerequisites for Aurora machine learning

Aurora machine learning is available for any Aurora cluster that's running an Aurora MySQL 2.07.0 or higher version in an AWS Region that supports Aurora machine learning. You can upgrade an Aurora cluster that's running a lower version of Aurora MySQL to a supported higher version if you want to use Aurora machine learning with that cluster. For more information, see Database engine updates for Amazon Aurora MySQL (p. 1047).

For more information about Regions and Aurora version availability, see Aurora machine learning (p. 23).

### Enabling Aurora machine learning

Enabling the ML capabilities involves the following steps:

- You enable the Aurora cluster to access the Amazon machine learning services SageMaker or Amazon Comprehend, depending the kinds of ML algorithms you want for your application.
- For SageMaker, then you use the Aurora `CREATE FUNCTION` statement to set up stored functions that access inference features.

**Note**

Aurora machine learning includes built-in functions that call Amazon Comprehend for sentiment analysis. You don't need to run any `CREATE FUNCTION` statements if you only use Amazon Comprehend.

### Topics

- Setting up IAM access to Amazon Comprehend and SageMaker (p. 987)
- Granting SQL privileges for invoking Aurora machine learning services (p. 991)
- Enabling network communication from Aurora MySQL to other AWS services (p. 991)
Setting up IAM access to Amazon Comprehend and SageMaker

Before you can access SageMaker and Amazon Comprehend services, enable the Aurora MySQL cluster to access AWS ML services. For your Aurora MySQL DB cluster to access AWS ML services on your behalf, create and configure AWS Identity and Access Management (IAM) roles. These roles authorize the users of your Aurora MySQL database to access AWS ML services.

When you use the AWS Management Console, AWS does the IAM setup for you automatically. You can skip the following information and follow the procedure in Connecting an Aurora DB cluster to Amazon S3, SageMaker, or Amazon Comprehend using the console (p. 987).

Setting up the IAM roles for SageMaker or Amazon Comprehend using the AWS CLI or the RDS API consists of the following steps:

1. Create an IAM policy to specify which SageMaker endpoints can be invoked by your Aurora MySQL cluster or to enable access to Amazon Comprehend.
2. Create an IAM role to permit your Aurora MySQL database cluster to access AWS ML services. The IAM policy created above is attached to the IAM role.
3. To permit the Aurora MySQL database cluster to access AWS ML services, you associate the IAM role that you created above to the database cluster.
4. To permit database applications to invoke AWS ML services, you must also grant privileges to specific database users. For SageMaker, because the calls to the endpoints are wrapped inside a stored function, you also grant EXECUTE privileges on the stored functions to any database users that call them.

For general information about how to permit your Aurora MySQL DB cluster to access other AWS services on your behalf, see Authorizing Amazon Aurora MySQL to access other AWS services on your behalf (p. 950).

Connecting an Aurora DB cluster to Amazon S3, SageMaker, or Amazon Comprehend using the console

Aurora machine learning requires that your DB cluster use some combination of Amazon S3, SageMaker, and Amazon Comprehend. Amazon Comprehend is for sentiment analysis. SageMaker is for a wide variety of machine learning algorithms. For Aurora machine learning, Amazon S3 is only for training SageMaker models. You only need to use Amazon S3 with Aurora machine learning if you don't already have a trained model available and the training is your responsibility. To connect a DB cluster to these services requires that you set up an AWS Identity and Access Management (IAM) role for each Amazon service. The IAM role enables users of your DB cluster to authenticate with the corresponding service.

To connect a IAM roles for Amazon S3, SageMaker, or Amazon Comprehend, repeat the following steps for each service that you need.

To connect a DB cluster to an Amazon service

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the Aurora MySQL DB cluster that you want to use.
3. Choose the Connectivity & security tab.
4. Choose Select a service to connect to this cluster in the Manage IAM roles section, and choose the service that you want to connect to:
   - Amazon S3
   - Amazon Comprehend
   - SageMaker
5. Choose **Connect service**.

6. Enter the required information for the specific service on the **Connect cluster** window:

   • For SageMaker, enter the Amazon Resource Name (ARN) of a SageMaker endpoint. For details about what the endpoint represents, see [Deploy a model on Amazon SageMaker hosting services](#).

     In the navigation pane of the **SageMaker console**, choose **Endpoints** and copy the ARN of the endpoint you want to use.

   • For Amazon Comprehend, don't specify any additional parameter.

   • For Amazon S3, enter the ARN of an Amazon S3 bucket to use.

     The format of an Amazon S3 bucket ARN is `arn:aws:s3:::<bucket_name>`. Ensure that the Amazon S3 bucket that you use is set up with the requirements for training SageMaker models. When you train a model, your Aurora DB cluster requires permission to export data to the Amazon S3 bucket, and also to import data from the bucket.

     To learn more about Amazon S3 bucket ARNs, see [Specifying resources in a policy](#) in the **Amazon Simple Storage Service User Guide**. For more about using an Amazon S3 bucket with SageMaker, see [Step 1: Create an Amazon Amazon S3 bucket](#) in the **Amazon SageMaker Developer Guide**.

7. Choose **Connect service**.

8. Aurora creates a new IAM role and adds it to the DB cluster's list of **Current IAM roles for this cluster**. The IAM role's status is initially **In progress**. The IAM role name is autogenerated with the following pattern for each connected service:

   • The Amazon S3 IAM role name pattern is `rds-cluster_ID-S3-policy-timestamp`.
   • The SageMaker IAM role name pattern is `rds-cluster_ID-SageMaker-policy-timestamp`.
   • The Amazon Comprehend IAM role name pattern is `rds-cluster_ID-Comprehend-policy-timestamp`.

Aurora also creates a new IAM policy and attaches it to the role. The policy name follows a similar naming convention and also has a timestamp.

**Creating an IAM policy to access SageMaker (AWS CLI only)**

**Note**
When you use the AWS Management Console, Aurora creates the IAM policy automatically. In that case, you can skip this section.

The following policy adds the permissions required by Aurora MySQL to invoke an SageMaker function on your behalf. You can specify all of your SageMaker endpoints that you need your database applications to access from your Aurora MySQL cluster in a single policy. The policy allows you to specify the AWS Region for an SageMaker endpoint. However, an Aurora MySQL cluster can only invoke SageMaker models deployed in the same AWS Region as the cluster.

```json
{"Version": "2012-10-17",
 "Statement": [
  {
    "Sid": "AllowAuroraToInvokeRCFEndPoint",
    "Effect": "Allow",
    "Action": "sagemaker:InvokeEndpoint",
    "Resource": "arn:aws:sagemaker:region:123456789012:endpoint/endpointName"
  }
]
}
```
The following command performs the same operation through the AWS CLI.

```bash
```

Creating an IAM policy to access Amazon Comprehend (AWS CLI only)

**Note**
When you use the AWS Management Console, Aurora creates the IAM policy automatically. In that case, you can skip this section.

The following policy adds the permissions required by Aurora MySQL to invoke Amazon Comprehend on your behalf.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAuroraToInvokeComprehendDetectSentiment",
      "Effect": "Allow",
      "Action": [
        "comprehend:DetectSentiment",
        "comprehend:BatchDetectSentiment"
      ],
      "Resource": "*"
    }
  ]
}
```

The following command performs the same operation through the AWS CLI.

```bash
aws iam put-role-policy --role-name role_name --policy-name policy_name --policy-document '{ "Version": "2012-10-17", "Statement": [ { "Sid": "AllowAuroraToInvokeComprehendDetectSentiment", "Effect": "Allow", "Action": [
  "comprehend:DetectSentiment",
  "comprehend:BatchDetectSentiment"
],
  "Resource": "*" } ]}
```

To create an IAM policy to grant access to Amazon Comprehend

1. Open the IAM Management Console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose Comprehend.
5. For Actions, choose Detect Sentiment and BatchDetectSentiment.
7. For Name, enter a name for your IAM policy. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.
8. Choose Create policy.
9. Complete the procedure in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956).

Creating an IAM role to access SageMaker and Amazon Comprehend

After you create the IAM policies, create an IAM role that the Aurora MySQL cluster can assume on behalf of your database users to access ML services. To create an IAM role, you can use the AWS Management
Console or the AWS CLI. To create an IAM role and attach the preceding policies to the role, follow the steps described in Creating an IAM role to allow Amazon Aurora to access AWS services (p. 956). For more information about IAM roles, see IAM roles in the AWS Identity and Access Management User Guide.

You can only use a global IAM role for authentication. You can't use an IAM role associated with a database user or a session. This requirement is the same as for Aurora integration with the Lambda and Amazon S3 services.

**Associating an IAM role with an Aurora MySQL DB cluster (AWS CLI only)**

**Note**
When you use the AWS Management Console, Aurora creates the IAM policy automatically. In that case, you can skip this section.

The last step is to associate the IAM role with the attached IAM policy with your Aurora MySQL DB cluster. To associate an IAM role with an Aurora DB cluster, you do two things:

1. Add the role to the list of associated roles for a DB cluster by using the AWS Management Console, the `add-role-to-db-cluster` AWS CLI command, or the AddRoleToDBCluster RDS API operation.
2. Set the cluster-level parameter for the related AWS ML service to the ARN for the associated IAM role. Use the `aws_default_sagemaker_role`, `aws_default_comprehend_role`, or both parameters depending on which AWS ML services you intend to use with your Aurora cluster.

Cluster-level parameters are grouped into DB cluster parameter groups. To set the preceding cluster parameters, use an existing custom DB cluster group or create a new one. To create a new DB cluster parameter group, call the `create-db-cluster-parameter-group` command from the AWS CLI, as shown following.

```
PROMPT> aws rds create-db-cluster-parameter-group  --db-cluster-parameter-group-name AllowAWSAccessToExternalServices  
   --db-parameter-group-family aurora-mysql5.7  --description "Allow access to Amazon S3, AWS Lambda, AWS SageMaker, and AWS Comprehend"
```

Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group, as shown in the following.

```
PROMPT> aws rds modify-db-cluster-parameter-group  
   --db-cluster-parameter-group-name AllowAWSAccessToExternalServices  
   --parameters  "ParameterName=aws_default_s3_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraS3Role,ApplyMethod=pending-reboot"  
   --parameters  "ParameterName=aws_default_sagemaker_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraSageMakerRole,ApplyMethod=pending-reboot"  
   --parameters  "ParameterName=aws_default_comprehend_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraComprehendRole,ApplyMethod=pending-reboot"
```

Modify the DB cluster to use the new DB cluster parameter group. Then, reboot the cluster. The following shows how.

```
PROMPT> aws rds modify-db-cluster --db-cluster-identifier your_cluster_id  
       --db-cluster-parameter-group-name AllowAWSAccessToExternalServices
PROMPT> aws rds failover-db-cluster --db-cluster-identifier your_cluster_id
```

When the instance has rebooted, your IAM roles are associated with your DB cluster.
Granting SQL privileges for invoking Aurora machine learning services

After you create the required IAM policies and roles and associating the role to the Aurora MySQL DB cluster, you authorize individual database users to invoke the Aurora machine learning stored functions for SageMaker and built-in functions for Amazon Comprehend.

The database user invoking a native function must be granted a corresponding role or privilege. For Aurora MySQL version 3, you grant the AWS_SAGEMAKER_ACCESS role or the AWS_COMPREHEND_ACCESS role. For Aurora MySQL version 1 or 2, you grant the INVOKE_SAGEMAKER or INVOKE_COMPREHEND privilege. To grant this privilege to a user, connect to the DB instance as the administrative user, and run the following statements. Substitute the appropriate details for the database user.

Use the following statements for Aurora MySQL version 3:

```
GRANT AWS_SAGEMAKER_ACCESS TO user@domain-or-ip-address
GRANT AWS_COMPREHEND_ACCESS TO user@domain-or-ip-address
```

**Tip**

When you use the role technique in Aurora MySQL version 3, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren’t familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model (p. 730). You can also find more details in Using Roles in the MySQL Reference Manual.

Use the following statements for Aurora MySQL version 1 or 2:

Use the following statements for Aurora MySQL version 3:

```
GRANT AWS_SAGEMAKER_ACCESS TO user@domain-or-ip-address
GRANT AWS_COMPREHEND_ACCESS TO user@domain-or-ip-address
```

Use the following statements for Aurora MySQL version 1 or 2:

```
GRANT INVOKE_SAGEMAKER ON *.* TO user@domain-or-ip-address
GRANT INVOKE_COMPREHEND ON *.* TO user@domain-or-ip-address
```

For SageMaker, user-defined functions define the parameters to be sent to the model for producing the inference and to configure the endpoint name to be invoked. You grant EXECUTE permission to the stored functions configured for SageMaker for each of the database users who intend to invoke the endpoint.

```
GRANT EXECUTE ON FUNCTION db1.anomaly_score TO user1@domain-or-ip-address1
GRANT EXECUTE ON FUNCTION db2.company_forecasts TO user2@domain-or-ip-address2
```

Enabling network communication from Aurora MySQL to other AWS services

Since SageMaker and Amazon Comprehend are external AWS services, you must also configure your Aurora DB cluster to allow outbound connections to the target AWS service. For more information, see Enabling network communication from Amazon Aurora MySQL to other AWS services (p. 961).

You can use VPC endpoints to connect to Amazon S3. AWS PrivateLink can't be used to connect Aurora to AWS machine learning services or Amazon S3 at this time.

Exporting data to Amazon S3 for SageMaker model training

Depending on how your team divides the machine learning tasks, you might not perform this task. If someone else provides the SageMaker model for you, you can skip this section.
To train SageMaker models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by a Jupyter SageMaker notebook instance to train your model before it is deployed. You can use the `SELECT INTO OUTFILE S3` statement to query data from an Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then the notebook instance consumes the data from the Amazon S3 bucket for training.

Aurora machine learning extends the existing `SELECT INTO OUTFILE` syntax in Aurora MySQL to export data to CSV format. The generated CSV file can be directly consumed by models that need this format for training purposes.

```sql
SELECT * INTO OUTFILE S3 's3_uri' [FORMAT {CSV|TEXT} [HEADER]] FROM table_name;
```

The extension supports the standard CSV format.

- Format `TEXT` is the same as the existing MySQL export format. This is the default format.
- Format `CSV` is a newly introduced format that follows the specification in RFC-4180.
- If you specify the optional keyword `HEADER`, the output file contains one header line. The labels in the header line correspond to the column names from the `SELECT` statement.
- You can still use the keywords `CSV` and `HEADER` as identifiers.

The extended syntax and grammar of `SELECT INTO` is now as follows:

```sql
INTO OUTFILE S3 's3_uri'
[CHARACTER SET charset_name]
[FORMAT {CSV|TEXT} [HEADER]]
[{FIELDS | COLUMNS}
[TERMINATED BY 'string']
[[OPTIONALLY] ENCLOSED BY 'char']
[ESCAPED BY 'char']
]
[LINES
[STARTING BY 'string']
[TERMINATED BY 'string']
]
```

**Using SageMaker to run your own ML models**

SageMaker is a fully managed machine learning service. With SageMaker, data scientists and developers can quickly and easily build and train machine learning models. Then they can directly deploy the models into a production-ready hosted environment. SageMaker provides an integrated Jupyter authoring notebook instance for easy access to your data sources. That way, you can perform exploration and analysis without managing the hardware infrastructure for servers. It also provides common machine learning algorithms that are optimized to run efficiently against extremely large datasets in a distributed environment. With native support for bring-your-own-algorithms and frameworks, SageMaker offers flexible distributed training options that adjust to your specific workflows.

Currently, Aurora machine learning supports any SageMaker endpoint that can read and write comma-separated value format, through a `ContentType` of `text/csv`. The built-in SageMaker algorithms that currently accept this format are Random Cut Forest, Linear Learner, 1P, XGBoost, and 3P. If the algorithms return multiple outputs per item, the Aurora machine learning function returns only the first item. This first item is expected to be a representative result.

Aurora machine learning always invokes SageMaker endpoints in the same AWS Region as your Aurora cluster. Therefore, for a single-region Aurora cluster, always deploy the model in the same AWS Region as your Aurora MySQL cluster.
If you are using an Aurora global database, you set up the same integration between the services for each AWS Region that's part of the global database. In particular, make sure the following conditions are satisfied for all AWS Regions in the global database:

- Configure the appropriate IAM roles for accessing external services such as SageMaker, Amazon Comprehend, or Lambda for the global database cluster in each AWS Region.
- Ensure that all AWS Regions have the same trained SageMaker models deployed with the same endpoint names. Do so before running the `CREATE FUNCTION` statement for your Aurora machine learning function in the primary AWS Region. In a global database, all `CREATE FUNCTION` statements you run in the primary AWS Region are immediately run in all the secondary regions also.

To use models deployed in SageMaker for inference, you create user-defined functions using the familiar MySQL data definition language (DDL) statements for stored functions. Each stored function represents the SageMaker endpoint hosting the model. When you define such a function, you specify the input parameters to the model, the specific SageMaker endpoint to invoke, and the return type. The function returns the inference computed by the SageMaker endpoint after applying the model to the input parameters. All Aurora machine learning stored functions return numeric types or `VARCHAR`. You can use any numeric type except `BIT`. Other types, such as `JSON`, `BLOB`, `TEXT`, and `DATE` are not allowed. Use model input parameters that are the same as the input parameters that you exported to Amazon S3 for model training.

```sql
CREATE FUNCTION function_name (arg1 type1, arg2 type2, ...) -- variable number of arguments
[DEFINER = user] -- same as existing MySQL
CREATE FUNCTION
RETURNS mysql_type -- For example, INTEGER, REAL, ...
[SQL SECURITY { DEFINER | INVOKER } ] -- same as existing MySQL
CREATE FUNCTION
ALIAS AWS_SAGEMAKER_INVOKE_ENDPOINT -- ALIAS replaces the stored function body. Only
AWS_SAGEMAKER_INVOKE_ENDPOINT is supported for now.
ENDPOINT NAME 'endpoint_name'
[MAX_BATCH_SIZE max_batch_size]; -- default is 10,000
```

This is a variation of the existing `CREATE FUNCTION` DDL statement. In the `CREATE FUNCTION` statement that defines the SageMaker function, you don't specify a function body. Instead, you specify the new keyword `ALIAS` where the function body usually goes. Currently, Aurora machine learning only supports `aws_sagemaker_invoke_endpoint` for this extended syntax. You must specify the `endpoint_name` parameter. The optional parameter `max_batch_size` restricts the maximum number of inputs processed in an actual batched request to SageMaker. An SageMaker endpoint can have different characteristics for each model. The `max_batch_size` parameter can help to avoid an error caused by inputs that are too large, or to make SageMaker return a response more quickly. The `max_batch_size` parameter affects the size of an internal buffer used for ML request processing. Specifying too large a value for `max_batch_size` might cause substantial memory overhead on your DB instance.

We recommend leaving the `MANIFEST` setting at its default value of `OFF`. Although you can use the `MANIFEST ON` option, some SageMaker features can't directly use the CSV exported with this option. The manifest format is not compatible with the expected manifest format from SageMaker.

You create a separate stored function for each of your SageMaker models. This mapping of functions to models is required because an endpoint is associated with a specific model, and each model accepts different parameters. Using SQL types for the model inputs and the model output type helps to avoid type conversion errors passing data back and forth between the AWS services. You can control who can apply the model. You can also control the runtime characteristics by specifying a parameter representing the maximum batch size.

Currently, all Aurora machine learning functions have the `NOT DETERMINISTIC` property. If you don't specify that property explicitly, Aurora sets `NOT DETERMINISTIC` automatically. This requirement is because the ML model can be changed without any notification to the database. If that happens, calls...
to an Aurora machine learning function might return different results for the same input within a single transaction.

You can’t use the characteristics CONTAINS SQL, NO SQL, READS SQL DATA, or MODIFIES SQL DATA in your CREATE FUNCTION statement.

Following is an example usage of invoking an SageMaker endpoint to detect anomalies. There is an SageMaker endpoint random-cut-forest-model. The corresponding model is already trained by the random-cut-forest algorithm. For each input, the model returns an anomaly score. This example shows the data points whose score is greater than 3 standard deviations (approximately the 99.9th percentile) from the mean score.

```sql
create function anomaly_score(value real) returns real
  alias aws_sagemaker_invoke_endpoint endpoint name 'random-cut-forest-model-demo';

set @score_cutoff = (select avg(anomaly_score(value)) + 3 * std(anomaly_score(value)) from nyc_taxi);

select *, anomaly_detection(value) score from nyc_taxi
  where anomaly_detection(value) > @score_cutoff;
```

**Character set requirement for SageMaker functions that return strings**

We recommend specifying a character set of utf8mb4 as the return type type for your SageMaker functions that return string values. If that isn't practical, use a large enough string length for the return type to hold a value represented in the utf8mb4 character set. The following example shows how to declare the utf8mb4 character set for your function.

```sql
CREATE FUNCTION my_ml_func(...) RETURNS VARCHAR(5) CHARSET utf8mb4 ALIAS ...
```

Currently, each SageMaker function that returns a string uses the character set utf8mb4 for the return value. The return value uses this character set even if your ML function declares a different character set for its return type implicitly or explicitly. If your ML function declares a different character set for the return value, the returned data might be silently truncated if you store it in a table column that isn't long enough. For example, a query with a DISTINCT clause creates a temporary table. Thus, the ML function result might be truncated due to the way strings are handled internally during a query.

**Using Amazon Comprehend for sentiment detection**

Amazon Comprehend uses machine learning to find insights and relationships in textual data. You can use this AWS machine learning service even if you don't have any machine learning experience or expertise. Aurora machine learning uses Amazon Comprehend for sentiment analysis of text that is stored in your database. For example, using Amazon Comprehend you can analyze contact center call-in documents to detect sentiment and better understand caller-agent dynamics. You can find a further description in the post Analyzing contact center calls on the AWS Machine Learning blog.

You can also combine sentiment analysis with analysis of other information in your database using a single query. For example, you can detect the average sentiment of call-in center documents for issues that combine the following:

- Open for more than 30 days.
- About a specific product or feature.
- Made by the customers who have the greatest social media influence.

Using Amazon Comprehend from Aurora machine learning is as easy as calling a SQL function. Aurora machine learning provides two built-in Amazon Comprehend functions, `aws_comprehend_detect_sentiment()` and
aws_comprehend_detect_sentiment_confidence() to perform sentiment analysis through Amazon Comprehend. For each text fragment that you analyze, these functions help you to determine the sentiment and the confidence level.

```sql
-- Returns one of 'POSITIVE', 'NEGATIVE', 'NEUTRAL', 'MIXED'
aws_comprehend_detect_sentiment(
    input_text
    ,language_code
    [,max_batch_size]  -- default is 25. should be greater than 0
)

-- Returns a double value that indicates confidence of the result of
aws_comprehend_detect_sentiment.
aws_comprehend_detect_sentiment_confidence(
    input_text
    ,language_code
    [,max_batch_size]  -- default is 25. should be greater than 0.
)
```

The max_batch_size helps you to tune the performance of the Amazon Comprehend function calls. A large batch size trades off faster performance for greater memory usage on the Aurora cluster. For more information, see Performance considerations for Aurora machine learning (p. 995).

For information about parameters and return types for the sentiment detection functions in Amazon Comprehend, see DetectSentiment

A typical Amazon Comprehend query looks for rows where the sentiment is a certain value, with a confidence level greater than a certain number. For example, the following query shows how you can determine the average sentiment of documents in your database. The query considers only documents where the confidence of the assessment is at least 80%.

```sql
SELECT AVG(CASE aws_comprehend_detect_sentiment(productTable.document, 'en')
    WHEN 'POSITIVE' THEN 1.0
    WHEN 'NEGATIVE' THEN -1.0
    ELSE 0.0 END) AS avg_sentiment, COUNT(*) AS total
FROM productTable
WHERE productTable.productCode = 1302 AND
    aws_comprehend_detect_sentiment_confidence(productTable.document, 'en') >= 0.80;
```

Note
Amazon Comprehend is currently available only in some AWS Regions. To check in which AWS Regions you can use Amazon Comprehend, see the AWS Region table page.

Performance considerations for Aurora machine learning
Most of the work in an Aurora machine learning function call happens within the external ML service. This separation enables you to scale the resources for the machine learning service independent of your Aurora cluster. Within Aurora, you mostly focus on making the function calls themselves as efficient as possible.

Query cache
The Aurora MySQL query cache doesn't work for ML functions. Aurora MySQL doesn't store query results in the query cache for any SQL statements that call ML functions.

Batch optimization for Aurora machine learning function calls
The main Aurora machine learning performance aspect that you can influence from your Aurora cluster is the batch mode setting for calls to the Aurora machine learning stored functions. Machine learning
functions typically require substantial overhead, making it impractical to call an external service separately for each row. Aurora machine learning can minimize this overhead by combining the calls to the external Aurora machine learning service for many rows into a single batch. Aurora machine learning receives the responses for all the input rows, and delivers the responses, one row at a time, to the query as it runs. This optimization improves the throughput and latency of your Aurora queries without changing the results.

When you create an Aurora stored function that's connected to an SageMaker endpoint, you define the batch size parameter. This parameter influences how many rows are transferred for every underlying call to SageMaker. For queries that process large numbers of rows, the overhead to make a separate SageMaker call for each row can be substantial. The larger the data set processed by the stored procedure, the larger you can make the batch size.

If the batch mode optimization can be applied to an SageMaker function, you can tell by checking the query plan produced by the `EXPLAIN PLAN` statement. In this case, the `extra` column in the execution plan includes `Batched machine learning`. The following example shows a call to an SageMaker function that uses batch mode.

```
mysql> create function anomaly_score(val real) returns real alias aws_sagemaker_invoke_endpoint endpoint name 'my-rcf-model-20191126';
Query OK, 0 rows affected (0.01 sec)
mysql> explain select timestamp, value, anomaly_score(value) from nyc_taxi;
+----+-------------+----------+------------+------+---------------+------+---------+------+
| id | select_type | table    | partitions | type | possible_keys | key  | key_len | ref  |
| rows | filtered | Extra |--------------------------|
| 1 | SIMPLE | nyc_taxi | NULL | ALL | NULL | NULL | NULL | NULL | 48 | 100.00 | Batched machine learning |
| 1 row in set, 1 warning (0.01 sec)
```

When you call one of the built-in Amazon Comprehend functions, you can control the batch size by specifying the optional `max_batch_size` parameter. This parameter restricts the maximum number of `input_text` values processed in each batch. By sending multiple items at once, it reduces the number of round trips between Aurora and Amazon Comprehend. Limiting the batch size is useful in situations such as a query with a `LIMIT` clause. By using a small value for `max_batch_size`, you can avoid invoking Amazon Comprehend more times than you have input texts.

The batch optimization for evaluating Aurora machine learning functions applies in the following cases:

- Function calls within the select list or the `WHERE` clause of `SELECT` statements. There are some exceptions, as described following.
- Function calls in the `VALUES` list of `INSERT` and `REPLACE` statements.
- ML functions in `SET` values in `UPDATE` statements.

```
INSERT INTO MY_TABLE (col1, col2, col3) VALUES
(ML_FUNC(1), ML_FUNC(2), ML_FUNC(3)),
(ML_FUNC(4), ML_FUNC(5), ML_FUNC(6));
UPDATE MY_TABLE SET col1 = ML_FUNC(col2), SET col3 = ML_FUNC(col4) WHERE ...;
```

### Monitoring Aurora machine learning

To monitor the performance of Aurora machine learning batch operations, Aurora MySQL includes several global variables that you can query as follows.
show status like 'Aurora_ml%';

You can reset these status variables by using a `FLUSH STATUS` statement. Thus, all of the figures represent totals, averages, and so on, since the last time the variable was reset.

**Aurora_ml_logical_response_cnt**

The aggregate response count that Aurora MySQL receives from the ML services across all queries run by users of the DB instance.

**Aurora_ml_actual_request_cnt**

The aggregate request count that Aurora MySQL receives from the ML services across all queries run by users of the DB instance.

**Aurora_ml_actual_response_cnt**

The aggregate response count that Aurora MySQL receives from the ML services across all queries run by users of the DB instance.

**Aurora_ml_cache_hit_cnt**

The aggregate internal cache hit count that Aurora MySQL receives from the ML services across all queries run by users of the DB instance.

**Aurora_ml_single_request_cnt**

The aggregate count of ML functions that are evaluated by non-batch mode across all queries run by users of the DB instance.

For information about monitoring the performance of the SageMaker operations called from Aurora machine learning functions, see [Monitor Amazon SageMaker](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-monitoring-sagemaker.html).

### Limitations of Aurora machine learning

The following limitations apply to Aurora machine learning.

You can't use an Aurora machine learning function for a generated-always column. The same limitation applies to any Aurora MySQL stored function. Functions aren't compatible with this binary log (binlog) format. For information about generated columns, see the MySQL documentation.

The setting `--binlog-format=STATEMENT` throws an exception for calls to Aurora machine learning functions. The reason for the error is that Aurora machine learning considers all ML functions to be nondeterministic, and nondeterministic stored functions aren't compatible with this binlog format. For information about this binlog format, see the MySQL documentation.

---

### Amazon Aurora MySQL lab mode

Aurora lab mode is used to enable Aurora features that are available in the current Aurora database version, but are not enabled by default. While Aurora lab mode features are not recommended for use in production DB clusters, you can use Aurora lab mode to enable these features for DB clusters in your development and test environments. For more information about Aurora features available when Aurora lab mode is enabled, see [Aurora lab mode features](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-lab-mode.html).

The `aurora_lab_mode` parameter is an instance-level parameter that is in the default parameter group. The parameter is set to 0 (disabled) in the default parameter group. To enable Aurora lab mode, create a custom parameter group, set the `aurora_lab_mode` parameter to 1 (enabled) in
the custom parameter group, and modify one or more DB instances in your Aurora cluster to use the custom parameter group. Then connect to the appropriate instance endpoint to try the lab mode features. For information on modifying a DB parameter group, see Modifying parameters in a DB parameter group (p. 343). For information on parameter groups and Amazon Aurora, see Aurora MySQL configuration parameters (p. 1007).

Aurora lab mode features

The following table lists the Aurora features currently available when Aurora lab mode is enabled. You must enable Aurora lab mode before any of these features can be used.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scan Batching</td>
<td>Aurora MySQL scan batching speeds up in-memory, scan-oriented queries significantly. The feature boosts the performance of table full scans, index full scans, and index range scans by batch processing.</td>
</tr>
<tr>
<td>Hash Joins</td>
<td>This feature can improve query performance when you need to join a large amount of data by using an equijoin. It requires lab mode in Aurora MySQL version 1. You can use this feature without lab mode in Aurora MySQL version 2. For more information about using this feature, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).</td>
</tr>
<tr>
<td>Fast DDL</td>
<td>This feature allows you to run an ALTER TABLE tbl_name ADD COLUMN col_name column_definition operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. Since it does not consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes. Fast DDL is currently only supported for adding a nullable column, without a default value, at the end of a table. For more information about using this feature, see Altering tables in Amazon Aurora using fast DDL (p. 798).</td>
</tr>
</tbody>
</table>

Best practices with Amazon Aurora MySQL

This topic includes information on best practices and options for using or migrating data to an Amazon Aurora MySQL DB cluster. The information in this topic summarizes and reiterates some of the guidelines and procedures that you can find in Managing an Amazon Aurora DB cluster (p. 363).

Contents

- Determining which DB instance you are connected to (p. 999)
- Best practices for using AWS features with Aurora MySQL (p. 999)
  - Using T instance classes for development and testing (p. 999)
Determining which DB instance you are connected to

To determine which DB instance in an Aurora MySQL DB cluster a connection is connected to, check the `innodb_read_only` global variable, as shown in the following example.

```
SHOW GLOBAL VARIABLES LIKE 'innodb_read_only';
```

The `innodb_read_only` variable is set to `ON` if you are connected to a reader DB instance. This setting is `OFF` if you are connected to a writer DB instance, such as primary instance in a provisioned cluster.

This approach can be helpful if you want to add logic to your application code to balance the workload or to ensure that a write operation is using the correct connection. This technique only applies to Aurora clusters using single-master replication. For multi-master clusters, all the DB instances have the setting `innodb_read_only=OFF`.

Best practices for using AWS features with Aurora MySQL

You can apply the following best practices to use Aurora MySQL in combination with AWS aspects such as instance classes and other AWS services.

Topics
- Using T instance classes for development and testing (p. 999)
- Invoking AWS Lambda functions using native functions (p. 1001)

Using T instance classes for development and testing

Amazon Aurora MySQL instances that use the `db.t2`, `db.t3`, or `db.t4g` DB instance classes are best suited for applications that do not support a high workload for an extended amount of time. The T instances are designed to provide moderate baseline performance and the capability to burst to significantly higher performance as required by your workload. They are intended for workloads that
don't use the full CPU often or consistently, but occasionally need to burst. We recommend only using the T DB instance classes for development and test servers, or other non-production servers. For more details on the T instance classes, see Burstable performance instances.

If your Aurora cluster is larger than 40 TB, don't use the T instance classes. When your database has a large volume of data, the memory overhead for managing schema objects can exceed the capacity of a T instance.

Don't enable the MySQL Performance Schema on Amazon Aurora MySQL T instances. If the Performance Schema is enabled, the instance might run out of memory.

When you use a T instance as a DB instance in an Aurora MySQL DB cluster, we recommend the following:

- If you use a T instance as a DB instance class in your DB cluster, use the same DB instance class for all instances in your DB cluster. For example, if you use db.t2.medium for your writer instance, then we recommend that you use db.t2.medium for your reader instances also.
- Don't adjust any memory-related configuration settings, such as innodb_buffer_pool_size. Aurora uses a highly tuned set of default values for memory buffers on T instances. These special defaults are needed for Aurora to run on memory-constrained instances. If you change any memory-related settings on a T instance, you are much more likely to encounter out-of-memory conditions, even if your change is intended to increase buffer sizes.
- Monitor your CPU Credit Balance (CPUCreditBalance) to ensure that it is at a sustainable level. That is, CPU credits are being accumulated at the same rate as they are being used.

When you have exhausted the CPU credits for an instance, you see an immediate drop in the available CPU and an increase in the read and write latency for the instance. This situation results in a severe decrease in the overall performance of the instance.

If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use a one of the supported R DB instance classes (scale compute).

For more information on monitoring metrics, see Monitoring Amazon Aurora metrics with Amazon CloudWatch (p. 628).

- For your Aurora MySQL DB clusters using single-master replication, monitor the replica lag (AuroraReplicaLag) between the writer instance and the reader instances.

If a reader instance runs out of CPU credits before the writer instance does, the resulting lag can cause the reader instance to restart frequently. This result is common when an application has a heavy load of read operations distributed among reader instances, at the same time that the writer instance has a minimal load of write operations.

If you see a sustained increase in replica lag, make sure that your CPU credit balance for the reader instances in your DB cluster is not being exhausted.

If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use one of the supported R DB instance classes (scale compute).

- Keep the number of inserts per transaction below 1 million for DB clusters that have binary logging enabled.

If the DB cluster parameter group for your DB cluster has the binlog_format parameter set to a value other than OFF, then your DB cluster might experience out-of-memory conditions if the DB cluster receives transactions that contain over 1 million rows to insert. You can monitor the freeable memory (FreeableMemory) metric to determine if your DB cluster is running out of available memory. You then check the write operations (VolumeWriteIOPS) metric to see if a writer instance is receiving a heavy load of write operations. If this is the case, then we recommend that you update your application to limit the number of inserts in a transaction to less than 1 million. Alternatively, you can modify your instance to use one of the supported R DB instance classes (scale compute).
Invoking AWS Lambda functions using native functions

If you are using Amazon Aurora version 1.16 or later, we recommend using the native functions `lambda_sync` and `lambda_async` to invoke Lambda functions.

If you are using the deprecated `mysql.lambda_async` procedure, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure. You can call this stored procedure from different sources, such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier for your database programmers to invoke Lambda functions.

For more information on invoking Lambda functions from Amazon Aurora, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 975).

Best practices for Aurora MySQL performance and scaling

You can apply the following best practices to improve the performance and scalability of your Aurora MySQL clusters.

Topics

- Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001)
- Optimizing large Aurora MySQL join queries with hash joins (p. 1003)
- Using Amazon Aurora to scale reads for your MySQL database (p. 1005)

Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch

Note

The asynchronous key prefetch (AKP) feature is available for Amazon Aurora MySQL version 1.15 and later. For more information about Aurora MySQL versions, see Database engine updates for Amazon Aurora MySQL (p. 1047).

Amazon Aurora can use AKP to improve the performance of queries that join tables across indexes. This feature improves performance by anticipating the rows needed to run queries in which a JOIN query requires use of the Batched Key Access (BKA) Join algorithm and Multi-Range Read (MRR) optimization features. For more information about BKA and MRR, see Block nested-loop and batched key access joins and Multi-range read optimization in the MySQL documentation.

To take advantage of the AKP feature, a query must use both BKA and MRR. Typically, such a query occurs when the JOIN clause of a query uses a secondary index, but also needs some columns from the primary index. For example, you can use AKP when a JOIN clause represents an equijoin on index values between a small outer and large inner table, and the index is highly selective on the larger table. AKP works in concert with BKA and MRR to perform a secondary to primary index lookup during the evaluation of the JOIN clause. AKP identifies the rows required to run the query during the evaluation of the JOIN clause. It then uses a background thread to asynchronously load the pages containing those rows into memory before running the query.

Enabling asynchronous key prefetch

You can enable the AKP feature by setting `aurora_use_key_prefetch`, a MySQL server variable, to `on`. By default, this value is set to `on`. However, AKP cannot be enabled until you also enable the BKA Join algorithm and disable cost-based MRR functionality. To do so, you must set the following values for `optimizer_switch`, a MySQL server variable:
- Set `batched_key_access` to on. This value controls the use of the BKA Join algorithm. By default, this value is set to off.
- Set `mrr_cost_based` to off. This value controls the use of cost-based MRR functionality. By default, this value is set to on.

Currently, you can set these values only at the session level. The following example illustrates how to set these values to enable AKP for the current session by executing SET statements.

```
mysql> set @@session.aurora_use_key_prefetch=on;
mysql> set @@session.optimizer_switch='batched_key_access=on,mrr_cost_based=off';
```

Similarly, you can use SET statements to disable AKP and the BKA Join algorithm and re-enable cost-based MRR functionality for the current session, as shown in the following example.

```
mysql> set @@session.aurora_use_key_prefetch=off;
mysql> set @@session.optimizer_switch='batched_key_access=off,mrr_cost_based=on';
```

For more information about the `batched_key_access` and `mrr_cost_based` optimizer switches, see Switchable optimizations in the MySQL documentation.

### Optimizing queries for asynchronous key prefetch

You can confirm whether a query can take advantage of the AKP feature. To do so, use the EXPLAIN statement with the EXTENDED keyword to profile the query before running it. The EXPLAIN statement provides information about the execution plan to use for a specified query.

In the output for the EXPLAIN statement, the `Extra` column describes additional information included with the execution plan. If the AKP feature applies to a table used in the query, this column includes one of the following values:

- Using Key Prefetching
- Using join buffer (Batched Key Access with Key Prefetching)

The following example shows use of EXPLAIN with EXTENDED to view the execution plan for a query that can take advantage of AKP.

```
mysql> explain extended select sql_no_cache
   ->     ps_partkey,
   ->     sum(ps_supplycost * ps_availqty) as value
   -> from
   ->     partsupp,
   ->     supplier,
   ->     nation
   -> where
   ->     ps_suppkey = s_suppkey
   ->     and s_nationkey = n_nationkey
   ->     and n_name = 'ETHIOPIA'
   -> group by
   ->     ps_partkey having
   ->     sum(ps_supplycost * ps_availqty) > (select
   ->       sum(ps_supplycost * ps_availqty) * 0.0000003333
   ->     from
   ->     partsupp,
   ->     supplier,
```
Optimizing large Aurora MySQL join queries with hash joins

When you need to join a large amount of data by using an equijoin, a hash join can improve query performance. You can enable hash joins for Aurora MySQL.

A hash join column can be any complex expression. In a hash join column, you can compare across data types in the following ways:

- You can compare anything across the category of precise numeric data types, such as `int`, `bigint`, `numeric`, and `bit`.
- You can compare anything across the category of approximate numeric data types, such as `float` and `double`.
- You can compare items across string types if the string types have the same character set and collation.
- You can compare items with date and timestamp data types if the types are the same.

**Note**
Data types in different categories cannot compare.
The following restrictions apply to hash joins for Aurora MySQL:

- Left-right outer joins are not supported.
- Semijoins such as subqueries are not supported, unless the subqueries are materialized first.
- Multiple-table updates or deletes are not supported.

**Note**

Single-table updates or deletes are supported.

- BLOB and spatial data type columns cannot be join columns in a hash join.

### Enabling hash joins

To enable hash joins, set the MySQL server variable `optimizer_switch` to `hash_join=on` (Aurora MySQL version 1 and 2) or `block_nested_loop=on` (Aurora MySQL version 3). Hash joins are turned on by default in Aurora MySQL version 3. This optimization is turned off by default in Aurora MySQL version 1 and 2. The following example illustrates how to enable hash joins. You can issue the statement `select @@optimizer_switch` first to see what other settings are present in the `SET` parameter string. Updating one setting in the `optimizer_switch` parameter doesn't erase or modify the other settings.

For Aurora MySQL version 1 and 2:
```sql
mysql> SET optimizer_switch='hash_join=on';
```

For Aurora MySQL version 3:
```sql
mysql> SET optimizer_switch='block_nested_loop=on';
```

With this setting, the optimizer chooses to use a hash join based on cost, query characteristics, and resource availability. If the cost estimation is incorrect, you can force the optimizer to choose a hash join. You do so by setting `hash_join_cost_based`, a MySQL server variable, to `off`. The following example illustrates how to force the optimizer to choose a hash join.

```sql
mysql> SET optimizer_switch='hash_join_cost_based=off';
```

**Note**

For Aurora MySQL version 3, hash join support is available in all minor versions and is turned on by default.

For Aurora MySQL version 2, hash join support is available in version 2.06 and higher. In Aurora MySQL version 2, the hash join feature is always controlled by the `optimizer_switch` value. Prior to Aurora MySQL version 1.22, the way to enable hash joins in Aurora MySQL version 1 is by enabling the `aurora_lab_mode` session-level setting. In those Aurora MySQL versions, the `optimizer_switch` setting for hash joins is enabled by default and you only need to enable `aurora_lab_mode`.

### Optimizing queries for hash joins

To find out whether a query can take advantage of a hash join, use the `EXPLAIN` statement to profile the query first. The `EXPLAIN` statement provides information about the execution plan to use for a specified query.

In the output for the `EXPLAIN` statement, the `Extra` column describes additional information included with the execution plan. If a hash join applies to the tables used in the query, this column includes values similar to the following:

- Using where; Using join buffer (Hash Join Outer table table1_name)
• Using where; Using join buffer (Hash Join Inner table `table2_name`)

The following example shows the use of EXPLAIN to view the execution plan for a hash join query.

```sql
mysql> explain SELECT sql_no_cache * FROM hj_small, hj_big, hj_big2
    -> WHERE hj_small.col1 = hj_big.col1 and hj_big.col1=hj_big2.col1 ORDER BY 1;
```

<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>hj_small</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>6</td>
<td>Using temporary; Using filesort</td>
</tr>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>hj_big</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>10</td>
<td>Using where; Using join buffer (Hash Join Outer table hj_big)</td>
</tr>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>hj_big2</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>15</td>
<td>Using where; Using join buffer (Hash Join Inner table hj_big2)</td>
</tr>
</tbody>
</table>

3 rows in set (0.04 sec)

In the output, the `Hash Join Inner table` is the table used to build hash table, and the `Hash Join Outer table` is the table that is used to probe the hash table.

For more information about the extended EXPLAIN output format, see Extended EXPLAIN output format in the MySQL product documentation.

In Aurora MySQL 2.08 and higher, you can use SQL hints to influence whether a query uses hash join or not, and which tables to use for the build and probe sides of the join. For details, see Aurora MySQL hints (p. 1038).

## Using Amazon Aurora to scale reads for your MySQL database

You can use Amazon Aurora with your MySQL DB instance to take advantage of the read scaling capabilities of Amazon Aurora and expand the read workload for your MySQL DB instance. To use Aurora to read scale your MySQL DB instance, create an Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance. Then connect to the Aurora MySQL cluster to process the read queries. The source database can be an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS. For more information, see Using Amazon Aurora to scale reads for your MySQL database (p. 911).

## Best practices for Aurora MySQL high availability

You can apply the following best practices to improve the availability of your Aurora MySQL clusters.

Topics

- Using Amazon Aurora for Disaster Recovery with your MySQL databases (p. 1005)
- Migrating from MySQL to Amazon Aurora MySQL with reduced downtime (p. 1006)

## Using Amazon Aurora for Disaster Recovery with your MySQL databases

You can use Amazon Aurora with your MySQL DB instance to create an offsite backup for disaster recovery. To use Aurora for disaster recovery of your MySQL DB instance, create an Amazon Aurora DB
cluster and make it a read replica of your MySQL DB instance. This applies to an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS.

**Important**
When you set up replication between a MySQL DB instance and an Amazon Aurora MySQL DB cluster, you should monitor the replication to ensure that it remains healthy and repair it if necessary.

For instructions on how to create an Amazon Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance, follow the procedure in Using Amazon Aurora to scale reads for your MySQL database (p. 1005).

**Migrating from MySQL to Amazon Aurora MySQL with reduced downtime**

When importing data from a MySQL database that supports a live application to an Amazon Aurora MySQL DB cluster, you might want to reduce the time that service is interrupted while you migrate. To do so, you can use the procedure documented in Importing data to a MySQL or MariaDB DB instance with reduced downtime in the Amazon Relational Database Service User Guide. This procedure can especially help if you are working with a very large database. You can use the procedure to reduce the cost of the import by minimizing the amount of data that is passed across the network to AWS.

The procedure lists steps to transfer a copy of your database data to an Amazon EC2 instance and import the data into a new RDS for MySQL DB instance. Because Amazon Aurora is compatible with MySQL, you can instead use an Amazon Aurora DB cluster for the target Amazon RDS MySQL DB instance.

**Best practices for limiting certain MySQL features with Aurora MySQL**

The following features are available in Aurora MySQL for MySQL compatibility. However, they have performance, scalability, or stability issues in the Aurora environment. Thus, we recommend that you limit your use of these features. For example, we recommend that you don't use certain features for production Aurora deployments.

**Topics**
- Using multithreaded replication in Aurora MySQL version 3 (p. 1006)
- Avoiding XA transactions with Amazon Aurora MySQL (p. 1007)
- Keeping foreign keys turned on during DML statements (p. 1007)

**Using multithreaded replication in Aurora MySQL version 3**

By default, Aurora uses single-threaded replication when an Aurora MySQL DB cluster is used as a read replica for binary log replication.

Although Aurora MySQL doesn't prohibit multithreaded replication, this feature is only supported in Aurora MySQL version 3 and higher.

Aurora MySQL version 1 and 2 inherited several issues regarding multithreaded replication from MySQL. For those versions, we recommend that you don't use multithreaded replication in production.

If you do use multithreaded replication, we recommend that you test any use thoroughly.

For more information about using replication in Amazon Aurora, see Replication with Amazon Aurora (p. 69). For information about multithreaded replication in Aurora MySQL version 3, see Multithreaded binary log replication (Aurora MySQL version 3 and higher) (p. 914).
Avoiding XA transactions with Amazon Aurora MySQL

We recommend that you don't use eXtended Architecture (XA) transactions with Aurora MySQL, because they can cause long recovery times if the XA was in the PREPARED state. If you must use XA transactions with Aurora MySQL, follow these best practices:

- Don't leave an XA transaction open in the PREPARED state.
- Keep XA transactions as small as possible.

For more information about using XA transactions with MySQL, see XA transactions in the MySQL documentation.

Keeping foreign keys turned on during DML statements

We strongly recommend that you don't run any data definition language (DDL) statements when the foreign_key_checks variable is set to 0 (off).

If you need to insert or update rows that require a transient violation of foreign keys, follow these steps:

1. Set foreign_key_checks to 0.
2. Make your data manipulation language (DML) changes.
3. Make sure that your completed changes don't violate any foreign key constraints.
4. Set foreign_key_checks to 1 (on).

In addition, follow these other best practices for foreign key constraints:

- Make sure that your client applications don't set the foreign_key_checks variable to 0 as a part of the init_connect variable.
- If a restore from a logical backup such as mysqldump fails or is incomplete, make sure that foreign_key_checks is set to 1 before starting any other operations in the same session. A logical backup sets foreign_key_checks to 0 when it starts.

Amazon Aurora MySQL reference

This reference includes information about Aurora MySQL parameters, status variables, and general SQL extensions or differences from the community MySQL database engine.

Topics

- Aurora MySQL configuration parameters (p. 1007)
- MySQL parameters that don't apply to Aurora MySQL (p. 1025)
- MySQL status variables that don't apply to Aurora MySQL (p. 1026)
- Aurora MySQL wait events (p. 1027)
- Aurora MySQL thread states (p. 1031)
- Aurora MySQL isolation levels (p. 1034)
- Aurora MySQL hints (p. 1038)
- Aurora MySQL stored procedures (p. 1040)

Aurora MySQL configuration parameters
You manage your Amazon Aurora MySQL DB cluster in the same way that you manage other Amazon RDS DB instances, by using parameters in a DB parameter group. Amazon Aurora differs from other DB engines in that you have a DB cluster that contains multiple DB instances. As a result, some of the parameters that you use to manage your Aurora MySQL DB cluster apply to the entire cluster. Other parameters apply only to a particular DB instance in the DB cluster.

To manage cluster-level parameters, you use DB cluster parameter groups. To manage instance-level parameters, you use DB parameter groups. Each DB instance in an Aurora MySQL DB cluster is compatible with the MySQL database engine. However, you apply some of the MySQL database engine parameters at the cluster level, and you manage these parameters using DB cluster parameter groups. You can't find cluster-level parameters in the DB parameter group for an instance in an Aurora DB cluster. A list of cluster-level parameters appears later in this topic.

You can manage both cluster-level and instance-level parameters using the AWS Management Console, the AWS CLI, or the Amazon RDS API. You use separate commands for managing cluster-level parameters and instance-level parameters. For example, you can use the modify-db-cluster-parameter-group CLI command to manage cluster-level parameters in a DB cluster parameter group. You can use the modify-db-parameter-group CLI command to manage instance-level parameters in a DB parameter group for a DB instance in a DB cluster.

You can view both cluster-level and instance-level parameters in the console, or by using the CLI or RDS API. For example, you can use the describe-db-cluster-parameters AWS CLI command to view cluster-level parameters in a DB cluster parameter group. You can use the describe-db-parameters CLI command to view instance-level parameters in a DB parameter group for a DB instance in a DB cluster.

Note

Each default parameter group (p. 335) contains the default values for all parameters in the parameter group. If the parameter has "engine default" for this value, see the version-specific MySQL or PostgreSQL documentation for the actual default value.

For more information on DB parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 335). For rules and restrictions for Aurora Serverless clusters, see Parameter groups and Aurora Serverless v1 (p. 155).

Topics

- Cluster-level parameters (p. 1008)
- Instance-level parameters (p. 1014)

Cluster-level parameters

The following table shows all of the parameters that apply to the entire Aurora MySQL DB cluster.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Modifiable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>aurora_binlog_read_buffer_size</td>
<td>Yes</td>
<td>Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 897). Removed from Aurora MySQL version 3.</td>
</tr>
<tr>
<td>aurora_binlog_replication_max_yield_seconds</td>
<td>Yes</td>
<td>Only affects clusters that use binary log (binlog) replication. For information about binlog replication, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication) (p. 897).</td>

#### Instance-level parameters

The following table shows all of the parameters that apply to a specific DB instance in an Aurora MySQL DB cluster.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Modifiable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>activate_all_roles_on_login</td>
<td>Yes</td>
<td>This parameter applies to Aurora MySQL version 3 and higher.</td>
</tr>
<tr>
<td>allow-suspicious-udfs</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>aurora_lab_mode</td>
<td>Yes</td>
<td>For more information, see <a href="https://aws.amazon.com/en_us/service/documentation/amazon-aurora/mysql/index.html#aurora-lab-mode">Amazon Aurora MySQL lab mode (p. 997)</a> Removed from Aurora MySQL version 3.</td>
</tr>
<tr>
<td>aurora_oom_response</td>
<td>Yes</td>
<td>This parameter only applies to Aurora MySQL version 1.18 and higher. It isn't used in Aurora MySQL version 2 or 3. For more information, see <a href="https://aws.amazon.com/en_us/service/documentation/amazon-aurora/mysql/index.html#aurora-oom-response">Amazon Aurora MySQL out of memory issues (p. 1738)</a></td>
</tr>
<tr>
<td>aurora_parallel_query</td>
<td>Yes</td>
<td>Set to <strong>ON</strong> to turn on parallel query in Aurora MySQL versions 1.23 and 2.09 or higher. The old aurora_pq parameter isn't used in these versions. For more information, see <a href="https://aws.amazon.com/en_us/service/documentation/amazon-aurora/mysql/index.html#aurora-parallel-query">Working with parallel query for Amazon Aurora MySQL (p. 847)</a></td>
</tr>
<tr>
<td>aurora_pq</td>
<td>Yes</td>
<td>Set to <strong>OFF</strong> to turn off parallel query for specific DB instances in Aurora MySQL versions before 1.23 and 2.09. In 1.23 and 2.09 or higher, turn parallel query on and off with aurora_parallel_query instead. For more information, see <a href="https://aws.amazon.com/en_us/service/documentation/amazon-aurora/mysql/index.html#aurora-pq">Working with parallel query for Amazon Aurora MySQL (p. 847)</a></td>

### MySQL parameters that don't apply to Aurora MySQL

Because of architectural differences between Aurora MySQL and MySQL, some MySQL parameters don't apply to Aurora MySQL.

The following MySQL parameters don't apply to Aurora MySQL. This list is not exhaustive.

- `activate_all_roles_on_login`. This parameter isn't applicable to Aurora MySQL version 1 and 2. It is available in Aurora MySQL version 3.
- `big_tables`
- `bind_address`
MySQL status variables that don't apply to Aurora MySQL

Because of architectural differences between Aurora MySQL and MySQL, some MySQL status variables don't apply to Aurora MySQL.

The following MySQL status variables don't apply to Aurora MySQL. This list is not exhaustive.

- `innodb_buffer_pool_bytes_dirty`
- `innodb_buffer_pool_pages_dirty`
- `innodb_buffer_pool_pages_flushed`

Aurora MySQL version 3 removes the following status variables that were in Aurora MySQL version 2:

- `AuroraDb_lockmgr_bitmaps0_in_use`
Aurora MySQL wait events

These MySQL status variables are available in Aurora MySQL version 1 or 2, but they aren't available in Aurora MySQL version 3:

- Innodb_redo_log_enabled
- Innodb_undo_tablespaces_total
- Innodb_undo_tablespaces_implicit
- Innodb_undo_tablespaces_explicit
- Innodb_undo_tablespaces_active

**Aurora MySQL wait events**

The following are some common wait events for Aurora MySQL.

**Note**

For information about the naming conventions used in MySQL wait events, see Performance Schema Instrument naming conventions in the MySQL documentation.
**cpu**

The number of active connections that are ready to run is consistently higher than the number of vCPUs. For more information, see cpu (p. 807).

**io/aurora_redo_log_flush**

A session is persisting data to Aurora storage. Typically, this wait event is for a write I/O operation in Aurora MySQL. For more information, see io/aurora_redo_log_flush (p. 810).

**io/aurora_respond_to_client**

Query processing has completed and results are being returned to the application client for the following Aurora MySQL versions: 2.10.2 and higher 2.10 versions, 2.09.3 and higher 2.09 versions, 2.07.7 and higher 2.07 versions, and 1.22.6 and higher 1.22 versions. Compare the network bandwidth of the DB instance class with the size of the result set being returned. Also, check client-side response times. If the client is unresponsive and can't process the TCP packets, packet drops and TCP retransmissions can occur. This situation negatively affects network bandwidth. In versions lower than 2.10.2, 2.09.3, 2.07.7, and 1.22.6, the wait event erroneously includes idle time. To learn how to tune your database when this wait is prominent, see io/aurora_respond_to_client (p. 813).

**io/file/csv/data**

Threads are writing to tables in comma-separated value (CSV) format. Check your CSV table usage. A typical cause of this event is setting log_output on a table.

**io/file/innodb/innodb_data_file**

Threads are waiting on I/O from storage. This event is more prevalent in I/O-intensive workloads. When this wait event is prevalent, SQL statements might be running disk-intensive queries or requesting data that can't be satisfied from the InnoDB buffer pool. For more information, see io/file/innodb/innodb_data_file (p. 815).

**io/file/sql/binlog**

A thread is waiting on a binary log (binlog) file that is being written to disk.

**io/socket/sql/client_connection**

The mysqld program is busy creating threads to handle incoming new client connections. For more information, see io/socket/sql/client_connection (p. 817).

**io/table/sql/handler**

The engine is waiting for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. For more information, see io/table/sql/handler (p. 819).

**lock/table/sql/handler**

This wait event is a table lock wait event handler. For more information about atom and molecule events in the Performance Schema, see Performance Schema atom and molecule events in the MySQL documentation.

**synch/cond/mysys/my_thread_var::suspend**

The thread is suspended while waiting on a table-level lock because another thread issued LOCK TABLES ... READ.

**synch/cond/sql/MDL_context::COND_wait_status**

Threads are waiting on a table metadata lock. The engine uses this type of lock to manage concurrent access to a database schema and to ensure data consistency. For more information, see Optimizing locking operations in the MySQL documentation. To learn how to tune your database when this event is prominent, see synch/cond/sql/MDL_context::COND_wait_status (p. 824).
You have turned on binary logging. There might be a high commit throughput, large number transactions committing, or replicas reading binlogs. Consider using mutlirow statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication, or use the `aurora_binlog_*` parameters.

Multiple data manipulation language (DML) statements are accessing the same database rows at the same time. For more information, see `synch/mutex/innodb/aurora_lock_thread_slot_futex` (p. 830).

The buffer pool isn’t large enough to hold the working data set. Or the workload accesses pages from a specific table, which leads to contention in the buffer pool. For more information, see `synch/mutex/innodb/buf_pool_mutex` (p. 832).

The process is waiting for access to the tablespace memory cache. For more information, see `synch/mutex/innodb/fil_system_mutex` (p. 834).

This event is part of an event semaphore. It provides exclusive access to variables used for signaling between threads. Uses include statistics threads, full-text search, buffer pool dump and load operations, and log flushes. This wait event is specific to Aurora MySQL version 1. For more information, see `synch/mutex/innodb/trx_sys_mutex` (p. 837).

The `keycache->cache_lock` mutex controls access to the key cache for MyISAM tables. In Aurora MySQL, this wait event is related to temporary table usage. Check the size of the `key_buffer_size`. Also check the values for `created_tmp_tables` or `created_tmp_disk_tables` at the time of the wait event spike. When it’s justified, use multiple key caches.

The engine acquires this mutex when opening or creating a table metadata file. When this wait event occurs with excessive frequency, the number of tables being created or opened has spiked.

The engine acquires this mutex while performing operations such as `reset_size`, `detach_contents`, or `add_contents` on the internal structure that keeps track of opened tables. The mutex synchronizes access to the list contents. When this wait event occurs with high frequency, it indicates a sudden change in the set of tables that were previously accessed. The engine needs to access new tables or let go of the context related to previously accessed tables.

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches.
**synch/mutex/sql/LOCK_table_cache**

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches.

**synch/mutex/sql/LOG**

In this wait event, there are threads waiting on a log lock. For example, a thread might wait for a lock to write to the slow query log file.

**synch/mutex/sql/MYSQL_BIN_LOG::LOCK_commit**

In this wait event, there is a thread that is waiting to acquire a lock with the intention of committing to the binary log. Binary logging contention can occur on databases with a very high change rate. Depending on your version of MySQL, there are certain locks being used to protect the consistency and durability of the binary log. In RDS for MySQL, binary logs are used for replication and the automated backup process. In Aurora MySQL, binary logs are not needed for native replication or backups. They are disabled by default but can be enabled and used for external replication or change data capture. For more information, see The binary log in the MySQL documentation.

**sync/mutex/sql/MYSQL_BIN_LOG::LOCK_dump_thread_metrics_collection**

If binary logging is turned on, the engine acquires this mutex when it prints active dump threads metrics to the engine error log and to the internal operations map.

**sync/mutex/sql/MYSQL_BIN_LOG::LOCK_inactive_binlogs_map**

If binary logging is turned on, the engine acquires this mutex when it adds to, deletes from, or searches through the list of binlog files behind the latest one.

**sync/mutex/sql/MYSQL_BIN_LOG::LOCK_io_cache**

If binary logging is turned on, the engine acquires this mutex during Aurora binlog IO cache operations: allocate, resize, free, write, read, purge, and access cache info. If this event occurs frequently, the engine is accessing the cache where binlog events are stored. To reduce wait times, reduce commits. Try grouping multiple statements into a single transaction.

**synch/mutex/sql/MYSQL_BIN_LOG::LOCK_log**

You have turned on binary logging. There might be high commit throughput, many transactions committing, or replicas reading binlogs. Consider using multirow statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication or use the `aurora_binlog_*` parameters.

**sync/mutex/sql/SERVER_THREAD::LOCK_sync**

The mutex `SERVER_THREAD::LOCK_sync` is acquired during the scheduling, processing, or launching of threads for file writes. The excessive occurrence of this wait event indicates increased write activity in the database.

**sync/mutex/sql/TABLESPACES:lock**

The engine acquires the `TABLESPACES:lock` mutex during the following tablespace operations: create, delete, truncate, and extend. The excessive occurrence of this wait event indicates a high frequency of tablespace operations. An example is loading a large amount of data into the database.

**synch/rwlock/innodb/dict**

In this wait event, there are threads waiting on an rwlock held on the InnoDB data dictionary.

**synch/rwlock/innodb/dict_operation_lock**

In this wait event, there are threads holding locks on InnoDB data dictionary operations.

**synch/rwlock/innodb/dict sys RW lock**

A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.
Aurora MySQL thread states

The following are some common thread states for Aurora MySQL.

checking permissions

The thread is checking whether the server has the required privileges to run the statement.

checking query cache for query

The server is checking whether the current query is present in the query cache.

cleaned up

This is the final state of a connection whose work is complete but which hasn't been closed by the client. The best solution is to explicitly close the connection in code. Or you can set a lower value for wait_timeout in your parameter group.

closing tables

The thread is flushing the changed table data to disk and closing the used tables. If this isn't a fast operation, verify the network bandwidth consumption metrics against the instance class network bandwidth. Also, check that the parameter values for table_open_cache and table_definition_cache parameter allow for enough tables to be simultaneously open so that the engine doesn't need to open and close tables frequently. These parameters influence the memory consumption on the instance.
converting HEAP to MyISAM

The query is converting a temporary table from in-memory to on-disk. This conversion is necessary because the temporary tables created by MySQL in the intermediate steps of query processing grew too big for memory. Check the values of `tmp_table_size` and `max_heap_table_size`. In later versions, this thread state name is converting HEAP to ondisk.

converting HEAP to ondisk

The thread is converting an internal temporary table from an in-memory table to an on-disk table.

copy to tmp table

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it. For a thread in this state, you can use the Performance Schema to obtain information about the progress of the copy operation.

creating sort index

Aurora MySQL is performing a sort because it can't use an existing index to satisfy the `ORDER BY` or `GROUP BY` clause of a query. For more information, see creating sort index (p. 842).

creating table

The thread is creating a permanent or temporary table.

delayed commit ok done

An asynchronous commit in Aurora MySQL has received an acknowledgement and is complete.

delayed commit ok initiated

The Aurora MySQL thread has started the async commit process but is waiting for acknowledgement. This is usually the genuine commit time of a transaction.

delayed send ok done

An Aurora MySQL worker thread that is tied to a connection can be freed while a response is sent to the client. The thread can begin other work. The state `delayed send ok` means that the asynchronous acknowledgement to the client completed.

delayed send ok initiated

An Aurora MySQL worker thread has sent a response asynchronously to a client and is now free to do work for other connections. The transaction has started an async commit process that hasn't yet been acknowledged.

executing

The thread has begun running a statement.

freeing items

The thread has run a command. Some freeing of items done during this state involves the query cache. This state is usually followed by cleaning up.

init

This state occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions in this state include flushing the binary log or InnoDB log, and some cleanup of the query cache.

master has sent all binlog to slave

The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

opening tables

The thread is trying to open a table. This operation is fast unless an `ALTER TABLE` or a `LOCK TABLE` statement needs to finish, or it exceeds the value of `table_open_cache`. 
optimizing

The server is performing initial optimizations for a query.

preparing

This state occurs during query optimization.

query end

This state occurs after processing a query but before the freeing items state.

removing duplicates

Aurora MySQL couldn't optimize a DISTINCT operation in the early stage of a query. Aurora MySQL must remove all duplicated rows before sending the result to the client.

searching rows for update

The thread is finding all matching rows before updating them. This stage is necessary if the UPDATE is changing the index that the engine uses to find the rows.

sending binlog event to slave

The thread read an event from the binary log and is sending it to the replica.

sending cached result to client

The server is taking the result of a query from the query cache and sending it to the client.

sending data

The thread is reading and processing rows for a SELECT statement but hasn't yet started sending data to the client. The process is identifying which pages contain the results necessary to satisfy the query. For more information, see sending data (p. 845).

sending to client

The server is writing a packet to the client. In earlier MySQL versions, this wait event was labeled writing to net.

starting

This is the first stage at the beginning of statement execution.

statistics

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound while performing other work.

storing result in query cache

The server is storing the result of a query in the query cache.

system lock

The thread has called mysql_lock_tables, but the thread state hasn't been updated since the call. This general state occurs for many reasons.

update

The thread is preparing to start updating the table.

updating

The thread is searching for rows and is updating them.

user lock

The thread issued a GET_LOCK call. The thread either requested an advisory lock and is waiting for it, or is planning to request it.
waiting for more updates

The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

waiting for schema metadata lock

This is a wait for a metadata lock.

waiting for stored function metadata lock

This is a wait for a metadata lock.

waiting for stored procedure metadata lock

This is a wait for a metadata lock.

waiting for table flush

The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables. Or the thread received notification that the underlying structure for a table changed, so it must reopen the table to get the new structure. To reopen the table, the thread must wait until all other threads have closed the table. This notification takes place if another thread has used one of the following statements on the table: `FLUSH TABLES`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

waiting for table level lock

One session is holding a lock on a table while another session tries to acquire the same lock on the same table.

waiting for table metadata lock

Aurora MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. In this wait event, one session is holding a metadata lock on a table while another session tries to acquire the same lock on the same table. When the Performance Schema is enabled, this thread state is reported as the wait event `synch/cond/sql/MDL_context::COND_wait_status`.

writing to net

The server is writing a packet to the network. In later MySQL versions, this wait event is labeled `Sending to client`.

Aurora MySQL isolation levels

Following, you can learn how DB instances in an Aurora MySQL cluster implement the database property of isolation. Doing so helps you understand how the Aurora MySQL default behavior balances between strict consistency and high performance. You can also decide when to change the default settings based on the characteristics of your workload.

Available isolation levels for writer instances

You can use the isolation levels `REPEATABLE READ`, `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE` on the primary instance of an Aurora MySQL single-master cluster. You can use the isolation levels `REPEATABLE READ`, `READ COMMITTED`, and `READ UNCOMMITTED` on any DB instance in an Aurora MySQL multi-master cluster. These isolation levels work the same in Aurora MySQL as in RDS for MySQL.

REPEATABLE READ isolation level for reader instances

By default, Aurora MySQL DB instances configured as read-only Aurora Replicas always use the `REPEATABLE READ` isolation level. These DB instances ignore any `SET TRANSACTION ISOLATION LEVEL` statements and continue using the `REPEATABLE READ` isolation level.
READ COMMITTED isolation level for reader instances

If your application includes a write-intensive workload on the primary instance and long-running queries on the Aurora Replicas, you might experience substantial purge lag. Purge lag happens when internal garbage collection is blocked by long-running queries. The symptom that you see is a high value for history list length in output from the SHOW ENGINE INNODB STATUS command. You can monitor this value using the RollbackSegmentHistoryListLength metric in CloudWatch. This condition can reduce the effectiveness of secondary indexes and lead to reduced overall query performance and wasted storage space.

If you experience such issues, you can use an Aurora MySQL session-level configuration setting, aurora_read_replica_read_committed, to use the READ COMMITTED isolation level on Aurora Replicas. Using this setting can help reduce slowdowns and wasted space that can result from performing long-running queries at the same time as transactions that modify your tables.

We recommend making sure that you understand the specific Aurora MySQL behavior of the READ COMMITTED isolation before using this setting. The Aurora Replica READ COMMITTED behavior complies with the ANSI SQL standard. However, the isolation is less strict than typical MySQL READ COMMITTED behavior that you might be familiar with. Thus, you might see different query results under READ COMMITTED on an Aurora MySQL read replica than for the same query under READ COMMITTED on the Aurora MySQL primary instance or on RDS for MySQL. You might use the aurora_read_replica_read_committed setting for such use cases as a comprehensive report that scans a very large database. You might avoid it for short queries with small result sets, where precision and repeatability are important.

The READ COMMITTED isolation level isn't available for sessions within a secondary cluster in an Aurora global database that use the write forwarding feature. For information about write forwarding, see Using write forwarding in an Amazon Aurora global database (p. 253).

Enabling READ COMMITTED for readers

To enable the READ COMMITTED isolation level for Aurora Replicas, enable the aurora_read_replica_read_committed configuration setting. Enable this setting at the session level while connected a specific Aurora Replica. To do so, run the following SQL commands.

```
set session aurora_read_replica_read_committed = ON;
set session transaction isolation level read committed;
```

You might enable this configuration setting temporarily to perform interactive ad hoc (one-time) queries. You might also want to run a reporting or data analysis application that benefits from the READ COMMITTED isolation level, while leaving the default unchanged for other applications.

When the aurora_read_replica_read_committed setting is enabled, use the SET TRANSACTION ISOLATION LEVEL command to specify the isolation level for the appropriate transactions.

```
set transaction isolation level read committed;
```

Differences in READ COMMITTED behavior on Aurora replicas

The aurora_read_replica_read_committed setting makes the READ COMMITTED isolation level available for an Aurora Replica, with consistency behavior that is optimized for long-running transactions. The READ COMMITTED isolation level on Aurora Replicas has less strict isolation than on Aurora primary instances or multi-master instances. For that reason, enable this setting only on Aurora Replicas where you know that your queries can accept the possibility of certain types of inconsistent results.

Your queries can experience certain kinds of read anomalies when the aurora_read_replica_read_committed setting is turned on. Two kinds of anomalies are especially
important to understand and handle in your application code. A *non-repeatable read* occurs when another transaction commits while your query is running. A long-running query can see different data at the start of the query than it sees at the end. A *phantom read* occurs when other transactions cause existing rows to be reorganized while your query is running, and one or more rows are read twice by your query.

Your queries might experience inconsistent row counts as a result of phantom reads. Your queries might also return incomplete or inconsistent results due to non-repeatable reads. For example, suppose that a join operation refers to tables that are concurrently modified by SQL statements such as `INSERT` or `DELETE`. In this case, the join query might read a row from one table but not the corresponding row from another table.

The ANSI SQL standard allows both of these behaviors for the `READ COMMITTED` isolation level. However, those behaviors are different than the typical MySQL implementation of `READ COMMITTED`. Thus, before enabling the `aurora_read_replica_read_committed` setting, check any existing SQL code to verify if it operates as expected under the looser consistency model.

Row counts and other results might not be strongly consistent under the `READ COMMITTED` isolation level while this setting is enabled. Thus, you typically enable the setting only while running analytic queries that aggregate large amounts of data and don't require absolute precision. If you don't have these kinds of long-running queries alongside a write-intensive workload, you probably don't need the `aurora_read_replica_read_committed` setting. Without the combination of long-running queries and a write-intensive workload, you're unlikely to encounter issues with the length of the history list.

**Example Queries showing isolation behavior for READ COMMITTED on Aurora replicas**

The following example shows how `READ COMMITTED` queries on an Aurora Replica might return non-repeatable results if transactions modify the associated tables at the same time. The table `BIG_TABLE` contains 1 million rows before any queries start. Other data manipulation language (DML) statements add, remove, or change rows while the are running.

The queries on the Aurora primary instance under the `READ COMMITTED` isolation level produce predictable results. However, the overhead of keeping the consistent read view for the lifetime of every long-running query can lead to expensive garbage collection later.

The queries on the Aurora Replica under the `READ COMMITTED` isolation level are optimized to minimize this garbage collection overhead. The tradeoff is that the results might vary depending on whether the queries retrieve rows that are added, removed, or reorganized by transactions that commit while the query is running. The queries are allowed to consider these rows but aren't required to. For demonstration purposes, the queries check only the number of rows in the table by using the `COUNT(*)` function.

<tr>
<td>T11</td>
<td></td>
<td>Q5: SELECT COUNT(<em>) FROM parent_table p JOIN child_table c ON (p.id = c.id) WHERE p.id = 1000; Q6: SELECT COUNT(</em>) FROM parent_table p JOIN child_table c ON (p.id = c.id) WHERE p.id = 1000;</td>
<td></td>
</tr>
<tr>
<td>T12</td>
<td>INSERT INTO parent_table (id, s) VALUES (1000, 'hello'); INSERT INTO child_table (id, s) VALUES (1000, 'world'); COMMIT;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>T13</td>
<td></td>
<td>If Q5 finishes now, result is 0.</td>
<td>If Q6 finishes now, result is 0 or 1.</td>
</tr>
</tbody>
</table>

If the queries finish quickly, before any other transactions perform DML statements and commit, the results are predictable and the same between the primary instance and the Aurora Replica.
The results for Q1 are highly predictable, because READ COMMITTED on the primary instance uses a strong consistency model similar to the REPEATABLE READ isolation level.

The results for Q2 might vary depending on what transactions commit while that query is running. For example, suppose that other transactions perform DML statements and commit while the queries are running. In this case, the query on the Aurora Replica with the READ COMMITTED isolation level might or might not take the changes into account. The row counts are not predictable in the same way as under the REPEATABLE READ isolation level. They also aren't as predictable as queries running under the READ COMMITTED isolation level on the primary instance, or on an RDS for MySQL instance.

The UPDATE statement at T7 doesn't actually change the number of rows in the table. However, by changing the length of a variable-length column, this statement can cause rows to be reorganized internally. A long-running READ COMMITTED transaction might see the old version of a row, and later within the same query see the new version of the same row. The query can also skip both the old and new versions of the row. Thus, the row count might be different than expected.

The results of Q5 and Q6 might be identical or slightly different. Query Q6 on the Aurora Replica under READ COMMITTED is able to see, but is not required to see, the new rows that are committed while the query is running. It might also see the row from one table but not from the other table. If the join query doesn't find a matching row in both tables, it returns a count of zero. If the query does find both the new rows in PARENT_TABLE and CHILD_TABLE, the query returns a count of one. In a long-running query, the lookups from the joined tables might happen at widely separated times.

**Note**
These differences in behavior depend on the timing of when transactions are committed and when the queries process the underlying table rows. Thus, you're most likely to see such differences in report queries that take minutes or hours and that run on Aurora clusters processing OLTP transactions at the same time. These are the kinds of mixed workloads that benefit the most from the READ COMMITTED isolation level on Aurora Replicas.

### Aurora MySQL hints

You can use SQL hints with Aurora MySQL queries to fine-tune performance. You can also use hints to prevent execution plans for important queries to change based on unpredictable conditions.

**Tip**
To verify the effect that a hint has on a query, examine the query plan produced by the EXPLAIN statement. Compare the query plans with and without the hint.

In Aurora MySQL version 3, you can use all the hints that are available in community MySQL 8.0. For details about these hints, see Optimizer Hints in the MySQL Reference Manual.

The following hints are available in Aurora MySQL 2.08 and higher. These hints apply to queries that use the hash join feature in Aurora MySQL version 2, especially queries that use the parallel query optimization.

**HASH_JOIN, NO_HASH_JOIN**

Turns on or off the ability of the optimizer to choose whether to use the hash join optimization method for a query. HASH_JOIN enables the optimizer to use hash join if that mechanism is more efficient. NO_HASH_JOIN prevents the optimizer from using hash join for the query. This hint is available in Aurora MySQL 2.08 and higher minor versions. It has no effect in Aurora MySQL version 3.

The following examples show how to use this hint.

```sql
EXPLAIN SELECT/*+ HASH_JOIN(t2) */ f1, f2 FROM t1, t2 WHERE t1.f1 = t2.f1;
```
EXPLAIN SELECT /*+ NO_HASH_JOIN(t2) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

**HASH_JOIN_PROBING, NO_HASH_JOIN_PROBING**

In a hash join query, specifies whether or not to use the specified table for the probe side of the join. The query tests whether column values from the build table exist in the probe table, instead of reading the entire contents of the probe table. You can use HASH_JOIN_PROBING and HASH_JOIN_BUILDING to specify how hash join queries are processed without reordering the tables within the query text. This hint is available in Aurora MySQL 2.08 and higher minor versions. It has no effect in Aurora MySQL version 3.

The following examples show how to use this hint. Specifying the HASH_JOIN_PROBING hint for the table T2 has the same effect as specifying NO_HASH_JOIN_PROBING for the table T1.

EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_PROBING(t2) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ HASH_JOIN(t2) NO_HASH_JOIN_PROBING(t1) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

**HASH_JOIN_BUILDING, NO_HASH_JOIN_BUILDING**

In a hash join query, specifies whether or not to use the specified table for the build side of the join. The query processes all the rows from this table to build the list of column values to cross-reference with the other table. You can use HASH_JOIN_PROBING and HASH_JOIN_BUILDING to specify how hash join queries are processed without reordering the tables within the query text. This hint is available in Aurora MySQL 2.08 and higher minor versions. It has no effect in Aurora MySQL version 3.

The following examples show how to use this hint. Specifying the HASH_JOIN_BUILDING hint for the table T2 has the same effect as specifying NO_HASH_JOIN_BUILDING for the table T1.

EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_BUILDING(t2) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ HASH_JOIN(t2) NO_HASH_JOIN_BUILDING(t1) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

**JOIN_FIXED_ORDER**

Specifies that tables in the query are joined based on the order they are listed in the query. It is especially useful with queries involving three or more tables. It is intended as a replacement for the MySQL STRAIGHT_JOIN hint. Equivalent to the MySQL JOIN_FIXED_ORDER hint. This hint is available in Aurora MySQL 2.08 and higher.

The following examples show how to use this hint.

EXPLAIN SELECT /*+ JOIN_FIXED_ORDER */ f1, f2
FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
The following examples show how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_ORDER (t4, t2, t1, t3) */ f1, f2
    FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

**JOIN_PREFIX**

Specifies the tables to put first in the join order. It is especially useful with queries involving three or more tables. Equivalent to the MySQL JOIN_PREFIX hint. This hint is available in Aurora MySQL 2.08 and higher.

The following examples show how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_ORDER (t4, t2) */ f1, f2
    FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

**JOIN_SUFFIX**

Specifies the tables to put last in the join order. It is especially useful with queries involving three or more tables. Equivalent to the MySQL JOIN_SUFFIX hint. This hint is available in Aurora MySQL 2.08 and higher.

The following examples show how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_ORDER (t1, t3) */ f1, f2
    FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

For information about using hash join queries, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).

### Aurora MySQL stored procedures

You can call the following stored procedures while connected to the primary instance in an Aurora MySQL cluster. These procedures control how transactions are replicated from an external database into Aurora MySQL, or from Aurora MySQL to an external database. To learn how to use replication based on global transaction identifiers (GTIDs) with Aurora MySQL, see Using GTID-based replication for Aurora MySQL (p. 920).

**Topics**

- mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3 and higher) (p. 1040)
- mysql.rds_set_master_auto_position (Aurora MySQL version 1 and 2) (p. 1042)
- mysql.rds_set_source_auto_position (Aurora MySQL version 3 and higher) (p. 1042)
- mysql.rds_set_source_auto_position (Aurora MySQL version 3 and higher) (p. 1042)
- mysql.rds_set_external_master_with_auto_position (Aurora MySQL version 1 and 2) (p. 1043)
- mysql.rds_set_external_source_with_auto_position (Aurora MySQL version 3 and higher) (p. 1045)
- mysql.rds_skip_transaction_with_gtid (p. 1046)

mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3 and higher)
**Syntax**

```sql
CALL mysql.rds_assign_gtids_to_anonymous_transactions( gtid_option );
```

**Parameters**

*gtid_option*

String value. The allowed values are OFF, LOCAL, or a specified UUID.

**Usage notes**

This procedure has the same effect as issuing the statement `CHANGE REPLICATION SOURCE TO ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = gtid_option` in community MySQL.

GTID must be turned to ON for *gtid_option* to be set to LOCAL or a specific UUID.

The default is OFF, meaning that the feature is not used.

LOCAL assigns a GTID including the replica's own UUID (the `server_uuid` setting).

Passing a parameter that is a UUID assigns a GTID that includes the specified UUID, such as the `server_uuid` setting for the replication source server.

**Examples**

To turn off this feature:

```sql
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('OFF');
+-------------------------------------------------------------+
| Message           |
+-------------------------------------------------------------+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: OFF |
+-------------------------------------------------------------+
1 row in set (0.07 sec)
```

To use the replica's own UUID:

```sql
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('LOCAL');
+---------------------------------------------------------------+
| Message |                                                  |
+---------------------------------------------------------------+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: LOCAL |
+---------------------------------------------------------------+
1 row in set (0.07 sec)
```

To use a specified UUID:

```sql
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('317a4760-f3dd-3b74-8e45-0615ed29de0e');
+---------------------------------------------------------------+
| Message |                                                  |
+---------------------------------------------------------------+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: 317a4760-f3dd-3b74-8e45-0615ed29de0e |
```
**mysql.rds_set_master_auto_position (Aurora MySQL version 1 and 2)**

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

**Syntax**

```sql
CALL mysql.rds_set_master_auto_position (auto_position_mode);
```

**mysql.rds_set_source_auto_position (Aurora MySQL version 3 and higher)**

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

**Syntax**

```sql
CALL mysql.rds_set_source_auto_position (auto_position_mode);
```

**Parameters**

- `auto_position_mode`
  
  A value that indicates whether to use log file position replication or GTID-based replication:
  - 0 – Use the replication method based on binary log file position. The default is 0.
  - 1 – Use the GTID-based replication method.

**Usage notes**

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance. The master user must run the `mysql.rds_set_master_auto_position` procedure.

For Aurora, this procedure is supported for Aurora MySQL version 2.04 and later MySQL 5.7-compatible versions. GTID-based replication isn't supported for Aurora MySQL 1.1 or 1.0.
Stored procedures

Parameters

auto_position_mode

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The administrative user must run the mysql.rds_set_source_auto_position procedure.

For Aurora, this procedure is supported for Aurora MySQL version 2.04 and later MySQL 5.7-compatible versions. GTID-based replication isn't supported for Aurora MySQL 1.1 or 1.0.

mysql.rds_set_external_master_with_auto_position (Aurora MySQL version 1 and 2)

Configures an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs).

This procedure is available for both RDS for MySQL and Aurora MySQL. It works differently depending on the context. When used with Aurora MySQL, this procedure doesn't configure delayed replication. This limitation is because RDS for MySQL supports delayed replication but Aurora MySQL doesn't.

Syntax

CALL mysql.rds_set_external_master_with_auto_position (host_name, host_port, replication_user_name, replication_user_password, ssl_encryption);

Parameters

host_name

The host name or IP address of the MySQL instance running external to Aurora to become the replication master.

host_port

The port used by the MySQL instance running external to Aurora to be configured as the replication master. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.
replication_user_password

The password of the user ID specified in replication_user_name.

ssl_encryption

This option is not currently implemented. The default is 0.

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The master user must run the mysql.rds_set_external_master_with_auto_position procedure. The master user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.

For Aurora, this procedure is supported for Aurora MySQL version 2.04 and later MySQL 5.7-compatible versions. GTID-based replication isn’t supported for Aurora MySQL 1.1 or 1.0. For Aurora MySQL version 3, use the procedure mysql.rds_set_external_source_with_auto_position instead.

Before you run mysql.rds_set_external_master_with_auto_position, configure the external MySQL DB instance to be a replication master. To connect to the external MySQL instance, specify values for replication_user_name and replication_user_password. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external MySQL instance.

To configure an external MySQL instance as a replication master

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.

CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'

2. On the external MySQL instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'

When you call mysql.rds_set_external_master_with_auto_position, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the mysql.rds_history and mysql.rds_replication_status tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the mysql.rds_skip_transaction_with_gtid stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Aurora MySQL.

Examples

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

call mysql.rds_set_external_master_with_auto_position('Externaldb.some.com', 3306)
The procedure is used to configure an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs). This procedure is available for both RDS for MySQL and Aurora MySQL. It works differently depending on the context. When used with Aurora MySQL, this procedure doesn't configure delayed replication. This limitation is because RDS for MySQL supports delayed replication but Aurora MySQL doesn't.

### Syntax

```sql
CALL mysql.rds_set_external_source_with_auto_position (host_name, host_port, replication_user_name, replication_user_password, ssl_encryption);
```

### Parameters

- **host_name**
  
  The host name or IP address of the MySQL instance running external to Aurora to become the replication source.

- **host_port**
  
  The port used by the MySQL instance running external to Aurora to be configured as the replication source. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

- **replication_user_name**
  
  The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.

- **replication_user_password**
  
  The password of the user ID specified in `replication_user_name`.

- **ssl_encryption**
  
  This option is not currently implemented. The default is 0.

### Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance. The administrative user must run the `mysql.rds_set_external_source_with_auto_position` procedure. The administrative user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.
For Aurora, this procedure is supported for Aurora MySQL version 2.04 and later MySQL 5.7-compatible versions. It's also supported for Aurora MySQL version 3. GTID-based replication isn't supported for Aurora MySQL 1.1 or 1.0.

Before you run `mysql.rds_set_external_source_with_auto_position`, configure the external MySQL DB instance to be a replication source. To connect to the external MySQL instance, specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external MySQL instance.

To configure an external MySQL instance as a replication source

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external MySQL instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the `repl_user` user for your domain.

   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

When you call `mysql.rds_set_external_source_with_auto_position`, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for Aurora MySQL (p. 920).

Examples

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

```sql
CALL mysql.rds_set_external_source_with_auto_position(    'Externaldb.some.com',    3306,    'repl_user'@'mydomain.com',    'SomePassW0rd');
```

`mysql.rds_skip_transaction_with_gtid`

Skips replication of a transaction with the specified global transaction identifier (GTID) on an Aurora primary instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

Syntax

```sql
CALL mysql.rds_skip_transaction_with_gtid (gtid_to_skip);
```
Parameters

\texttt{gtid\_to\_skip}

The GTID of the replication transaction to skip.

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance. The master user must run the \texttt{mysql.rds\_skip\_transaction\_with\_gtid} procedure.

For Aurora, this procedure is supported for Aurora MySQL version 2.04 and later MySQL 5.7-compatible versions. It's also supported for Aurora MySQL version 3. GTID-based replication isn't supported for Aurora MySQL 1.1 or 1.0.

Database engine updates for Amazon Aurora MySQL

Amazon Aurora releases updates regularly. Updates are applied to Aurora DB clusters during system maintenance windows. The timing when updates are applied depends on the region and maintenance window setting for the DB cluster, as well as the type of update.

Updates are applied to all instances in a DB cluster at the same time. An update requires a database restart on all instances in a DB cluster, so you experience 20 to 30 seconds of downtime, after which you can resume using your DB cluster or clusters. You can view or change your maintenance window settings from the AWS Management Console.

Following, you can learn how to choose the right Aurora MySQL version for your cluster, how to specify the version when you create or upgrade a cluster, and the procedures to upgrade a cluster from one version to another with minimal interruption.

Topics

- Aurora MySQL version numbers and special versions (p. 1047)
- Upgrading Amazon Aurora MySQL DB clusters (p. 1050)
- Database engine updates for Amazon Aurora MySQL version 3 (p. 1070)
- Database engine updates for Amazon Aurora MySQL version 2 (p. 1071)
- Database engine updates for Amazon Aurora MySQL version 1 (p. 1148)
- Database engine updates for Aurora MySQL Serverless clusters (p. 1200)
- MySQL bugs fixed by Aurora MySQL database engine updates (p. 1203)
- Security vulnerabilities fixed in Amazon Aurora MySQL (p. 1223)

Aurora MySQL version numbers and special versions

Although Aurora MySQL-Compatible Edition is compatible with the MySQL database engines, Aurora MySQL includes features and bug fixes that are specific to particular Aurora MySQL versions. Application developers can check the Aurora MySQL version in their applications by using SQL. Database administrators can check and specify Aurora MySQL versions when creating or upgrading Aurora MySQL DB clusters and DB instances.
Checking or specifying Aurora MySQL engine versions through AWS

When you perform administrative tasks using the AWS Management Console, AWS CLI, or RDS API, you specify the Aurora MySQL version in a descriptive alphanumeric format.

Starting with Aurora MySQL 2.03.2 and 1.19.0, Aurora engine versions have the following syntax.

```
mysql-major-version.mysql_aurora.aurora-mysql-version
```

The `mysql-major-version-` portion is 5.6, 5.7, or 8.0. This value represents the version of the client protocol and general level of MySQL feature support for the corresponding Aurora MySQL version.

The `aurora-mysql-version` is a dotted value with three parts: the Aurora MySQL major version, the Aurora MySQL minor version, and the patch level. The major version is 1, 2, or 3. Those values represent Aurora MySQL compatible with MySQL 5.6, 5.7, or 8.0 respectively. The minor version represents the feature release within the 1.x, 2.x, or 3.x series. The patch level begins at 0 for each minor version, and represents the set of subsequent bug fixes that apply to the minor version. Occasionally, a new feature is incorporated into a minor version but not made visible immediately. In these cases, the feature undergoes fine-tuning and is made public in a later patch level.

All 1.x Aurora MySQL engine versions are wire-compatible with Community MySQL 5.6.10a. All 2.x Aurora MySQL engine versions are wire-compatible with Community MySQL 5.7.12. All 3.x Aurora MySQL engine versions are wire-compatible with MySQL 8.0.23.

For example, the engine versions for Aurora MySQL 3.01.0, 2.03.2, and 1.19.0 are the following.

```
8.0.mysql_aurora.3.01.0
5.7.mysql_aurora.2.03.2
5.6.mysql_aurora.1.19.0
```

Note
There isn't a one-to-one correspondence between community MySQL versions and the Aurora MySQL 1.x and 2.x versions. For Aurora MySQL version 3, there is a more direct mapping. To check which bug fixes and new features are in a particular Aurora MySQL release, see Database engine updates for Amazon Aurora MySQL version 3 (p. 1070), Database engine updates for Amazon Aurora MySQL version 2 (p. 1071) and Database engine updates for Amazon Aurora MySQL version 1 (p. 1148). For a chronological list of new features and releases, see Document history (p. 1745). To check the minimum version required for a security-related fix, see Security vulnerabilities fixed in Amazon Aurora MySQL (p. 1223).

For Aurora MySQL 2.x, all versions 2.03.1 and lower are represented by the engine version 5.7.12. In the same way, all versions before 1.19.0 are represented by the engine version 5.6.10a. These older version designations don't include the `mysql_aurora` prefix. When you specified 5.7.12 or 5.6.10a while creating or modifying a cluster, you got the highest version before the 2.03.2 and 1.19.0 versions where the version numbering changed. To determine the exact version number for those older versions, you used the SQL technique explained in Checking Aurora MySQL versions using SQL (p. 1049).
You specify the Aurora MySQL engine version in some AWS CLI commands and RDS API operations. For example, you specify the `--engine-version` option when you run the AWS CLI commands `create-db-cluster` and `modify-db-cluster`. You specify the `EngineVersion` parameter when you run the RDS API operations `CreateDBCluster` and `ModifyDBCluster`.

In Aurora MySQL 1.19.0 and higher or 2.03.2 and higher, the engine version in the AWS Management Console also includes the Aurora version. Upgrading the cluster changes the displayed value. This change helps you to specify and check the precise Aurora MySQL versions, without the need to connect to the cluster or run any SQL commands.

**Tip**
For Aurora clusters managed through AWS CloudFormation, this change in the `EngineVersion` setting can trigger actions by AWS CloudFormation. For information about how AWS CloudFormation treats changes to the `EngineVersion` setting, see the AWS CloudFormation documentation.

Before Aurora MySQL 1.19.0 and 2.03.2, the process to update the engine version is to use the **Apply a Pending Maintenance Action** option for the cluster. This process doesn't change the Aurora MySQL engine version that the console displays. For example, suppose that you see an Aurora MySQL cluster with a reported engine version of `5.6.10a` or `5.7.12`. To find out the specific version, connect to the cluster and query the `AURORA_VERSION` system variable as described previously.

### Checking Aurora MySQL versions using SQL

The Aurora version numbers that you can retrieve in your application using SQL queries use the format `<major version>.<minor version>.<patch version>`. You can get this version number for any DB instance in your Aurora MySQL cluster by querying the `AURORA_VERSION` system variable. To get this version number, use one of the following queries.

```sql
select aurora_version();
select @@aurora_version;
```

Those queries produce output similar to the following.

```
mysql> select aurora_version(), @@aurora_version;
+------------------+------------------+
| aurora_version() | @@aurora_version |
+------------------+------------------+
| 2.08.1           | 2.08.1           |
+------------------+------------------+
```

The version numbers that the console, CLI, and RDS API return by using the techniques described in Checking or specifying Aurora MySQL engine versions through AWS (p. 1048) are typically more descriptive. However, for versions before 2.03.2 and 1.19, AWS always returns the version numbers `5.6.12` or `5.6.10a`. For those older versions, use the SQL technique to check the precise version number.

### Aurora MySQL long-term support (LTS) releases

Each new Aurora MySQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora MySQL version is no longer supported.

Aurora designates certain Aurora MySQL versions as long-term support (LTS) releases. DB clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. Aurora supports each LTS release for at least one year after that release.
becomes available. When a DB cluster that's on an LTS release is required to upgrade, Aurora upgrades it to the next LTS release. That way, the cluster doesn't need to be upgraded again for a long time.

During the lifetime of an Aurora MySQL LTS release, new patch levels introduce fixes to important issues. The patch levels don't include any new features. You can choose whether to apply such patches to DB clusters running the LTS release. For certain critical fixes, Amazon might perform a managed upgrade to a patch level within the same LTS release. Such managed upgrades are performed automatically within the cluster maintenance window.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora MySQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. The LTS releases are intended for clusters with the following characteristics:

- You can't afford downtime on your Aurora MySQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora MySQL database engine.
- The database version for your Aurora MySQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS releases for Aurora MySQL are the following:

- **Aurora MySQL version 2.07.** For more details about this version, see Aurora MySQL database engine updates 2021-09-02 (version 2.07.6) (p. 1100).
- **Aurora MySQL version 1.22.** For more details about this version, see Aurora MySQL database engine updates 2021-06-03 (version 1.22.5) (p. 1156).

These older versions are also designated as LTS releases:

- Aurora MySQL version 2.04.
- Aurora MySQL version 1.19.

### Upgrade paths between 5.6-compatible and 5.7-compatible clusters

For most Aurora MySQL 1.x and 2.x versions, you can upgrade a MySQL 5.6-compatible cluster to any version of a MySQL 5.7-compatible cluster.

However, if your cluster is running Aurora MySQL 1.23 or higher, any upgrade to Aurora MySQL version 2.x must be to Aurora MySQL 2.09 or higher. This restriction applies even when you upgrade by restoring a snapshot to create a new Aurora cluster. Aurora MySQL 1.23 includes improvements in Aurora storage. For example, the maximum size of the cluster volume is larger in Aurora MySQL 1.23 and later. Aurora MySQL 2.09 is the first 2.x version that has the same storage enhancements.

### Upgrading Amazon Aurora MySQL DB clusters

You can upgrade an Aurora MySQL DB cluster to get bug fixes, new Aurora MySQL features, or to change to an entirely new version of the underlying database engine. The following sections show how.

**Tip**

The type of upgrade that you do depends on how much downtime you can afford for your cluster, how much verification testing you plan to do, how important the specific bug fixes or new features are for your use case, and whether you plan to do frequent small upgrades.
or occasional upgrades that skip several intermediate versions. For each upgrade, you can change the major version, the minor version, and the patch level for your cluster. If you aren't familiar with the distinction between Aurora MySQL major versions, minor versions, and patch levels, you can read the background information at Aurora MySQL version numbers and special versions (p. 1047).

Topics
- Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051)
- Upgrading the major version of an Aurora MySQL DB cluster (p. 1056)

Upgrading the minor version or patch level of an Aurora MySQL DB cluster

You can use the following methods to upgrade the minor version of a DB cluster or to patch a DB cluster:
- Upgrading Aurora MySQL by modifying the engine version (p. 1051) (for Aurora MySQL 1.19.0 and higher, or 2.03.2 and higher)
- Enabling automatic upgrades between minor Aurora MySQL versions (p. 1052)
- Upgrading Aurora MySQL by applying pending maintenance to an Aurora MySQL DB cluster (p. 1053) (before Aurora MySQL 1.19.0 or 2.03.2)

For information about how zero-downtime patching can reduce interruptions during the upgrade process, see Using zero-downtime patching (p. 1054).

Upgrading Aurora MySQL by modifying the engine version

Upgrading the minor version of an Aurora MySQL cluster applies additional fixes and new features to an existing cluster. You can do this type of upgrade for clusters that are running Amazon Aurora MySQL version 1.19.0 and higher, or 2.03.2 and higher.

This kind of upgrade applies to Aurora MySQL clusters where the original version and the upgraded version are both in the Aurora MySQL 1.x series, or both in the Aurora MySQL 2.x series. The process is fast and straightforward because it doesn't involve any conversion for the Aurora MySQL metadata or reorganization of your table data.

You perform this kind of upgrade by modifying the engine version of the DB cluster using the AWS Management Console, AWS CLI, or the RDS API. If your cluster is running Aurora MySQL 1.x, choose a higher 1.x version. If your cluster is running Aurora MySQL 2.x, choose a higher 2.x version.

To modify the engine version of a DB cluster

- **By using the console** – Modify the properties of your cluster. In the Modify DB cluster window, change the Aurora MySQL engine version in the DB engine version box. If you aren't familiar with the general procedure for modifying a cluster, follow the instructions at Modifying the DB cluster by using the console, CLI, and API (p. 368).
- **By using the AWS CLI** – Call the modify-db-cluster AWS CLI command, and specify the name of your DB cluster for the --db-cluster-identifier option and the engine version for the --engine-version option.
- **By using the RDS API** – Call the ModifyDBCluster API operation, and specify the name of your DB cluster for the DBClusterIdentifier parameter and the engine version for the EngineVersion option.
parameter. Set the `ApplyImmediately` parameter to `true` to immediately update the engine version for your DB cluster.

### Enabling automatic upgrades between minor Aurora MySQL versions

For an Amazon Aurora MySQL DB cluster, you can specify that Aurora upgrades the DB cluster automatically to new minor versions as those versions are released. You do so by enabling the automatic minor version upgrade property of the DB cluster using the AWS Management Console, AWS CLI, or the RDS API.

The automatic upgrades occur during the maintenance window for the database.

**Important**

Until August 2020, you could specify this setting for a DB instance that was part of an Aurora MySQL DB cluster, but the setting had no effect. Now, the setting does apply to Aurora MySQL. If you have clusters created before August 2020, check whether the DB instances in the cluster already had the `Enable auto minor version upgrade` setting enabled. If so, confirm that this setting is still appropriate and change it if not. Aurora only performs the automatic upgrade if all DB instances in your cluster have this setting enabled.

Automatic minor version upgrade applies also to clusters running the LTS version for Aurora MySQL 1.x or 2.x. To prevent those clusters from being automatically upgraded, make sure to turn off the `Enable auto minor version upgrade` setting.

Automatic minor version upgrade doesn't apply to the following kinds of Aurora MySQL clusters:

- Multi-master clusters.
- Clusters that are part of an Aurora global database.
- Clusters that have cross-Region replicas.

If any of the DB instances in a cluster don't have the auto minor version upgrade setting turned on, Aurora doesn't automatically upgrade any of the instances in that cluster. Make sure to keep that setting consistent for all the DB instances in the cluster.

The outage duration varies depending on workload, cluster size, the amount of binary log data, and if Aurora can use the zero-downtime patching (ZDP) feature. Aurora restarts the database cluster, so you might experience a short period of unavailability before resuming use of your cluster. In particular, the amount of binary log data affects recovery time. The DB instance processes the binary log data during recovery. Thus, a high volume of binary log data increases recovery time.

**To enable automatic minor version upgrades for an Aurora MySQL DB cluster**

1. Follow the general procedure to modify the DB instances in your cluster, as described in [Modify a DB instance in a DB cluster](p. 369). Repeat this procedure for each DB instance in your cluster.
2. Do the following to enable automatic minor version upgrades for your cluster:
   
   - **By using the console** – Complete the following steps:
     1. Sign in to the Amazon RDS console. Choose **Databases**, and find the DB cluster where you want to turn automatic minor version upgrade on or off.
     2. Choose each DB instance in the DB cluster that you want to modify. Apply the following change for each DB instance in sequence:
        a. Choose **Modify**.
        b. Choose the **Enable auto minor version upgrade** setting. This setting is part of the **Maintenance** section.
        c. Choose **Continue** and check the summary of modifications.
d. (Optional) Choose **Apply immediately** to apply the changes immediately.
e. On the confirmation page, choose **Modify DB instance**.
   - **By using the AWS CLI** – Call the `modify-db-instance` AWS CLI command. Specify the name of your DB instance for the `--db-instance-identifier` option and `true` for the `--auto-minor-version-upgrade` option. Optionally, specify the `--apply-immediately` option to immediately enable this setting for your DB instance. Run a separate `modify-db-instance` command for each DB instance in the cluster.
   - **By using the RDS API** – Call the ModifyDBInstance API operation and specify the name of your DB cluster for the `DBInstanceIdentifier` parameter and `true` for the `AutoMinorVersionUpgrade` parameter. Optionally, set the `ApplyImmediately` parameter to `true` to immediately enable this setting for your DB instance. Call a separate ModifyDBInstance operation for each DB instance in the cluster.

You can use a CLI command such as the following to check the status of the **Enable auto minor version upgrade** for all of the DB instances in your Aurora MySQL clusters.

```
aws rds describe-db-instances
--query '*[].
{DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVersionUpgrade:AutoMinorVersionUpgrade}'
```

That command produces output similar to the following.

```
[
  {
    "DBInstanceIdentifier": "db-t2-medium-instance",
    "DBClusterIdentifier": "cluster-57-2020-06-03-6411",
    "AutoMinorVersionUpgrade": true
  },
  {
    "DBInstanceIdentifier": "db-t2-small-original-size",
    "DBClusterIdentifier": "cluster-57-2020-06-03-6411",
    "AutoMinorVersionUpgrade": false
  },
  {
    "DBInstanceIdentifier": "instance-2020-05-01-2332",
    "DBClusterIdentifier": "cluster-57-2020-05-01-4615",
    "AutoMinorVersionUpgrade": true
  },
  ... output omitted ...
```

### Upgrading Aurora MySQL by applying pending maintenance to an Aurora MySQL DB cluster

When upgrading to Aurora MySQL version 1.x versions, new database engine minor versions and patches show as an **available** maintenance upgrade for your DB cluster. You can upgrade or patch the database version of your DB cluster by applying the available maintenance action. We recommend applying the update on a nonproduction DB cluster first, so that you can see how changes in the new version affect your instances and applications.

**To apply pending maintenance actions**

- **By using the console** – Complete the following steps:
  1. Sign in to the Amazon RDS console, choose **Databases**, and choose the DB cluster that shows the **available** maintenance upgrade.
  2. For **Actions**, choose **Upgrade now** to immediately update the database version for your DB cluster, or **Upgrade at next window** to update the database version for your DB cluster during the next DB cluster maintenance window.
Upgrading Amazon Aurora MySQL DB clusters

• **By using the AWS CLI** – Call the `apply-pending-maintenance-action` AWS CLI command, and specify the Amazon Resource Name (ARN) for your DB cluster for the `--resource-id` option and `system-update` for the `--apply-action` option. Set the `--opt-in-type` option to `immediate` to immediately update the database version for your DB cluster, or `next-maintenance` to update the database version for your DB cluster during the next cluster maintenance window.

• **By using the RDS API** – Call the `ApplyPendingMaintenanceAction` API operation, and specify the ARN for your DB cluster for the `ResourceId` parameter and `system-update` for the `ApplyAction` parameter. Set the `OptInType` parameter to `immediate` to immediately update the database version for your DB cluster, or `next-maintenance` to update the database version for your instance during the next cluster maintenance window.

For more information on how Amazon RDS manages database and operating system updates, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**

If your current Aurora MySQL version is 1.14.x but lower than 1.14.4, you can upgrade only to 1.14.4 (which supports db.r4 instance classes). Also, to upgrade from 1.14.x to a higher minor Aurora MySQL version, such as 1.17, the 1.14.x version must be 1.14.4.

**Using zero-downtime patching**

Performing upgrades for Aurora MySQL DB clusters involves the possibility of an outage when the database is shut down and while it’s being upgraded. By default, if you start the upgrade while the database is busy, you lose all the connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an Aurora MySQL upgrade. If ZDP completes successfully, application sessions are preserved and the database engine restarts while the upgrade is in progress. The database engine restart can cause a drop in throughput lasting for a few seconds to approximately one minute.

ZDP is available in Aurora MySQL 2.07.2 and higher 2.07 versions, and 2.10.0 and higher, compatible with MySQL 5.7, and 3.01.0 and higher, compatible with MySQL 8.0.

In Aurora MySQL version 2, ZDP only applies to Aurora MySQL DB instances that use the `db.t2` or `db.t3` instance classes. In Aurora MySQL version 3, ZDP applies to all instance classes.

You can see metrics of important attributes during ZDP in the MySQL error log. You can also see information about when Aurora MySQL uses ZDP or chooses not use ZDP on the **Events** page in the AWS Management Console.

In Aurora MySQL 2.10 and higher, Aurora can perform a zero-downtime patch when binary log replication is enabled. Aurora MySQL automatically drops the connection to the binlog target during a ZDP operation. Aurora MySQL automatically reconnects to the binlog target and resumes replication after the restart finishes.

ZDP also works in combination with the reboot enhancements in Aurora MySQL 2.10 and higher. Patching the writer DB instance automatically patches readers at the same time. After performing the patch, Aurora restores the connections on both the writer and reader DB instances. Before Aurora MySQL 2.10, ZDP applies only to the writer DB instance of a cluster.

ZDP might not complete successfully under the following conditions:

- Long-running queries or transactions are in progress. If Aurora can perform ZDP in this case, any open transactions are canceled.
- Open Secure Socket Layer (SSL) connections exist.
- Temporary tables or table locks are in use, for example while data definition language (DDL) statements run. If Aurora can perform ZDP in this case, any open transactions are canceled.
• Pending parameter changes exist.

If no suitable time window for performing ZDP becomes available because of one or more of these conditions, patching reverts to the standard behavior.

Although connections remain intact following a successful ZDP operation, some variables and features are reinitialized. The following kinds of information aren't preserved through a restart caused by zero-downtime patching:

• Global variables. Aurora restores session variables, but it doesn't restore global variables after the restart.
• Status variables. In particular, the uptime value reported by the engine status is reset after a restart that uses the ZDR or ZDP mechanisms.
• LAST_INSERT_ID.
• In-memory auto_increment state for tables. The in-memory auto-increment state is reinitialized. For more information about auto-increment values, see MySQL Reference Manual.
• Diagnostic information from INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables. This diagnostic information also appears in the output of commands such as SHOW PROFILE and SHOW PROFILES.

The following activities related to zero-downtime restart are reported on the Events page:

• Attempting to upgrade the database with zero downtime.
• Attempt to upgrade the database with zero downtime finished. The event reports how long the process took. The event also reports how many connections were preserved during the restart and how many connections were dropped. You can consult the database error log to see more details about what happened during the restart.

The following table summarizes how ZDP works for upgrading from and to specific Aurora MySQL versions. The instance class of the DB instance also affects whether Aurora uses the ZDP mechanism.

<table>
<thead>
<tr>
<th>Original version</th>
<th>Upgraded version</th>
<th>Does ZDP apply?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL 1.*</td>
<td>Any</td>
<td>No</td>
</tr>
<tr>
<td>Aurora MySQL 2.*, before 2.07.2</td>
<td>Any</td>
<td>No</td>
</tr>
<tr>
<td>Aurora MySQL 2.07.2, 2.07.3</td>
<td>2.07.4 and higher 2.07 versions, 2.10.*</td>
<td>Yes, on the writer instance for T2 and T3 instance classes only. Aurora only performs ZDP if a quiet point is found before a timeout occurs. After the timeout, Aurora performs a regular restart.</td>
</tr>
<tr>
<td>2.07.4 and higher 2.07 versions</td>
<td>2.10.*</td>
<td>Yes, on the writer instance for T2 and T3 instances only. Aurora rolls back transactions for active and idle transactions. Connections using SSL, temporary tables, table locks, or user locks are disconnected. Aurora might restart the engine and drop all connections if the engine takes too long to start after ZDP finishes.</td>
</tr>
</tbody>
</table>

Alternative blue-green upgrade technique

Blog post: Performing major version upgrades for Aurora MySQL with minimum downtime.
Upgrading the major version of an Aurora MySQL DB cluster

In an Aurora MySQL version number such as 2.08.1, the 2 represents the major version. Aurora MySQL version 1 is compatible with MySQL 5.6. Aurora MySQL version 2 is compatible with MySQL 5.7. Aurora MySQL version 3 is compatible with MySQL 8.0.23.

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. After the upgrade is finished, you also might have followup work to do. For example, this might occur due to differences in SQL compatibility, the way certain MySQL-related features work, or parameter settings between the old and new versions.

Upgrading from Aurora MySQL 2.x to 3.x

Currently, upgrading to Aurora MySQL version 3 requires restoring a snapshot of an Aurora MySQL version 2 cluster to create a new version 3 cluster. If your original cluster is running Aurora MySQL version 1, you first upgrade to version 2 and then use the snapshot restore technique to create the version 3 cluster. For general information about Aurora MySQL version 3 and the new features that you can use after you upgrade, see Aurora MySQL version 3 compatible with MySQL 8.0 (p. 716). For details and examples of performing this type of upgrade, see Upgrade planning for Aurora MySQL version 3 (p. 733) and Upgrading to Aurora MySQL version 3 (p. 733).

Tip

When you upgrade the major version of your cluster from 2.x to 3.x, the original cluster and the upgraded one both use the same aurora-mysql value for the engine attribute.

Upgrading from Aurora MySQL 1.x to 2.x

Upgrading the major version from 1.x to 2.x changes the engine attribute of the cluster from aurora to aurora-mysql. Make sure to update any AWS CLI or API automation that you use with this cluster to account for the changed engine value.

If you have a MySQL 5.6-compatible cluster and want to upgrade it to a MySQL-5.7 compatible cluster, you can do so by running an upgrade process on the cluster itself. This kind of upgrade is an in-place upgrade, in contrast to upgrades that you do by creating a new cluster. This technique keeps the same endpoint and other characteristics of the cluster. The upgrade is relatively fast because it doesn't require copying all your data to a new cluster volume. This stability helps to minimize any configuration changes in your applications. It also helps to reduce the amount of testing for the upgraded cluster, because the number of DB instances and their instance classes all stay the same.
The in-place upgrade mechanism involves shutting down your DB cluster while the operation takes place. Aurora performs a clean shutdown and completes outstanding operations such as transaction rollback and undo purge.

The in-place upgrade is convenient, because it is simple to perform and minimizes configuration changes to associated applications. For example, an in-place upgrade preserves the endpoints and set of DB instances for your cluster. However, the time needed for an in-place upgrade can vary depending on the properties of your schema and how busy the cluster is. Thus, depending on the needs for your cluster, you can choose between in-place upgrade, snapshot restore as described in Restoring from a DB cluster snapshot (p. 493), or other upgrade techniques such as the one described in Alternative blue-green upgrade technique (p. 1070).

If your cluster is running a version that's lower than 1.22.3, the upgrade might take longer because Aurora MySQL automatically performs an upgrade to 1.22.3 as a first step. To minimize downtime during the major version upgrade, you can do an initial minor version upgrade to Aurora MySQL 1.22.3 in advance.

Planning a major version upgrade for an Aurora MySQL cluster

To make sure that your applications and administration procedures work smoothly after upgrading a cluster between major versions, you can do some advance planning and preparation. To see what sorts of management code to update for your AWS CLI scripts or RDS API–based applications, see How in-place upgrades affect the parameter groups for a cluster (p. 1062) and Changes to cluster properties between Aurora MySQL version 1 and 2 (p. 1063).

You can learn the sorts of issues that you might encounter during the upgrade by reading Troubleshooting for Aurora MySQL in-place upgrade (p. 1064). For issues that might cause the upgrade to take a long time, you can test those conditions in advance and correct them.

To verify application compatibility, performance, maintenance procedures, and similar considerations for the upgraded cluster, you can perform a simulation of the upgrade before doing the real upgrade. This technique can be especially useful for production clusters. Here, it's important to minimize downtime and have the upgraded cluster ready to go as soon as the upgrade as finished.

**Note**

This technique applies to upgrades from Aurora MySQL version 1 to version 2. Currently, you can't upgrade from Aurora MySQL version 2 to 3 by using cloning.

Use the following steps:

1. Create a clone of the original cluster. Follow the procedure in Cloning a volume for an Aurora DB cluster (p. 398).
2. Set up a similar set of writer and reader DB instances as in the original cluster.
3. Perform an in-place upgrade of the cloned cluster. Follow the procedure in How to perform an in-place upgrade (p. 1060). Start the upgrade immediately after creating the clone. That way, the cluster volume is still identical to the state of the original cluster. If the clone sits idle before you do the upgrade, Aurora performs database cleanup processes in the background. In that case, the upgrade of the clone isn't an accurate simulation of upgrading the original cluster.
4. Test application compatibility, performance, administration procedures, and so on, using the cloned cluster.
5. If you encounter any issues, adjust your upgrade plans to account for them. For example, adapt any application code to be compatible with the feature set of the higher version. Estimate how long the upgrade is likely to take based on the amount of data in your cluster. You might also choose to schedule the upgrade for a time when the cluster isn't busy.
6. After you are satisfied that your applications and workload work properly with the test cluster, you can perform the in-place upgrade for your production cluster.
7. To minimize the total downtime of your cluster during a major version upgrade, make sure that the workload on the cluster is low or zero at the time of the upgrade. In particular, make sure that there are no long running transactions in progress when you start the upgrade.

**Aurora MySQL major version upgrade paths**

Not all kinds or versions of Aurora MySQL clusters can use the in-place upgrade mechanism. You can learn the appropriate upgrade path for each Aurora MySQL cluster by consulting the following table.

<table>
<thead>
<tr>
<th>Type of Aurora MySQL DB cluster</th>
<th>Can it use in-place upgrade?</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL provisioned cluster, 1.22.3 or higher</td>
<td>Yes</td>
<td>This is the fastest upgrade path. Aurora doesn't need to perform an intermediate upgrade first.</td>
</tr>
<tr>
<td>Aurora MySQL provisioned cluster, earlier than 1.22.3</td>
<td>Yes</td>
<td>The upgrade might take longer than if the cluster is already running Aurora MySQL 1.22.3 or higher. During a major version upgrade, Aurora MySQL performs some database cleanup using a minimum Aurora MySQL version of 1.22.3. Aurora MySQL automatically performs an upgrade to 1.22.3 as a first step before doing that cleanup.</td>
</tr>
<tr>
<td>Aurora MySQL provisioned cluster, 2.0 or higher</td>
<td>No</td>
<td>In-place upgrade is only for 5.6-compatible Aurora MySQL clusters, to make possible compatibility with MySQL 5.7. Aurora MySQL version 2 is already compatible with 5.7. Use the procedure for upgrading the minor version or patch level to change from one 5.7-compatible version to another.</td>
</tr>
<tr>
<td>Aurora MySQL provisioned cluster, 3.1.0 or higher</td>
<td>No</td>
<td>For information about upgrading to Aurora MySQL version 3, see Upgrade planning for Aurora MySQL version 3 (p. 733) and Upgrading to Aurora MySQL version 3 (p. 733).</td>
</tr>
<tr>
<td>Aurora MySQL provisioned cluster, 3.1.0 or higher</td>
<td>No</td>
<td>For information about upgrading to Aurora MySQL version 3, see Upgrade planning for Aurora MySQL version 3 (p. 733) and Upgrading to Aurora MySQL version 3 (p. 733).</td>
</tr>
<tr>
<td>Aurora Serverless cluster</td>
<td>No</td>
<td>Make a snapshot of the 5.6-compatible Aurora Serverless cluster. Restore the snapshot to a 5.7-compatible cluster. You can choose to make the new cluster Aurora Serverless or some other kind of 5.7-compatible cluster.</td>
</tr>
<tr>
<td>Cluster in an Aurora global database</td>
<td>Yes</td>
<td>Follow the procedure for doing an in-place upgrade for clusters in an Aurora global database. Perform the upgrade on the primary cluster in the global database. Aurora upgrades the primary cluster and all the secondary clusters in the global database at the same time. If you use the AWS CLI or RDS API, call the <code>modify-global-cluster</code> command or <code>ModifyGlobalCluster</code> operation instead of <code>modify-db-cluster</code> or <code>ModifyDBCluster</code>.</td>
</tr>
<tr>
<td>Multi-master cluster</td>
<td>No</td>
<td>Currently, multi-master replication isn't available for Aurora MySQL 5.7-compatible clusters.</td>
</tr>
<tr>
<td>Type of Aurora MySQL DB cluster</td>
<td>Can it use in-place upgrade?</td>
<td>Action</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>Parallel query cluster</td>
<td>Maybe</td>
<td>If you have an existing parallel query cluster using an older Aurora MySQL version, upgrade the cluster to Aurora MySQL 1.23 first. Follow the procedure in Upgrade considerations for parallel query (p. 859). You make some changes to configuration parameters to turn parallel query back on after this initial upgrade. Then you can perform an in-place upgrade. In this case, choose 2.09.1 or higher for the Aurora MySQL version.</td>
</tr>
<tr>
<td>Cluster that is the target of binary log replication</td>
<td>Maybe</td>
<td>If the binary log replication is from a 5.6-compatible Aurora MySQL cluster, you can perform an in-place upgrade. You can't perform the upgrade if the binary log replication is from an RDS MySQL or an on-premises MySQL DB instance. In that case, you can upgrade using the snapshot restore mechanism.</td>
</tr>
</tbody>
</table>
| Cluster with zero DB instances    | No                            | Using the AWS CLI or the RDS API, you can create an Aurora MySQL cluster without any attached DB instances. In the same way, you can also remove all DB instances from an Aurora MySQL cluster while leaving the data in the cluster volume intact. While a cluster has zero DB instances, you can't perform an in-place upgrade.

The upgrade mechanism requires a writer instance in the cluster to perform conversions on the system tables, data files, and so on. In this case, use the AWS CLI or the RDS API to create a writer instance for the cluster. Then you can perform an in-place upgrade. |
| Cluster with backtrack enabled    | Yes                           | You can perform an in-place upgrade for an Aurora MySQL cluster that uses the backtrack feature. However, after the upgrade, you can't backtrack the cluster to a time before the upgrade. |

How the Aurora MySQL in-place major version upgrade works

Aurora MySQL performs a major version upgrade as a multistage process. You can check the current status of an upgrade. Some of the upgrade steps also provide progress information. As each stage begins, Aurora MySQL records an event. You can examine events as they occur on the Events page in the RDS console. For more information about working with events, see Using Amazon RDS event notification (p. 646).

**Important**

Once the process begins, it runs until the upgrade either succeeds or fails. You can't cancel the upgrade while it's underway. If the upgrade fails, Aurora rolls back all the changes and your cluster has the same engine version, metadata, and so on as before.

The upgrade process consists of these stages:

1. Aurora performs a series of checks before beginning the upgrade process. Your cluster keeps running while Aurora does these checks. For example, the cluster can't have any XA transactions in the prepared state or be processing any data definition language (DDL) statements. For example, you might need to shut down applications that are submitting certain kinds of SQL statements. Or you
might simply wait until certain long-running statements are finished. Then try the upgrade again. Some checks test for conditions that don’t prevent the upgrade but might make the upgrade take a long time.

If Aurora detects that any required conditions aren’t met, modify the conditions identified in the event details. Follow the guidance in Troubleshooting for Aurora MySQL in-place upgrade (p. 1064). If Aurora detects conditions that might cause a slow upgrade, plan to monitor the upgrade over an extended period.

2. Aurora takes your cluster offline. Then Aurora performs a similar set of tests as in the previous stage, to confirm that no new issues arose during the shutdown process. If Aurora detects any conditions at this point that would prevent the upgrade, Aurora cancels the upgrade and brings the cluster back online. In this case, confirm when the conditions no longer apply and start the upgrade again.

3. Aurora creates a snapshot of your cluster volume. Suppose that you discover compatibility or other kinds of issues after the upgrade is finished. Or suppose that you want to perform testing using both the original and upgraded clusters. In such cases, you can restore from this snapshot to create a new cluster with the original engine version and the original data.

   **Tip**
   This snapshot is a manual snapshot. However, Aurora can create it and continue with the upgrade process even if you have reached your quota for manual snapshots. This snapshot remains permanently until you delete it. After you finish all post-upgrade testing, you can delete this snapshot to minimize storage charges.

4. Aurora clones your cluster volume. Cloning is a fast operation that doesn’t involve copying the actual table data. If Aurora encounters an issue during the upgrade, it reverts to the original data from the cloned cluster volume and brings the cluster back online. The temporary cloned volume during the upgrade isn’t subject to the usual limit on the number of clones for a single cluster volume.

5. Aurora performs a clean shutdown for the writer DB instance. During the clean shutdown, progress events are recorded every 15 minutes for the following operations. You can examine events as they occur on the **Events** page in the RDS console.
   - Aurora purges the undo records for old versions of rows.
   - Aurora rolls back any uncommitted transactions.

6. Aurora upgrades the engine version on the writer DB instance:
   - Aurora installs the binary for the new engine version on the writer DB instance.
   - Aurora uses the writer DB instance to upgrade your data to MySQL 5.7-compatible format. During this stage, Aurora modifies the system tables and performs other conversions that affect the data in your cluster volume. In particular, Aurora upgrades the partition metadata in the system tables to be compatible with the MySQL 5.7 partition format. This stage can take a long time if the tables in your cluster have a large number of partitions.
     If any errors occur during this stage, you can find the details in the MySQL error logs. After this stage starts, if the upgrade process fails for any reason, Aurora restores the original data from the cloned cluster volume.

7. Aurora upgrades the engine version on the reader DB instances.

8. The upgrade process is completed. Aurora records a final event to indicate that the upgrade process completed successfully. Now your DB cluster is running the new major version.

**How to perform an in-place upgrade**

**Console**

**To upgrade the major version of an Aurora MySQL DB cluster**

1. (Optional) Review the background material in How the Aurora MySQL in-place major version upgrade works (p. 1059). Perform any pre-upgrade planning and testing, as described in Planning a major version upgrade for an Aurora MySQL cluster (p. 1057).
2. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

3. If you used a custom parameter group with the original 1.x cluster, create a corresponding MySQL 5.7-compatible parameter group. Make any necessary adjustments to the configuration parameters in that new parameter group. For more information, see How in-place upgrades affect the parameter groups for a cluster (p. 1062).

4. In the navigation pane, choose Databases.

5. In the list, choose the DB cluster that you want to modify.

6. Choose Modify.

7. For Version, choose an Aurora MySQL 2.x version.

8. Choose Continue.

9. On the next page, specify when to perform the upgrade. Choose During the next scheduled maintenance window or Immediately.

10. (Optional) Periodically examine the Events page in the RDS console during the upgrade. Doing so helps you to monitor the progress of the upgrade and identify any issues. If the upgrade encounters any issues, consult Troubleshooting for Aurora MySQL in-place upgrade (p. 1064) for the steps to take.

11. If you created a new MySQL 5.7-compatible parameter group at the start of this procedure, associate the custom parameter group with your upgraded cluster. For more information, see How in-place upgrades affect the parameter groups for a cluster (p. 1062).

   **Note**
   Performing this step requires you to restart the cluster again to apply the new parameter group.

12. (Optional) After you complete any post-upgrade testing, delete the manual snapshot that Aurora created at the beginning of the upgrade.

**AWS CLI**

To upgrade the major version of an Aurora MySQL DB cluster, use the AWS CLI modify-db-cluster command with the following required parameters:

- `--db-cluster-identifier`
- `--engine aurora-mysql`
- `--engine-version`
- `--allow-major-version-upgrade`
- `--apply-immediately` or `--no-apply-immediately`

If your cluster uses any custom parameter groups, also include one or both of the following options:

- `--db-cluster-parameter-group-name`, if the cluster uses a custom cluster parameter group
- `--db-instance-parameter-group-name`, if any instances in the cluster use a custom DB parameter group

The following example upgrades the sample-cluster DB cluster to Aurora MySQL version 2.09.0. The upgrade happens immediately, instead of waiting for the next maintenance window.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
```
Upgrading Amazon Aurora MySQL DB clusters

```
--db-cluster-identifier sample-cluster \
--engine aurora-mysql \
--engine-version 5.7.mysql_aurora.2.09.0 \
--allow-major-version-upgrade \ 
--apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier sample-cluster ^
  --engine aurora-mysql ^
  --engine-version 5.7.mysql_aurora.2.09.0 ^
  --allow-major-version-upgrade ^
  --apply-immediately
```

You can combine other CLI commands with `modify-db-cluster` to create an automated end-to-end process for performing and verifying upgrades. For more information and examples, see Aurora MySQL in-place upgrade tutorial (p. 1065).

**Note**

If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the `modify-global-cluster` command operation instead of `modify-db-cluster`. For more information, see In-place upgrades for global databases (p. 1063).

**RDS API**

To upgrade the major version of an Aurora MySQL DB cluster, use the RDS API `ModifyDBCluster` operation with the following required parameters:

- **DBClusterIdentifier**
- **Engine**
- **EngineVersion**
- **AllowMajorVersionUpgrade**
- **ApplyImmediately** (set to true or false)

**Note**

If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the `ModifyGlobalCluster` operation instead of `ModifyDBCluster`. For more information, see In-place upgrades for global databases (p. 1063).

**How in-place upgrades affect the parameter groups for a cluster**

Aurora parameter groups have different sets of configuration settings for clusters that are compatible with MySQL 5.6 or 5.7. When you perform an in-place upgrade, the upgraded cluster and all its instances must use corresponding 5.7-compatible cluster and instance parameter groups. If your cluster and instances use the default 5.6-compatible parameter groups, the upgraded cluster and instance start with the default 5.7-compatible parameter groups. If your cluster and instances use any custom parameter groups, you must create corresponding 5.7-compatible parameter groups and specify those during the upgrade process.

If your original cluster uses a custom 5.6-compatible cluster parameter group, create a corresponding 5.7-compatible cluster parameter group. You associate that parameter group with the cluster as part of the upgrade process.

Similarly, create any corresponding 5.7-compatible DB parameter group. You associate that parameter group with all the DB instances in the cluster as part of the upgrade process.
Important
If you specify any custom parameter group during the upgrade process, you must manually reboot the cluster after the upgrade finishes. Doing so makes the cluster begin using your custom parameter settings.

Changes to cluster properties between Aurora MySQL version 1 and 2

For MySQL 5.6-compatible clusters, the value that you use for the engine parameter in AWS CLI commands or RDS API operations is aurora. For MySQL 5.7-compatible or MySQL 8.0-compatible clusters, the corresponding value is aurora-mysql. When you upgrade from Aurora MySQL version 1 to version 2 or version 3, make sure to change any applications or scripts you use to set up or manage Aurora MySQL clusters and DB instances.

Also, change your code that manipulates parameter groups to account for the fact that the default parameter group names are different for MySQL 5.6-, 5.7-, and 8.0-compatible clusters. The default parameter group name for Aurora MySQL version 1 clusters is default.aurora5.6. The corresponding parameter group names for Aurora MySQL version 2 and 3 clusters are default.aurora-mysql5.7 and default.aurora-mysql8.0.

For example, you might have code like the following that applies to your cluster before an upgrade.

```
# Add a new DB instance to a MySQL 5.6-compatible cluster.
create-db-instance --db-instance-identifier instance-2020-04-28-6889 --db-cluster-identifier cluster-2020-04-28-2690 \
  --db-instance-class db.t2.small --engine aurora --region us-east-1

# Find the Aurora MySQL v1.x versions available for minor version upgrades and patching.
aws rds describe-orderable-db-instance-options \
  --engine aurora --region us-east-1 \
  --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output text

# Check the default parameter values for MySQL 5.6-compatible clusters.
aws rds describe-db-parameters --db-parameter-group-name default.aurora5.6 --region us-east-1
```

After upgrading the major version of the cluster, modify that code as follows.

```
# Add a new DB instance to a MySQL 5.7-compatible cluster.
create-db-instance --db-instance-identifier instance-2020-04-28-3333 --db-cluster-identifier cluster-2020-04-28-2690 \
  --db-instance-class db.t2.small --engine aurora-mysql --region us-east-1

# Find the Aurora MySQL v2.x versions available for minor version upgrades and patching.
aws rds describe-orderable-db-instance-options --engine aurora-mysql --region us-east-1 \
  --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output text

# Check the default parameter values for MySQL 5.7-compatible clusters.
aws rds describe-db-parameters --db-parameter-group-name default.aurora-mysql5.7 --region us-east-1
```

In-place upgrades for global databases

For an Aurora global database, you upgrade the primary cluster as explained in How the Aurora MySQL in-place major version upgrade works (p. 1059). Perform the upgrade on the primary cluster in the global database. Aurora automatically upgrades all the secondary clusters at the same time. All primary and secondary clusters must run the same Aurora MySQL major version. This requirement is because any changes to system tables, data file formats, and so on, are automatically replicated to all the secondary clusters.
If you use the AWS CLI or RDS API, start the upgrade process by calling the `modify-global-cluster` command or `ModifyGlobalCluster` operation instead of `modify-db-cluster` or `ModifyDBCluster`.

**After the upgrade**

If the cluster you upgraded had the backtrack feature enabled, you can't backtrack the upgraded cluster to a time that's before the upgrade.

**Troubleshooting for Aurora MySQL in-place upgrade**

<table>
<thead>
<tr>
<th>Reason for in-place upgrade being canceled or slow</th>
<th>Solution to allow in-place upgrade to complete within maintenance window</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster has XA transactions in the prepared state</td>
<td>Aurora cancels the upgrade. Commit or roll back all prepared XA transactions.</td>
</tr>
<tr>
<td>Cluster is processing any data definition language (DDL) statements</td>
<td>Aurora cancels the upgrade. Consider waiting and performing the upgrade after all DDL statements are finished.</td>
</tr>
<tr>
<td>Cluster has uncommitted changes for many rows</td>
<td>Upgrade might take a long time. The upgrade process rolls back the uncommitted changes. The indicator for this condition is the value of <code>TRX_ROWS_MODIFIED</code> in the <code>INFORMATION_SCHEMA.INNODB_TRX</code> table. Consider performing the upgrade only after all large transactions are committed or rolled back.</td>
</tr>
<tr>
<td>Cluster has high number of undo records</td>
<td>Upgrade might take a long time. Even if the uncommitted transactions don't affect a large number of rows, they might involve a large volume of data. For example, you might be inserting large BLOBs. Aurora doesn't automatically detect or generate an event for this kind of transaction activity. The indicator for this condition is the history list length. The upgrade process rolls back the uncommitted changes. Consider performing the upgrade only after the history list length is smaller.</td>
</tr>
<tr>
<td>Cluster is in the process of committing a large binary log transaction</td>
<td>Upgrade might take a long time. The upgrade process waits until the binary log changes are applied. More transactions or DDL statements could start during this period, further slowing down the upgrade process. Schedule the upgrade process when the cluster isn't busy with generating binary log replication changes. Aurora doesn't automatically detect or generate an event for this condition.</td>
</tr>
</tbody>
</table>
You can use the following steps to perform your own checks for some of the conditions in the preceding table. That way, you can schedule the upgrade at a time when you know the database is in a state where the upgrade can complete successfully and quickly.

- You can check for open XA transactions by executing the `XA RECOVER` statement. You can then commit or roll back the XA transactions before starting the upgrade.
- You can check for DDL statements by executing a `SHOW PROCESSLIST` statement and looking for `CREATE`, `DROP`, `ALTER`, `RENAME`, and `TRUNCATE` statements in the output. Allow all DDLs to finish before starting the upgrade.
- You can check the total number of uncommitted rows by querying the `INFORMATION_SCHEMA.INNODB_TRX` table. The table contains one row for each transaction. The `TRX_ROWS_MODIFIED` column contains the number of rows modified or inserted by the transaction.
- You can check the length of the InnoDB history list by executing the `SHOW ENGINE INNODB STATUS` SQL statement and looking for the `History list length` in the output. You can also check the value directly by running the following query:

```sql
SELECT count FROM information_schema.innodb_metrics WHERE name = 'trx_rseg_history_len';
```

The length of the history list corresponds to the amount of undo information stored by the database to implement multi-version concurrency control (MVCC).

**Aurora MySQL in-place upgrade tutorial**

The following Linux examples show how you might perform the general steps of the in-place upgrade procedure using the AWS CLI.

This first example creates an Aurora DB cluster that’s running a 1.x version of Aurora MySQL. The cluster includes a writer DB instance and a reader DB instance. The `wait db-instance-available` command pauses until the writer DB instance is available. That's the point when the cluster is ready to be upgraded.

```
# aws rds create-db-cluster --db-cluster-identifier cluster-56-2020-11-17-3824 --engine aurora \
   --db-cluster-version 5.6.mysql_aurora.1.22.3
...
# aws rds create-db-instance --db-instance-identifier instance-2020-11-17-7832 \
   --db-cluster-identifier cluster-56-2020-11-17-3824 --db-instance-class db.t2.medium --engine aurora
...
# aws rds wait db-instance-available --db-instance-identifier instance-2020-11-17-7832 --region us-east-1
```

The Aurora MySQL 2.x versions that you can upgrade the cluster to depend on the 1.x version that the cluster is currently running and on the AWS Region where the cluster is located. The first command, with `--output text`, just shows the available target version. The second command shows the full JSON output of the response. In that detailed response, you can see details such as the `aurora-mysql` value you use for the engine parameter, and the fact that upgrading to 2.07.3 represents a major version upgrade.

```
# aws rds describe-db-clusters --db-cluster-identifier cluster-56-2020-11-17-9355 \
   --query '*[].{EngineVersion:EngineVersion}' --output text
5.6.mysql_aurora.1.22.3

# aws rds describe-db-engine-versions --engine aurora --engine-version 5.6.mysql_aurora.1.22.3 \
   --query '*[].[ValidUpgradeTarget]' [ 
```
This example shows how if you enter a target version number that isn't a valid upgrade target for the
cluster, Aurora won't perform the upgrade. Aurora also won't perform a major version upgrade unless
you include the `--allow-major-version-upgrade` parameter. That way, you can't accidentally
perform an upgrade that has the potential to require extensive testing and changes to your application
code.

```
$ aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-9355 \
--engine-version 5.7.mysql_aurora.2.04.9 --region us-east-1 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster
operation: Cannot find upgrade target from 5.6.mysql_aurora.1.22.3 with requested version
5.7.mysql_aurora.2.04.9.

$ aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-9355 \
--engine-version 5.7.mysql_aurora.2.09.0 --region us-east-1 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster operation:
The AllowMajorVersionUpgrade flag must be present when upgrading to a new major version.

$ aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-9355 \
--engine-version 5.7.mysql_aurora.2.09.0 --region us-east-1 --apply-immediately --allow-
major-version-upgrade

```

```
{
"DBClusterIdentifier": "cluster-56-2020-11-17-9355",
"Status": "available",
"Engine": "aurora",
"EngineVersion": "5.6.mysql_aurora.1.22.3"
}
```

It takes a few moments for the status of the cluster and associated DB instances to change to
upgrading. The version numbers for the cluster and DB instances only change when the upgrade is
finished. Again, you can use the `wait db-instance-available` command for the writer DB instance
to wait until the upgrade is finished before proceeding.

```
$ aws rds describe-db-clusters --db-cluster-identifier cluster-56-2020-11-17-9355 \
--query '[][Status,EngineVersion]' --output text
upgrading 5.6.mysql_aurora.1.22.3

$ aws rds describe-db-instances --db-instance-identifier instance-2020-11-17-5158 \
--query '[]={DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceStatus:DBInstanceStatus} | [0]'
{
"DBInstanceIdentifier": "instance-2020-11-17-5158",
"DBInstanceStatus": "upgrading"
}

$ aws rds wait db-instance-available --db-instance-identifier instance-2020-11-17-5158
At this point, the version number for the cluster matches the one that was specified for the upgrade.

```
$ aws rds describe-db-clusters --region us-east-1 --db-cluster-identifier
cluster-56-2020-11-17-9355 \
```

```
The preceding example did an immediate upgrade by specifying the `--apply-immediately` parameter. To let the upgrade happen at a convenient time when the cluster isn't expected to be busy, you can specify the `--no-apply-immediately` parameter. Doing so makes the upgrade start during the next maintenance window for the cluster. The maintenance window defines the period during which maintenance operations can start. A long-running operation might not finish during the maintenance window. Thus, you don't need to define a larger maintenance window even if you expect that the upgrade might take a long time.

The following example upgrades a cluster that's initially running Aurora MySQL version 1.22.2. In the `describe-db-engine-versions` output, the `False` and `True` values represent the `IsMajorVersionUpgrade` property. From version 1.22.2, you can upgrade to some other 1.* versions. Those upgrades aren't considered major version upgrades and so don't require an in-place upgrade. In-place upgrade is only available for upgrades to the 2.07 and 2.09 versions that are shown in the list.

```bash
$ aws rds describe-db-clusters --region us-east-1 --db-cluster-identifier cluster-56-2020-11-17-3824 \\
   --query '[].{EngineVersion:EngineVersion}' --output text
5.6.mysql_aurora.1.22.2
$ aws rds describe-db-engine-versions --engine aurora --engine-version 5.6.mysql_aurora.1.22.2 \\
   --query '[].[ValidUpgradeTarget][0][0][*].[EngineVersion,IsMajorVersionUpgrade]' --output text
5.6.mysql_aurora.1.22.3 False
5.6.mysql_aurora.1.23.0 False
5.6.mysql_aurora.1.23.1 False
5.7.mysql_aurora.2.07.1 True
5.7.mysql_aurora.2.07.1 True
5.7.mysql_aurora.2.07.2 True
5.7.mysql_aurora.2.07.3 True
5.7.mysql_aurora.2.09.1 True

# aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-9355 \\
#   --engine-version 5.7.mysql_aurora.2.09.0 --region us-east-1 --no-apply-immediately --allow-major-version-upgrade
```

When a cluster is created without a specified maintenance window, Aurora picks a random day of the week. In this case, the `modify-db-cluster` command is submitted on a Monday. Thus, we change the maintenance window to be Tuesday morning. All times are represented in the UTC time zone. The `tue:10:00-tue:10:30` window corresponds to 2-2:30 AM Pacific time. The change in the maintenance window takes effect immediately.

```bash
$ aws rds describe-db-clusters --db-cluster-identifier cluster-56-2020-11-17-9355 --region us-east-1 --query '[].[PreferredMaintenanceWindow]' 
[ 
  "sat:08:20-sat:08:50"
]

# aws rds modify-db-cluster --db-cluster-identifier cluster-56-2020-11-17-3824 --preferred-maintenance-window tue:10:00-tue:10:30" 
# aws rds describe-db-clusters --db-cluster-identifier cluster-56-2020-11-17-3824 --region us-east-1 --query '[].[PreferredMaintenanceWindow]' 
[ 
  "tue:10:00-tue:10:30"
]
```
The following example shows how to get a report of the events generated by the upgrade. The `--duration` argument represents the number of minutes to retrieve the event information. This argument is needed because by default, describe-events only returns events from the last hour.

```
$ aws rds describe-events --source-type db-cluster --source-identifier cluster-56-2020-11-17-3824 --duration 20160
{
  "Events": [
    {
      "SourceIdentifier": "cluster-56-2020-11-17-3824",

Alternative blue-green upgrade technique

For situations where the top priority is to perform an immediate switchover from the old cluster to an upgraded one, you can use a multistep process that runs the old and new clusters side-by-side. In this case, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see this blog post: Performing major version upgrades for Amazon Aurora MySQL with minimum downtime.

Database engine updates for Amazon Aurora MySQL version 3

The following are database engine updates for Amazon Aurora MySQL version 3.

Topics

- Aurora MySQL database engine updates 2021-11-18 (version 3.01.0, compatible with MySQL 8.0.23) (p. 1070)

Aurora MySQL database engine updates 2021-11-18 (version 3.01.0, compatible with MySQL 8.0.23)

Version: 3.01.0

Aurora MySQL 3.01.0 is generally available. Aurora MySQL 3.01 versions are compatible with MySQL 8.0.23, Aurora MySQL 2.x versions are compatible with MySQL 5.7, and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

For details of new features in Aurora MySQL version 3 and differences between Aurora MySQL version 3 and Aurora MySQL version 2 or community MySQL 8.0, see Comparison of Aurora MySQL version 2 and Aurora MySQL version 3 (p. 717) and Comparison of Aurora MySQL version 3 and community MySQL 8.0 (p. 729).

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, 2.09.*, 2.10.*, and 3.01.*.

You can restore a snapshot from any currently supported Aurora MySQL version 2 cluster into Aurora MySQL 3.01.0.

For information on planning an upgrade to Aurora MySQL version 3, see Upgrade planning for Aurora MySQL version 3 (p. 733). For the upgrade procedure itself, see Upgrading to Aurora MySQL version 3 (p. 733). For general information about Aurora MySQL upgrades, see Upgrading Amazon Aurora MySQL DB clusters (p. 1050).
To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

Aurora MySQL version 3.01.0 is generally compatible with community MySQL 8.0.23. This version includes the security fixes for Common Vulnerabilities and Exposures (CVE) issues as of community MySQL 8.0.23.

Aurora MySQL version 3.01.0 contains all the Aurora-specific bug fixes through Aurora MySQL version 2.10.0.

For details of new features in Aurora MySQL version 3, see Features from community MySQL 8.0 (p. 716) and New parallel query optimizations (p. 717).

**Database engine updates for Amazon Aurora MySQL version 2**

The following are Amazon Aurora version 2 database engine updates:

- Aurora MySQL database engine updates 2021-10-21 (version 2.10.1) (p. 1072)
- Aurora MySQL database engine updates 2021-05-25 (version 2.10.0) (p. 1074)
- Aurora MySQL database engine updates 2021-11-12 (version 2.09.3) (p. 1079)
- Aurora MySQL database engine updates 2021-02-26 (version 2.09.2) (p. 1082)
- Aurora MySQL database engine updates 2020-12-11 (version 2.09.1) (p. 1084)
- Aurora MySQL database engine updates 2020-09-17 (version 2.09.0) (p. 1086)
- Aurora MySQL database engine updates 2020-11-12 (version 2.08.3) (p. 1091)
- Aurora MySQL database engine updates 2020-08-28 (version 2.08.2) (p. 1093)
- Aurora MySQL database engine updates 2020-06-18 (version 2.08.1) (p. 1094)
- Aurora MySQL database engine updates 2020-06-02 (version 2.08.0) (p. 1096)
- Aurora MySQL database engine updates 2021-11-24 (version 2.07.7) (p. 1099)
- Aurora MySQL database engine updates 2021-09-02 (version 2.07.6) (p. 1100)
- Aurora MySQL database engine updates 2021-07-06 (version 2.07.5) (p. 1102)
- Aurora MySQL database engine updates 2021-03-04 (version 2.07.4) (p. 1103)
- Aurora MySQL database engine updates 2020-11-10 (version 2.07.3) (p. 1105)
- Aurora MySQL database engine updates 2020-04-17 (version 2.07.2) (p. 1108)
- Aurora MySQL database engine updates 2019-12-23 (version 2.07.1) (p. 1110)
- Aurora MySQL database engine updates 2019-11-25 (version 2.07.0) (p. 1111)
- Aurora MySQL database engine updates 2019-11-22 (version 2.06.0) (p. 1113)
- Aurora MySQL database engine updates 2019-11-11 (version 2.05.0) (p. 1116)
- Aurora MySQL database engine updates 2020-08-14 (version 2.04.9) (p. 1118)
- Aurora MySQL database engine updates 2019-11-20 (version 2.04.8) (p. 1121)
- Aurora MySQL database engine updates 2019-11-14 (version 2.04.7) (p. 1123)
- Aurora MySQL database engine updates 2019-09-19 (version 2.04.6) (p. 1125)
- Aurora MySQL database engine updates 2019-07-08 (version 2.04.5) (p. 1126)
- Aurora MySQL database engine updates 2019-05-29 (version 2.04.4) (p. 1128)
Aurora MySQL database engine updates 2021-10-21 (version 2.10.1)

Version: 2.10.1

Aurora MySQL 2.10.1 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7, and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, 2.09.*, and 2.10.*.

You can upgrade an existing Aurora MySQL 2.* database cluster to Aurora MySQL 2.10.1. For clusters running Aurora MySQL version 1, you can upgrade an existing Aurora MySQL 1.23 or higher cluster directly to 2.10.1. You can also restore a snapshot from any currently supported Aurora MySQL release into Aurora MySQL 2.10.1.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

Security fixes:

- CVE-2021-2194
- CVE-2021-2174
- CVE-2021-2154
- CVE-2021-2307
• CVE-2021-2226
• CVE-2021-2171
• CVE-2021-2169
• CVE-2021-2166
• CVE-2021-2160
• CVE-2021-2060
• CVE-2021-2032
• CVE-2021-2001

Availability improvements:
• Added the ability to cleanly shut down the cluster for future major version upgrades.

General improvements:
• Fixed an issue that can cause high CPU consumption on the reader instances due to excessive logging of informational messages in internal diagnostic log files.
• Fixed an issue where the value of a TIMESTAMP column of an existing row is updated to the latest timestamp when all of the following conditions are satisfied:
  1. A trigger exists for the table.
  2. An INSERT is performed on the table that has an ON DUPLICATE KEY UPDATE clause.
  3. The inserted row causes a duplicate value violation in a UNIQUE index or PRIMARY KEY.
  4. One or more columns are of TIMESTAMP data type and have a default value of CURRENT_TIMESTAMP.
• Fixed an issue introduced in version 2.10.0 which causes use of json_merge function to raise an error code in certain cases. In particular, when json_merge function is used in a DDL containing generated columns, it can return error code 1305.
• Fixed an issue where, in rare conditions, read replicas restarts when a large object’s update history is being validated for a transaction's read view on the read replica.
• Fixed an issue which, in rare conditions, causes a writer instance to restart when an in-memory data-integrity check fails.

Integration of MySQL community edition bug fixes
• CURRENT_TIMESTAMP PRODUCES ZEROS IN TRIGGER. (Bug #25209512)

Comparison with Aurora MySQL version 1
The following Amazon Aurora MySQL features are supported in Aurora MySQL version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL version 2 (compatible with MySQL 5.7).
• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2021-05-25 (version 2.10.0)

Version: 2.10.0

Aurora MySQL 2.10.0 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7, and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, 2.09.*, and 2.10.*.

You can upgrade an existing Aurora MySQL 2.* database cluster to Aurora MySQL 2.10.0. For clusters running Aurora MySQL version 1, you can upgrade an existing Aurora MySQL 1.23 or higher cluster directly to 2.10.0. You can also restore a snapshot from any currently supported Aurora MySQL release into Aurora MySQL 2.10.0.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

Security fixes:

• CVE-2021-23841
New features:

- The `db.t3.large` instance class is now supported for Aurora MySQL.
- **Binary log replication:**
  - Introduced the binlog I/O cache to improve binlog performance by reducing contention between writer threads and dump threads. For more information, see Optimizing binary log replication (p. 914).
  - In Aurora MySQL version 2.08, we introduced improved binary log (binlog) processing to reduce crash recovery time and commit time latency when very large transactions are involved. These improvements are now supported for clusters that have GTID enabled.
- **Improved reader instance availability:**
  - Previously, when a writer instance restarted, all reader instances in an Aurora MySQL cluster restarted as well. With today's launch, in-Region reader instances continue to serve read requests during a writer instance restart, improving read availability in the cluster. For more information, see Rebooting an Aurora MySQL cluster (version 2.10 and higher) (p. 448).
    
    **Important**
    After you upgrade to Aurora MySQL 2.10, rebooting the writer instance doesn't perform a reboot of the entire cluster. If you want to reboot the entire cluster, now you reboot any reader instances in the cluster after rebooting the writer instance.
  - Improved the performance of the read ahead page reads requested by logical read ahead (LRA) technique. This was done by batching the multiple page reads in a single request sent to Aurora storage. As a result, the queries that use the LRA optimization execute up to 3x faster.
- **Zero-downtime restarts and patching:**
  - Improved zero-downtime restart (ZDR) and zero–downtime patching (ZDP) to enable ZDR and ZDP in a wider range of scenarios, including the added support for cases when binary logging is enabled. Also, improved visibility into ZDR and ZDP events. See documentation for details: Zero-downtime restart (ZDR) for Amazon Aurora MySQL (p. 885) and Using zero-downtime patching (p. 1054).

Availability improvements:

- Improvements for faster startup when the database has a large number of temporary indexes and tables created during a prior interrupted DDL activity.
- Fixed multiple issues related to repeated restarts during the crash recovery of interrupted DDL operations, such as `DROP TRIGGER`, `ALTER TABLE`, and specifically `ALTER TABLE` that modifies the type of partitioning or number of partitions in a table.
• Fixed an issue that could cause a server restart during Database Activity Streams (DAS) log processing.
• Fixed an issue printing an error message while processing an `ALTER` query on system tables.

**General improvements:**

• Fixed an issue where the query cache could return stale results on a reader instance.
• Fixed an issue where some Aurora commit metrics were not being updated when the system variable `innodb_flush_log_at_trx_commit` was set to 0 or 2.
• Fixed an issue where a query result stored in the query cache was not refreshed by multistatement transactions.
• Fixed an issue that could cause the last-modified timestamp of binary log files to not be updated correctly. This could lead to binary log files being purged prematurely, before reaching the customer-configured retention period.
• Fixed incorrect reported binlog filename and position from InnoDB after crash recovery.
• Fixed an issue that could cause large transactions to generate incorrect binlog events if the `binlog_checksum` parameter was set to `NONE`.
• Fixed an issue that caused a binlog replica to stop with an error if the replicated transaction contained a DDL statement and a large number of row changes.
• Fixed an issue leading to a restart in a reader instance when dropping a table.
• Fixed an issue that caused open source connectors to fail when attempting to consume a binlog file with a large transaction.
• Fixed an issue that could lead to incorrect query results on the large geometry column after creating a spatial index on the table with the large geometry values.
• The database now recreates the temporary tablespace during restart, which allows the associated storage space to be freed and reclaimed.
• Fixed an issue that prevented `performance_schema` tables from being truncated on Aurora reader instances.
• Fixed an issue that caused a binlog replica to stop with an `HA_ERR_KEY_NOT_FOUND` error.
• Fixed an issue that caused the database to restart when running `FLUSH TABLES WITH READ LOCK` statement.
• Fixed an issue that prevented the use of user-level lock functions on Aurora reader instances.

**Integration of MySQL community edition bug fixes**

• Interleaved transactions could sometimes deadlock the replica applier when the transaction isolation level was set to `REPEATABLE READ`. (Bug #25040331)
• When a stored procedure contained a statement referring to a view which in turn referred to another view, the procedure could not be invoked successfully more than once. (Bug #87858, Bug #26864199)
• For queries with many `OR` conditions, the optimizer now is more memory-efficient and less likely to exceed the memory limit imposed by the `range_optimizer_max_mem_size` system variable. In addition, the default value for that variable has been raised from 1,536,000 to 8,388,608. (Bug #79450, Bug #22283790)
• Replication: In the `next_event()` function, which is called by a replica's SQL thread to read the next event from the relay log, the SQL thread did not release the `relaylog.log_lock` it acquired when it ran into an error (for example, due to a closed relay log), causing all other threads waiting to acquire a lock on the relay log to hang. With this fix, the lock is released before the SQL thread leaves the function under the situation. (Bug #21697821)
• Fixing a memory corruption for `ALTER TABLE` with virtual column. (Bug #24961167; Bug #24960450)
• Replication: Multithreaded replicas could not be configured with small queue sizes using `slave_pending_jobs_size_max` if they ever needed to process transactions larger than that
size. Any packet larger than `slave_pending_jobs_size_max` was rejected with the error `ER_MTS_EVENT_BIGGER_PENDING_JOBS_SIZE_MAX`, even if the packet was smaller than the limit set by `slave_max_allowed_packet`. With this fix, `slave_pending_jobs_size_max` becomes a soft limit rather than a hard limit. If the size of a packet exceeds `slave_pending_jobs_size_max` but is less than `slave_max_allowed_packet`, the transaction is held until all the replica workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed. The queue size for replica workers can therefore be limited while still allowing occasional larger transactions. (Bug #21280753, Bug #77406)

- **Replication:** When using a multithreaded replica, applier errors displayed worker ID data that was inconsistent with data externalized in Performance Schema replication tables. (Bug #25231367)

- **Replication:** When using a multithreaded replica, applier errors displayed worker ID data that was inconsistent with data externalized in Performance Schema replication tables. (Bug #25231367)

- **Replication:** A partially failed statement was not correctly consuming an auto-generated or specified GTID when binary logging was disabled. The fix ensures that a partially failed DROP TABLE, a partially failed DROP USER, or a partially failed DROP VIEW consume respectively the relevant GTID and save it into `@@GLOBAL.GTID_EXECUTED` and `mysql.gtid_executed` table when binary logging is disabled. (Bug #21686749)

- **Replication:** Replicas running MySQL 5.7 could not connect to a MySQL 5.5 source due to an error retrieving the `server_uuid`, which is not part of MySQL 5.5. This was caused by changes in the method of retrieving the `server_uuid`. (Bug #22748612)

- **Replication:** The GTID transaction skipping mechanism that silently skips a GTID transaction that was previously executed did not work properly for XA transactions. (Bug #25041920)

- **Replication:** `~XA ROLLBACK` statements that failed because an incorrect transaction ID was given, could be recorded in the binary log with the correct transaction ID, and could therefore be actioned by replication replicas. A check is now made for the error situation before binary logging takes place, and failed `XA ROLLBACK` statements are not logged. (Bug #26618925)

- **Replication:** If a replica was set up using a CHANGE MASTER TO statement that did not specify the source log file name and source log position, then shut down before START SLAVE was issued, then restarted with the option `--relay-log-recovery` set, replication did not start. This happened because the receiver thread had not been started before relay log recovery was attempted, so no log rotation event was available in the relay log to provide the source log file name and source log position. In this situation, the replica now skips relay log recovery and logs a warning, then proceeds to start replication. (Bug #28996606, Bug #93397)

- **Replication:** In row-based replication, a message that incorrectly displayed field lengths was returned when replicating from a table with a `utf8mb3` column to a table of the same definition where the column was defined with a `utf8mb4` character set. (Bug #25135304, Bug #83918)

- **Replication:** When a `RESET SLAVE` statement was issued on a replication replica with GTIDs in use, the existing relay log files were purged, but the replacement new relay log file was generated before the set of received GTIDs for the channel had been cleared. The former GTID set was therefore written to the new relay log file as the `PREVIOUS_GTIDS` event, causing a fatal error in replication stating that the replica had more GTIDs than the source, even though the `gtid_executed` set for both servers was empty. Now, when `RESET SLAVE` is issued, the set of received GTIDs is cleared before the new relay log file is generated, so that this situation does not occur. (Bug #27411175)

- **Replication:** With GTIDs in use for replication, transactions including statements that caused a parsing error (ER_PARSE_ERROR) could not be skipped manually by the recommended method of injecting an empty or replacement transaction with the same GTID. This action should result in the replica identifying the GTID as already used, and therefore skipping the unwanted transaction that shared its GTID. However, in the case of a parsing error, because the statement was parsed before the GTID was
checked to see if it needed to be skipped, the replication applier thread stopped due to the parsing error, even though the intention was for the transaction to be skipped anyway. With this fix, the replication applier thread now ignores parsing errors if the transaction concerned needs to be skipped because the GTID was already used. Note that this behavior change does not apply in the case of workloads consisting of binary log output produced by mysqlbinlog. In that situation, there would be a risk that a transaction with a parsing error that immediately follows a skipped transaction would also be silently skipped, when it ought to raise an error. (Bug #27638268)

• Replication: Enable the SQL thread to GTID skip a partial transaction. (Bug #25800025)

• Replication: When a negative or fractional timeout parameter was supplied to WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(), the server behaved in unexpected ways. With this fix:
  • A fractional timeout value is read as-is, with no round-off.
  • A negative timeout value is rejected with an error if the server is on a strict SQL mode; if the server is not on a strict SQL mode, the value makes the function return NULL immediately without any waiting and then issue a warning. (Bug #24976304, Bug #83537)

• Replication: If the WAIT_FOR_EXECUTED_GTID_SET() function was used with a timeout value including a fractional part (for example, 1.5), an error in the casting logic meant that the timeout was rounded down to the nearest whole second, and to zero for values less than 1 second (for example, 0.1). The casting logic has now been corrected so that the timeout value is applied as originally specified with no rounding. Thanks to Dirkjan Bussink for the contribution. (Bug #29324564, Bug #94247)

• With GTIDs enabled, XA COMMIT on a disconnected XA transaction within a multiple-statement transaction raised an assertion. (Bug #22173903)

• Replication: An assertion was raised in debug builds if an XA ROLLBACK statement was issued for an unknown transaction identifier when the gtid_next value had been set manually. The server now does not attempt to update the GTID state if an XA ROLLBACK statement fails with an error. (Bug #27928837, Bug #90640)

• Fix wrong sorting order issue when multiple CASE functions are used in ORDER BY clause (Bug#22810883).

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).

• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).

• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).

• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.
This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement

Aurora MySQL database engine updates 2021-11-12 (version 2.09.3)

Version: 2.09.3

Aurora MySQL 2.09.3 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7, and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

Security fixes:

Fixes and other enhancements to fine-tune handling in a managed environment. Additional CVE fixes below:

- CVE-2021-23841
- CVE-2021-3712
- CVE-2021-3449
- CVE-2021-2307
- CVE-2021-2226
- CVE-2021-2174
- CVE-2021-2171
- CVE-2021-2169
- CVE-2021-2166
- CVE-2021-2154
- CVE-2021-2060
Amazon Aurora User Guide for Aurora
Database engine updates for
Amazon Aurora MySQL version 2

• CVE-2021-2032
• CVE-2021-2001
• CVE-2020-28196
• CVE-2020-14769
• CVE-2019-17543
• CVE-2019-2960

Availability improvements:

• Introduced an optimization which can reduce contention for queries that are executed on tables in information_schema.
• Add support for ECDHE SSL ciphers.

General improvements:

• Fixed an issue which, in rare conditions, can cause a writer instance to restart when an in-memory data-integrity check fails.
• Fixed an issue which, in rare conditions, can cause the database instance to restart when the cluster volume is expanding while binary logging is enabled.
• Fixed a rare race condition during a database instance restart, which can cause more than one restart.
• Fixed an issue which can cause a database instance restart to fail when the database has a large number of user and privilege combinations.
• Fixed an issue with parallel query which can cause the database to restart when executing SQL statements with LIMIT clause.
• Fixed an issue with incorrect reporting of aurora replication lag.
• Fixed an issue which can cause general_log and slow_log tables to become inaccessible after in-place major version upgrade from Aurora-MySQL 1.x (based on MySQL 5.6) to Aurora-MySQL 2.x (based on MySQL 5.7).
• Fixed an issue which, in rare cases, can cause the database instance to restart when innodb_trx, innodb_locks or innodb_lockwait tables are queried while the database is under heavy workload. Monitoring tools and features such as performance insights may query such tables.
• Fixed an issue which can cause a database instance to restart when "FLUSH TABLES WITH READ LOCK" SQL statement is executed.
• Fixed an issue where the InnoDB purge process pauses during the deletion of a reader instance leading to a temporary increase in history list length.
• Fixed an issue with parallel query which can cause the database to restart when executing a SQL statement against a table containing a virtual column.
• Fixed an issue with parallel query which can cause the database to return incorrect groupings or sort order when executing queries with GROUP BY clause and a WHERE clause containing a range predicate.
• Fixed an issue in parallel query which, in rare conditions, can cause the database to restart when executing SQL statements with JSON functions.
• Fixed an issue which, in rare conditions, can cause the writer instance in primary Global Database cluster to restart because of a race condition during Global Database Replication.
• Fixed an issue that can cause a Binlog replica to stop with an HA_ERR_FOUND_DUPP_KEY error when replicating certain DDL and DCL statements. The issue occurs when the source instance is configured with MIXED binary logging format and READ COMMITTED or READ UNCOMMITTED isolation level.
• Fixed an issue which, in rare conditions, can cause the database instance to restart when using XA transactions in READ COMMITTED isolation level.
• Fixed an issue where the value of a TIMESTAMP column of an existing row is updated to the latest timestamp when all of the following conditions are satisfied: 1\ A trigger exists for the table; 2\ an INSERT is performed on the table that has an ON DUPLICATE KEY UPDATE clause; 3\ the inserted row can cause a duplicate value violation in a UNIQUE index or PRIMARY KEY; and, 4\ one or more columns are of TIMESTAMP data type and have a default value of CURRENT_TIMESTAMP.

• Fixed an issue which, in rare conditions, can cause a reader instance to restart due to an incorrect check processing.

• Fixed an issue which, in rare conditions, can cause a writer instance to restart when an in-memory data-integrity check fails.

• Fixed an issue which can cause the reader instance to restart when the writer instance grows the database volume to cross specific volume size boundaries.

• Fixed an issue which can cause longer restart times for database instances using cloned cluster volumes.

• Fixed an issue where a database instance restart may fail one or more times after a TRUNCATE TABLE operation was performed on the writer instance.

• Fixed an issue which, in rare conditions, can cause the database instance to restart.

Integration of MySQL community edition bug fixes

• Bug #23533396 - When adding a new index, the server dropped an internally defined foreign key index and attempted to use a secondary index defined on a virtual generated column as the foreign key index, causing a server exit. InnoDB now permits a foreign key constraint to reference a secondary index defined on a virtual generated column.

• Bug #29550513 - Replication: A locking issue in the WAIT_FOR_EXECUTED_GTID_SET() function can cause the server to hang in certain circumstances. The issue has now been corrected.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).

• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).

• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).

• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:
• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The `CREATE TABLESPACE` SQL statement

Aurora MySQL database engine updates 2021-02-26 (version 2.09.2)

**Version:** 2.09.2

Aurora MySQL 2.09.2 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, and 2.09.*.

You can upgrade an existing Aurora MySQL 2.* database cluster to Aurora MySQL 2.09.2. For clusters running Aurora MySQL version 1, you can upgrade an existing Aurora MySQL 1.23 or higher cluster directly to 2.09.2. You can also restore a snapshot from any currently supported Aurora MySQL release into Aurora MySQL 2.09.2.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

**New features:**

- Aurora MySQL clusters now support the following EC2 R6g instances powered by Arm-based AWS Graviton2 processors: r6g.large, r6g.xlarge, r6g.2xlarge, r6g.4xlarge, r6g.8xlarge, r6g.12xlarge, r6g.16xlarge. For more information, see Aurora DB instance classes (p. 53).

**Security fixes:**

Fixes and other enhancements to fine-tune handling in a managed environment. Additional CVE fixes below:

- CVE-2020-14775
- CVE-2020-14793
Availability improvements:

- Fixed an issue introduced in 2.09.0 that can cause elevated write latency during the scaling of the cluster storage volume.
- Fixed an issue in the dynamic resizing feature that could cause Aurora Read Replicas to restart.
- Fixed an issue that could cause longer downtime during upgrade from 1.23.* to 2.09.*.
- Fixed an issue where a DDL or DML could cause engine restart during a page prefetch request.
- Fixed an issue that caused a binlog replica to stop with an error if the replicated transaction contains a DDL statement and a large number of row changes.
- Fixed an issue where a database acting as a binlog replica could restart while replicating a DDL event on the `mysql time_zone` table.
- Fixed an issue that could cause large transactions to generate incorrect binlog events if the `binlog_checksum` parameter was set to `NONE`.
- Fixed an issue that caused a binlog replica to stop with an `HA_ERR_KEY_NOT_FOUND` error.
- Improved overall stability.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- CVE-2020-14765
- CVE-2020-14769
- CVE-2020-14812
- CVE-2020-14760
- CVE-2020-14672
- CVE-2020-14790
- CVE-2020-1971
• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The `CREATE TABLESPACE` SQL statement

**Aurora MySQL database engine updates 2020-12-11 (version 2.09.1)**

**Version:** 2.09.1

Aurora MySQL 2.09.1 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, and 2.09.*.

You can upgrade an existing Aurora MySQL 2.* database cluster to Aurora MySQL 2.09.1. For clusters running Aurora MySQL version 1, you can upgrade an existing Aurora MySQL 1.23 or higher cluster directly to 2.09.1. You can also restore a snapshot from any currently supported Aurora MySQL release into Aurora MySQL 2.09.1.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

**Security fixes:**

Fixes and other enhancements to fine-tune handling in a managed environment. Additional CVE fixes below:

• CVE-2020-14567
• CVE-2020-14559
• CVE-2020-14553
• CVE-2020-14547
• CVE-2020-14540
• CVE-2020-2812
• CVE-2020-2806
Incompatible changes:

This version introduces a permission change that affects the behavior of the `mysqldump` command. Users must have the `PROCESS` privilege to access the `INFORMATION_SCHEMA.FILES` table. To run the `mysqldump` command without any changes, grant the `PROCESS` privilege to the database user that the `mysqldump` command connects to. You can also run the `mysqldump` command with the `--no-tablespaces` option. With that option, the `mysqldump` output doesn't include any `CREATE LOGFILE GROUP` or `CREATE TABLESPACE` statements. In that case, the `mysqldump` command doesn't access the `INFORMATION_SCHEMA.FILES` table, and you don't need to grant the `PROCESS` permission.

Availability improvements:

- Fixed an issue that might cause a client session to hang when the database engine encounters an error while reading from or writing to the network.
- Fixed a memory leak in dynamic resizing feature, introduced in 2.09.0.

Global databases:

- Fixed multiple issues where a global database secondary Region's replicas might restart when upgraded to release 2.09.0 while the primary Region writer was on an older release version.

Integration of MySQL community edition bug fixes

- **Replication**: Interleaved transactions could sometimes deadlock the slave applier when the transaction isolation level was set to `REPEATABLE READ`. (Bug #25040331)
- For a table having a `TIMESTAMP` or `DATETIME` column having a default of `CURRENT_TIMESTAMP`, the column could be initialized to `0000-00-00 00:00:00` if the table had a `BEFORE INSERT` trigger. (Bug #25209512, Bug #84077)
- For an `INSERT` statement for which the `VALUES` list produced values for the second or later row using a subquery containing a join, the server could exit after failing to resolve the required privileges. (Bug #23762382)

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement

Aurora MySQL database engine updates 2020-09-17 (version 2.09.0)

Version: 2.09.0

Aurora MySQL 2.09.0 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, and 2.09.*.

You can restore a snapshot from Aurora MySQL 1.23.* into Aurora MySQL 2.09.0. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.09.0. You can't upgrade an existing Aurora MySQL 1.23.* cluster directly to 2.09.0; however, you can restore its snapshot to Aurora MySQL 2.09.0.

**Important**
The improvements to Aurora storage in this version limit the available upgrade paths from Aurora MySQL 1.* to Aurora MySQL 2.09. When you upgrade an Aurora MySQL 1.* cluster to 2.09, you must upgrade from Aurora MySQL 1.23.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).
### Improvements

**New features:**

- With this release, you can create Amazon Aurora MySQL database instances with up to 128 tebibytes (TiB) of storage. The new storage limit is an increase from the prior 64 TiB. The 128 TiB storage size supports larger databases. This capability is not supported on small instances sizes (db.t2 or db.t3). A single tablespace cannot grow beyond 64 TiB due to InnoDB limitations with 16 KB page size.

  Aurora alerts you when the cluster volume size is near 128 TiB, so that you can take action prior to hitting the size limit. The alerts appear in the mysql log and RDS Events in the AWS Management Console.

- You can now turn parallel query on or off for an existing cluster by changing the value of the DB cluster parameter `aurora_parallel_query`. You don't need to use the `parallelquery` setting for the `--engine-mode` parameter when creating the cluster.

  Parallel query is now expanded to be available in all regions where Aurora MySQL is available.

  There are a number of other functionality enhancements and changes to the procedures for upgrading and enabling parallel query in an Aurora cluster. For more information, see Working with parallel query for Amazon Aurora MySQL (p. 847).

- Aurora dynamically resizes your cluster storage space. With dynamic resizing, the storage space for your Aurora DB cluster automatically decreases when you remove data from the DB cluster. For more information, see Storage scaling (p. 392).

  **Note**

  The dynamic resizing feature is being deployed in phases to the AWS Regions where Aurora is available. Depending on the Region where your cluster is, this feature might not be available yet. For more information, see the What's New announcement.

**High priority fixes:**

- Backport of Community Bug #27659490: SELECT USING DYNAMIC RANGE AND INDEX MERGE USE TOO MUCH MEMORY (OOM)
- Bug #26881508: MYSQL #1: DISABLE_ABORT_ON_ERROR IN AUTH_COMMON.H
- Backport of Community Bug #24437124: POSSIBLE BUFFER OVERFLOW ON CREATE TABLE
- Backport of Bug #27158030: INNODB ONLINE ALTER CRASHES WITH CONCURRENT DML
- Bug #29770705: SERVER CRASHED WHILE EXECUTING SELECT WITH SPECIFIC WHERE CLAUSE
- Backport of Bug #26502135: MYSQLD SEGFAULTS IN MDL_CONTEXT::TRY_ACQUIRE_LOCK_IMPL
- Backport of Bug #26935001: ALTER TABLE AUTO_INCREMENT TRIES TO READ INDEX FROM DISCARDED TABLESPACE
- Bug #28491099: [FATAL] MEMORY BLOCK IS INVALID | INNODB: ASSERTION FAILURE: UTOUT.CC:670
- Bug #30499288: GCC 9.2.1 REPORTS A NEW WARNING FOR OS_FILE_GET_PARENT_DIR
- Bug #29952565 where MYSQLD GOT SIGNAL 11 WHILE EXECUTING A QUERY(UNION + ORDER BY + SUB-QUERY)
- Bug #30628268: OUT OF MEMORY CRASH
- Bug #30441969: BUG #29723340: MYSQL SERVER CRASH AFTER SQL QUERY WITH DATA ?AST
- Bug #30569003: 5.7 REPLICATION BREAKAGE WITH SYNTAX ERROR WITH GRANT MANAGEMENT
- Bug #29915479: RUNNING COM_REGISTER_SLAVE WITHOUT COM_BINLOG_DUMP CAN RESULTS IN SERVER EXIT
- Bug #30569003: 5.7 REPLICATION BREAKAGE WITH SYNTAX ERROR WITH GRANT MANAGEMENT
- Bug #29915479: RUNNING COM_REGISTER_SLAVE WITHOUT COM_BINLOG_DUMP CAN RESULTS IN SERVER EXIT
• Bug #20712046: SHOW PROCESSLIST AND PERFORMANCE_SCHEMA TABLES DO NOT MASK PASSWORD FROM QUERY

• Backport bug #18898433: EXTREMELY SLOW PERFORMANCE WITH OUTER JOINS AND JOIN BUFFER (fixed in 5.7.21). Queries with many left joins were slow if join buffering was used (for example, using the block nested loop algorithm). (Bug #18898433, Bug #72854)"

• Backport bug #26402045: MYSQLD CRASHES ON QUERY (fixed in MySQL 5.7.23). Certain cases of subquery materialization could cause a server exit. These queries now produce an error suggesting that materialization be disabled. (Bug #26402045)

• [Backport from MySQL] users other than rdsadmin is disallowed to update pfs table in the reader replica.

• Fix the issue where the customer can not update the perf schema in the reader replica

• Bug #26666274: INFINITE LOOP IN PERFORMANCE SCHEMA BUFFER CONTAINER

• Bug #26997096: relay_log_space value is not updated in a synchronized manner so that its value sometimes much higher than the actual disk space used by relay logs.

• BUG #25082593: FOREIGN KEY VALIDATION DOESN’T NEED TO ACQUIRE GAP LOCK IN READ COMMITTED

• CVE-2019-2731
• CVE-2018-2645
• CVE-2019-2581
• CVE-2018-2787
• CVE-2019-2482
• CVE-2018-2640
• CVE-2018-2784
• CVE-2019-2628
• CVE-2019-2911
• CVE-2019-2628
• CVE-2018-3284
• CVE-2018-3065
• CVE-2019-2537
• CVE-2019-2948
• CVE-2019-2434
• CVE-2019-2420

Availability improvements:

• Enable lock manager ABA fix by default.

• Fixed an issue in the lock manager where a race condition can cause a lock to be shared by two transactions, causing the database to restart.

• Fixed an issue when creating a temporary table with compressed row format might result in a restart.

• Fix default value of table_open_cache on 16XL and 24XL instances which could cause repeated failovers and high CPU utilization on large instances classes (R4/R5-16XL, R5-12XL, R5-24XL). This impacted 2.07.x.

• Fixed an issue where restoring a cluster from Amazon S3 to Aurora MySQL version 2.08.0 takes longer than expected when the S3 backup didn't include the mysql.host table.

• Fixed an issue which might cause repeated failovers due to updates of virtual columns with secondary indexes.
• Fixed an issue related to transaction lock memory management with long-running write transactions resulting in a database restart.
• Fixed multiple issues where the engine might crash during zero-downtime patching while checking for safe point for patching.
• Fixed an issue to skip redo logging for temporary tables, which was previously causing a crash.
• Fixed a race condition in the lock manager between killing connection/query and the session killed.
• Fixed an issue where the database could crash if it is a binlog replica and receives a DDL event over the MySQL time_zone table.

Global databases:
• MySQL INFORMATION_SCHEMA.REPLICA_HOST_STATUS view in a secondary Region now shows the entries for the replicas belonging to that Region.
• Fixed unexpected query failures that could occur in a Global DB secondary Region after temporary network connectivity issues between the primary and secondary Regions.

Parallel query:
• Fixed the EXPLAIN plan for a Parallel Query query, which is incorrect for a simple single-table query.
• Fixed self-deadlatch that may occur when Parallel Query is enabled.

General improvements:
• Export to S3 now supports the ENCRYPTION keyword.
• The aurora_binlog_replication_max_yield_seconds parameter now has a max value of 36,000. The previous maximum accepted value was 45. This parameter works only when the parameter aurora_binlog_use_large_read_buffer is set to 1.
• Changed the behavior to map MIXED binlog_format to ROW instead of STATEMENT when executing LOAD DATA FROM INFILE | S3.
• Fixed an issue where a binlog replica connected to an Aurora MySQL binlog primary might show incomplete data when the primary executed LOAD DATA FROM S3 and binlog_format is set to STATEMENT.
• Increased maximum allowable length for audit system variables server_audit_incl_users and server_audit_excl_users from 1024 bytes to 2000 bytes.
• Fixed an issue where users may lose access to the database when lowering the max_connections parameter in the parameter group when the current connections is greater than the value being set.
• Fixed an issue in Data Activity Streams where a single quote and backslash were not escaped properly.

Integration of MySQL community edition bug fixes
• Bug #27659490: SELECT USING DYNAMIC RANGE AND INDEX MERGE USE TOO MUCH MEMORY(OOM)
• Bug #26881508: MYSQL #1: DISABLE_ABORT_ON_ERROR IN AUTH_COMMON.H
• Bug #24437124: POSSIBLE BUFFER OVERFLOW ON CREATE TABLE
• Bug #27158030: INNODB ONLINE ALTER CRASHES WITH CONCURRENT DML
• Bug #29770705: SERVER CRASHED WHILE EXECUTING SELECT WITH SPECIFIC WHERE CLAUSE
• Bug #26502135: MYSQLD SEGFAULTS IN MDL_CONTEXT::TRY_ACQUIRE_LOCK_IMPL
• Bug #26935001: ALTER TABLE AUTO_INCREMENT TRIES TO READ INDEX FROM DISCARDED TABLESPACE
• Bug #28491099: [FATAL] MEMORY BLOCK IS INVALID | INNODB: ASSERTION FAILURE: UTOUT.CC:670
• Bug #30499288: GCC 9.2.1 REPORTS A NEW WARNING FOR OS_FILE_GET_PARENT_DIR
• Bug #29952565: where MYNDL GOT SIGNAL 11 WHILE EXECUTING A QUERY(UNION + ORDER BY + SUB-QUERY)
• Bug #30628268: OUT OF MEMORY CRASH
• Bug #30441969: BUG #29723340: MYSQL SERVER CRASH AFTER SQL QUERY WITH DATA ?AST
• Bug #30569003: 5.7 REPLICATION BREAKAGE WITH SYNTAX ERROR WITH GRANT MANAGEMENT
• Bug #29915479: RUNNING COM_REGISTER_SLAVE WITHOUT COM_BINLOG_DUMP CAN RESULTS IN SERVER EXIT
• Bug #30569003: 5.7 REPLICATION BREAKAGE WITH SYNTAX ERROR WITH GRANT MANAGEMENT
• Bug #29915479: RUNNING COM_REGISTER_SLAVE WITHOUT COM_BINLOG_DUMP CAN RESULTS IN SERVER EXIT
• Bug #20712046: SHOW PROCESSLIST AND PERFORMANCE_SCHEMA TABLES DO NOT MASK PASSWORD FROM QUERY
• Bug #18898433: EXTREMELY SLOW PERFORMANCE WITH OUTER JOINS AND JOIN BUFFER (fixed in 5.7.21)
• Bug #26402045: MYSQLD CRASHES ON QUERY (fixed in MySQL 5.7.23)
• Bug #23103937: PS_TRUNCATE_ALL_TABLES() DOES NOT WORK IN SUPER_READ_ONLY MODE
• Bug #26666274: INFINITE LOOP IN PERFORMANCE_SCHEMA BUFFER CONTAINER
• Bug #26997096: relay_log_space value is not updated in a synchronized manner so that its value sometimes much higher than the actual disk space used by relay logs. (https://github.com/mysql/mysql-server/commit/78f25d2809ad457e81f90342239c9bc32a36cdfa)
• Bug #25082593: FOREIGN KEY VALIDATION DOESN'T NEED TO ACQUIRE GAP LOCK IN READ COMMITTED
• Bug #24764800: REPLICATION FAILING ON SLAVE WITH XAER_RMFAIL ERROR.
• Bug #81441: WARNING ABOUT LOCALHOST WHEN USING SKIP-NAME-RESOLVE.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of
Spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement

**Aurora MySQL database engine updates 2020-11-12 (version 2.08.3)**

**Version:** 2.08.3

Aurora MySQL 2.08.3 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases for upgrade to 2.08.3 are: 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, and 2.08.*.

You can upgrade existing Aurora MySQL 2.* database clusters directly to Aurora MySQL 2.08.3. You can upgrade an existing Aurora MySQL 1.* cluster directly to 2.07.3 or higher and then directly upgrade to 2.08.3.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**

For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

**Security fixes:**

Fixes and other enhancements to fine-tune handling in a managed environment. Additional CVE fixes below:

- CVE-2020-14567
- CVE-2020-14559
- CVE-2020-14553
- CVE-2020-14547
Incompatible changes:

This version introduces a permission change that affects the behavior of the `mysqldump` command. Users must have the `PROCESS` privilege to access the `INFORMATION_SCHEMA.FILES` table. To run the `mysqldump` command without any changes, grant the `PROCESS` privilege to the database user that the `mysqldump` command connects to. You can also run the `mysqldump` command with the `--no-tablespaces` option. With that option, the `mysqldump` output doesn't include any `CREATE LOGFILE GROUP` or `CREATE TABLESPACE` statements. In that case, the `mysqldump` command doesn't access the `INFORMATION_SCHEMA.FILES` table, and you don't need to grant the `PROCESS` permission.

Integration of MySQL community edition bug fixes

- Bug #23762382 - INSERT VALUES QUERY WITH JOIN IN A SELECT CAUSES INCORRECT BEHAVIOR.
- Bug #25209512 - CURRENT_TIMESTAMP PRODUCES ZEROS IN TRIGGER.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The `CREATE TABLESPACE` SQL statement

Aurora MySQL database engine updates 2020-08-28 (version 2.08.2)

Version: 2.08.2

Aurora MySQL 2.08.2 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, and 2.08.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.08.2. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.08.2. You can't upgrade an existing Aurora MySQL 1.* cluster directly to 2.08.2; however, you can restore its snapshot to Aurora MySQL 2.08.2. See Restoring from a DB cluster snapshot (p. 493) for more information about restoring snapshots.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

Critical fixes:

• Fixed an issue that might cause an unplanned outage and affect database availability.

Availability fixes:

• Fixed an issue where the Aurora MySQL database could restart if it is a binlog replica and replicates a DDL event over the `mysql time_zone` table.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).
• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:
• Group replication plugin
• Increased page size

• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2020-06-18 (version 2.08.1)

Version: 2.08.1

Aurora MySQL 2.08.1 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, and 2.08.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.08.1. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.08.1. You can’t upgrade an existing Aurora MySQL 1.* cluster directly to 2.08.1; however, you can restore its snapshot to Aurora MySQL 2.08.1.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).
Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

New features:

- Global database write forwarding. In an Aurora global database, now you can perform certain write operations, such as DML statements, while connected to a secondary cluster. The write operations are forwarded to the primary cluster, and any changes are replicated back to the secondary clusters. For more information, see Using write forwarding in an Amazon Aurora global database (p. 253).

General stability fixes:

- Fixed an issue where restoring a cluster from Amazon S3 to Aurora MySQL version 2.08.0 took longer than expected if the S3 backup didn't include the mysql.host table.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7):

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2020-06-02 (version 2.08.0)

Version: 2.08.0

Aurora MySQL 2.08.0 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, and 2.08.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.08.0. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.08.0. You can’t upgrade an existing Aurora MySQL 1.* cluster directly to 2.08.0; however, you can restore its snapshot to Aurora MySQL 2.08.0.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

New features:
• Improved binary log (binlog) processing to reduce crash recovery time and commit time latency when very large transactions are involved.
• Launching Database Activity Streams (DAS) feature for Aurora MySQL. This feature provides a near-real-time data stream of the database activity in your relational database to help you monitor activity. For more information, see Monitoring Amazon Aurora using Database Activity Streams (p. 683).
• Updated timezone files to support the latest Brazil timezone change.
• Introduced new keywords in SQL to exercise the hash join functionality for a specific table and/or inner table: HASH_JOIN, HASH_JOIN_PROBING, and HASH_JOIN_BUILDING. For additional details, see Aurora MySQL hints (p. 1038).
• Introduced join order hint support in Aurora MySQL 5.7 by backporting a MySQL 8.0 feature. The new hints are JOIN_FIXED_ORDER, JOIN_ORDER, JOIN_PREFIX, and JOIN_SUFFIX. For detailed documentation of join order hint support, see WL#9158: Join order hints.
• Aurora Machine Learning now supports user-defined functions with MEDIUMINT as the return type.
• The lambda_async() stored procedure now supports all MySQL utf8 characters.

High priority fixes:
• Fixed an issue that could cause a reader DB instance to return incomplete results for an FTS query after the INFORMATION_SCHEMA.INNODB_SYS_TABLES table is queried on the writer DB instance.
• CVE-2019-5443
• **CVE-2019-3822**

**Availability improvements:**

- Fixed an issue that resulted in a database restart after a multi-query statement that accesses multiple tables or databases is executed with the query cache enabled.
- Fixed a race condition in the lock manager that resulted in a database restart or failover during transaction rollback.
- Fixed an issue that triggered database restart or failover when multiple connections are trying to update the same table with a Full-Text Search index.
- Fixed an issue that could trigger a database restart or failover during a `kill session` command. If you encounter this issue, contact AWS support to enable this fix on your instance.
- Fixed an issue that caused reader DB instance to restart during a multi-statement transaction with multiple `SELECT` statements and a heavy write workload on the writer DB instance with `AUTOCOMMIT` enabled.
- Fixed an issue that caused reader DB instance to restart after executing long-running queries while the writer DB instance is under a heavy OLTP write workload.

**General improvements:**

- Improved database recovery time and commit latency for long running transactions when binlog is enabled.
- Improved the algorithm to generate better statistics for estimating distinct value counts on indexed columns, including columns with skewed data distributions.
- Reduced the response time and CPU utilization of join queries that access MyISAM temporary tables and the results spill to local storage.
- Fixed an issue that prevented Aurora MySQL 5.6 snapshots with database or table names containing spaces from being restored to a new Aurora MySQL 5.7 cluster.
- Included victim transaction info when deadlock is resolved in `show engine innodb status`.
- Fixed an issue that caused connections to get stuck when clients of multiple different versions are connected to the same database and are accessing the query cache.
- Fixed a memory leak resulting from multiple invocations of the Zero-Downtime Patch (ZDP) or Zero-Downtime Restart (ZDR) workflow throughout the lifetime of a database instance.
- Fixed an error message in Zero-Downtime Patch (ZDP) or Zero-Downtime Restart (ZDR) operations wrongly stating that the last transaction was aborted if the auto-commit flag is turned off.
- Fixed an issue in Zero-Downtime Patch (ZDP) operations that could lead to a server failure error message when restoring user session variables in the new database process.
- Fixed an issue in Zero Downtime Patch (ZDP) operations that might cause intermittent database failures when there are long running queries during patching.
- Fixed an issue where queries including an Aurora Machine Learning function returned empty error messages due to an incorrectly handled error response from Machine Learning services such as Amazon Sagemaker and Amazon Comprehend.
- Fixed an issue in the out-of-memory monitoring functionality that did not honor a custom value of the `table_definition_cache` parameter.
- The error message “Query execution was interrupted” is returned if an Aurora Machine Learning query is interrupted. Previously, the generic message “Internal error in processing ML request” was returned instead.
- Fixed an issue that could cause a binlog worker to experience a connection timeout when the `slave_net_timeout` parameter is less than the `aurora_binlog_replication_max_yield_seconds` parameter and there is low workload on the binlog master cluster.
• Improved monitoring of the binlog recovery progress by outputting informational messages in the error log at a frequency of one message per minute.
• Fixed an issue that could cause active transactions not to be reported by the SHOW ENGINE INNODB STATUS query.

Integration of MySQL community edition bug fixes

• Bug #25289359: A full-text cache lock taken when data is synchronized was not released if the full-text cache size exceeded the full-text cache size limit.
• Bug #29138644: Manually changing the system time while the MySQL server was running caused page cleaner thread delays.
• Bug #2522337: A NULL virtual column field name in a virtual index caused a server exit during a field name comparison that occurs while populating virtual columns affected by a foreign key constraint.
• Bug #25053286: Executing a stored procedure containing a query that accessed a view could allocate memory that was not freed until the session ended.
• Bug #25586773: Executing a stored procedure containing a statement that created a table from the contents of certain SELECT statements could result in a memory leak.
• Bug #28834208: During log application, after an OPTIMIZE TABLE operation, InnoDB did not populate virtual columns before checking for virtual column index updates.
• Bug #26666274: Infinite loop in performance schema buffer container due to 32-bit unsigned integer overflow.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement

**Aurora MySQL database engine updates 2021-11-24 (version 2.07.7)**

**Version:** 2.07.7

Aurora MySQL 2.07.7 is generally available. Aurora MySQL 2.* versions are compatible with MySQL 5.7 and Aurora MySQL 1.* versions are compatible with MySQL 5.6.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

**Security fixes:**

Fixes and other enhancements to fine-tune handling in a managed environment. Additional CVE fixes below:

- CVE-2019-17543
- CVE-2019-2960

**General improvements:**

- Fixed security issues related to Aurora MySQL integration with other AWS Services such as Amazon S3, Amazon ML, Lambda.
- Fixed an issue with incorrect reporting of an Aurora replication lag.
- Fixed an issue which can cause a database instance restart to fail when the database has a large number of user and privilege combinations.
- Fixed an issue which can cause `general_log` and `slow_log` tables to become inaccessible after in-place major version upgrade from Aurora MySQL 1.x (based on MySQL 5.6) to Aurora MySQL 2.x (based on MySQL 5.7).
- Fixed an issue which, in rare conditions, can cause a reader instance to restart due to an incorrect check processing.
- Fixed an issue which, in rare conditions, shows the “Database Load” chart in Performance Insights (PI) sessions as actively using CPU even though the sessions have finished processing and are idle.
- Fixed an issue with parallel query which can cause the database to restart when executing SQL statements with a LIMIT clause.
- Fixed an issue where the value of a TIMESTAMP column of an existing row is updated to the latest timestamp when all of the following conditions are satisfied: 1. A trigger exists for the table; 2. an `INSERT` is performed on the table that has an ON DUPLICATE KEY UPDATE clause; 3. the inserted row can cause a duplicate value violation in a UNIQUE index or PRIMARY KEY; and, 4. one or more columns are of TIMESTAMP data type and have a default value of CURRENT_TIMESTAMP.
Fixed an issue which, in rare conditions, can cause the database instance to restart when using XA transactions in READ COMMITTED isolation level.

Integration of MySQL community edition bug fixes

- INSERTING 64K SIZE RECORDS TAKE TOO MUCH TIME. (Bug#23031146)

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2021-09-02 (version 2.07.6)

Version: 2.07.6
Aurora MySQL 2.07.6 is generally available. Aurora MySQL 2.* versions are compatible with MySQL 5.7 and Aurora MySQL 1.* versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, 2.09.*, and 2.10.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.07.6. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.07.6. You can't upgrade an existing Aurora MySQL 1.* cluster directly to 2.07.6; however, you can restore its snapshot to Aurora MySQL 2.07.6.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

Note
This version is designated as a long-term support (LTS) release. For more information, see Aurora MySQL long-term support (LTS) releases (p. 1049).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Integration of MySQL community edition bug fixes

- INSERTING 64K SIZE RECORDS TAKE TOO MUCH TIME. (Bug#23031146)

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2021-07-06 (version 2.07.5)

Version: 2.07.5

Aurora MySQL 2.07.5 is generally available. Aurora MySQL 2.* versions are compatible with MySQL 5.7 and Aurora MySQL 1.* versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, 2.09.*, and 2.10.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.07.5. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.07.5. You can’t upgrade an existing Aurora MySQL 1.* cluster directly to 2.07.5; however, you can restore its snapshot to Aurora MySQL 2.07.5.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

Note
This version is designated as a long-term support (LTS) release. For more information, see Aurora MySQL long-term support (LTS) releases (p. 1049).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

Availability improvements:
• Fixed an issue that user-level locks are not allowed on an Aurora Replica.
• Fixed an issue that could cause a restart of a database when using XA transactions in READ COMMITTED isolation level.
• Extended maximum allowable length to 2000 for the server_audit_incl_users and server_audit_excl_users global parameters.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:
• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2021-03-04 (version 2.07.4)

Version: 2.07.4

Aurora MySQL 2.07.4 is generally available. Aurora MySQL 2.* versions are compatible with MySQL 5.7 and Aurora MySQL 1.* versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, and 2.09.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.07.4. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.07.4. You can’t upgrade an existing Aurora MySQL 1.* cluster directly to 2.07.4; however, you can restore its snapshot to Aurora MySQL 2.07.4.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

Note
This version is designated as a long-term support (LTS) release. For more information, see Aurora MySQL long-term support (LTS) releases (p. 1049).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).
Improvements

Security fixes:

- CVE-2020-14812
- CVE-2020-14793
- CVE-2020-14790
- CVE-2020-14775
- CVE-2020-14769
- CVE-2020-14765
- CVE-2020-14760
- CVE-2020-14672
- CVE-2020-1971

Availability improvements:

- Fixed an issue that could cause a client to hang in case of a network error while reading or writing a network packet.
- Improved engine restart times in some cases after interrupted DDL.
- Fixed an issue where a DDL or DML could cause engine restart during a page prefetch request.
- Fixed an issue where a replica could restart while performing a reverse scan of a table/index on an Aurora Read Replica.
- Fixed an issue in clone cluster operation that could cause the clone to take longer.
- Fixed an issue that could cause a restart of a database when using parallel query optimization for geospatial column.
- Fixed an issue that caused a binlog replica to stop with an HA_ERR_KEY_NOT_FOUND error.

Integration of MySQL community edition bug fixes

- Fixed an issue in the Full-text ngram parser when dealing with tokens containing '' (space), '%', or ','. Customers should rebuild their FTS indexes if using ngram parser. (Bug #25873310)
- Fixed an issue that could cause engine restart during query execution with nested SQL views. (Bug #27214153, Bug #26864199)

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).
MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement

Aurora MySQL database engine updates 2020-11-10 (version 2.07.3)

Version: 2.07.3

Aurora MySQL 2.07.3 is generally available. Aurora MySQL 2.* versions are compatible with MySQL 5.7 and Aurora MySQL 1.* versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, and 2.09.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.07.3. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.07.3. You can’t upgrade an existing Aurora MySQL 1.* cluster directly to 2.07.3; however, you can restore its snapshot to Aurora MySQL 2.07.3.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

Note

This version is designated as a long-term support (LTS) release. For more information, see Aurora MySQL long-term support (LTS) releases (p. 1049).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

Security fixes:

Fixes and other enhancements to fine-tune handling in a managed environment. Additional CVE fixes below:

- CVE-2020-14567
Incompatible changes:

This version introduces a permission change that affects the behavior of the `mysqldump` command. Users must have the `PROCESS` privilege to access the `INFORMATION_SCHEMA.FILES` table. To run the `mysqldump` command without any changes, grant the `PROCESS` privilege to the database user that the `mysqldump` command connects to. You can also run the `mysqldump` command with the `--no-tablespaces` option. With that option, the `mysqldump` output doesn't include any `CREATE LOGFILE GROUP` or `CREATE TABLESPACE` statements. In that case, the `mysqldump` command doesn't access the `INFORMATION_SCHEMA.FILES` table, and you don't need to grant the `PROCESS` permission.

Availability improvements:

- Fixed a race condition in the lock manager between the killing of a connection/query and the termination of the session resulting in a database restart.
- Fixed an issue that results in a database restart after a multi-query statement that accesses multiple tables or databases is executed with the query cache enabled.
- Fixed an issue that might cause repeated restarts due to updates of virtual columns with secondary indexes.

Integration of MySQL community edition bug fixes

- **InnoDB**: Concurrent XA transactions that ran successfully to the XA prepare stage on the master conflicted when replayed on the slave, resulting in a lock wait timeout in the applier thread. The conflict was due to the GAP lock range which differed when the transactions were replayed serially on the slave. To prevent this type of conflict, GAP locks taken by XA transactions in `READ COMMITTED` isolation level are now released (and no longer inherited) when XA transactions reach the prepare stage. (Bug #27189701, Bug #25866046)
- **InnoDB**: A gap lock was taken unnecessarily during foreign key validation while using the `READ COMMITTED` isolation level. (Bug #25082593)
- **Replication**: When using XA transactions, if a lock wait timeout or deadlock occurred for the applier (SQL) thread on a replication slave, the automatic retry did not work. The cause was that while the SQL thread would do a rollback, it would not roll the XA transaction back. This meant that when the transaction was retried, the first event was XA START which was invalid as the XA transaction was already in progress, leading to an XAER_RMFAIL error. (Bug #24764800)
- **Replication**: Interleaved transactions could sometimes deadlock the slave applier when the transaction isolation level was set to `REPEATABLE READ`. (Bug #25040331)
- **Replication**: The value returned by a `SHOW SLAVE STATUS` statement for the total combined size of all existing relay log files (`Relay_Log_Space`) could become much larger than the actual disk space.
used by the relay log files. The I/O thread did not lock the variable while it updated the value, so the SQL thread could automatically delete a relay log file and write a reduced value before the I/O thread finished updating the value. The I/O thread then wrote its original size calculation, ignoring the SQL thread’s update and so adding back the space for the deleted file. The Relay_Log_Space value is now locked during updates to prevent concurrent updates and ensure an accurate calculation. (Bug #26997096, Bug #87832)

- For an INSERT statement for which the VALUES list produced values for the second or later row using a subquery containing a join, the server could exit after failing to resolve the required privileges. (Bug #23762382)

- For a table having a TIMESTAMP or DATETIME column having a default of CURRENT_TIMESTAMP, the column could be initialized to 0000-00-00 00:00:00 if the table had a BEFORE INSERT trigger. (Bug #25209512, Bug #84077)

- A server exit could result from simultaneous attempts by multiple threads to register and deregister metadata Performance Schema objects. (Bug #26502135)

- Executing a stored procedure containing a statement that created a table from the contents of certain SELECT statements could result in a memory leak. (Bug #25586773)

- Executing a stored procedure containing a query that accessed a view could allocate memory that was not freed until the session ended. (Bug #25053286)

- Certain cases of subquery materialization could cause a server exit. These queries now produce an error suggesting that materialization be disabled. (Bug #26402045)

- Queries with many left joins were slow if join buffering was used (for example, using the block nested loop algorithm). (Bug #18898433, Bug #72854)

- The optimizer skipped the second column in a composite index when executing an inner join with a LIKE clause against the second column. (Bug #28086754)

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).

- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).

- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).

- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
Amazon Aurora User Guide for Aurora
Database engine updates for
Amazon Aurora MySQL version 2

- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement

Aurora MySQL database engine updates 2020-04-17 (version 2.07.2)

Version: 2.07.2

Aurora MySQL 2.07.2 is generally available. Aurora MySQL 2.* versions are compatible with MySQL 5.7 and Aurora MySQL 1.* versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, and 2.07.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.07.2. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.07.2. You can't upgrade an existing Aurora MySQL 1.* cluster directly to 2.07.2; however, you can restore its snapshot to Aurora MySQL 2.07.2.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

**Note**
This version is currently not available in the following AWS Region: [us-east-1], AWS GovCloud (US-West) [us-gov-west-1]. There will be a separate announcement once it is made available.
This version is designated as a long-term support (LTS) release. For more information, see Aurora MySQL long-term support (LTS) releases (p. 1049).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

**High priority fixes:**
- Fixed an issue that caused cloning to take longer on some database clusters with high write loads.
- Fixed an issue that could cause queries on a reader DB instance with execution plans using secondary indexes to return uncommitted data. The issue is limited to data affected by data manipulation language (DML) operations that modify primary or secondary index key columns.

**General improvements:**
- Fixed an issue that resulted in a slow restore of an Aurora 1.x DB cluster containing FTS (Full Text Search) indexes to an Aurora 2.x DB cluster.
• Fixed an issue that caused slower restores of an Aurora 1.x database snapshot containing partitioned tables with special characters in table names to an Aurora 2.x DB cluster.

• Fixed an issue that caused errors when querying slow query logs and general logs in reader DB instances.

Integration of MySQL community edition bug fixes

• Bug #23104498: Fixed an issue in Performance Schema in reporting total memory used. (https://github.com/mysql/mysql-server/commit/20b6840df5452f47313c6f9a6ca075bfbc00a96b)

• Bug #22551677: Fixed an issue in Performance Schema that could lead to the database engine crashing when attempting to take it offline. (https://github.com/mysql/mysql-server/commit/05e2386eccd32b6b444b90c9f8a87a1d8d531e9)

• Bug #23550835, Bug #23298025, Bug #81464: Fixed an issue in Performance Schema that causes a database engine crash due to exceeding the capacity of an internal buffer. (https://github.com/mysql/mysql-server/commit/b4287f93857bf2f99b18fd06f555bbe5b12debfc)

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).

• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).

• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).

• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

• Group replication plugin

• Increased page size

• InnoDB buffer pool loading at startup

• InnoDB full-text parser plugin

• Multisource replication

• Online buffer pool resizing

• Password validation plugin

• Query rewrite plugins
Amazon Aurora User Guide for Aurora

Amazon Aurora MySQL version 2

- Replication filtering
- The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2019-12-23 (version 2.07.1)

Version: 2.07.1

Aurora MySQL 2.07.1 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, and 2.07.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.07.1. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.07.1. You cannot upgrade an existing Aurora MySQL 1.* cluster directly to 2.07.1; however, you can restore its snapshot to Aurora MySQL 2.07.1.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

**Note**
This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], Asia Pacific (Hong Kong) [ap-east-1], and Middle East (Bahrain) [me-south-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

**High priority fixes:**

- Fixed a slow memory leak in Aurora specific database tracing and logging sub-system that lowers the freeable memory.

**General Stability fixes:**

- Fixed a crash during execution of a complex query involving multi-table joins and aggregation that use intermediate tables internally.

**Comparison with Aurora MySQL Version 1**

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2019-11-25 (version 2.07.0)

Version: 2.07.0

Aurora MySQL 2.07.0 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, and 2.07.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.07.0. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.07.0. You cannot upgrade an existing Aurora MySQL 1.* cluster directly to 2.07.0; however, you can restore its snapshot to Aurora MySQL 2.07.0.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

Note

This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], Asia Pacific (Hong Kong) [ap-east-1], Middle East (Bahrain) [me-south-1], and South America (São Paulo) [sa-east-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).
Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the
minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

New features:

- Global Databases now allow adding secondary read-only replica regions for database clusters
deployed in these AWS Regions: regions: US East (N. Virginia) (us-east-1), US East (Ohio) (us-east-2),
US West (N. California) (us-west-1), US West (Oregon) (us-west-2), Europe (Ireland) (eu-west-1),
Europe (London) (eu-west-2), Europe (Paris) (eu-west-3), Asia Pacific (Tokyo) (ap-northeast-1), Asia
Pacific (Seoul) (ap-northeast-2), Asia Pacific (Singapore) (ap-southeast-1), Asia Pacific (Sydney) (ap-
southeast-2), Canada (Central) (ca-central-1), Europe (Frankfurt) (eu-central-1), and Asia Pacific
(Mumbai) (ap-south-1).

- Amazon Aurora machine learning is a highly optimized integration between the Aurora MySQL
database and AWS machine learning (ML) services. Aurora machine learning allows developers to add
a variety of ML-based predictions to their database applications by invoking ML models using the
familiar SQL programming language they already use for database development, without having to
build custom integrations or learn separate tools. For more information, see Using machine learning
(ML) capabilities with Amazon Aurora.

- Added support for the ANSI READ COMMITTED isolation level on the read replicas. This isolation level
enables long-running queries on the read replica to execute without impacting the high throughput of
writes on the writer node. For more information, see Aurora MySQL isolation levels.

Critical fixes:

- CVE-2019-2922
- CVE-2019-2923
- CVE-2019-2924
- CVE-2019-2910

High-priority fixes:

- Fixed an issue in the DDL recovery that resulted in prolonged database downtime. Clusters that
become unavailable after executing multi-table drop statement, for example DROP TABLE t1, t2,
t3, should be updated to this version.

- Fixed an issue in the DDL recovery that resulted in prolonged database downtime. Clusters that
become unavailable after executing INPLACE ALTER TABLE DDL statements should be updated to
this version.

General stability fixes:

- Fixed an issue that generated inconsistent data in the
  information_schema.replica_host_status table.

Integration of MySQL community edition bug fixes

- Bug #26251621: INCORRECT BEHAVIOR WITH TRIGGER AND GCOL
- Bug #22574695: ASSERTION `TABLE || (!TABLE->READ_SET || BITMAP_IS_SET(TABLE->READ_SET,
  FIEL
- Bug #25966845: INSERT ON DUPLICATE KEY GENERATE A DEADLOCK
• Bug #23070734: CONCURRENT TRUNCATE TABLES CAUSE STALL
• Bug #26191879: FOREIGN KEY CASCADES USE EXCESSIVE MEMORY
• Bug #20989615: INNODB AUTO_INCREMENT PRODUCES SAME VALUE TWICE

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

Aurora MySQL 2.07.0 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.07.0 does not currently support the following MySQL 5.7 features:

• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2019-11-22 (version 2.06.0)

Version: 2.06.0

Aurora MySQL 2.06.0 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, and 2.06.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.06.0. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL...
2.06.0. You cannot upgrade an existing Aurora MySQL 1.* cluster directly to 2.06.0; however, you can restore its snapshot to Aurora MySQL 2.06.0.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

**Note**
This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], Asia Pacific (Hong Kong) [ap-east-1], and Middle East (Bahrain) [me-south-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

**New features:**

- Aurora MySQL clusters now support the instance types db.r5.8xlarge, db.r5.16xlarge, and db.r5.24xlarge. For more information about instance types for Aurora MySQL clusters, see Aurora DB instance classes (p. 53).

- The hash join feature is now generally available and does not require the Aurora lab mode setting to be ON. This feature can improve query performance when you need to join a large amount of data by using an equi-join. For more information about using this feature, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).

- The hot row contention feature is now generally available and does not require the Aurora lab mode setting to be ON. This feature substantially improves throughput for workloads with many transactions contending for rows on the same page.

- Aurora MySQL 2.06 and higher support "rewinding" a DB cluster to a specific time, without restoring data from a backup. This feature, known as Backtrack, provides a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack completes within seconds, even for large databases. Read the AWS blog for an overview, and refer to Backtracking an Aurora DB cluster (p. 782) for more details.

- Aurora 2.06 and higher support synchronous AWS Lambda invocations through the native function `lambda_sync()`. Also available is native function `lambda_async()`, which can be used as an alternative to the existing stored procedure for asynchronous Lambda invocation. For information about calling Lambda functions, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 975).

**Critical fixes:**

None.

**High-priority fixes:**

**CVE fixes**

- CVE-2019-2805
- CVE-2019-2730
- CVE-2019-2739
- CVE-2019-2778
Connection handling

- Database availability has been improved to better service a surge in client connections while executing one or more DDLs. It is handled by temporarily creating additional threads when needed. You are advised to upgrade if the database becomes unresponsive following a surge in connections while processing DDL.

Engine restart

- Fixed an issue of prolonged unavailability while restarting the engine. This addresses an issue in the buffer pool initialization. This issue occurs rarely but can potentially impact any supported release.
- Fixed an issue that causes a database configured as a binlog master to restart while a heavy write workload is running.

General stability fixes:

- Made improvements where queries accessing uncached data could be slower than usual. Customers experiencing unexplained elevated read latency while accessing uncached data are encouraged to upgrade as they may be experiencing this issue.
- Fixed an issue that failed to restore partitioned tables from a database snapshot. Customers who encounter errors when accessing partitioned tables in a database that has been restored from the snapshot of an Aurora MySQL 1.* database are advised to use this version.
- Improved stability of the Aurora Replicas by fixing lock contention between threads serving read queries and the one applying schema changes while a DDL query is in progress on the writer DB instance.
- Fixed a stability issue related to mysql.innodb_table_stats table update triggered by DDL operations.
- Fixed an issue that incorrectly reported ERROR 1836 when a nested query is executed against a temporary table on the Aurora Replica.

Performance enhancements:

- Improved performance of binlog replication by preventing unnecessary API calls to the cache if the query cache has been disabled on the binlog worker.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).
• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).

• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

Aurora MySQL 2.06.0 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.06.0 does not currently support the following MySQL 5.7 features:

• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2019-11-11 (version 2.05.0)

Version: 2.05.0

Aurora MySQL 2.05.0 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.* and 2.04.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.05.0. You also have the option to upgrade existing Aurora MySQL 2.* database clusters, up to 2.04.6, to Aurora MySQL 2.05.0. You cannot upgrade an existing Aurora MySQL 1.* cluster directly to 2.05.0; however, you can restore its snapshot to Aurora MySQL 2.05.0.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

Note
This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], Asia Pacific (Hong Kong) [ap-east-1], Europe (Stockholm) [eu-north-1], and Middle East (Bahrain) [me-south-1]. There will be a separate announcement once it is made available.
If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

**Critical fixes:**
- CVE-2018-0734
- CVE-2019-2534
- CVE-2018-3155
- CVE-2018-2612
- CVE-2017-3599
- CVE-2018-3056
- CVE-2018-2562
- CVE-2017-3329
- CVE-2018-2696
- Fixed an issue where the events in current binlog file on the master were not replicated on the worker if the value of the parameter `sync_binlog` was not set to 1.

**High-priority fixes:**
- Customers with database size close to 64 tebibytes (TiB) are strongly advised to upgrade to this version to avoid downtime due to stability bugs affecting volumes close to the Aurora storage limit.
- The default value of the parameter `aurora_binlog_repl_max_yield_seconds` has been changed to zero to prevent an increase in replication lag in favor of foreground query performance on the binlog master.

**Integration of MySQL bug fixes**
- Bug#23054591: `PURGE BINARY LOGS TO` is reading the whole binlog file and causing MySql to Stall

**Comparison with Aurora MySQL version 1**

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).
MySQL 5.7 compatibility

Aurora MySQL 2.05.0 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.05.0 does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement

Aurora MySQL database engine updates 2020-08-14 (version 2.04.9)

Version: 2.04.9

Aurora MySQL 2.04.9 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, and 2.05.*. You can restore a snapshot of any 2.* Aurora MySQL release into Aurora MySQL 2.04.9. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.04.9.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], Asia Pacific (Hong Kong) [ap-east-1], and Middle East (Bahrain) [me-south-1]. There will be a separate announcement once it is made available.

Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

High-priority fixes:

CVE fixes
Availability improvements:

- Fixed an issue that could cause a database restart or failover due to execution of a `kill session` command. If you encounter this issue, contact AWS support to enable this fix on your instance.
- Fixed an issue that causes a database restart during execution of a complex query involving multi-table joins and aggregation that use intermediate tables internally.
- Fixed an issue that causes database restarts due to an interrupted `DROP TABLE` on multiple tables.
- Fixed an issue that causes a database failover during database recovery.
- Fixed a database restart caused by incorrect reporting of `threads_running` when audit and slow query logs are enabled.
- Fixed an issue where a `kill query` command might get stuck during execution.
- Fixed a race condition in the lock manager that resulted in a database restart or failover during transaction rollback.
- Fixed an issue that triggered database restart or failover when multiple connections are trying to update the same table with a Full-Text Search index.
- Fixed an issue that can cause a deadlock when purging an index resulting in a failover or restart.

General improvements:
• Fixed issues that could cause queries on read replicas to use data from an uncommitted transaction. This issue is limited to the transactions that are started immediately after a database restart.
• Fixed an issue encountered during `INPLACE ALTER TABLE` for a table with triggers defined and when the DDL did not contain a `RENAME` clause.
• Fixed an issue that caused cloning to take longer on some database clusters with high writeload.
• Fixed an issue encountered during an upgrade when a partitioned table has embedded spaces in the name.
• Fixed an issue where the read replica might transiently see partial results of a recently committed transaction on the writer.
• Fixed an issue where queries on a read replica against an FTS table may produce stale results. This will only occur when the FTS query on the read replica closely follows a query on `INFORMATION_SCHEMA.INNODB_SYS_TABLES` for the same FTS table on the writer.
• Fixed an issue that resulted in a slow restore of Aurora 1.x database cluster containing FTS (Full-Text Search) indexes to an Aurora 2.x database cluster.
• Extended maximum allowable length to 2000 for `server_audit_incl_users` and `server_audit_excl_users` global parameters.
• Fixed an issue where Aurora 1.x to Aurora 2.x restore might take an extended time to complete.
• Fixed an issue where a `lambda_async` invocation through stored procedure doesn't work with Unicode.
• Fixed an issue encountered when a spatial index does not properly handle an off-record geometry column.
• Fixed an issue that might cause a query to fail on a reader DB instance with `InternalFailureException` error with message"Operation terminated (internal error)".

Integration of MySQL bug fixes

• Bug #23070734, Bug #80060: Concurrent TRUNCATE TABLEs cause stalls
• Bug #23103937: PS_TRUNCATE_ALL_TABLES() DOES NOT WORK IN SUPER_READ_ONLY MODE
• Bug #22551677: When taking the server offline, a race condition within the Performance Schema could lead to a server exit.
• Bug #27082268: Invalid FTS sync synchronization.
• BUG #12589870: Fixed an issues which causes a restart with multi-query statement when query cache is enabled.
• Bug #26402045: Certain cases of subquery materialization could cause a server exit. These queries now produce an error suggesting that materialization be disabled.
• Bug #18898433: Queries with many left joins were slow if join buffering was used (for example, using the block nested loop algorithm).
• Bug #25222337: A NULL virtual column field name in a virtual index caused a server exit during a field name comparison that occurs while populating virtual columns affected by a foreign key constraint. (https://github.com/mysql/mysql-server/commit/273d5c9d7072c63b6c47dbef6963d7dc491d5131)
• Bug #25053286: Executing a stored procedure containing a query that accessed a view could allocate memory that was not freed until the session ended. (https://github.com/mysql/mysql-server/commit/d7b37d4d141a95f57791648650c429f0d6e193d)
• Bug #25586773: Executing a stored procedure containing a statement that created a table from the contents of certain SELECT statements could result in a memory leak. (https://github.com/mysql/mysql-server/commit/88301e5adab65f6750f6af284be410c4369d0c1)
• Bug #26666274: INFINITE LOOP IN PERFORMANCE SCHEMA BUFFER CONTAINER.

1120
• Bug #23550835, Bug #23298025, Bug #81464: A SELECT Performance Schema tables when an internal buffer was full could cause a server exit.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

Aurora MySQL 2.04.9 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.04.9 does not currently support the following MySQL 5.7 features:

• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2019-11-20 (version 2.04.8)

Version: 2.04.8

Aurora MySQL 2.04.8 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, and 2.05.*. You can restore a snapshot of any 2.* Aurora MySQL release into Aurora MySQL
2.04.8. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.04.8.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], Asia Pacific (Hong Kong) [ap-east-1], and Middle East (Bahrain) [me-south-1]. There will be a separate announcement once it is made available.

Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

New features:

- Read replica improvements:
  - Reduced network traffic from the writer instance by efficiently transmitting data to reader instances within the Aurora DB cluster. This improvement is enabled by default, because it helps prevent replicas from falling behind and restarting. The parameter for this feature is `aurora_enable_repl_bin_log_filtering`.
  - Reduced network traffic from the writer to reader instances within the Aurora DB cluster using compression. This improvement is enabled by default for 8xlarge and 16xlarge instance classes only, because these instances can tolerate additional CPU overhead for compression. The parameter for this feature is `aurora_enable_replica_log_compression`.

High-priority fixes:

- Improved memory management in the Aurora writer instance that prevents restart of writer due to out of memory conditions during heavy workload in presence of reader instances within the Aurora DB cluster.
- Fix for a non-deterministic condition in the scheduler that results in engine restart while accessing the performance schema object concurrently.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

Aurora MySQL 2.04.8 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.04.8 does not currently support the following MySQL 5.7 features:

• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2019-11-14 (version 2.04.7)

Version: 2.04.7

Aurora MySQL 2.04.7 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.* and 2.04.*.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL 2.04.7. You also have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.04.7. You can't upgrade an existing Aurora MySQL 1.* cluster directly to 2.04.7; however, you can restore its snapshot to Aurora MySQL 2.04.7.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI, or the RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note

This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], Asia Pacific (Hong Kong) [ap-east-1], and Middle East (Bahrain) [me-south-1]. There will be a separate announcement once it is made available.

Note

For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).
Improvements

High-priority fixes:

Connection Handling

- Database availability has been improved to better service a surge in client connections while executing one or more DDLs. It is handled by temporarily creating additional threads when needed. You are advised to upgrade if the database becomes unresponsive following a surge in connections while processing DDL.
- Fixed an issue that resulted in an incorrect value for the `Threads_running` global status variable.

Engine Restart

- Fixed an issue of prolonged unavailability while restarting the engine. This addresses an issue in the buffer pool initialization. This issue occurs rarely but can potentially impact any supported release.

General stability fixes:

- Made improvements where queries accessing uncached data could be slower than usual. Customers experiencing unexplained elevated read latencies while accessing uncached data are encouraged to upgrade as they may be experiencing this issue.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

Aurora MySQL 2.04.7 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.04.7 does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The `CREATE TABLESPACE` SQL statement

**Aurora MySQL database engine updates 2019-09-19 (version 2.04.6)**

**Version:** 2.04.6

Aurora MySQL 2.04.6 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

You have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.04.6. We do not allow in-place upgrade of Aurora MySQL 1.* clusters. This restriction will be lifted in a later Aurora MySQL 2.* release. You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.* and 2.04.* into Aurora MySQL 2.04.6.

To use an older version of Aurora MySQL, you can create new database clusters by specifying the engine version through the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**

This version is currently not available in the following AWS Regions: Europe (London) [eu-west-2], AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], and Asia Pacific (Hong Kong) [ap-east-1]. There will be a separate announcement once it is made available.

**Note**

For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

• Fixed an issue where the events in current binlog file on the master were not replicated on the worker if the value of the parameter `sync_binlog` was not set to 1.

• The default value of the parameter `aurora_binlog_replication_max_yield_seconds` has been changed to zero to prevent an increase in replication lag in favor of foreground query performance on the binlog master.

**Integration of MySQL bug fixes**

• Bug#23054591: `PURGE BINARY LOGS TO` is reading the whole binlog file and causing MySQL to Stall

**Comparison with Aurora MySQL version 1**

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).
• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility
Aurora MySQL 2.04.6 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.04.6 does not currently support the following MySQL 5.7 features:
• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2019-07-08 (version 2.04.5)

Version: 2.04.5
Aurora MySQL 2.04.5 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

You have the option to upgrade existing Aurora MySQL 2.* database clusters to Aurora MySQL 2.04.5. We do not allow in-place upgrade of Aurora MySQL 1.* clusters. This restriction will be lifted in a later Aurora MySQL 2.* release. You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.* and 2.04.* into Aurora MySQL 2.04.5.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements
• Fixed a race condition during storage volume growth that caused the database to restart.
• Fixed an internal communication failure during volume open that caused the database to restart.
• Added DDL recovery support for `ALTER TABLE ALGORITHM=INPLACE` on partitioned tables.
• Fixed an issue with DDL recovery of `ALTER TABLE ALGORITHM=COPY` that caused the database to restart.
• Improved Aurora Replica stability under heavy delete workload on the writer.
• Fixed a database restart caused by a deadlatch between the thread performing full-text search index sync and the thread performing eviction of full-text search table from dictionary cache.
• Fixed a stability issue on the binlog worker during DDL replication while the connection to the binlog master is unstable.
• Fixed an out-of-memory issue in the full-text search code that caused the database to restart.
• Fixed an issue on the Aurora Writer that caused it to restart when the entire 64 tebibyte (TiB) volume is used.
• Fixed a race condition in the Performance Schema feature that caused the database to restart.
• Fixed an issue that caused aborted connections when handling an error in network protocol management.

**Comparison with Aurora MySQL version 1**

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

**MySQL 5.7 compatibility**

Aurora MySQL 2.04.5 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.04.5 does not currently support the following MySQL 5.7 features:

• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The `CREATE TABLESPACE` SQL statement

**Aurora MySQL database engine updates 2019-05-29 (version 2.04.4)**

**Version:** 2.04.4

Aurora MySQL 2.04.4 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster (including restoring a snapshot), you have the option of choosing compatibility with either MySQL 5.7 or MySQL 5.6. We do not allow in-place upgrade of Aurora MySQL 1.* clusters or restore of Aurora MySQL 1.* clusters from an Amazon S3 backup into Aurora MySQL 2.04.4. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.*, and 2.04.* into Aurora MySQL 2.04.4.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1], Europe (Stockholm) [eu-north-1], China (Ningxia) [cn-northwest-1], and Asia Pacific (Hong Kong) [ap-east-1] AWS Regions. There will be a separate announcement once it is made available.

**Note**
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

- Fixed an issue that could cause failures when loading data into Aurora from S3.
- Fixed an issue that could cause failures when upload data from Aurora to S3.
- Fixed an issue that caused aborted connections when handling an error in network protocol management.
- Fixed an issue that could cause a crash when dealing with partitioned tables.
- Fixed an issue with the Performance Insights feature being unavailable in some regions.

**Comparison with Aurora MySQL version 1**

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

Aurora MySQL 2.04.4 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.04.4 does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2019-05-09 (version 2.04.3)

Version: 2.04.3

Aurora MySQL 2.04.3 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster (including restoring a snapshot), you have the option of choosing compatibility with either MySQL 5.7 or MySQL 5.6. We do not allow in-place upgrade of Aurora MySQL 1.* clusters or restore of Aurora MySQL 1.* clusters from an Amazon S3 backup into Aurora MySQL 2.04.3. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.*, and 2.04.* into Aurora MySQL 2.04.3.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note

This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Ningxia) [cn-northwest-1] AWS Regions. There will be a separate announcement once it is made available.

Improvements

- Fixed a bug in binlog replication that can cause an issue on Aurora instances configured as binlog worker.
* Fixed an out-of-memory condition when handling large stored routines.
* Fixed an error in handling certain kinds of `ALTER TABLE` commands.
* Fixed an issue with aborted connections because of an error in network protocol management.

**Comparison with Aurora MySQL version 1**

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

**MySQL 5.7 compatibility**

Aurora MySQL 2.04.3 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.04.3 does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement

**Aurora MySQL database engine updates 2019-05-02 (version 2.04.2)**

**Version:** 2.04.2

Aurora MySQL 2.04.2 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster (including restoring a snapshot), you have the option of choosing compatibility with either MySQL 5.7 or MySQL 5.6. We do not allow in-place upgrade of Aurora...
MySQL 1.* clusters or restore of Aurora MySQL 1.* clusters from an Amazon S3 backup into Aurora MySQL 2.04.2. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.*, 2.04.0, and 2.04.1 into Aurora MySQL 2.04.2.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Ningxia) [cn-northwest-1] AWS Regions. There will be a separate announcement once it is made available.

Note
For information on how to upgrade your Aurora MySQL database cluster, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

• Added support for SSL binlog replication using custom certificates. For information on using SSL binlog replication in Aurora MySQL, see mysql_rds_import_binlog_ssl_material.
• Fixed a deadlatch on the Aurora primary instance that occurs when a table with a Full Text Search index is being optimized.
• Fixed an issue on the Aurora Replicas where performance of certain queries using SELECT(*) could be impacted on tables that have secondary indexes.
• Fixed a condition that resulted in Error 1032 being posted.
• Improved the stability of Aurora Replicas by fixing multiple deadlatches.

Integration of MySQL bug fixes

• Bug #24829050 - INDEX_MERGE_INTERSECTION OPTIMIZATION CAUSES WRONG QUERY RESULTS

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

Aurora MySQL 2.04.2 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing.
using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.04.2 does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The `CREATE TABLESPACE` SQL statement

**Aurora MySQL database engine updates 2019-03-25 (version 2.04.1)**

**Version:** 2.04.1

Aurora MySQL 2.04.1 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster (including restoring a snapshot), you have the option of choosing compatibility with either MySQL 5.7 or MySQL 5.6. We do not allow in-place upgrade of Aurora MySQL 1.* clusters or restore of Aurora MySQL 1.* clusters from an Amazon S3 backup into Aurora MySQL 2.04.1. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 2.01.*, 2.02.*, 2.03.*, 2.04.0 into Aurora MySQL 2.04.1.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] region. There will be a separate announcement once it is made available.

**Note**
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

- Fixed an issue where an Aurora MySQL 5.6 snapshot for versions lower than 1.16 could not be restored to the latest Aurora MySQL 5.7 cluster.

**Comparison with Aurora MySQL version 1**

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).
• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).

• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).

• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).

• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement

Aurora MySQL database engine updates 2019-03-25 (version 2.04.0)

Version: 2.04

Aurora MySQL 2.04 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster (including restoring a snapshot), you have the option of choosing compatibility with either MySQL 5.7 or MySQL 5.6. We do not allow in-place upgrade of Aurora MySQL 1.x clusters or restore of Aurora MySQL 1.x clusters from an Amazon S3 backup into Aurora MySQL 2.04.0. We plan to remove these restrictions in a later Aurora MySQL 2.x release.

You can restore snapshots of Aurora MySQL 1.19.*, 2.01.*, 2.02.*, and 2.03.* into Aurora MySQL 2.04.0. You cannot restore snapshots of Aurora MySQL 1.14.* or lower, 1.15.*, 1.16.*, 1.17.*, 1.18.* into Aurora MySQL 2.04.0. This restriction is removed in Aurora MySQL 2.04.1.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).
Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] region. There will be a separate announcement once it is made available.

Note
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

- Supports GTID-based replication. For information about using GTID-based replication with Aurora MySQL, see Using GTID-based replication for Aurora MySQL (p. 920).
- Fixed an issue where an Aurora Replica incorrectly throws a Running in read-only mode error when a statement deleting or updating rows in a temporary table contains an InnoDB subquery.

Integration of MySQL bug fixes

- Bug #26225783: MYSQL CRASH ON CREATE TABLE (REPRODUCEABLE) -> INNODB: ALONG SEMAPHORE WAIT.

Comparison with Aurora MySQL version 1

The following Amazon Aurora MySQL features are supported in Aurora MySQL Version 1 (compatible with MySQL 5.6), but these features are currently not supported in Aurora MySQL Version 2 (compatible with MySQL 5.7).

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

MySQL 5.7 compatibility

This Aurora MySQL version is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

This Aurora MySQL version does not currently support the following MySQL 5.7 features:

- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
• Query rewrite plugins
• Replication filtering
• The `CREATE TABLESPACE` SQL statement

Aurora MySQL database engine updates 2019-02-07

Version: 2.03.4

Aurora MySQL 2.03.4 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster (including restoring a snapshot), you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

We don't allow in-place upgrade of Aurora MySQL 1.* clusters into Aurora MySQL 2.03.4 or restore to Aurora MySQL 2.03.4 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

Note
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

• Support for UTF8MB4 Unicode 9.0 accent-sensitive and case-insensitive collation, `utf8mb4_0900_as_ci`.

Aurora MySQL database engine updates 2019-01-18

Version: 2.03.3

Aurora MySQL 2.03.3 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster (including restoring a snapshot), you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

We don't allow in-place upgrade of Aurora MySQL 1.* clusters into Aurora MySQL 2.03.3 or restore to Aurora MySQL 2.03.3 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.
Note
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

- Fixed an issue where an Aurora Replica might become dead-latched when running a backward scan on an index.
- Fixed an issue where an Aurora Replica might restart when the Aurora primary instance runs in-place DDL operations on partitioned tables.
- Fixed an issue where an Aurora Replica might restart during query cache invalidation after a DDL operation on the Aurora primary instance.
- Fixed an issue where an Aurora Replica might restart during a SELECT query on a table while the Aurora primary instance runs truncation on that table.
- Fixed a wrong result issue with MyISAM temporary tables where only indexed columns are accessed.
- Fixed an issue in slow logs that generated incorrect large values for `query_time` and `lock_time` periodically after approximately 40,000 queries.
- Fixed an issue where a schema named "tmp" could cause migration from RDS for MySQL to Aurora MySQL to become stuck.
- Fixed an issue where the audit log might have missing events during log rotation.
- Fixed an issue where the Aurora primary instance restored from an Aurora 5.6 snapshot might restart when the Fast DDL feature in the lab mode is enabled.
- Fixed an issue where the CPU usage is 100% caused by the dictionary stats thread.
- Fixed an issue where an Aurora Replica might restart when running a `CHECK TABLE` statement.

Integration of MySQL bug fixes

- Bug #25361251: INCORRECT BEHAVIOR WITH INSERT ON DUPLICATE KEY IN SP
- Bug #26734162: INCORRECT BEHAVIOR WITH INSERT OF BLOB + ON DUPLICATE KEY UPDATE
- Bug #27460607: INCORRECT BEHAVIOR OF IODKU WHEN INSERT SELECT's SOURCE TABLE IS EMPTY
- A query using a `DISTINCT` or `GROUP BY` clause could return incorrect results. (MySQL 5.7 Bug #79591, Bug #22343910)
- A `DELETE` from joined tables using a derived table in the `WHERE` clause fails with error 1093 (Bug #23074801).
- `GCOLS`: INCORRECT BEHAVIOR WITH CHARSET CHANGES (Bug #25287633).

Aurora MySQL database engine updates 2019-01-09

Version: 2.03.2

Aurora MySQL 2.03.2 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster (including restoring a snapshot), you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

We don't allow in-place upgrade of Aurora MySQL 1.* clusters into Aurora MySQL 2.03.2 or restore to Aurora MySQL 2.03.2 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.* release.
If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

Note
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

• **Aurora Version Selector** – Starting with Aurora MySQL 2.03.2, you can choose from among multiple versions of MySQL 5.7-compatible Aurora on the AWS Management Console. For more information, see Checking or specifying Aurora MySQL engine versions through AWS (p. 1048).

Aurora MySQL database engine updates 2018-10-24

Version: 2.03.1

Aurora MySQL 2.03.1 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster, you can choose compatibility with either MySQL 5.7 or MySQL 5.6. When restoring a MySQL 5.6-compatible snapshot, you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 2.01.*, 2.02.*, and 2.03 into Aurora MySQL 2.03.1.

We don't allow in-place upgrade of Aurora MySQL 1.* clusters into Aurora MySQL 2.03.1 or restore to Aurora MySQL 2.03.1 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

Improvements

• Fix an issue where the Aurora Writer might restart when running transaction deadlock detection.

Aurora MySQL database engine updates 2018-10-11

Version: 2.03

Aurora MySQL 2.03 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster, you can choose compatibility with either MySQL 5.7 or MySQL 5.6. When restoring a MySQL 5.6-compatible snapshot, you can choose compatibility with either MySQL 5.7 or MySQL 5.6.
You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 2.01.*, and 2.02.* into Aurora MySQL 2.03.

We don't allow in-place upgrade of Aurora MySQL 1.* clusters into Aurora MySQL 2.03 or restore to Aurora MySQL 2.03 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

**Note**
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

- Performance schema is available.
- Fixed an issue where zombie sessions with killed state might consume more CPU.
- Fixed a dead latch issue when a read-only transaction is acquiring a lock on a record on the Aurora Writer.
- Fixed an issue where the Aurora Replica without customer workload might have high CPU utilization.
- Multiple fixes on issues that might cause the Aurora Replica or the Aurora writer to restart.
- Added capability to skip diagnostic logging when the disk throughput limit is reached.
- Fixed a memory leak issue when binlog is enabled on the Aurora Writer.

**Integration of MySQL community edition bug fixes**

- REVERSE SCAN ON A PARTITIONED TABLE DOES ICP - ORDER BY DESC (Bug #24929748).
- JSON_OBJECT CREATES INVALID JSON CODE (Bug #26867509).
- INSERTING LARGE JSON DATA TAKES AN INORDINATE AMOUNT OF TIME (Bug #22843444).
- PARTITIONED TABLES USE MORE MEMORY IN 5.7 THAN 5.6 (Bug #25080442).

**Aurora MySQL database engine updates 2018-10-08**

**Version:** 2.02.5

Aurora MySQL 2.02.5 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster, you can choose compatibility with either MySQL 5.7 or MySQL 5.6. When restoring a MySQL 5.6-compatible snapshot, you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 2.01.*, and 2.02.* into Aurora MySQL 2.02.5. You can also perform an in-place upgrade from Aurora MySQL 2.01.* or 2.02.* to Aurora MySQL 2.02.5.

We don't allow in-place upgrade of Aurora MySQL 1.* clusters into Aurora MySQL 2.02.5 or restore to Aurora MySQL 2.02.5 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

The performance schema is disabled for this release of Aurora MySQL 5.7. Upgrade to Aurora 2.03 for performance schema support.
Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

• Fix an issue where an Aurora Replica might restart when it is doing a reverse scan on a table.

Aurora MySQL database engine updates 2018-09-21

Version: 2.02.4

Aurora MySQL 2.02.4 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster, you can choose compatibility with either MySQL 5.7 or MySQL 5.6. When restoring a MySQL 5.6-compatible snapshot, you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 2.01.*, and 2.02.* into Aurora MySQL 2.02.4. You can also perform an in-place upgrade from Aurora MySQL 2.01.* or 2.02.* to Aurora MySQL 2.02.4.

We don't allow in-place upgrade of Aurora MySQL 1.* clusters into Aurora MySQL 2.02.4 or restore to Aurora MySQL 2.02.4 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

The performance schema is disabled for this release of Aurora MySQL 5.7. Upgrade to Aurora 2.03 for performance schema support.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

• Fixed a stability issue related to Full Text Search indexes on tables restored from an Aurora MySQL 5.6 snapshot.

Integration of MySQL community edition bug fixes

• BUG#13651665 INNODB MAY BE UNABLE TO LOAD TABLE DEFINITION AFTER RENAME
• BUG#21371070 INNODB: CANNOT ALLOCATE 0 BYTES.
• BUG#21378944 FTS ASSERT ENC.SRC_ILIST_PTR != NULL, FTS_OPTIMIZE_WORD(), OPTIMIZE TABLE
• BUG#21508537 ASSERTION FAILURE UT_A(!VICTIM_TRX->READ_ONLY)
• BUG#21983865 UNEXPECTED DEADLOCK WITH INNODB_AUTOINC_LOCK_MODE=0
• BUG#22679185 INVALID INNODB FTS DOC ID DURING INSERT
• BUG#22899305 GCOLS: ASSERTION: !(COL->PRTYPE & 256).
• BUG#22956469 MEMORY LEAK INTRODUCED IN 5.7.8 IN MEMORY/INNODB/OS0FILE
• BUG#22996488 CRASH IN FTS_SYNC_INDEX WHEN DOING DDL IN A LOOP
Aurora MySQL database engine updates 2018-08-23

Version: 2.02.3

Aurora MySQL 2.02.3 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster, you can choose compatibility with either MySQL 5.7 or MySQL 5.6. When restoring a MySQL 5.6-compatible snapshot, you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 2.01.*, and 2.02.* into Aurora MySQL 2.02.3. You can also perform an in-place upgrade from Aurora MySQL 2.01.* or 2.02.* to Aurora MySQL 2.02.3.

We don't allow in-place upgrade of Aurora MySQL 1.* clusters into Aurora MySQL 2.02.3 or restore to Aurora MySQL 2.02.3 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

The performance schema is disabled for this release of Aurora MySQL 5.7. Upgrade to Aurora 2.03 for performance schema support.

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Comparison with Aurora MySQL 5.6

The following Amazon Aurora MySQL features are supported in Aurora MySQL 5.6, but these features are currently not supported in Aurora MySQL 5.7.

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. These functions are available for MySQL 5.7-compatible clusters in Aurora MySQL 2.06 and higher. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

Currently, Aurora MySQL 2.01 does not support features added in Aurora MySQL version 1.16 and later. For information about Aurora MySQL version 1.16, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

MySQL 5.7 compatibility

Aurora MySQL 2.02.3 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.02.3 does not currently support the following MySQL 5.7 features:

• Global transaction identifiers (GTIDs). Aurora MySQL supports GTIDs in version 2.04 and higher.
• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement
• X Protocol

CLI differences between Aurora MySQL 2.x and Aurora MySQL 1.x

• The engine name for Aurora MySQL 2.x is aurora-mysql; the engine name for Aurora MySQL 1.x continues to be aurora.
• The engine version for Aurora MySQL 2.x is 5.7.12; the engine version for Aurora MySQL 1.x continues to be 5.6.10a.
• The default parameter group for Aurora MySQL 2.x is default.aurora-mysql5.7; the default parameter group for Aurora MySQL 1.x continues to be default.aurora5.6.
• The DB cluster parameter group family name for Aurora MySQL 2.x is aurora-mysql5.7; the DB cluster parameter group family name for Aurora MySQL 1.x continues to be aurora5.6.

Refer to the Aurora documentation for the full set of CLI commands and differences between Aurora MySQL 2.x and Aurora MySQL 1.x.

Improvements

• Fixed an issue where an Aurora Replica can restart when using optimistic cursor restores while reading records.
• Updated the default value of the parameter innodb_stats_persistent_sample_pages to 128 to improve index statistics.
• Fixed an issue where an Aurora Replica might restart when it accesses a small table that is being concurrently modified on the Aurora primary instance.
• Fixed \texttt{ANALYZE TABLE} to stop flushing the table definition cache.
• Fixed an issue where the Aurora primary instance or an Aurora Replica might restart when converting a point query for geospatial to a search range.

\textbf{Aurora MySQL database engine updates 2018-06-04}

\textit{Version:} 2.02.2

Aurora MySQL 2.02.2 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster, you can choose compatibility with either MySQL 5.7 or MySQL 5.6. When restoring a MySQL 5.6-compatible snapshot, you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

You can restore snapshots of Aurora MySQL 1.14*, 1.15*, 1.16*, 1.17*, 2.01*, and 2.02 into Aurora MySQL 2.02.2. You can also perform an in-place upgrade from Aurora MySQL 2.01* or 2.02 to Aurora MySQL 2.02.2.

We don't allow in-place upgrade of Aurora MySQL 1.* clusters into Aurora MySQL 2.02.2 or restore to Aurora MySQL 2.02.2 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.* release.

The performance schema is disabled for this release of Aurora MySQL 5.7. Upgrade to Aurora 2.03 for performance schema support.

\textbf{Note}

This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through \textit{AWS Premium Support}. For more information, see \textit{Maintaining an Amazon Aurora DB cluster} (p. 439).

\textbf{Comparison with Aurora MySQL 5.6}

The following Amazon Aurora MySQL features are supported in Aurora MySQL 5.6, but these features are currently not supported in Aurora MySQL 5.7.

• Asynchronous key prefetch (AKP). For more information, see \textit{Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch} (p. 1001).
• Hash joins. For more information, see \textit{Optimizing large Aurora MySQL join queries with hash joins} (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see \textit{Invoking a Lambda function with an Aurora MySQL native function} (p. 977).
• Scan batching. For more information, see \textit{Aurora MySQL database engine updates 2017-12-11} (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see \textit{Migrating data from MySQL by using an Amazon S3 bucket} (p. 749).

Currently, Aurora MySQL 2.01 does not support features added in Aurora MySQL version 1.16 and later. For information about Aurora MySQL version 1.16, see \textit{Aurora MySQL database engine updates 2017-12-11} (p. 1178).
MySQL 5.7 compatibility

Aurora MySQL 2.02.2 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.02.2 does not currently support the following MySQL 5.7 features:

- Global transaction identifiers (GTIDs). Aurora MySQL supports GTIDs in version 2.04 and higher.
- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The CREATE TABLESPACE SQL statement
- X Protocol

CLI differences between Aurora MySQL 2.x and Aurora MySQL 1.x

- The engine name for Aurora MySQL 2.x is aurora-mysql; the engine name for Aurora MySQL 1.x continues to be aurora.
- The engine version for Aurora MySQL 2.x is 5.7.12; the engine version for Aurora MySQL 1.x continues to be 5.6.10a nn.
- The default parameter group for Aurora MySQL 2.x is default.aurora-mysql5.7; the default parameter group for Aurora MySQL 1.x continues to be default.aurora5.6.
- The DB cluster parameter group family name for Aurora MySQL 2.x is aurora-mysql5.7; the DB cluster parameter group family name for Aurora MySQL 1.x continues to be aurora5.6.

Refer to the Aurora documentation for the full set of CLI commands and differences between Aurora MySQL 2.x and Aurora MySQL 1.x.

Improvements

- Fixed an issue where an Aurora Writer can occasionally restart when tracking Aurora Replica progress.
- Fixed an issue where an Aurora Replica restarts or throws an error when a partitioned table is accessed after running index create or drop statements on the table on the Aurora Writer.
- Fixed an issue where a table on an Aurora Replica is inaccessible while it is applying the changes caused by running ALTER table ADD/DROP column statements on the Aurora Writer.

Aurora MySQL database engine updates 2018-05-03

Version: 2.02

Aurora MySQL 2.02 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.
When creating a new Aurora MySQL DB cluster, you can choose compatibility with either MySQL 5.7 or MySQL 5.6. When restoring a MySQL 5.6-compatible snapshot, you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

You can restore snapshots of Aurora MySQL 1.14*, 1.15*, 1.16*, 1.17* and 2.01* into Aurora MySQL 2.02. You can also perform an in-place upgrade from Aurora MySQL 2.01* to Aurora MySQL 2.02.

We don’t allow in-place upgrade of Aurora MySQL 1.x clusters into Aurora MySQL 2.02 or restore to Aurora MySQL 2.02 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.x release.

The performance schema is disabled for this release of Aurora MySQL 5.7. Upgrade to Aurora 2.03 for performance schema support.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Comparison with Aurora MySQL 5.6**

The following Amazon Aurora MySQL features are supported in Aurora MySQL 5.6, but these features are currently not supported in Aurora MySQL 5.7.

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

Currently, Aurora MySQL 2.01 does not support features added in Aurora MySQL version 1.16 and later. For information about Aurora MySQL version 1.16, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

**MySQL 5.7 compatibility**

Aurora MySQL 2.02 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.02 does not currently support the following MySQL 5.7 features:

- Global transaction identifiers (GTIDs). Aurora MySQL supports GTIDs in version 2.04 and higher.
- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The `CREATE TABLESPACE` SQL statement
• X Protocol

**CLI differences between Aurora MySQL 2.x and Aurora MySQL 1.x**

• The engine name for Aurora MySQL 2.x is `aurora-mysql`; the engine name for Aurora MySQL 1.x continues to be `aurora`.
• The engine version for Aurora MySQL 2.x is 5.7.12; the engine version for Aurora MySQL 1.x continues to be 5.6.10a.
• The default parameter group for Aurora MySQL 2.x is `default.aurora-mysql5.7`; the default parameter group for Aurora MySQL 1.x continues to be `default.aurora5.6`.
• The DB cluster parameter group family name for Aurora MySQL 2.x is `aurora-mysql5.7`; the DB cluster parameter group family name for Aurora MySQL 1.x continues to be `aurora5.6`.

Refer to the Aurora documentation for the full set of CLI commands and differences between Aurora MySQL 2.x and Aurora MySQL 1.x.

**Improvements**

• Fixed an issue where an Aurora Writer restarts when running INSERT statements and exploiting the Fast Insert optimization.
• Fixed an issue where an Aurora Replica restarts when running ALTER DATABASE statements on the Aurora Replica.
• Fixed an issue where an Aurora Replica restarts when running queries on tables that have just been dropped on the Aurora Writer.
• Fixed an issue where an Aurora Replica restarts when setting `innodb_adaptive_hash_index` to `OFF` on the Aurora Replica.
• Fixed an issue where an Aurora Replica restarts when running TRUNCATE TABLE queries on the Aurora Writer.
• Fixed an issue where the Aurora Writer freezes in certain circumstances when running INSERT statements. On a multi-node cluster, this can result in a failover.
• Fixed a memory leak associated with setting session variables.
• Fixed an issue where the Aurora Writer freezes in certain circumstances associated with purging undo for tables with generated columns.
• Fixed an issue where the Aurora Writer can sometimes restart when binary logging is enabled.

**Integration of MySQL bug fixes**

• Left join returns incorrect results on the outer side (Bug #22833364).

**Aurora MySQL database engine updates 2018-03-13**

**Version:** 2.01.1

Aurora MySQL 2.01.1 is generally available. Aurora MySQL 2.x versions are compatible with MySQL 5.7 and Aurora MySQL 1.x versions are compatible with MySQL 5.6.
When creating a new Aurora MySQL DB cluster, you can choose compatibility with either MySQL 5.7 or MySQL 5.6. When restoring a MySQL 5.6-compatible snapshot, you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

You can restore snapshots of Aurora MySQL 1.14*, 1.15*, 1.16*, and 1.17* into Aurora MySQL 2.01.1.

We don’t allow in-place upgrade of Aurora MySQL 1.x clusters into Aurora MySQL 2.01.1 or restore to Aurora MySQL 2.01.1 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.x release.

The performance schema is disabled for this release of Aurora MySQL 5.7. Upgrade to Aurora 2.03 for performance schema support.

**Comparison with Aurora MySQL 5.6**

The following Amazon Aurora MySQL features are supported in Aurora MySQL 5.6, but these features are currently not supported in Aurora MySQL 5.7.

- Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
- Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
- Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
- Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

Currently, Aurora MySQL 2.01.1 does not support features added in Aurora MySQL version 1.16 and later. For information about Aurora MySQL version 1.16, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

**MySQL 5.7 compatibility**

Aurora MySQL 2.01.1 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.01.1 does not currently support the following MySQL 5.7 features:

- Global transaction identifiers (GTIDs). Aurora MySQL supports GTIDs in version 2.04 and higher.
- Group replication plugin
- Increased page size
- InnoDB buffer pool loading at startup
- InnoDB full-text parser plugin
- Multisource replication
- Online buffer pool resizing
- Password validation plugin
- Query rewrite plugins
- Replication filtering
- The CREATE TABLESPACE SQL statement
• X Protocol

CLI differences between Aurora MySQL 2.x and Aurora MySQL 1.x

• The engine name for Aurora MySQL 2.x is `aurora-mysql`; the engine name for Aurora MySQL 1.x continues to be `aurora`.
• The engine version for Aurora MySQL 2.x is `5.7.12`; the engine version for Aurora MySQL 1.x continues to be `5.6.10a`.
• The default parameter group for Aurora MySQL 2.x is `default.aurora-mysql5.7`; the default parameter group for Aurora MySQL 1.x continues to be `default.aurora5.6`.
• The DB cluster parameter group family name for Aurora MySQL 2.x is `aurora-mysql5.7`; the DB cluster parameter group family name for Aurora MySQL 1.x continues to be `aurora5.6`.

Refer to the Aurora documentation for the full set of CLI commands and differences between Aurora MySQL 2.x and Aurora MySQL 1.x.

Improvements

• Fixed an issue with snapshot restore where Aurora-specific database privileges were created incorrectly when a MySQL 5.6-compatible snapshot was restored with MySQL 5.7 compatibility.
• Added support for 1.17 snapshot restores.

Aurora MySQL database engine updates 2018-02-06

Version: 2.01

Aurora MySQL 2.01 is generally available. Going forward, Aurora MySQL 2.x versions will be compatible with MySQL 5.7 and Aurora MySQL 1.x versions will be compatible with MySQL 5.6.

When creating a new Aurora MySQL DB cluster, including those restored from snapshots, you can choose compatibility with either MySQL 5.7 or MySQL 5.6.

You can restore snapshots of Aurora MySQL 1.14*, 1.15*, and 1.16* into Aurora MySQL 2.01.

We don't allow in-place upgrade of Aurora MySQL 1.x clusters into Aurora MySQL 2.01 or restore to Aurora MySQL 2.01 from an Amazon S3 backup. We plan to remove these restrictions in a later Aurora MySQL 2.x release.

The performance schema is disabled for this release of Aurora MySQL 5.7. Upgrade to Aurora 2.03 for performance schema support.

Comparison with Aurora MySQL 5.6

The following Amazon Aurora MySQL features are supported in Aurora MySQL 5.6, but these features are currently not supported in Aurora MySQL 5.7.

• Asynchronous key prefetch (AKP). For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).
• Hash joins. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
• Native functions for synchronously invoking AWS Lambda functions. For more information, see Invoking a Lambda function with an Aurora MySQL native function (p. 977).
• Scan batching. For more information, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).
• Migrating data from MySQL using an Amazon S3 bucket. For more information, see Migrating data from MySQL by using an Amazon S3 bucket (p. 749).

Currently, Aurora MySQL 2.01 does not support features added in Aurora MySQL version 1.16 and later. For information about Aurora MySQL version 1.16, see Aurora MySQL database engine updates 2017-12-11 (p. 1178).

MySQL 5.7 compatibility

Aurora MySQL 2.01 is wire-compatible with MySQL 5.7 and includes features such as JSON support, spatial indexes, and generated columns. Aurora MySQL uses a native implementation of spatial indexing using z-order curves to deliver >20x better write performance and >10x better read performance than MySQL 5.7 for spatial datasets.

Aurora MySQL 2.01 does not currently support the following MySQL 5.7 features:

• Global transaction identifiers (GTIDs). Aurora MySQL supports GTIDs in version 2.04 and higher.
• Group replication plugin
• Increased page size
• InnoDB buffer pool loading at startup
• InnoDB full-text parser plugin
• Multisource replication
• Online buffer pool resizing
• Password validation plugin
• Query rewrite plugins
• Replication filtering
• The CREATE TABLESPACE SQL statement
• X Protocol

CLI differences between Aurora MySQL 2.x and Aurora MySQL 1.x

• The engine name for Aurora MySQL 2.x is aurora-mysql; the engine name for Aurora MySQL 1.x continues to be aurora.
• The engine version for Aurora MySQL 2.x is 5.7.12; the engine version for Aurora MySQL 1.x continues to be 5.6.10ann.
• The default parameter group for Aurora MySQL 2.x is default.aurora-mysql5.7; the default parameter group for Aurora MySQL 1.x continues to be default.aurora5.6.
• The DB cluster parameter group family name for Aurora MySQL 2.x is aurora-mysql5.7; the DB cluster parameter group family name for Aurora MySQL 1.x continues to be aurora5.6.

Refer to the Aurora documentation for the full set of CLI commands and differences between Aurora MySQL 2.x and Aurora MySQL 1.x.

Database engine updates for Amazon Aurora MySQL version 1

The following are Amazon Aurora version 1 database engine updates:

• Aurora MySQL database engine updates 2021-09-30 (version 1.23.4) (p. 1150)
• Aurora MySQL database engine updates 2021-06-28 (version 1.23.3) (p. 1150)
• Aurora MySQL database engine updates 2021-03-18 (version 1.23.2) (p. 1151)
• Aurora MySQL database engine updates 2020-11-24 (version 1.23.1) (p. 1152)
• Aurora MySQL database engine updates 2020-09-02 (version 1.23.0) (p. 1153)
• Aurora MySQL database engine updates 2021-06-03 (version 1.22.5) (p. 1156)
• Aurora MySQL database engine updates 2021-03-04 (version 1.22.4) (p. 1157)
• Aurora MySQL database engine updates 2020-11-09 (version 1.22.3) (p. 1158)
• Aurora MySQL database engine updates 2020-03-05 (version 1.22.2) (p. 1159)
• Aurora MySQL database engine updates 2019-12-23 (version 1.22.1) (p. 1160)
• Aurora MySQL database engine updates 2019-11-25 (version 1.22.0) (p. 1161)
• Aurora MySQL database engine updates 2019-11-25 (version 1.21.0) (p. 1163)
• Aurora MySQL database engine updates 2020-03-05 (version 1.20.1) (p. 1165)
• Aurora MySQL database engine updates 2019-11-11 (version 1.20.0) (p. 1165)
• Aurora MySQL database engine updates 2020-03-05 (version 1.19.6) (p. 1167)
• Aurora MySQL database engine updates 2019-09-19 (version 1.19.5) (p. 1167)
• Aurora MySQL database engine updates 2019-06-05 (version 1.19.2) (p. 1168)
• Aurora MySQL database engine updates 2019-05-09 (version 1.19.1) (p. 1169)
• Aurora MySQL database engine updates 2019-02-07 (version 1.19.0) (p. 1170)
• Aurora MySQL database engine updates 2018-09-20 (p. 1171) (Version 1.18.0)
• Aurora MySQL database engine updates 2020-03-05 (p. 1172) (Version 1.17.9)
• Aurora MySQL database engine updates 2019-01-17 (p. 1172) (Version 1.17.8)
• Aurora MySQL database engine updates 2018-10-08 (p. 1173) (Version 1.17.7)
• Aurora MySQL database engine updates 2018-09-06 (p. 1174) (Version 1.17.6)
• Aurora MySQL database engine updates 2018-08-14 (p. 1174) (Version 1.17.5)
• Aurora MySQL database engine updates 2018-08-07 (p. 1175) (Version 1.17.4)
• Aurora MySQL database engine updates 2018-06-05 (p. 1176) (Version 1.17.3)
• Aurora MySQL database engine updates 2018-04-27 (p. 1176) (Version 1.17.2)
• Aurora MySQL database engine updates 2018-03-23 (p. 1177) (Version 1.17.1)
• Aurora MySQL database engine updates 2018-03-13 (p. 1177) (Version 1.17)
• Aurora MySQL database engine updates 2017-12-11 (p. 1178) (Version 1.16)
• Aurora MySQL database engine updates 2017-11-20 (p. 1179) (Version 1.15.1)
• Aurora MySQL database engine updates 2017-10-24 (p. 1180) (Version 1.15)
• Aurora MySQL database engine updates: 2018-03-13 (p. 1182) (Version 1.14.4)
• Aurora MySQL database engine updates: 2017-09-22 (p. 1182) (Version 1.14.1)
• Aurora MySQL database engine updates: 2017-08-07 (p. 1183) (Version 1.14)
• Aurora MySQL database engine updates: 2017-05-15 (p. 1184) (Version 1.13)
• Aurora MySQL database engine updates: 2017-04-05 (p. 1185) (Version 1.12)
• Aurora MySQL database engine updates: 2017-02-23 (p. 1187) (Version 1.11)
• Aurora MySQL database engine updates: 2017-01-12 (p. 1189) (Version 1.10.1)
• Aurora MySQL database engine updates: 2016-12-14 (p. 1189) (Version 1.10)
• Aurora MySQL database engine updates: 2016-11-10 (p. 1190) (Versions 1.9.0, 1.9.1)
• Aurora MySQL database engine updates: 2016-10-26 (p. 1191) (Version 1.8.1)
• Aurora MySQL database engine updates: 2016-10-18 (p. 1191) (Version 1.8)
• Aurora MySQL database engine updates: 2016-09-20 (p. 1193) (Version 1.7.1)
• Aurora MySQL database engine updates: 2016-08-30 (p. 1193) (Version 1.7)
• Aurora MySQL database engine updates: 2016-06-01 (p. 1194) (Version 1.6.5)
• Aurora MySQL database engine updates: 2016-04-06 (p. 1194) (Version 1.6)
• Aurora MySQL database engine updates: 2016-01-11 (p. 1196) (Version 1.5)
• Aurora MySQL database engine updates: 2015-12-03 (p. 1196) (Version 1.4)
• Aurora MySQL database engine updates: 2015-10-16 (p. 1198) (Versions 1.2, 1.3)
• Aurora MySQL database engine updates: 2015-08-24 (p. 1200) (Version 1.1)

Aurora MySQL database engine updates 2021-09-30 (version 1.23.4)

Version: 1.23.4

Aurora MySQL 1.23.4 is generally available. Aurora MySQL 2.* versions are compatible with MySQL 5.7 and Aurora MySQL 1.* versions are compatible with MySQL 5.6.

Currently supported Aurora MySQL releases for upgrade to 1.23.4 are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, and 1.23.*.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the RDS Console, the AWS CLI, or the Amazon RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

General improvements:

• Fixed an issue that can cause high CPU consumption on the reader instances due to excessive logging of informational messages in internal diagnostic log files.

High-priority fixes:

• CVE-2021-2307
• CVE-2021-2226
• CVE-2021-2160
• CVE-2021-2154
• CVE-2021-2060
• CVE-2021-2032
• CVE-2021-2001

Aurora MySQL database engine updates 2021-06-28 (version 1.23.3)

Version: 1.23.3

Aurora MySQL 1.23.3 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.
Currently supported Aurora MySQL releases for upgrade to 1.23.3 are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*,
1.19.*, 1.20.*, 1.21.*, 1.22.*, and 1.23.*.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the RDS
Console, the AWS CLI, or the Amazon RDS API.

If you have any questions or concerns, AWS Support is available on the community forums and through
AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

General stability and availability enhancements.

Security fixes:

- CVE-2021-23841
- CVE-2021-3449
- CVE-2020-28196

Aurora MySQL database engine updates 2021-03-18 (version 1.23.2)

Version: 1.23.2

Aurora MySQL 1.23.2 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6
and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, and 2.04.*, 2.05.*,
2.06.*, 2.07.*, 2.08.* and 2.09.*. You can restore the snapshot of an Aurora MySQL 1.* database into
Aurora MySQL 1.23.2.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the RDS
Console, the AWS CLI, or the Amazon RDS API.

Note
This version is currently not available in the following regions: AWS GovCloud (US-East) [us-gov-
est-1], AWS GovCloud (US-West) [us-gov-west-1]. There will be a separate announcement once
it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through
AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

High priority fixes:

- CVE-2020-14867
- CVE-2020-14812
- CVE-2020-14769
- CVE-2020-14765
- CVE-2020-14793
- CVE-2020-14672
- CVE-2020-1971
• CVE-2018-3143

Availability improvements:

• Fixed an issue in the dynamic cluster storage resizing feature that could cause reader DB instances to restart.
• Fixed a failover issue due to a race condition in `RESET QUERY CACHE` statement.
• Fixed a crash in a nested stored procedure call with query cache.
• Fixed an issue to prevent repeated restart of `mysqld` when recovering from an incomplete truncation of partitioned or sub-partitioned tables.
• Fixed an issue that could cause migration from on-prem or RDS for MySQL to Aurora MySQL to not succeed.
• Fixed a rare race condition where the database can restart during the scaling of the storage volume.
• Fixed an issue in the lock manager where a race condition can cause a lock to be shared by two transactions, causing the database to restart.
• Fixed an issue related to transaction lock memory management with long-running write transactions resulting in a database restart.
• Fixed a race condition in the lock manager that resulted in a database restart or failover during transaction rollback.
• Fixed an issue during upgrade from 5.6 to 5.7 when the table had Fast Online DDL enabled in lab mode in 5.6.
• Fixed multiple issues where the engine might restart during zero-downtime patching while checking for a quiesced point in database activity for patching.
• Fixed multiple issues related to repeated restarts due to interrupted DDL operations, such as `DROP TRIGGER`, `ALTER TABLE`, and specifically `ALTER TABLE` that modifies the type of partitioning or number of partitions in a table.
• Updated the default value of `table_open_cache` on 16XL and 24XL instances to avoid repeated restarts and high CPU utilization on large instances classes (R4/R5-16XL, R5-12XL, R5-24XL). This impacted 1.21.x and 1.22.x releases.
• Fixed an issue that caused a binlog replica to stop with an `HA_ERR_KEY_NOT_FOUND` error.

Integration of MySQL community edition bug fixes

• `Replication`: While a `SHOW BINLOG EVENTS` statement was executing, any parallel transaction was blocked. The fix ensures that the `SHOW BINLOG EVENTS` process now only acquires a lock for the duration of calculating the file's end position, therefore parallel transactions are not blocked for long durations. (Bug #76618, Bug #20928790)

Aurora MySQL database engine updates 2020-11-24 (version 1.23.1)

Version: 1.23.1

Aurora MySQL 1.23.1 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases for upgrade to 1.23.1 are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, and 1.23.*.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the RDS Console, the AWS CLI, or the Amazon RDS API.
If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

**Security fixes:**

Fixes and other enhancements to fine-tune handling in a managed environment. Additional CVE fixes below:

- CVE-2020-14559
- CVE-2020-14539

**Incompatible changes:**

This version introduces a permission change that affects the behavior of the `mysqldump` command. Users must have the `PROCESS` privilege to access the `INFORMATION_SCHEMA.FILES` table. To run the `mysqldump` command without any changes, grant the `PROCESS` privilege to the database user that the `mysqldump` command connects to. You can also run the `mysqldump` command with the `--no-tablespaces` option. With that option, the `mysqldump` output doesn't include any `CREATE LOGFILE GROUP` or `CREATE TABLESPACE` statements. In that case, the `mysqldump` command doesn't access the `INFORMATION_SCHEMA.FILES` table, and you don't need to grant the `PROCESS` permission.

**Availability improvements:**

- Fixed an issue that causes an Aurora reader instance in a global database secondary cluster running 1.23.0 to restart repeatedly.
- Fixed an issue where a global database secondary Region's replicas might restart when upgraded to release 1.23.0 while the primary Region writer was on an older release version.
- Fixed a memory leak in dynamic resizing feature, introduced in Aurora MySQL 1.23.0.
- Fixed an issue that might cause server restart during execution of a query using the parallel query feature.
- Fixed an issue that might cause a client session to hang when the database engine encounters an error while reading from or writing to the network.

**Aurora MySQL database engine updates 2020-09-02 (version 1.23.0)**

**Version:** 1.23.0

Aurora MySQL 1.23.0 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 1.23.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, 2.07.*, 2.08.*, and 2.09.*. You can restore the snapshot of an Aurora MySQL 1.* database into Aurora MySQL 1.23.0.

**Important**

The improvements to Aurora storage in this version limit the available upgrade paths from Aurora MySQL 1.23 to Aurora MySQL 2.*. When you upgrade an Aurora MySQL 1.23 cluster to 2.*, you must upgrade to Aurora MySQL 2.09.0 or later.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the RDS Console, the AWS CLI, or the Amazon RDS API.
Note
This version is currently not available in the following regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

New features:

• You can now turn parallel query on or off for an existing cluster by changing the value of the DB cluster parameter `aurora_parallel_query`. You don’t need to use the `parallelquery` setting for the `--engine-mode` parameter when creating the cluster. Parallel query is now expanded to be available in all regions where Aurora MySQL is available.

There are a number of other functionality enhancements and changes to the procedures for upgrading and enabling parallel query in an Aurora cluster. For more information, see Working with parallel query for Amazon Aurora MySQL (p. 847).

• With this release, you can create Amazon Aurora MySQL database instances with up to 128 tebibytes (TiB) of storage. The new storage limit is an increase from the prior 64 TiB. The 128 TiB storage size supports larger databases. This capability is not supported on small instances sizes (db.t2 or db.t3). A single tablespace cannot grow beyond 64 TiB due to InnoDB limitations with 16 KB page size.

Aurora alerts you when the cluster volume size is near 128 TiB, so that you can take action prior to hitting the size limit. The alerts appear in the mysql log and RDS Events in the AWS Management Console.

• Improved binary log (binlog) processing to reduce crash recovery time and commit time latency when very large transactions are involved.

• Aurora dynamically resizes your cluster storage space. With dynamic resizing, the storage space for your Aurora DB cluster automatically decreases when you remove data from the DB cluster. For more information, see Storage scaling (p. 392).

Note
The dynamic resizing feature is being deployed in phases to the AWS Regions where Aurora is available. Depending on the Region where your cluster is, this feature might not be available yet. For more information, see the What’s New announcement.

High priority fixes:

• CVE-2019-2911
• CVE-2019-2537
• CVE-2018-2787
• CVE-2018-2784
• CVE-2018-2645
• CVE-2018-2640

Availability improvements:

• Fixed an issue in the lock manager where a race condition can cause a lock to be shared by two transactions, causing the database to restart.

• Fixed an issue related to transaction lock memory management with long-running write transactions resulting in a database restart.
• Fixed a race condition in the lock manager that resulted in a database restart or failover during transaction rollback.
• Fixed an issue during upgrade from 5.6 to 5.7 when the innodb_file_format changed on a table that had Fast DDL enabled.
• Fixed multiple issues where the engine might restart during zero-downtime patching while checking for a quiesced point in database activity for patching.
• Fixed an issue related to DDL recovery that impacts restart of the DB instance while recovering an interrupted DROP TRIGGER operation.
• Fixed a bug that might cause unavailability of the database if a crash occurs during the execution of certain partitioning operations. Specifically, an interrupted ALTER TABLE operation that modifies the type of partitioning or the number of partitions in a table.
• Fix default value of table_open_cache on 16XL and 24XL instances which could cause repeated failovers and high CPU utilization on large instances classes (R4/R5-16XL, R5-12XL, R5-24XL). This impacted 1.21.x and 1.22.x.

Global databases:
• Populate missing data in the MySQL INFORMATION_SCHEMA.REPLICA_HOST_STATUS view on primary and secondary AWS Regions in an Aurora global database.
• Fixed unexpected query failures that could occur in a Global DB secondary Region due to garbage collection of UNDO records in the primary Region, after temporary network connectivity issues between the primary and secondary Regions.

Parallel query:
• Fixed an issue where parallel query might cause a long-running query to return an empty result.
• Fixed an issue where a query on a small table on the Aurora read replica might take more than one second.
• Fixed an issue that might cause a restart when a parallel query and a DML statement are executing concurrently under a heavy workload.

General improvements:
• Fixed an issue where queries using spatial index might return partial results if spatial index was created on tables with already existing large spatial values.
• Increased maximum allowable length for audit system variables server_audit_incl_users and server_audit_excl_users from 1024 bytes to 2000 bytes.
• Fixed an issue where a binlog replica connected to an Aurora MySQL binlog primary might show incomplete data when the Aurora MySQL binlog primary loads data from S3 under statement binlog_format.
• Comply with community behavior to map mixed binlog_format to row instead of statement for loading data.
• Fixed an issue causing binlog replication to stop working when the user closes the connection and the session is using temporary tables.
• Improved response time of a query involving MyISAM temporary tables.
• Fix permission issue when binlog worker runs a native lambda function.
• Fixed an issue on Aurora read replicas when trying to query or rotate the slow log or general log.
• Fixed an issue that broke logical replication when the binlog_checksum parameter is set to different values on the master and the replica.
• Fixed an issue where the read replica might transiently see partial results of a recently committed transaction on the writer.
• Include transaction info of the rolled-back transaction in `show engine innodb status` when a deadlock is resolved.

Integration of MySQL community edition bug fixes

• Binlog events with `ALTER TABLE ADD COLUMN ALGORITHM=QUICK` will be rewritten as `ALGORITHM=DEFAULT` to be compatible with the community edition.

• Bug #2350047: IF CLIENT KILLED AFTER ROLLBACK TO SAVEPOINT PREVIOUS STMNTS COMMITTED

• Bug #29915479: RUNNING COM_REGISTER_SLAVE WITHOUT COM_BINLOG_DUMP CAN RESULTS IN SERVER EXIT

• Bug #30441969: Bug #29723340: MYSQL SERVER CRASH AFTER SQL QUERY WITH DATA ?AST

• Bug #30628268: OUT OF MEMORY CRASH

• Bug #27081349: UNEXPECTED BEHAVIOUR WHEN DELETE WITH SPATIAL FUNCTION

• Bug #27230859: UNEXPECTED BEHAVIOUR WHILE HANDLING INVALID POLYGON

• Bug #27081349: UNEXPECTED BEHAVIOUR WHEN DELETE WITH SPATIAL

• Bug #26935001: ALTER TABLE AUTO_INCREMENT TRIES TO READ INDEX FROM DISCARDED TABLESPACE

• Bug #29770705: SERVER CRASHED WHILE EXECUTING SELECT WITH SPECIFIC WHERE CLAUSE

• Bug #27659490: SELECT USING DYNAMIC RANGE AND INDEX MERGE USE TOO MUCH MEMORY (OOM)

• Bug #24786290: REPLICATION BREAKS AFTER BUG #74145 HAPPENS IN MASTER

• Bug #27703912: EXCESSIVE MEMORY USAGE WITH MANY PREPARE

• Bug #20527363: TRUNCATE TEMPORARY TABLE CRASH: IDICT_TF2_FLAG_IS_SET(TABLE, DICT_TF2_TEMPORARY)

• Bug #23105973 PS_TRUNCATE_ALL_TABLES() DOES NOT WORK IN SUPER_READ_ONLY MODE

• Bug #25053286: USE VIEW WITH CONDITION IN PROCEDURE CAUSES INCORRECT BEHAVIOR (fixed in 5.6.36)

• Bug #25586773: INCORRECT BEHAVIOR FOR CREATE TABLE SELECT IN A LOOP IN SP (fixed in 5.6.39)

• Bug #27407480: AUTOMATIC_SP_PRIVILEGES REQUIRES NEED THE INSERT PRIVILEGES FOR MYSQL.USER TABLE

• Bug #26997096: relay_log_space value is not updated in a synchronized manner so that its value is sometimes much higher than the actual disk space used by relay logs.

• Bug #15831300 SLAVE_TYPE_CONVERSIONS=ALL_NON_LOSSY NOT WORKING AS EXPECTED

• SSL Bug backport Bug #17087862, Bug #20551271

• Bug #16894092: PERFORMANCE REGRESSION IN 5.6.6+ FOR INSERT INTO ... SELECT ... FROM (fixed in 5.6.15).

• Port a bug fix related to SLAVE_TYPE_CONVERSIONS.

Aurora MySQL database engine updates 2021-06-03 (version 1.22.5)

Version: 1.22.5

Aurora MySQL 1.22.5 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases for upgrade to 1.22.5 are 1.14.*, 1.15.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, and 1.22.*.
To create a cluster with an older version of Aurora MySQL, specify the engine version through the RDS Console, the AWS CLI, or the Amazon RDS API.

**Note**
This version is designated as a long-term support (LTS) release. For more information, see Aurora MySQL long-term support (LTS) releases (p. 1049).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

**Availability improvements:**

- Resolved an issue that could cause the database to stall, and subsequently restart or fail over due to a concurrency conflict between internal cleanup threads.
- Resolved an issue that could cause the cluster to become unavailable if the database restarted while holding XA transactions in prepared state, and then restarted again before those transactions were committed or rolled back. Prior to this fix, you can address the issue by restoring the cluster to a point in time before the first restart.
- Resolved an issue that could cause the InnoDB purge to become blocked if the database restarts while processing a DDL statement. As a result, the InnoDB history list length would grow and the cluster storage volume would keep growing until it fills up, making the database unavailable. Prior to this fix, you can mitigate the issue by restarting the database again to unblock purge.

**Aurora MySQL database engine updates 2021-03-04 (version 1.22.4)**

**Version:** 1.22.4

Aurora MySQL 1.22.4 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases for upgrade to 1.22.4 are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, and 1.22.*.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the RDS Console, the AWS CLI, or the Amazon RDS API.

**Note**
This version is designated as a long-term support (LTS) release. For more information, see Aurora MySQL long-term support (LTS) releases (p. 1049).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

**Security fixes:**

Fixes and other enhancements to fine-tune handling in a managed environment. Additional CVE fixes below:

- CVE-2020-14867
- CVE-2020-14812
- CVE-2020-14793
Amazon Aurora User Guide for Aurora
Database engine updates for
Amazon Aurora MySQL version 1

- CVE-2020-14769
- CVE-2020-14765
- CVE-2020-14672
- CVE-2020-1971

**Availability improvements:**

- Fixed an issue that could trigger a database restart or failover during a `kill session` command. If you encounter this issue, contact AWS support to enable this fix on your instance.
- Improved binary logging to reduce crash recovery time and commit latency when large transactions are involved.
- Fixed an issue that caused a binlog replica to stop with an `HA_ERR_KEY_NOT_FOUND` error.

**Aurora MySQL database engine updates 2020-11-09 (version 1.22.3)**

**Version:** 1.22.3

Aurora MySQL 1.22.3 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases for upgrade to 1.22.3 are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, and 1.22.*.

To create a cluster with an older version of Aurora MySQL, specify the engine version through the RDS Console, the AWS CLI, or the Amazon RDS API.

**Note**

This version is designated as a long-term support (LTS) release. For more information, see **Aurora MySQL long-term support (LTS) releases** (p. 1049).

If you have any questions or concerns, AWS Support is available on the community forums and through **AWS Premium Support**. For more information, see **Maintaining an Amazon Aurora DB cluster** (p. 439).

**Improvements**

**Security fixes:**

Fixes and other enhancements to fine-tune handling in a managed environment. Additional CVE fixes below:

- CVE-2020-14559
- CVE-2020-14539
- CVE-2020-2579
- CVE-2020-2812
- CVE-2020-2780
- CVE-2020-2763

**Incompatible changes:**

This version introduces a permission change that affects the behavior of the `mysqldump` command. Users must have the `PROCESS` privilege to access the `INFORMATION_SCHEMA.FILES` table. To run the
mysqldump command without any changes, grant the PROCESS privilege to the database user that the
mysqldump command connects to. You can also run the mysqldump command with the --no-
tablespaces option. With that option, the mysqldump output doesn't include any CREATE LOGFILE
GROUP or CREATE TABLESPACE statements. In that case, the mysqldump command doesn't access the
INFORMATION_SCHEMA.FILES table, and you don't need to grant the PROCESS permission.

Availability improvements:

- Fixed issues that might cause server restarts during recovery of a DDL statement that was not
  committed.
- Fixed race conditions in the lock manager that can cause a server restart.
- Fixed an issue that might cause the monitoring agent to restart the server during recovery of a large
  transaction

General improvements:

- Changed the behavior to map MIXED binlog_format to ROW instead of STATEMENT when executing
  LOAD DATA FROM INFILE | S3.
- Fixed an issue where a binlog replica connected to an Aurora MySQL binlog primary might show
  incomplete data when the primary executed LOAD DATA FROM S3 and binlog_format is set to
  STATEMENT.

Integration of MySQL community edition bug fixes

- Bug #26654685: A corrupt index ID encountered during a foreign key check raised an assertion
- Bug #15831300: By default, when promoting integers from a smaller type on the master to a larger
  type on the slave (for example, from a SMALLINT column on the master to a BIGINT column on the
  slave), the promoted values are treated as though they are signed. Now in such cases it is possible
  to modify or override this behavior using one or both of ALL_SIGNED, ALL_UNSIGNED in the set of
  values specified for the slave_type_conversions server system variable. For more information, see Row-
  based replication: attribute promotion and demotion, as well as the description of the variable.
- Bug #17449901: With foreign_key_checks=0, InnoDB permitted an index required by a foreign
  key constraint to be dropped, placing the table into an inconsistent and causing the foreign key check
  that occurs at table load to fail. InnoDB now prevents dropping an index required by a foreign key
  constraint, even with foreign_key_checks=0. The foreign key constraint must be removed before
  dropping the foreign key index.
- BUG #20768847: An ALTER TABLE ... DROP INDEX operation on a table with foreign key dependencies
  raised an assertion.

Aurora MySQL database engine updates 2020-03-05 (version 1.22.2)

Version: 1.22.2

Aurora MySQL 1.22.2 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6
and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 
1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.* and 2.07.*. You can restore the snapshot of an Aurora
MySQL 1.* database into Aurora MySQL 1.22.2.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the
RDS Console, the AWS CLI, or the Amazon RDS API.
Note
This version is currently not available in the following regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1]. There will be a separate announcement once it is made available.
This version is designated as a long-term support (LTS) release. For more information, see Aurora MySQL long-term support (LTS) releases (p. 1049).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

High priority fixes:

- Fixed an issue of intermittent connection failures after certificate rotation.
- Fixed an issue that caused cloning to take longer on some database clusters with high write loads.
- Fixed an issue that broke logical replication when the binlog_checksum parameter is set to different values on the master and the replica.
- Fixed an issue where slow log and general log may not properly rotate on read replicas.
- Fixed an issue with ANSI Read Committed Isolation Level behavior.

Aurora MySQL database engine updates 2019-12-23 (version 1.22.1)

Version: 1.22.1

Aurora MySQL 1.22.1 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, and 2.07.*. To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI or the RDS API. You have the option to upgrade existing Aurora MySQL 1.* database clusters to Aurora MySQL 1.22.1.

Note
This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], Asia Pacific (Hong Kong) [ap-east-1], and Middle East (Bahrain) [me-south-1. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

Critical fixes:

- Fixed issues that prevented engine recovery involving table locks and temporary tables.
- Improved the stability of binary log when temporary tables are used.

High priority fixes:
• Fixed a slow memory leak in Aurora specific database tracing and logging sub-system that lowers the freeable memory.

Aurora MySQL database engine updates 2019-11-25 (version 1.22.0)

Version: 1.22.0

Aurora MySQL 1.22.0 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.*, and 2.07.. To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI or the RDS API. You have the option to upgrade existing Aurora MySQL 1.* database clusters to Aurora MySQL 1.22.0.

Note
This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], Asia Pacific (Hong Kong) [ap-east-1], Middle East (Bahrain) [me-south-1], and South America (São Paulo) [sa-east-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

New features:

• Aurora MySQL clusters now support the instance types r5.8xlarge, r5.16xlarge and r5.24xlarge.
• Binlog has new enhancements for improved commit time latency when very large transactions are involved.
• Aurora MySQL now has a mechanism to minimize the time window during which events of a large transaction are written to binlog on commit. This effectively prevents lengthy offline recovery incurred when database crashes occur during that time window. This feature also fixes the issue where a large transaction blocks small transactions on binlog commit. This feature is off by default and can be enabled by the service team if needed for your workload. When enabled, it will be triggered when a transaction size is > 500MB.
• Added support for the ANSI READ COMMITTED isolation level on the read replicas. This isolation level enables long-running queries on the read replica to execute without impacting the high throughput of writes on the writer node. For more information, see Aurora MySQL isolation levels.
• Global Databases now allow adding secondary read-only replica regions for database clusters deployed in these AWS Regions: regions: US East (N. Virginia) [us-east-1], US East (Ohio) [us-east-2], US West (N. California) [us-west-1], US West (Oregon) [us-west-2], Europe (Ireland) [eu-west-1], Europe (London) [eu-west-2], Europe (Paris) [eu-west-3], Asia Pacific (Tokyo) [ap-northeast-1], Asia Pacific (Seoul) [ap-northeast-2], Asia Pacific (Singapore) [ap-southeast-1], Asia Pacific (Sydney) [ap-southeast-2], Canada (Central) [ca-central-1], Europe (Frankfurt) [eu-central-1], and Asia Pacific (Mumbai) [ap-south-1].
• The hot row contention feature is now generally available and does not require the Aurora lab mode setting to be ON. This feature substantially improves throughput for workloads with many transactions contending for rows on the same page.
This version has updated timezone files to support the latest Brazil timezone update for new clusters.

Critical fixes:
- CVE-2019-2922
- CVE-2019-2923
- CVE-2019-2924
- CVE-2019-2910

High priority fixes:
- CVE-2019-2805
- CVE-2019-2730
- CVE-2019-2740
- CVE-2018-3064
- CVE-2018-3058
- CVE-2017-3653
- CVE-2017-3464
- CVE-2017-3244
- CVE-2016-5612
- CVE-2016-5439
- CVE-2016-0606
- CVE-2015-4904

- CVE-2015-4864
- CVE-2015-4830
- CVE-2015-4826
- CVE-2015-2620
- CVE-2015-0382
- CVE-2015-0381
- CVE-2014-6555
- CVE-2014-4258
- CVE-2014-4260
- CVE-2014-2444
- CVE-2014-2436
- CVE-2013-5881
- CVE-2014-0393
- CVE-2013-5908
- CVE-2013-5807
- CVE-2013-3806
- CVE-2013-3811
- CVE-2013-3804
- CVE-2013-3807
- CVE-2013-2378
• CVE-2013-2375
• CVE-2013-1523
• CVE-2013-2381
• CVE-2012-5615
• CVE-2014-6489
• Fixed an issue in the DDL recovery component that resulted in prolonged database downtime. Clusters that become unavailable after executing `TRUNCATE TABLE` query on a table with an `AUTO_INCREMENT` column should be updated.
• Fixed an issue in the DDL recovery component that resulted in prolonged database downtime. Clusters that become unavailable after executing `DROP TABLE` query on multiple tables in parallel should be updated.

General stability fixes:
• Fixed an issue that caused read replicas to restart during a long-running transaction. Customers who encounter replica restarts that coincide with an accelerated drop in freeable memory should consider upgrading to this version.
• Fixed an issue that incorrectly reported `ERROR 1836` when a nested query is executed against a temporary table on the read replica.
• Fixed a parallel query abort error on an Aurora reader instance while a heavy write workload is running on the Aurora writer instance.
• Fixed an issue that causes a database configured as a Binlog Master to restart while a heavy write workload is running.
• Fixed an issue of prolonged unavailability while restarting the engine. This addresses an issue in the buffer pool initialization. This issue occurs rarely but can potentially impact any supported release.
• Fixed an issue that generated inconsistent data in the `information_schema.replica_host_status` table.
• Fixed a race condition between the parallel query and the standard execution paths that caused the Reader nodes to restart intermittently.
• Improved stability of the database when the number of number of client connections exceeds the `max_connections` parameter value.
• Improved stability of the reader instances by blocking unsupported DDL and `LOAD FROM S3` queries.

Integration of MySQL community edition bug fixes
• Bug#16346241 - SERVER CRASH IN ITEM_PARAM::QUERY_VAL_STR
• Bug#17733850 - NAME_CONST() CRASH IN ITEM_NAME_CONST::ITEM_NAME_CONST()
• Bug #20989615 - INNODB AUTO_INCREMENT PRODUCES SAME VALUE TWICE
• Bug #20181776 - ACCESS CONTROL DOESN'T MATCH MOST SPECIFIC HOST WHEN IT CONTAINS WILDCARD
• Bug #27326796 - MYSQL CRASH WITH INNODB ASSERTION FAILURE IN FILE PARS0PARS.CC
• Bug #20590013 - IF YOU HAVE A FULLTEXT INDEX AND DROP IT YOU CAN NO LONGER PERFORM ONLINE DDL

Aurora MySQL database engine updates 2019-11-25 (version 1.21.0)

Version: 1.21.0
Aurora MySQL 1.21.0 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 2.01.*, 2.02.*, 2.03.* and 2.04.*. To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI or the RDS API. You have the option to upgrade existing Aurora MySQL 1.* database clusters to Aurora MySQL 1.21.0.

**Note**
This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], Asia Pacific (Hong Kong) [ap-east-1], Europe (Stockholm) [eu-north-1], and Middle East (Bahrain) [me-south-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

**Critical fixes:**

- CVE-2018-0734
- CVE-2019-2534
- CVE-2018-2612
- CVE-2017-3599
- CVE-2018-2562
- CVE-2017-3329
- CVE-2018-2696
- CVE-2015-4737

**High priority fixes:**

- Customers with database size close to 64 tebibytes (TiB) are strongly advised to upgrade to this version to avoid downtime due to stability bugs affecting volumes close to the Aurora storage limit.

**General stability fixes:**

- Fixed a parallel query abort error on Aurora reader instances while a heavy write workload is running on the Aurora writer instance.
- Fixed an issue on Aurora reader instances that reduced free memory during long-running transactions while there is a heavy transaction commit traffic on the writer instance.
- The value of the parameter `aurora_disable_hash_join` is now persisted after database restart or host replacement.
- Fixed an issue related to the Full Text Search cache that caused the Aurora instance to run out of memory. Customers using Full Text Search should upgrade.
- Improved stability of the database when the hash join feature is enabled and the instance is low on memory. Customers using hash join should upgrade.
- Fixed an issue in the query cache where the "Too many connections" error could cause a reboot.
• Fixed the free memory calculation on T2 instances to include swap memory space to prevent unnecessary reboots.

Integration of MySQL community edition bug fixes

• Bug #19929406: HANDLE_FATAL_SIGNAL (SIG=11) IN __MEMMOVE_SSSE3_BACK FROM STRING::COPY
• Bug #17059925: For UNION statements, the rows-examined value was calculated incorrectly. This was manifested as too-large values for the ROWS_EXAMINED column of Performance Schema statement tables (such as events_statements_current).
• Bug #11827369: Some queries with SELECT ... FROM DUAL nested subqueries raised an assertion.
• Bug #16311231: Incorrect results were returned if a query contained a subquery in an IN clause that contained an XOR operation in the WHERE clause.

Aurora MySQL database engine updates 2020-03-05 (version 1.20.1)

Version: 1.20.1

Aurora MySQL 1.20.1 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.* and 2.07.*. You can restore the snapshot of an Aurora MySQL 1.* database into Aurora MySQL 1.20.1.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the RDS Console, the AWS CLI, or the Amazon RDS API.

Note
This version is currently not available in the following regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

High priority fixes:
• Fixed an issue of intermittent connection failures after certificate rotation.
• Fixed an issue related to connection close concurrency that would result in a failover under heavy workload.

General stability fixes:
• Fixed a crash during execution of a complex query involving multi-table joins and aggregation that uses intermediate tables internally.

Aurora MySQL database engine updates 2019-11-11 (version 1.20.0)

Version: 1.20.0
Aurora MySQL 1.20.0 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 2.01.*, 2.02.*, 2.03.* and 2.04.*. To create a cluster with an older version of Aurora MySQL, please specify the engine version through the AWS Management Console, the AWS CLI or the RDS API. You have the option to upgrade existing Aurora MySQL 1.* database clusters, up to 1.19.5, to Aurora MySQL 1.20.0.

**Note**
This version is currently not available in the following AWS Regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], Asia Pacific (Hong Kong) [ap-east-1], Europe (Stockholm) [eu-north-1], and Middle East (Bahrain) [me-south-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

**Critical fixes:**
- CVE-2018-0734
- CVE-2019-2534
- CVE-2018-2612
- CVE-2017-3599
- CVE-2018-2562
- CVE-2017-3329
- CVE-2018-2696
- CVE-2015-4737

**High priority fixes:**
- Customers with database size close to 64 tebibytes (TiB) are strongly advised to upgrade to this version to avoid downtime due to stability bugs affecting volumes close to the Aurora storage limit.

**General stability fixes:**
- Fixed a parallel query abort error on Aurora reader instances while a heavy write workload is running on the Aurora writer instance.
- Fixed an issue on Aurora reader instances that reduced free memory during long-running transactions while there is a heavy transaction commit traffic on the writer instance.
- The value of the parameter `aurora_disable_hash_join` is now persisted after database restart or host replacement.
- Fixed an issue related to the Full Text Search cache that caused the Aurora instance to run out of memory. Customers using Full Text Search should upgrade.
- Improved stability of the database when the hash join feature is enabled and the instance is low on memory. Customers using hash join should upgrade.
- Fixed an issue in the query cache where the "Too many connections" error could cause a reboot.
- Fixed the free memory calculation on T2 instances to include swap memory space to prevent unnecessary reboots.
Integration of MySQL community edition bug fixes

- Bug #19929406: HANDLE_FATAL_SIGNAL (SIG=11) IN __MEMMOVE_SSSE3_BACK FROM STRING::COPY
- Bug #17059925: For UNION statements, the rows-examined value was calculated incorrectly. This was manifested as too-large values for the ROWS_EXAMINED column of Performance Schema statement tables (such as events_statements_current).
- Bug #11827369: Some queries with SELECT ... FROM DUAL nested subqueries raised an assertion.
- Bug #16311231: Incorrect results were returned if a query contained a subquery in an IN clause that contained an XOR operation in the WHERE clause.

Aurora MySQL database engine updates 2020-03-05 (version 1.19.6)

Version: 1.19.6

Aurora MySQL 1.19.6 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.* and 2.07.*. You can restore the snapshot of an Aurora MySQL 1.* database into Aurora MySQL 1.19.6.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the RDS Console, the AWS CLI, or the Amazon RDS API.

Note
This version is currently not available in the following regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

High priority fixes:

- Fixed an issue of intermittent connection failures after certificate rotation.

Aurora MySQL database engine updates 2019-09-19 (version 1.19.5)

Version: 1.19.5

Aurora MySQL 1.19.5 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

You have the option to upgrade existing database clusters to Aurora MySQL 1.19.5. You can restore snapshots of Aurora MySQL 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.1, and 1.19.2 into Aurora MySQL 1.19.5.

To use an older version of Aurora MySQL, you can create new database clusters by specifying the engine version through the AWS Management Console, the AWS CLI, or the RDS API.
If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
This version is currently not available in the following AWS Regions: Europe (London) [eu-west-2], AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1], China (Ningxia) [cn-northwest-1], and Asia Pacific (Hong Kong) [ap-east-1]. There will be a separate announcement once it is made available.

**Note**
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Improvements**

- Fixed an issue on Aurora reader instances that reduced free memory during long-running transactions while there is a heavy transaction commit traffic on the writer instance.
- Fixed a parallel query abort error on Aurora reader instances while a heavy write workload is running on the Aurora writer instance.
- The value of the parameter `aurora_disable_hash_join` is now persisted after database restart or host replacement.
- Fixed an issue related to the Full Text Search cache that caused the Aurora instance to run out of memory.
- Improved stability of the database when the volume size is close to the 64 tebibyte (TiB) volume limit by reserving 160 GB of space for the recovery workflow to complete without a failover.
- Improved stability of the database when the hash join feature is enabled and the instance is low on memory.
- Fixed the free memory calculation to include swap memory space on T2 instances that caused them to reboot prematurely.
- Fixed an issue in the query cache where the "Too many connections" error could cause a reboot.

**Integration of MySQL community edition bug fixes**

- CVE-2018-2696
- CVE-2015-4737
- Bug #19929406: HANDLE_FATAL_SIGNAL (SIG=11) IN __MEMMOVE_SSSE3_BACK FROM STRING::COPY
- Bug #17059925: For UNION statements, the rows-examined value was calculated incorrectly. This was manifested as too-large values for the `ROWS_EXAMINED` column of Performance Schema statement tables (such as `events_statements_current`).
- Bug #11827369: Some queries with SELECT ... FROM DUAL nested subqueries raised an assertion.
- Bug #16311231: Incorrect results were returned if a query contained a subquery in an IN clause that contained an XOR operation in the WHERE clause.

**Aurora MySQL database engine updates 2019-06-05 (version 1.19.2)**

**Version:** 1.19.2

Aurora MySQL 1.19.2 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, can be created with 1.17.8, 1.19.0, 1.19.1, or 1.19.2. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL.
1.19.2. To use an older version, you can create new database clusters in Aurora MySQL 1.14.4, Aurora MySQL 1.15.1, Aurora MySQL 1.16, Aurora MySQL 1.17.8, or Aurora MySQL 1.18. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1], Europe (Stockholm) [eu-north-1], China (Ningxia) [cn-northwest-1], and Asia Pacific (Hong Kong) [ap-east-1] AWS Regions. There will be a separate announcement once it is made available.

Note
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

• Fixed an issue that could cause failures when loading data into Aurora from Amazon S3.
• Fixed an issue that could cause failures when uploading data from Aurora to Amazon S3.
• Fixed an issue that created zombie sessions left in a killed state.
• Fixed an issue that caused aborted connections when handling an error in network protocol management.
• Fixed an issue that could cause a crash when dealing with partitioned tables.
• Fixed an issue related to binlog replication of trigger creation.

Aurora MySQL database engine updates 2019-05-09 (version 1.19.1)

Version: 1.19.1

Aurora MySQL 1.19.1 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, can be created with 1.17.8, 1.19.0, or 1.19.1. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.19.1. To use an older version, you can create new database clusters in Aurora MySQL 1.14.4, Aurora MySQL 1.15.1, Aurora MySQL 1.16, Aurora MySQL 1.17.8, or Aurora MySQL 1.18. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

Note
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

Improvements

• Fixed a bug in binlog replication that can cause an issue on Aurora instances configured as binlog worker.
• Fixed an error in handling certain kinds of ALTER TABLE commands.
• Fixed an issue with aborted connections because of an error in network protocol management.

**Aurora MySQL database engine updates 2019-02-07 (version 1.19.0)**

**Version:** 1.19.0

Aurora MySQL 1.19.0 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, can be created with 1.17.8 or 1.19.0. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.19.0. To use an older version, you can create new database clusters in Aurora MySQL 1.14.4, Aurora MySQL 1.15.1, Aurora MySQL 1.16, Aurora MySQL 1.17.8, or Aurora MySQL 1.18.0. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

**Note**
The procedure to upgrade your DB cluster has changed. For more information, see Upgrading the minor version or patch level of an Aurora MySQL DB cluster (p. 1051).

**Features**

• **Aurora Version Selector** - Starting with Aurora MySQL 1.19.0, you can choose from among multiple versions of MySQL 5.6 compatible Aurora on the Amazon RDS console. For more information, see Checking or specifying Aurora MySQL engine versions through AWS (p. 1048).

**Improvements**

• Fixed a stability issue related to the CHECK TABLE query on an Aurora Replica.
• Introduced a new global user variable `aurora_disable_hash_join` to disable Hash Join.
• Fixed a stability issue when generating the output row during multiple table hash join.
• Fixed an issue that returned a wrong result because of a plan change during Hash Join applicability check.
• Zero Downtime Patching is supported with long running transactions. This enhancement will come into effect when upgrading from version 1.19 to a higher one.
• Zero Downtime Patching is now supported when binlog is enabled. This enhancement will come into effect when upgrading from version 1.19 to a higher one.
• Fixed an issue that caused a spike in CPU utilization on the Aurora Replica unrelated to the workload.
• Fixed a race condition in the lock manager that resulted in a database restart.
• Fixed a race condition in the lock manager component to improve stability of Aurora instances.
• Improved stability of the deadlock detector inside the lock manager component.
• `INSERT` operation on a table is prohibited if InnoDB detects that the index is corrupted.
• Fixed a stability issue in Fast DDL.
• Improved Aurora stability by reducing the memory consumption in scan batching for single-row subquery.
• Fixed a stability issue that occurred after a foreign key was dropped while the system variable `foreign_key_checks` is set to 0.
• Fixed an issue in the Out Of Memory Avoidance feature that erroneously overrode changes to the `table_definition_cache` value made by the user.
• Fixed stability issues in the Out Of Memory Avoidance feature.
• Fixed an issue that set `query_time` and `lock_time` in `slow_query_log` to garbage values.
• Fixed a parallel query stability issue triggered by improper handling of string collation internally.
• Fixed a parallel query stability issue triggered by a secondary index search.
• Fixed a parallel query stability issue triggered by a multi-table update.

Integration of MySQL community edition bug fixes

• BUG #32917: DETECT ORPHAN TEMP-POOL FILES, AND HANDLE GRACEFULLY
• BUG #63144 CREATE TABLE IF NOT EXISTS METADATA LOCK IS TOO RESTRICTIVE

Aurora MySQL database engine updates 2018-09-20

Version: 1.18.0

Aurora MySQL 1.18.0 is generally available. All new Aurora MySQL parallel query clusters with MySQL 5.6 compatibility, including those restored from snapshots, will be created in Aurora MySQL 1.18.0. You have the option, but are not required, to upgrade existing parallel query clusters to Aurora MySQL 1.18.0. You can create new DB clusters in Aurora MySQL 1.14.4, Aurora MySQL 1.15.1, Aurora MySQL 1.16, or Aurora MySQL 1.17.6. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.18.0 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time.

Important

Aurora MySQL 1.18.0 only applies to Aurora parallel query clusters. If you upgrade a provisioned 5.6.10a cluster, the resulting version is 1.17.8. If you upgrade a parallel query 5.6.10a cluster, the resulting version is 1.18.0.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Features

• Parallel Query is available with this release, for new clusters and restored snapshots. Aurora MySQL parallel query is an optimization that parallelizes some of the I/O and computation involved in processing data-intensive queries. The work that is parallelized includes retrieving rows from storage, extracting column values, and determining which rows match the conditions in the `WHERE` clause and join clauses. This data-intensive work is delegated (in database optimization terms, pushed down) to multiple nodes in the Aurora distributed storage layer. Without parallel query, each query brings all the scanned data to a single node within the Aurora MySQL cluster (the head node) and performs all the query processing there.
• When the parallel query feature is enabled, the Aurora MySQL engine automatically determines when queries can benefit, without requiring SQL changes such as hints or table attributes.

For more information, see Working with parallel query for Amazon Aurora MySQL (p. 847).
• OOM Avoidance: This feature monitors the system memory and tracks memory consumed by various components of the database. Once the system runs low on memory, it performs a list of actions to
release memory from various tracked components in an attempt to save the database from running into Out of Memory (OOM) and thereby avoiding a database restart. This best-effort feature is enabled by default for t2 instances and can be enabled on other instance classes via a new instance parameter named aurora_oom_response. The instance parameter takes a string of comma separated actions that an instance should take when its memory is low. Valid actions include "print", "tune", "decline", "kill_query" or any combination of these. Any empty string means there should be no actions taken and effectively renders the feature to be disabled. Note that the default actions for the feature is "print, tune". Usage examples:

- "print" – Only prints the queries taking high amount of memory.
- "tune" – Tunes the internal table caches to release some memory back to the system.
- "decline" – Declines new queries once the instance is low on memory.
- "kill_query" – Kills the queries in descending order of memory consumption until the instance memory surfaces above the low threshold. Data definition language (DDL) statements are not killed.
- "print, tune" – Performs actions described for both "print" and "tune".
- "tune, decline, kill_query" – Performs the actions described for "tune", "decline", and "kill_query".

For information about handling out-of-memory conditions and other troubleshooting advice, see Amazon Aurora MySQL out of memory issues (p. 1738).

Aurora MySQL database engine updates 2020-03-05

Version: 1.17.9

Aurora MySQL 1.17.9 is generally available. Aurora MySQL 1.* versions are compatible with MySQL 5.6 and Aurora MySQL 2.* versions are compatible with MySQL 5.7.

Currently supported Aurora MySQL releases are 1.14.*, 1.15.*, 1.16.*, 1.17.*, 1.18.*, 1.19.*, 1.20.*, 1.21.*, 1.22.*, 2.01.*, 2.02.*, 2.03.*, 2.04.*, 2.05.*, 2.06.* and 2.07.*. You can restore the snapshot of an Aurora MySQL 1.* database into Aurora MySQL 1.17.9.

To create a cluster with an older version of Aurora MySQL, please specify the engine version through the RDS Console, the AWS CLI, or the Amazon RDS API.

Note
This version is currently not available in the following regions: AWS GovCloud (US-East) [us-gov-east-1], AWS GovCloud (US-West) [us-gov-west-1]. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

High priority fixes:

- Fixed an issue of intermittent connection failures after certificate rotation.

Aurora MySQL database engine updates 2019-01-17

Version: 1.17.8

Aurora MySQL 1.17.8 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, will be created in Aurora MySQL 1.17.8. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.17.8. To use
an older version, you can create new database clusters in Aurora MySQL 1.14.4, 1.15.1, 1.16, or 1.17.7. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.17.8 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time.

**Note**
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

- Fixed a performance issue that increased the CPU utilization on an Aurora Replica after a restart.
- Fixed a stability issue for SELECT queries that used hash join.

**Integration of MySQL community edition bug fixes**

- **BUG #13418638**: CREATE TABLE IF NOT EXISTS METADATA LOCK IS TOO RESTRICTIVE

---

**Aurora MySQL database engine updates 2018-10-08**

**Version: 1.17.7**

Aurora MySQL 1.17.7 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, will be created in Aurora MySQL 1.17.7. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.17.7. To use an older version, you can create new database clusters in Aurora MySQL 1.14.4, 1.15.1, 1.16, or 1.17.6. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.17.7 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time.

**Note**
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

- The InnoDB status variable `innodb_buffer_pool_size` has been made publicly visible for the customers to modify.
- Fixed a stability issue on the Aurora cluster that occurred during failovers.
- Improved cluster availability by fixing a DDL recovery issue that occurred after an unsuccessful TRUNCATE operation.
- Fixed a stability issue related to the `mysql.innodb_table_stats` table update, triggered by DDL operations.
- Fixed Aurora Replica stability issues triggered during query cache invalidation after a DDL operation.
- Fixed a stability issue triggered by invalid memory access during periodic dictionary cache eviction in the background.
Integration of MySQL community edition bug fixes

- Bug #16208542: Drop index on a foreign key column leads to missing table.
- Bug #76349: memory leak in add_derived_key().
- Bug #16862316: For partitioned tables, queries could return different results depending on whether Index Merge was used.
- Bug #17588348: Queries using the index_merge optimization (see Index merge optimization) could return invalid results when run against tables that were partitioned by HASH.

Aurora MySQL database engine updates 2018-09-06

Version: 1.17.6

Aurora MySQL 1.17.6 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, will be created in Aurora MySQL 1.17.6. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.17.6. To use an older version, you can create new database clusters in Aurora MySQL 1.14.4, 1.15.1, 1.16, or 1.17.5. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.17.6 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time.

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

- Fixed a stability issue on the Aurora Reader for SELECT queries while the Aurora Writer is performing DDL operations on the same table.
- Fixed a stability issue caused by the creation and deletion of DDL logs for temporary tables that use Heap/Memory engine.
- Fixed a stability issue on the binlog worker when DDL statements are being replicated while the connection to the Binlog Master is unstable.
- Fixed a stability issue encountered while writing to the slow query log.
- Fixed an issue with the replica status table that exposed incorrect Aurora Reader lag information.

Integration of MySQL community edition bug fixes

- For an ALTER TABLE statement that renamed or changed the default value of a BINARY column, the alteration was done using a table copy and not in place. (Bug #67141, Bug #14735373, Bug #69580, Bug #17024290)
- An outer join between a regular table and a derived table that is implicitly groups could cause a server exit. (Bug #16177639)

Aurora MySQL database engine updates 2018-08-14

Version: 1.17.5
Aurora MySQL 1.17.5 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, will be created in Aurora MySQL 1.17.5. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.17.5. To use an older version, you can create new database clusters in Aurora MySQL 1.14.4, 1.15.1, 1.16, or 1.17.4. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.17.5 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time.

**Note**
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

- Fixed an issue where an Aurora Writer might experience a restart after an Aurora cluster is patched using the Zero-Downtime Patching feature.

### Aurora MySQL database engine updates 2018-08-07

**Version:** 1.17.4

Aurora MySQL 1.17.4 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, will be created in Aurora MySQL 1.17.4. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.17.4. To use an older version, you can create new database clusters in Aurora MySQL 1.14.4, 1.15.1, 1.16, or 1.17.3. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.17.4 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time.

**Note**
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

- Replication improvements:
  - Reduced network traffic by not transmitting binlog records to cluster replicas. This improvement is enabled by default.
  - Reduced network traffic by compressing replication messages. This improvement is enabled by default for 8xlarge and 16xlarge instance classes. Such large instances can sustain a heavy volume of write traffic that results in substantial network traffic for replication messages.
  - Fixes to the replica query cache.
- Fixed an issue where ORDER BY LOWER(\texttt{col\_name}) could produce incorrect ordering while using the utf8_bin collation.
- Fixed an issue where DDL statements (especially \texttt{TRUNCATE TABLE}) could cause problems on Aurora replicas, including instability or missing tables.
• Fixed an issue where sockets are left in a half-open state when storage nodes are restarted.
• The following new DB cluster parameters are available:
  • aurora_enable_zdr – Allow connections opened on an Aurora Replica to stay active on replica restart.
  • aurora_enable_replica_log_compression – Enable compression of replication payloads to improve network bandwidth utilization between the master and Aurora Replicas.
  • aurora_enable_repl_bin_log_filtering – Enable filtering of replication records that are unusable by Aurora Replicas on the master.

Aurora MySQL database engine updates 2018-06-05

Version: 1.17.3

Aurora MySQL 1.17.3 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, will be created in Aurora MySQL 1.17.3. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.17.3. You can create new database clusters in Aurora MySQL 1.14.4, Aurora MySQL 1.15.1, or Aurora MySQL 1.16. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.17.3 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time.

Note
This version is currently not available in the AWS GovCloud (US-West) [us-gov-west-1] and China (Beijing) [cn-north-1] regions. There will be a separate announcement once it is made available.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

• Fixed an issue where an Aurora Replica can restart when using optimistic cursor restores while reading records.
• Fixed an issue where an Aurora Writer restarts when trying to kill a MySQL session (kill "<session id>") with performance schema enabled.
• Fixed an issue where an Aurora Writer restarts when computing a threshold for garbage collection.
• Fixed an issue where an Aurora Writer can occasionally restart when tracking Aurora Replica progress in log application.
• Fixed an issue with the Query Cache when auto-commit is off and that could potentially cause stale reads.

Aurora MySQL database engine updates 2018-04-27

Version: 1.17.2

Aurora MySQL 1.17.2 is generally available. All new Aurora MySQL database clusters with MySQL 5.6 compatibility, including those restored from snapshots, will be created in Aurora MySQL 1.17.2. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.17.2. You can create new database clusters in Aurora MySQL 1.14.4, Aurora MySQL 1.15.1, or Aurora MySQL 1.16. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.17.2 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time.
If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Improvements**

- Fixed an issue which was causing restarts during certain DDL partition operations.
- Fixed an issue which was causing support for invocation of AWS Lambda functions via native Aurora MySQL functions to be disabled.
- Fixed an issue with cache invalidation which was causing restarts on Aurora Replicas.
- Fixed an issue in lock manager which was causing restarts.

**Aurora MySQL database engine updates 2018-03-23**

**Version:** 1.17.1

Aurora MySQL 1.17.1 is generally available. All new database clusters, including those restored from snapshots, will be created in Aurora MySQL 1.17.1. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.17.1. You can create new DB clusters in Aurora MySQL 1.15.1, Aurora MySQL 1.16, or Aurora MySQL 1.17. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.17.1 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time. This release fixes some known engine issues as well as regressions.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Note**

There is an issue in the latest version of the Aurora MySQL engine. After upgrading to 1.17.1, the engine version is reported incorrectly as 1.17. If you upgraded to 1.17.1, you can confirm the upgrade by checking the Maintenance column for the DB cluster in the AWS Management Console. If it displays none, then the engine is upgraded to 1.17.1.

**Improvements**

- Fixed an issue in binary log recovery that resulted in longer recovery times for situations with large binary log index files which can happen if binary logs rotate very often.
- Fixed an issue in the query optimizer that generated an inefficient query plan for partitioned tables.
- Fixed an issue in the query optimizer due to which a range query resulted in a restart of the database engine.

**Aurora MySQL database engine updates 2018-03-13**

**Version:** 1.17

Aurora MySQL 1.17 is generally available. Aurora MySQL 1.x versions are only compatible with MySQL 5.6, and not MySQL 5.7. All new 5.6-compatible database clusters, including those restored from snapshots, will be created in Aurora 1.17. You have the option, but are not required, to upgrade existing database clusters to Aurora 1.17. You can create new DB clusters in Aurora 1.14.1, Aurora 1.15.1, or Aurora 1.16. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.17 of Aurora, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time. We support zero-downtime patching, which works on a best-effort
basis to preserve client connections through the patching process. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support.

**Zero-downtime patching**

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an engine patch. For more information about ZDP, see Using zero-downtime patching (p. 1054).

**New features**

- Aurora MySQL now supports lock compression, which optimizes the lock manager's memory usage. Starting in version 1.17, you can use this feature without enabling lab mode.

**Improvements**

- Fixed an issue predominantly seen on instances with fewer cores where a single core might have 100% CPU utilization even when the database is idle.
- Improved the performance of fetching binary logs from Aurora clusters.
- Fixed an issue where Aurora Replicas attempt to write table statistics to persistent storage, and crash.
- Fixed an issue where query cache did not work as expected on Aurora Replicas.
- Fixed a race condition in lock manager that resulted in an engine restart.
- Fixed an issue where locks taken by read-only, auto-commit transactions resulted in an engine restart.
- Fixed an issue where some queries are not written to the audit logs.
- Fixed an issue with recovery of certain partition maintenance operations on failover.

**Integration of MySQL bug fixes**

- LAST_INSERT_ID is replicated incorrectly if replication filters are used (Bug #69861)
- Query returns different results depending on whether INDEX_MERGE setting (Bug #16862316)
- Query proc re-execute of stored routine, inefficient query plan (Bug #16346367)
- INNODB FTS : Assert in FTS_CACHE_APPEND_DELETED_DOC_IDS (BUG #18079671)
- Assert RBT_EMPTY(INDEX_CACHE->WORDS) in ALTER TABLE CHANGE COLUMN (BUG #17536995)
- INNODB fulltext search doesn't find records when savepoints are involved (BUG #70333, BUG #17458835)

**Aurora MySQL database engine updates 2017-12-11**

**Version:** 1.16

Aurora MySQL 1.16 is generally available. All new database clusters, including those restored from snapshots, will be created in Aurora 1.16. You have the option, but are not required, to upgrade existing database clusters to Aurora 1.16. You can create new DB clusters in Aurora 1.14.1 or Aurora 1.15.1. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.16 of Aurora, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time. We are enabling zero-downtime patching, which works on a best-
effort basis to preserve client connections through the patching process. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support.

Zero-downtime patching

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an engine patch. For more information about ZDP, see Using zero-downtime patching (p. 1054).

New features

• Aurora MySQL now supports synchronous AWS Lambda invocations via the native function `lambda_sync()`. Also available is native function `lambda_async()`, which can be used as an alternative to the existing stored procedure for asynchronous Lambda invocation. For more information, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 975).

• Aurora MySQL now supports hash joins to speed up equijoin queries. Aurora's cost-based optimizer can automatically decide when to use hash joins; you can also force their use in a query plan. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).

• Aurora MySQL now supports scan batching to speed up in-memory scan-oriented queries significantly. The feature boosts the performance of table full scans, index full scans, and index range scans by batch processing.

Improvements

• Fixed an issue where read replicas crashed when running queries on tables that have just been dropped on the master.

• Fixed an issue where restarting the writer on a database cluster with a very large number of `FULLTEXT` indexes results in longer than expected recovery.

• Fixed an issue where flushing binary logs causes `LOST_EVENTS` incidents in binlog events.

• Fixed stability issues with the scheduler when performance schema is enabled.

• Fixed an issue where a subquery that uses temporary tables could return partial results.

Integration of MySQL bug fixes

None

Aurora MySQL database engine updates 2017-11-20

Version: 1.15.1

Aurora MySQL 1.15.1 is generally available. All new database clusters, including those restored from snapshots, will be created in Aurora 1.15.1. You have the option, but are not required, to upgrade existing DB clusters to Aurora 1.15.1. You can create new DB clusters in Aurora 1.14.1. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.15.1 of Aurora, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time. We are enabling zero-downtime patching, which works on a best-effort basis to preserve client connections through the patching process. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).
**Zero-downtime patching**

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an engine patch. For more information about ZDP, see Using zero-downtime patching (p. 1054).

**Improvements**

- Fixed an issue in the adaptive segment selector for a read request that would cause it to choose the same segment twice causing a spike in read latency under certain conditions.
- Fixed an issue that stems from an optimization in Aurora MySQL for the thread scheduler. This problem manifests itself into what are spurious errors while writing to the slow log, while the associated queries themselves perform fine.
- Fixed an issue with stability of read replicas on large (> 5 TB) volumes.
- Fixed an issue where worker thread count increases continuously due to a bogus outstanding connection count.
- Fixed an issue with table locks that caused long semaphore waits during insert workloads.
- Reverted the following MySQL bug fixes included in Aurora MySQL 1.15:
  - MySQL instance stalling "doing SYNC index" (Bug #73816)
  - Assert RBT_EMPTY(INDEX_CACHE->WORDS) in ALTER TABLE CHANGE COLUMN (Bug #17536995)
  - InnoDB Fulltext search doesn't find records when savepoints are involved (Bug #70333)

**Integration of MySQL bug fixes**

None

**Aurora MySQL database engine updates 2017-10-24**

**Version: 1.15**

Aurora MySQL 1.15 is generally available. All new database clusters, including those restored from snapshots, will be created in Aurora 1.15. You have the option, but are not required, to upgrade existing DB clusters to Aurora 1.15. You can create new DB clusters in Aurora 1.14.1. You can do so using the AWS CLI or the Amazon RDS API and specifying the engine version.

With version 1.15 of Aurora, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time. Updates require a database restart, so you will experience 20 to 30 seconds of downtime, after which you can resume using your DB cluster or clusters. If your DB clusters are currently running Aurora 1.14 or Aurora 1.14.1, the zero-downtime patching feature in Aurora MySQL might allow client connections to your Aurora MySQL primary instance to persist through the upgrade, depending on your workload.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Zero-downtime patching**

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an engine patch. For more information about ZDP, see Using zero-downtime patching (p. 1054).

**New features**

- **Asynchronous Key Prefetch** – Asynchronous key prefetch (AKP) is a feature targeted to improve the performance of non-cached index joins, by prefetching keys in memory ahead of when they
Database engine updates for Amazon Aurora MySQL version 1

are needed. The primary use case targeted by AKP is an index join between a small outer and large inner table, where the index is highly selective on the larger table. Also, when the Multi-Range Read (MRR) interface is enabled, AKP will be leveraged for a secondary to primary index lookup. Smaller instances which have memory constraints might in some cases be able to leverage AKP, given the right key cardinality. For more information, see Optimizing Amazon Aurora indexed join queries with asynchronous key prefetch (p. 1001).

- **Fast DDL** – We have extended the feature that was released in Aurora 1.13 (p. 1184) to operations that include default values. With this extension, Fast DDL is applicable for operations that add a nullable column at the end of a table, with or without default values. The feature remains under Aurora lab mode. For more information, see Altering tables in Amazon Aurora using fast DDL (p. 798).

**Improvements**

- Fixed a calculation error during optimization of WITHIN/CONTAINS spatial queries which previously resulted in an empty result set.
- Fixed `SHOW VARIABLE` command to show the updated `innodb_buffer_pool_size` parameter value whenever it is changed in the parameter group.
- Improved stability of primary instance during bulk insert into a table altered using Fast DDL when adaptive hash indexing is disabled and the record to be inserted is the first record of a page.
- Improved stability of Aurora when the user attempts to set `server_audit_events` DB cluster parameter value to `default`.
- Fixed an issue in which a database character set change for an ALTER TABLE statement that ran on the Aurora primary instance was not being replicated on the Aurora Replicas until they were restarted.
- Improved stability by fixing a race condition on the primary instance which previously allowed it to register an Aurora Replica even if the primary instance had closed its own volume.
- Improved performance of the primary instance during index creation on a large table by changing the locking protocol to enable concurrent data manipulation language (DML) statements during index build.
- Fixed InnoDB metadata inconsistency during ALTER TABLE RENAME query which improved stability. Example: When columns of table `t1(c1, c2)` are renamed cyclically to `t1(c2,c3)` within the same ALTER statement.
- Improved stability of Aurora Replicas for the scenario where an Aurora Replica has no active workload and the primary instance is unresponsive.
- Improved availability of Aurora Replicas for a scenario in which the Aurora Replica holds an explicit lock on a table and blocks the replication thread from applying any DDL changes received from the primary instance.
- Improved stability of the primary instance when a foreign key and a column are being added to a table from two separate sessions at the same time and Fast DDL has been enabled.
- Improved stability of the purge thread on the primary instance during a heavy write workload by blocking truncate of undo records until they have been purged.
- Improved stability by fixing the lock release order during commit process of transactions which drop tables.
- Fixed a defect for Aurora Replicas in which the DB instance could not complete startup and complained that port 3306 was already in use.
- Fixed a race condition in which a SELECT query run on certain information_schema tables (innodb_trx, innodb_lock, innodb_lock_waits) increased cluster instability.

**Integration of MySQL bug fixes**

- `CREATE USER` accepts plugin and password hash, but ignores the password hash (Bug #78033)
• The partitioning engine adds fields to the read bit set to be able to return entries sorted from a partitioned index. This leads to the join buffer will try to read unneeded fields. Fixed by not adding all partitioning fields to the read set, but instead only sort on the already set prefix fields in the read set. Added a DBUG_ASSERT that if doing key_cmp, at least the first field must be read (Bug #16367691).
• MySQL instance stalling “doing SYNC index” (Bug #73816)
• Assert RBT_EMPTY(INDEX_CACHE->WORDS) in ALTER TABLE CHANGE COLUMN (Bug #17536995)
• InnoDB Fulltext search doesn’t find records when savepoints are involved (Bug #70333)

Aurora MySQL database engine updates: 2018-03-13

Version: 1.14.4

Aurora MySQL 1.14.4 is generally available. You can create new DB clusters in Aurora 1.14.4, using the AWS CLI or the Amazon RDS API and specifying the engine version. You have the option, but are not required, to upgrade existing 1.14.x DB clusters to Aurora 1.14.4.

With version 1.14.4 of Aurora, we are using a cluster-patching model where all nodes in an Aurora DB cluster are patched at the same time. We support zero-downtime patching, which works on a best-effort basis to preserve client connections through the patching process. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Zero-downtime patching

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an engine patch. For more information about ZDP, see Using zero-downtime patching (p. 1054).

New features

• Aurora MySQL now supports db.r4 instance classes.

Improvements

• Fixed an issue where LOST_EVENTS were generated when writing large binlog events.

Integration of MySQL bug fixes

• Ignorable events don’t work and are not tested (Bug #74683)
• NEW->OLD ASSERT FAILURE ‘GTID_MODE > 0’ (Bug #20436436)

Aurora MySQL database engine updates: 2017-09-22

Version: 1.14.1

Aurora MySQL 1.14.1 is generally available. All new database clusters, including those restored from snapshots, will be created in Aurora MySQL 1.14.1. Aurora MySQL 1.14.1 is also a mandatory upgrade for existing Aurora MySQL DB clusters. For more information, see Announcement: Extension to mandatory upgrade schedule for Amazon Aurora on the AWS Developer Forums website.

With version 1.14.1 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora MySQL DB cluster are patched at the same time. Updates require a database restart, so you will
experience 20 to 30 seconds of downtime, after which you can resume using your DB cluster or clusters. If your DB clusters are currently running version 1.13 or greater, the zero-downtime patching feature in Aurora MySQL might allow client connections to your Aurora MySQL primary instance to persist through the upgrade, depending on your workload.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support.

**Improvements**

- Fixed race conditions associated with inserts and purge to improve the stability of the Fast DDL feature, which remains in Aurora MySQL lab mode.

**Aurora MySQL database engine updates: 2017-08-07**

**Version:** 1.14

Aurora MySQL 1.14 is generally available. All new database clusters, including those restored from snapshots, will be created in Aurora MySQL 1.14. Aurora MySQL 1.14 is also a mandatory upgrade for existing Aurora MySQL DB clusters. We will send a separate announcement with the timeline for deprecating earlier versions of Aurora MySQL.

With version 1.14 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time. Updates require a database restart, so you will experience 20 to 30 seconds of downtime, after which you can resume using your DB cluster or clusters. If your DB clusters are currently running version 1.13, Aurora's zero-downtime patching feature may allow client connections to your Aurora primary instance to persist through the upgrade, depending on your workload.

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support.

**Zero-downtime patching**

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an engine patch. For more information about ZDP, see Using zero-downtime patching (p. 1054).

**Improvements**

- Fixed an incorrect "record not found" error when a record is found in the secondary index but not in the primary index.
- Fixed a stability issue that can occur due to a defensive assertion (added in 1.12) that was too strong in the case when an individual write spans over 32 pages. Such a situation can occur, for instance, with large BLOB values.
- Fixed a stability issue because of inconsistencies between the tablespace cache and the dictionary cache.
- Fixed an issue in which an Aurora Replica becomes unresponsive after it has exceeded the maximum number of attempts to connect to the primary instance. An Aurora Replica now restarts if the period of inactivity is more than the heartbeat time period used for health check by the primary instance.
- Fixed a livelock that can occur under very high concurrency when one connection tries to acquire an exclusive meta data lock (MDL) while issuing a command, such as `ALTER TABLE`.
- Fixed a stability issue in an Aurora Read Replica in the presence of logical/parallel read ahead.
- Improved `LOAD FROM S3` in two ways:
1. Better handling of Amazon S3 timeout errors by using the SDK retry in addition to the existing retry.
2. Performance optimization when loading very big files or large numbers of files by caching and reusing client state.

- Fixed the following stability issues with Fast DDL for \texttt{ALTER TABLE} operations:
  1. When the \texttt{ALTER TABLE} statement has multiple \texttt{ADD COLUMN} commands and the column names are not in ascending order.
  2. When the name string of the column to be updated and its corresponding name string, fetched from the internal system table, differs by a null terminating character (/0).
  3. Under certain B-tree split operations.
  4. When the table has a variable length primary key.

- Fixed a stability issue with Aurora Replicas when it takes too long to make its Full Text Search (FTS) index cache consistent with that of the primary instance. This can happen if a large portion of the newly created FTS index entries on the primary instance have not yet been flushed to disk.
- Fixed a stability issue that can happen during index creation.
- New infrastructure that tracks memory consumption per connection and associated telemetry that will be used for building out Out-Of-Memory (OOM) avoidance strategies.
- Fixed an issue where \texttt{ANALYZE TABLE} was incorrectly allowed on Aurora Replicas. This has now been blocked.
- Fixed a stability issue caused by a rare deadlock as a result of a race condition between logical read-ahead and purge.

Integration of MySQL bug fixes

- A full-text search combined with derived tables (subqueries in the \texttt{FROM} clause) caused a server exit. Now, if a full-text operation depends on a derived table, the server produces an error indicating that a full-text search cannot be done on a materialized table. (Bug #68751, Bug #16539903)

### Aurora MySQL database engine updates: 2017-05-15

**Version:** 1.13

**Note**

We enabled a new feature - \texttt{SELECT INTO OUTFILE S3} - in Aurora MySQL version 1.13 after the initial release, and have updated the release notes to reflect that change.

Aurora MySQL 1.13 is generally available. All new database clusters, including those restored from snapshots, will be created in Aurora MySQL 1.13. You have the option, but are not required, to upgrade existing database clusters to Aurora MySQL 1.13. With version 1.13 of Aurora, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time. We are enabling zero-downtime patching, which works on a best-effort basis to preserve client connections through the patching process. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

**Zero-downtime patching**

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an engine patch. For more information about ZDP, see Using zero-downtime patching (p. 1054).

**New features:**

- \texttt{SELECT INTO OUTFILE S3} – Aurora MySQL now allows you to upload the results of a query to one or more files in an Amazon S3 bucket. For more information, see Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket (p. 969).
Improvements:

- Implemented truncation of CSV format log files at engine startup to avoid long recovery time. The `general_log_backup`, `general_log`, `slow_log_backup`, and `slow_log` tables now don't survive a database restart.
- Fixed an issue where migration of a database named `test` would fail.
- Improved stability in the lock manager's garbage collector by reusing the correct lock segments.
- Improved stability of the lock manager by removing invalid assertions during deadlock detection algorithm.
- Re-enabled asynchronous replication, and fixed an associated issue which caused incorrect replica lag to be reported under no-load or read-only workload. The replication pipeline improvements that were introduced in version 1.10. These improvements were introduced in order to apply log stream updates to the buffer cache of an Aurora Replica, which helps to improve read performance and stability on Aurora Replicas.
- Fixed an issue where autocommit=OFF leads to scheduled events being blocked and long transactions being held open until the server reboots.
- Fixed an issue where general, audit, and slow query logs could not log queries handled by asynchronous commit.
- Improved the performance of the logical read ahead (LRA) feature by up to 2.5 times. This was done by allowing pre-fetches to continue across intermediate pages in a B-tree.
- Added parameter validation for audit variables to trim unnecessary spaces.
- Fixed a regression, introduced in Aurora MySQL version 1.11, in which queries can return incorrect results when using the `SQL_CALC_FOUND_ROWS` option and invoking the `FOUND_ROWS()` function.
- Fixed a stability issue when the Metadata Lock list was incorrectly formed.
- Improved stability when `sql_mode` is set to `PAD_CHAR_TO_FULL_LENGTH` and the command `SHOW FUNCTION STATUS WHERE Db= 'string'` is executed.
- Fixed a rare case when instances would not come up after Aurora version upgrade because of a false volume consistency check.
- Fixed the performance issue, introduced in Aurora MySQL version 1.12, where the performance of the Aurora writer was reduced when users have a large number of tables.
- Improved stability issue when the Aurora writer is configured as a binlog worker and the number of connections approaches 16,000.
- Fixed a rare issue where an Aurora Replica could restart when a connection gets blocked waiting for Metadata Lock when running DDL on the Aurora master.

Integration of MySQL bug fixes

- With an empty InnoDB table, it's not possible to decrease the auto_increment value using an ALTER TABLE statement, even when the table is empty. (Bug #69882)
- `MATCH() ... AGAINST()` queries that use a long string as an argument for AGAINST() could result in an error when run on an InnoDB table with a full-text search index. (Bug #17640261)
- Handling of `SQL_CALC_FOUND_ROWS` in combination with `ORDER BY` and `LIMIT` could lead to incorrect results for `FOUND_ROWS()`. (Bug #68458, Bug # 16383173)
- `ALTER TABLE` does not allow to change nullability of the column if foreign key exists. (Bug #77591)

Aurora MySQL database engine updates: 2017-04-05

Version: 1.12
Aurora MySQL 1.12 is now the preferred version for the creation of new DB clusters, including restores from snapshots.

This is not a mandatory upgrade for existing clusters. You will have the option to upgrade existing clusters to version 1.12 after we complete the fleet-wide patch to 1.11 (see Aurora 1.11 release notes (p. 1187) and corresponding forum announcement). With version 1.12 of Aurora, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

New features

- **Fast DDL** – Aurora MySQL now allows you to execute an ALTER TABLE `tbl_name` ADD COLUMN `col_name` `column_definition` operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. Since it does not consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes. Fast DDL is currently only supported for adding a nullable column, without a default value, at the end of a table. This feature is currently available in Aurora lab mode. For more information, see Altering tables in Amazon Aurora using fast DDL (p. 798).

- **Show volume status** – We have added a new monitoring command, SHOW VOLUME STATUS, to display the number of nodes and disks in a volume. For more information, see Displaying volume status for an Aurora MySQL DB cluster (p. 803).

Improvements

- Implemented changes to lock compression to further reduce memory allocated per lock object. This improvement is available in lab mode.
- Fixed an issue where the `trx_active_transactions` metric decrements rapidly even when the database is idle.
- Fixed an invalid error message regarding fault injection query syntax when simulating failure in disks and nodes.
- Fixed multiple issues related to race conditions and dead latches in the lock manager.
- Fixed an issue causing a buffer overflow in the query optimizer.
- Fixed a stability issue in Aurora read replicas when the underlying storage nodes experience low available memory.
- Fixed an issue where idle connections persisted past the `wait_timeout` parameter setting.
- Fixed an issue where `query_cache_size` returns an unexpected value after reboot of the instance.
- Fixed a performance issue that is the result of a diagnostic thread probing the network too often in the event that writes are not progressing to storage.

Integration of MySQL bug fixes

- Reloading a table that was evicted while empty caused an AUTO_INCREMENT value to be reset. (Bug #21454472, Bug #77743)
- An index record was not found on rollback due to inconsistencies in the purge_node_t structure. The inconsistency resulted in warnings and error messages such as "error in sec index entry update", "unable to purge a record", and "tried to purge sec index entry not marked for deletion". (Bug #19138298, Bug #70214, Bug #21126772, Bug #21065746)
- Wrong stack size calculation for qsort operation leads to stack overflow. (Bug #73979)
- Record not found in an index upon rollback. (Bug #70214, Bug #72419)
- ALTER TABLE add column TIMESTAMP on update CURRENT_TIMESTAMP inserts ZERO-datas (Bug #17392)
Aurora MySQL database engine updates: 2017-02-23

Version: 1.11

We will patch all Aurora MySQL DB clusters with the latest version over a short period following the release. DB clusters are patched using the legacy procedure with a downtime of about 5-30 seconds.

Patching occurs during the system maintenance window that you have specified for each of your database instances. You can view or change this window using the AWS Management Console. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Alternatively, you can apply the patch immediately in the AWS Management Console by choosing a DB cluster, choosing Cluster Actions, and then choosing Upgrade Now.

With version 1.11 of Aurora MySQL, we are using a cluster patching model where all nodes in an Aurora DB cluster are patched at the same time.

New features

- **MANIFEST option for LOAD DATA FROM S3** – LOAD DATA FROM S3 was released in version 1.8. The options for this command have been expanded, and you can now specify a list of files to be loaded into an Aurora DB cluster from Amazon S3 by using a manifest file. This makes it easy to load data from specific files in one or more locations, as opposed to loading data from a single file by using the FILE option or loading data from multiple files that have the same location and prefix by using the PREFIX option. The manifest file format is the same as that used by Amazon Redshift. For more information about using LOAD DATA FROM S3 with the MANIFEST option, see Using a manifest to specify data files to load (p. 965).

- **Spatial indexing enabled by default** – This feature was released in lab mode in version 1.10, and is now turned on by default. Spatial indexing improves query performance on large datasets for queries that use spatial data. For more information about using spatial indexing, see Amazon Aurora MySQL and spatial data (p. 715).

- **Advanced Auditing timing change** – This feature was released in version 1.10.1 to provide a high-performance facility for auditing database activity. In this release, the precision of audit log timestamps has been changed from one second to one microsecond. The more accurate timestamps allow you to better understand when an audit event happened. For more information about audit, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 880).

Improvements

- Modified the thread_handling parameter to prevent you from setting it to anything other than multiple-connections-per-thread, which is the only supported model with Aurora's thread pool.

- Fixed an issue caused when you set either the buffer_pool_size or the query_cache_size parameter to be larger than the DB cluster's total memory. In this circumstance, Aurora sets the modified parameter to the default value, so the DB cluster can start up and not crash.

- Fixed an issue in the query cache where a transaction gets stale read results if the table is invalidated in another transaction.

- Fixed an issue where binlog files marked for deletion are removed after a small delay rather than right away.

- Fixed an issue where a database created with the name tmp is treated as a system database stored on ephemeral storage and not persisted to Aurora distributed storage.

- Modified the behavior of SHOW TABLES to exclude certain internal system tables. This change helps avoid an unnecessary failover caused by mysqldump locking all files listed in SHOW TABLES, which in turn prevents writes on the internal system table, causing the failover.
• Fixed an issue where an Aurora Replica incorrectly restarts when creating a temporary table from a query that invokes a function whose argument is a column of an InnoDB table.
• Fixed an issue related to a metadata lock conflict in an Aurora Replica node that causes the Aurora Replica to fall behind the primary DB cluster and eventually get restarted.
• Fixed a dead latch in the replication pipeline in reader nodes, which causes an Aurora Replica to fall behind and eventually get restarted.
• Fixed an issue where an Aurora Replica lags too much with encrypted volumes larger than 1 terabyte (TB).
• Improved Aurora Replica dead latch detection by using an improved way to read the system clock time.
• Fixed an issue where an Aurora Replica can restart twice instead of once following de-registration by the writer.
• Fixed a slow query performance issue on Aurora Replicas that occurs when transient statistics cause statistics discrepancy on non-unique index columns.
• Fixed an issue where an Aurora Replica can crash when a DDL statement is replicated on the Aurora Replica at the same time that the Aurora Replica is processing a related query.
• Changed the replication pipeline improvements that were introduced in version 1.10 from enabled by default to disabled by default. These improvements were introduced in order to apply log stream updates to the buffer cache of an Aurora Replica, and although this feature helps to improve read performance and stability on Aurora Replicas, it increases replica lag in certain workloads.
• Fixed an issue where the simultaneous occurrence of an ongoing DDL statement and pending Parallel Read Ahead on the same table causes an assertion failure during the commit phase of the DDL transaction.
• Enhanced the general log and slow query log to survive DB cluster restart.
• Fixed an out-of-memory issue for certain long running queries by reducing memory consumption in the ACL module.
• Fixed a restart issue that occurs when a table has non-spatial indexes, there are spatial predicates in the query, the planner chooses to use a non-spatial index, and the planner incorrectly pushes the spatial condition down to the index.
• Fixed an issue where the DB cluster restarts when there is a delete, update, or purge of very large geospatial objects that are stored externally (like LOBs).
• Fixed an issue where fault simulation using ALTER SYSTEM SIMULATE ... FOR INTERVAL isn't working properly.
• Fixed a stability issue caused by an invalid assertion on an incorrect invariant in the lock manager.
• Disabled the following two improvements to InnoDB Full-Text Search that were introduced in version 1.10 because they introduce stability issues for some demanding workloads:
  • Updating the cache only after a read request to an Aurora Replica in order to improve full-text search index cache replication speed.
  • Offloading the cache sync task to a separate thread as soon as the cache size crosses 10% of the total size, in order to avoid MySQL queries stalling for too long during FTS cache sync to disk. (Bugs #22516559, #73816).

Integration of MySQL bug fixes
• Running ALTER table DROP foreign key simultaneously with another DROP operation causes the table to disappear. (Bug #16095573)
• Some INFORMATION_SCHEMA queries that used ORDER BY did not use a filesort optimization as they did previously. (Bug #16423536)
• FOUND_ROWS () returns the wrong count of rows on a table. (Bug #68458)
• The server fails instead of giving an error when too many temp tables are open. (Bug #18948649)
Aurora MySQL database engine updates: 2017-01-12

Version: 1.10.1

Version 1.10.1 of Aurora MySQL is an opt-in version and is not used to patch your database instances. It is available for creating new Aurora instances and for upgrading existing instances. You can apply the patch by choosing a cluster in the Amazon RDS console, choosing Cluster Actions, and then choosing Upgrade Now. Patching requires a database restart with downtime typically lasting 5-30 seconds, after which you can resume using your DB clusters. This patch is using a cluster patching model where all nodes in an Aurora cluster are patched at the same time.

New features

- **Advanced Auditing** – Aurora MySQL provides a high-performance Advanced Auditing feature, which you can use to audit database activity. For more information about enabling and using Advanced Auditing, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster (p. 880).

Improvements

- Fixed an issue with spatial indexing when creating a column and adding an index on it in the same statement.
- Fixed an issue where spatial statistics aren't persisted across DB cluster restart.

Aurora MySQL database engine updates: 2016-12-14

Version: 1.10

New features

- **Zero downtime patch** – This feature allows a DB instance to be patched without any downtime. That is, database upgrades are performed without disconnecting client applications, or rebooting the database. This approach increases the availability of your Aurora DB clusters during the maintenance window. Note that temporary data like that in the performance schema is reset during the upgrade process. This feature applies to service-delivered patches during a maintenance window as well as user-initiated patches.

When a patch is initiated, the service ensures there are no open locks, transactions or temporary tables, and then waits for a suitable window during which the database can be patched and restarted. Application sessions are preserved, although there is a drop in throughput while the patch is in progress (for approximately 5 seconds). If no suitable window can be found, then patching defaults to the standard patching behavior.

Zero downtime patching takes place on a best-effort basis, subject to certain limitations as described following:

- This feature is currently applicable for patching single-node DB clusters or writer instances in multi-node DB clusters.
- SSL connections are not supported in conjunction with this feature. If there are active SSL connections, Amazon Aurora MySQL won't perform a zero downtime patch, and instead will retry periodically to see if the SSL connections have terminated. If they have, zero downtime patching proceeds. If the SSL connections persist after more than a couple seconds, standard patching with downtime proceeds.
- The feature is available in Aurora release 1.10 and beyond. Going forward, we will identify any releases or patches that can't be applied by using zero downtime patching.
- This feature is not applicable if replication based on binary logging is active.
Spatial indexing – Spatial indexing improves query performance on large datasets for queries that use spatial data. For more information about using spatial indexing, see Amazon Aurora MySQL and spatial data (p. 715).

This feature is disabled by default and can be activated by enabling Aurora lab mode. For information, see Amazon Aurora MySQL lab mode (p. 997).

Replication pipeline improvements – Aurora MySQL now uses an improved mechanism to apply log stream updates to the buffer cache of an Aurora Replica. This feature improves the read performance and stability on Aurora Replicas when there is a heavy write load on the master as well as a significant read load on the Replica. This feature is enabled by default.

Throughput improvement for workloads with cached reads – Aurora MySQL now uses a latch-free concurrent algorithm to implement read views, which leads to better throughput for read queries served by the buffer cache. As a result of this and other improvements, Amazon Aurora MySQL can achieve throughput of up to 625K reads per second compared to 164K reads per second by MySQL 5.7 for a SysBench SELECT-only workload.

Throughput improvement for workloads with hot row contention – Aurora MySQL uses a new lock release algorithm that improves performance, particularly when there is hot page contention (that is, many transactions contending for the rows on the same page). In tests with the TPC-C benchmark, this can result in up to 16x throughput improvement in transactions per minute relative to MySQL 5.7. This feature is disabled by default and can be activated by enabling Aurora lab mode. For information, see Amazon Aurora MySQL lab mode (p. 997).

Improvements

• Full-text search index cache replication speed has been improved by updating the cache only after a read request to an Aurora Replica. This approach avoids any reads from disk by the replication thread.
• Fixed an issue where dictionary cache invalidation does not work on an Aurora Replica for tables that have a special character in the database name or table name.
• Fixed a STUCK IO issue during data migration for distributed storage nodes when storage heat management is enabled.
• Fixed an issue in the lock manager where an assertion check fails for the transaction lock wait thread when preparing to rollback or commit a transaction.
• Fixed an issue when opening a corrupted dictionary table by correctly updating the reference count to the dictionary table entries.
• Fixed a bug where the DB cluster minimum read point can be held by slow Aurora Replicas.
• Fixed a potential memory leak in the query cache.
• Fixed a bug where an Aurora Replica places a row-level lock on a table when a query is used in an IF statement of a stored procedure.

Integration of MySQL bug fixes

• UNION of derived tables returns wrong results with '1=0/false'-clauses. (Bug #69471)
• Server crashes in ITEM_FUNC_GROUP_CONCAT::FIX_FIELDS on 2nd execution of stored procedure. (Bug #20755389)
• Avoid MySQL queries from stalling for too long during FTS cache sync to disk by offloading the cache sync task to a separate thread, as soon as the cache size crosses 10% of the total size. (Bug #22516559, #73816)

Aurora MySQL database engine updates: 2016-11-10

Version: 1.9.0, 1.9.1
New features

- **Improved index build** – The implementation for building secondary indexes now operates by building the index in a bottom-up fashion, which eliminates unnecessary page splits. This can reduce the time needed to create an index or rebuild a table by up to 75% (based on an `db.r3.8xlarge` DB instance class). This feature was in lab mode in Aurora MySQL version 1.7 and is enabled by default in Aurora version 1.9 and later. For information, see Amazon Aurora MySQL lab mode (p. 997).

- **Lock compression (lab mode)** – This implementation significantly reduces the amount of memory that lock manager consumes by up to 66%. Lock manager can acquire more row locks without encountering an out-of-memory exception. This feature is disabled by default and can be activated by enabling Aurora lab mode. For information, see Amazon Aurora MySQL lab mode (p. 997).

- **Performance schema** – Aurora MySQL now includes support for performance schema with minimal impact on performance. In our testing using SysBench, enabling performance schema could degrade MySQL performance by up to 60%.

  SysBench testing of an Aurora DB cluster showed an impact on performance that is 4x less than MySQL. Running the `db.r3.8xlarge` DB instance class resulted in 100K SQL writes/sec and over 550K SQL reads/sec, even with performance schema enabled.

- **Hot row contention improvement** – This feature reduces CPU utilization and increases throughput when a small number of hot rows are accessed by a large number of connections. This feature also eliminates error 188 when there is hot row contention.

- **Improved out-of-memory handling** – When non-essential, locking SQL statements are executed and the reserved memory pool is breached, Aurora forces rollback of those SQL statements. This feature frees memory and prevents engine crashes due to out-of-memory exceptions.

- **Smart read selector** – This implementation improves read latency by choosing the optimal storage segment among different segments for every read, resulting in improved read throughput. SysBench testing has shown up to a 27% performance increase for write workloads.

Improvements

- Fixed an issue where an Aurora Replica encounters a shared lock during engine start up.
- Fixed a potential crash on an Aurora Replica when the read view pointer in the purge system is NULL.

**Aurora MySQL database engine updates: 2016-10-26**

**Version:** 1.8.1

**Improvements**

- Fixed an issue where bulk inserts that use triggers that invoke AWS Lambda procedures fail.
- Fixed an issue where catalog migration fails when autocommit is off globally.
- Resolved a connection failure to Aurora when using SSL and improved Diffie-Hellman group to deal with LogJam attacks.

**Integration of MySQL bug fixes**

- OpenSSL changed the Diffie-Hellman key length parameters due to the LogJam issue. (Bug #18367167)

**Aurora MySQL database engine updates: 2016-10-18**

**Version:** 1.8
New features

- **AWS Lambda integration** – You can now asynchronously invoke an AWS Lambda function from an Aurora DB cluster using the `mysql.lambda_async` procedure. For more information, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster (p. 975).
- **Load data from Amazon S3** – You can now load text or XML files from an Amazon S3 bucket into your Aurora DB cluster using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` commands. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket (p. 962).
- **Catalog migration** – Aurora now persists catalog metadata in the cluster volume to support versioning. This enables seamless catalog migration across versions and restores.
- **Cluster-level maintenance and patching** – Aurora now manages maintenance updates for an entire DB cluster. For more information, see Maintaining an Amazon Aurora DB cluster (p. 439).

Improvements

- Fixed an issue where an Aurora Replica crashes when not granting a metadata lock to an inflight DDL table.
- Allowed Aurora Replicas to modify non-InnoDB tables to facilitate rotation of the slow and general log CSV files where `log_output=TABLE`.
- Fixed a lag when updating statistics from the primary instance to an Aurora Replica. Without this fix, the statistics of the Aurora Replica can get out of sync with the statistics of the primary instance and result in a different (and possibly under-performing) query plan on an Aurora Replica.
- Fixed a race condition that ensures that an Aurora Replica does not acquire locks.
- Fixed a rare scenario where an Aurora Replica that registers or de-registers with the primary instance could fail.
- Fixed a race condition that could lead to a deadlock on `db.r3.large` instances when opening or closing a volume.
- Fixed an out-of-memory issue that can occur due to a combination of a large write workload and failures in the Aurora Distributed Storage service.
- Fixed an issue with high CPU consumption because of the purge thread spinning in the presence of a long-running transaction.
- Fixed an issue when running information schema queries to get information about locks under heavy load.
- Fixed an issue with a diagnostics process that could in rare cases cause Aurora writes to storage nodes to stall and restart/fail-over.
- Fixed a condition where a successfully created table might be deleted during crash recovery if the crash occurred while a `CREATE TABLE [if not exists]` statement was being handled.
- Fixed a case where the log rotation procedure is broken when the general log and slow log are not stored on disk using catalog mitigation.
- Fixed a crash when a user creates a temporary table within a user defined function, and then uses the user defined function in the select list of the query.
- Fixed a crash that occurred when replaying GTID events. GTID is not supported by Aurora MySQL.

Integration of MySQL bug fixes:

- When dropping all indexes on a column with multiple indexes, InnoDB failed to block a DROP INDEX operation when a foreign key constraint requires an index. (Bug #16896810)
- Solve add foreign key constraint crash. (Bug #16413976)
- Fixed a crash when fetching a cursor in a stored procedure, and analyzing or flushing the table at the same time. (Bug # 18158639)
• Fixed an auto-increment bug when a user alters a table to change the AUTO_INCREMENT value to less than the maximum auto-increment column value. (Bug #16310273)

Aurora MySQL database engine updates: 2016-09-20

Version: 1.7.1

Improvements

• Fixes an issue where an Aurora Replica crashes if the InnoDB full-text search cache is full.
• Fixes an issue where the database engine crashes if a worker thread in the thread pool waits for itself.
• Fixes an issue where an Aurora Replica crashes if a metadata lock on a table causes a deadlock.
• Fixes an issue where the database engine crashes due to a race condition between two worker threads in the thread pool.
• Fixes an issue where an unnecessary failover occurs under heavy load if the monitoring agent doesn't detect the advancement of write operations to the distributed storage subsystem.

Aurora MySQL database engine updates: 2016-08-30

Version: 1.7.0

New features

• NUMA aware scheduler – The task scheduler for the Aurora MySQL engine is now Non-Uniform Memory Access (NUMA) aware. This minimizes cross-CPU socket contention resulting in improved performance throughput for the db.r3.8xlarge DB instance class.
• Parallel read-ahead operates asynchronously in the background – Parallel read-ahead has been revised to improve performance by using a dedicated thread to reduce thread contention.
• Improved index build (lab mode) – The implementation for building secondary indexes now operates by building the index in a bottom-up fashion, which eliminates unnecessary page splits. This can reduce the time needed to create an index or rebuild a table. This feature is disabled by default and can be activated by enabling Aurora lab mode. For information, see Amazon Aurora MySQL lab mode (p. 997).

Improvements

• Fixed an issue where establishing a connection was taking a long time if there was a surge in the number of connections requested for an instance.
• Fixed an issue where a crash occurred if ALTER TABLE was run on a partitioned table that did not use InnoDB.
• Fixed an issue where heavy write workload can cause a failover.
• Fixed an erroneous assertion that caused a failure if RENAME TABLE was run on a partitioned table.
• Improved stability when rolling back a transaction during insert-heavy workload.
• Fixed an issue where full-text search indexes were not viable on an Aurora Replica.

Integration of MySQL bug fixes

• Improve scalability by partitioning LOCK_grant lock. (Port WL #8355)
• Opening cursor on SELECT in stored procedure causes segfault. (Port Bug #16499751)
• MySQL gives the wrong result with some special usage. (Bug #11751794)
• Crash in GET_SEL_ARG_FOR_KEYPART – caused by patch for bug #11751794. (Bug #16208709)
• Wrong results for a simple query with GROUP BY. (Bug #17909656)
• Extra rows on semijoin query with range predicates. (Bug #16221623)
• Adding an ORDER BY clause following an IN subquery could cause duplicate rows to be returned. (Bug #16308085)
• Crash with explain for a query with loose scan for GROUP BY, MyISAM. (Bug #16222245)
• Loose index scan with quoted int predicate returns random data. (Bug #16394084)
• If the optimizer was using a loose index scan, the server could exit while attempting to create a temporary table. (Bug #16436567)
• COUNT(DISTINCT) should not count NULL values, but they were counted when the optimizer used loose index scan. (Bug #17222452)
• If a query had both MIN()/MAX() and aggregate_function(DISTINCT) (for example, SUM(DISTINCT)) and was executed using loose index scan, the result values of MIN()/MAX() were set improperly. (Bug #17217128)

Aurora MySQL database engine updates: 2016-06-01

Version: 1.6.5

New features

• Efficient storage of Binary Logs – Efficient storage of binary logs is now enabled by default for all Aurora MySQL DB clusters, and is not configurable. Efficient storage of binary logs was introduced in the April 2016 update. For more information, see Aurora MySQL database engine updates: 2016-04-06 (p. 1194).

Improvements

• Improved stability for Aurora Replicas when the primary instance is encountering a heavy workload.
• Improved stability for Aurora Replicas when running queries on partitioned tables and tables with special characters in the table name.
• Fixed connection issues when using secure connections.

Integration of MySQL bug fixes

• SLAVE CAN'T CONTINUE REPLICATION AFTER MASTER'S CRASH RECOVERY (Port Bug #17632285)

Aurora MySQL database engine updates: 2016-04-06

Version: 1.6

This update includes the following improvements:

New features

• Parallel read-ahead – Parallel read-ahead is now enabled by default for all Aurora MySQL DB clusters, and is not configurable. Parallel read-ahead was introduced in the December 2015 update. For more information, see Aurora MySQL database engine updates: 2015-12-03 (p. 1196).

In addition to enabling parallel read-ahead by default, this release includes the following improvements to parallel read-ahead:
• Improved logic so that parallel read-ahead is less aggressive, which is beneficial when your DB cluster encounters many parallel workloads.
• Improved stability on smaller tables.
• **Efficient storage of Binary Logs (lab mode)** – MySQL binary log files are now stored more efficiently in Aurora MySQL. The new storage implementation enables binary log files to be deleted much earlier and improves system performance for an instance in an Aurora MySQL DB cluster that is a binary log replication master.

To enable efficient storage of binary logs, set the `aurora_lab_mode` parameter to 1 in the parameter group for your primary instance or Aurora Replica. The `aurora_lab_mode` parameter is an instance-level parameter that is in the `default.aurora5.6` parameter group by default. For information on modifying a DB parameter group, see [Modifying parameters in a DB parameter group](p. 343). For information on parameter groups and Aurora MySQL, see [Aurora MySQL configuration parameters](p. 1007).

Only turn on efficient storage of binary logs for instances in an Aurora MySQL DB cluster that are MySQL binary log replication master instances.

• **AURORA_VERSION system variable** – You can now get the Aurora version of your Aurora MySQL DB cluster by querying for the `AURORA_VERSION` system variable.

To get the Aurora version, use one of the following queries:

```sql
select AURORA_VERSION();
select @@aurora_version;
show variables like '%version';
```

You can also see the Aurora version in the AWS Management Console when you modify a DB cluster, or by calling the `describe-db-engine-versions` AWS CLI command or the `DescribeDBEngineVersions` API operation.

• **Lock manager memory usage metric** – Information about lock manager memory usage is now available as a metric.

To get the lock manager memory usage metric, use one of the following queries:

```sql
show global status where variable_name in ('aurora_lockmgr_memory_used');
select * from INFORMATION_SCHEMA.GLOBAL_STATUS where variable_name in ('aurora_lockmgr_memory_used');
```

**Improvements**

• Improved stability during binlog and XA transaction recovery.
• Fixed a memory issue resulting from a large number of connections.
• Improved accuracy in the following metrics: Read Throughput, Read IOPS, Read Latency, Write Throughput, Write IOPS, Write Latency, and Disk Queue Depth.
• Fixed a stability issue causing slow startup for large instances after a crash.
• Improved concurrency in the data dictionary regarding synchronization mechanisms and cache eviction.
• Stability and performance improvements for Aurora Replicas:
  • Fixed a stability issue for Aurora Replicas during heavy or burst write workloads for the primary instance.
  • Improved replica lag for `db.r3.4xlarge` and `db.r3.8xlarge` instances.
• Improved performance by reducing contention between application of log records and concurrent reads on an Aurora Replica.
• Fixed an issue for refreshing statistics on Aurora Replicas for newly created or updated statistics.
• Improved stability for Aurora Replicas when there are many transactions on the primary instance and concurrent reads on the Aurora Replicas across the same data.
• Improved stability for Aurora Replicas when running UPDATE and DELETE statements with JOIN statements.
• Improved stability for Aurora Replicas when running INSERT ... SELECT statements.

Integration of MySQL bug fixes

• BACKPORT Bug #18694052 FIX FOR ASSERTION `!M_ORDERED_REC_BUFFER' FAILED TO 5.6 (Port Bug #18305270)
• SEGV IN MEMCPY(), HA_PARTITION::POSITION (Port Bug # 18383840)
• WRONG RESULTS WITH PARTITIONING,INDEX_MERGE AND NO PK (Port Bug # 18167648)
• FLUSH TABLES FOR EXPORT: ASSERTION IN HA_PARTITION::EXTRA (Port Bug # 16943907)
• SERVER CRASH IN VIRTUAL HA_ROWS HANDLER::MULTI_RANGE_READ_INFOCONST (Port Bug # 16164031)
• RANGE OPTIMIZER CRASHES IN SEL_ARG::RB_INSERT() (Port Bug # 16241773)

Aurora MySQL database engine updates: 2016-01-11

Version: 1.5

This update includes the following improvements:

Improvements

• Fixed a 10 second pause of write operations for idle instances during Aurora storage deployments.
• Logical read-ahead now works when innodb_file_per_table is set to No. For more information on logical read-ahead, see Aurora MySQL database engine updates: 2015-12-03 (p. 1196).
• Fixed issues with Aurora Replicas reconnecting with the primary instance. This improvement also fixes an issue when you specify a large value for the quantity parameter when testing Aurora Replica failures using fault-injection queries. For more information, see Testing an Aurora replica failure (p. 796).
• Improved monitoring of Aurora Replicas falling behind and restarting.
• Fixed an issue that caused an Aurora Replica to lag, become deregistered, and then restart.
• Fixed an issue when you run the show innodb status command during a deadlock.
• Fixed an issue with failovers for larger instances during high write throughput.

Integration of MySQL bug fixes

• Addressed incomplete fix in MySQL full text search affecting tables where the database name begins with a digit. (Port Bug #17607956)
This update includes the following improvements:

**New features**

- **Fast Insert** – Accelerates parallel inserts sorted by primary key. For more information, see Amazon Aurora MySQL performance enhancements (p. 714).
- **Large dataset read performance** – Aurora MySQL automatically detects an IO heavy workload and launches more threads in order to boost the performance of the DB cluster. The Aurora scheduler looks into IO activity and decides to dynamically adjust the optimal number of threads in the system, quickly adjusting between IO heavy and CPU heavy workloads with low overhead.
- **Parallel read-ahead** – Improves the performance of B-Tree scans that are too large for the memory available on your primary instance or Aurora Replica (including range queries). Parallel read-ahead automatically detects page read patterns and pre-fetches pages into the buffer cache in advance of when they are needed. Parallel read-ahead works multiple tables at the same time within the same transaction.

**Improvements:**

- Fixed brief Aurora database availability issues during Aurora storage deployments.
- Correctly enforce the `max_connection` limit.
- Improve binlog purging where Aurora is the binlog master and the database is restarting after a heavy data load.
- Fixed memory management issues with the table cache.
- Add support for huge pages in shared memory buffer cache for faster recovery.
- Fixed an issue with thread-local storage not being initialized.
- Allow 16K connections by default.
- Dynamic thread pool for IO heavy workloads.
- Fixed an issue with properly invalidating views involving UNION in the query cache.
- Fixed a stability issue with the dictionary stats thread.
- Fixed a memory leak in the dictionary subsystem related to cache eviction.
- Fixed high read latency issue on Aurora Replicas when there is very low write load on the master.
- Fixed stability issues on Aurora Replicas when performing operations on DDL partitioned tables such as `ALTER TABLE ... REORGANIZE PARTITION` on the master.
- Fixed stability issues on Aurora Replicas during volume growth.
- Fixed performance issue for scans on non-clustered indexes in Aurora Replicas.
- Fix stability issue that makes Aurora Replicas lag and eventually get deregistered and re-started.

**Integration of MySQL bug fixes**

- SEGV in `FTSPARSE()`. (Bug #16446108)
- InnoDB data dictionary is not updated while renaming the column. (Bug #19465984)
- FTS crash after renaming table to different database. (Bug #16834860)
- Failed preparing of trigger on truncated tables cause error 1054. (Bug #18596756)
- Metadata changes might cause problems with trigger execution. (Bug #18684393)
- Materialization is not chosen for long UTF8 VARCHAR field. (Bug #17566396)
- Poor execution plan when ORDER BY with limit X. (Bug #16697792)
- Backport bug #11765744 TO 5.1, 5.5 AND 5.6. (Bug #17083851)
• Mutex issue in SQL/SQL_SHOW.CC resulting in SIG6. Source likely FILL_VARIABLES. (Bug #20788853)
• Backport bug #18008907 to 5.5+ versions. (Bug #18903155)
• Adapt fix for a stack overflow error in MySQL 5.7. (Bug #19678930)

**Aurora MySQL database engine updates: 2015-10-16**

**Versions:** 1.2, 1.3

This update includes the following improvements:

**Fixes**

• Resolved out-of-memory issue in the new lock manager with long-running transactions
• Resolved security vulnerability when replicating with non-RDS for MySQL databases
• Updated to ensure that quorum writes retry correctly with storage failures
• Updated to report replica lag more accurately
• Improved performance by reducing contention when many concurrent transactions are trying to modify the same row
• Resolved query cache invalidation for views that are created by joining two tables
• Disabled query cache for transactions with `UNCOMMITTED_READ` isolation

**Improvements**

• Better performance for slow catalog queries on warm caches
• Improved concurrency in dictionary statistics
• Better stability for the new query cache resource manager, extent management, files stored in Amazon Aurora smart storage, and batch writes of log records

**Integration of MySQL bug fixes**

• Killing a query inside innodb causes it to eventually crash with an assertion. (Bug #1608883)
• For failure to create a new thread for the event scheduler, event execution, or new connection, no message was written to the error log. (Bug #16865959)
• If one connection changed its default database and simultaneously another connection executed SHOW PROCESSLIST, the second connection could access invalid memory when attempting to display the first connection’s default database memory. (Bug #11765252)
• PURGE BINARY LOGS by design does not remove binary log files that are in use or active, but did not provide any notice when this occurred. (Bug #13727933)
• For some statements, memory leaks could result when the optimizer removed unneeded subquery clauses. (Bug #15875919)
• During shutdown, the server could attempt to lock an uninitialized mutex. (Bug #16016493)
• A prepared statement that used `GROUP_CONCAT()` and an ORDER BY clause that named multiple columns could cause the server to exit. (Bug #16075310)
• Performance Schema instrumentation was missing for replica worker threads. (Bug #16083949)
• `STOP SLAVE` could cause a deadlock when issued concurrently with a statement such as SHOW STATUS that retrieved the values for one or more of the status variables `Slave_retried_transactions, Slave_heartbeat_period, Slave_received_heartbeats, Slave_last_heartbeat, or Slave_running`. (Bug #16088188)
- A full-text query using Boolean mode could return zero results in some cases where the search term was a quoted phrase. (Bug #16206253)
- The optimizer's attempt to remove redundant subquery clauses raised an assertion when executing a prepared statement with a subquery in the ON clause of a join in a subquery. (Bug #16318585)
- GROUP_CONCAT unstable, crash in ITEM_SUM::CLEAN_UP_AFTER_REMOVAL. (Bug #16347450)
- Attempting to replace the default InnoDB full-text search (FTS) stopword list by creating an InnoDB table with the same structure as INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD would result in an error. (Bug #16373868)
- After the client thread on a worker performed a FLUSH TABLES WITH READ LOCK and was followed by some updates on the master, the worker hung when executing SHOW SLAVE STATUS. (Bug #16387720)
- When parsing a delimited search string such as "abc-def" in a full-text search, InnoDB now uses the same word delimiters as MyISAM. (Bug #16419661)
- Crash in FTS_AST_TERM_SET_WILDCARD. (Bug #16429306)
- SEGFAULT in FTS_AST_VISIT() for FTS RQG test. (Bug #16435855)
- For debug builds, when the optimizer removed an Item_ref pointing to a subquery, it caused a server exit. (Bug #16509874)
- Full-text search on InnoDB tables failed on searches for literal phrases combined with + or - operators. (Bug #16516193)
- START SLAVE failed when the server was started with the options --master-info-repository=TABLE relay-log-info-repository=TABLE and with autocommit set to 0, together with --skip-slave-start. (Bug #16533802)
- Very large InnoDB full-text search (FTS) results could consume an excessive amount of memory. (Bug #16625973)
- In debug builds, an assertion could occur in OPT_CHECK_ORDER_BY when using binary directly in a search string, as binary might include NULL bytes and other non-meaningful characters. (Bug #16766016)
- For some statements, memory leaks could result when the optimizer removed unneeded subquery clauses. (Bug #16807641)
- It was possible to cause a deadlock after issuing FLUSH TABLES WITH READ LOCK by issuing STOP SLAVE in a new connection to the worker, then issuing SHOW SLAVE STATUS using the original connection. (Bug #16856735)
- GROUP_CONCAT() with an invalid separator could cause a server exit. (Bug #16870783)
- The server did excessive locking on the LOCK_active_mi and active_mi->rli->data_lock mutexes for any SHOW STATUS LIKE 'pattern' statement, even when the pattern did not match status variables that use those mutexes (Slave_heartbeat_period, Slave_last_heartbeat, Slave_received_heartbeats, Slave_retried_transactions, Slave_running). (Bug #16904035)
- A full-text search using the IN BOOLEAN MODE modifier would result in an assertion failure. (Bug #16927092)
- Full-text search on InnoDB tables failed on searches that used the + boolean operator. (Bug #17280122)
- 4-way deadlock: zombies, purging binlogs, show processlist, show binlogs. (Bug #17283409)
- When an SQL thread which was waiting for a commit lock was killed and restarted it caused a transaction to be skipped on worker. (Bug #17450876)
- An InnoDB full-text search failure would occur due to an "unended" token. The string and string length should be passed for string comparison. (Bug #17659310)
- Large numbers of partitioned InnoDB tables could consume much more memory when used in MySQL 5.6 or 5.7 than the memory used by the same tables used in previous releases of the MySQL Server. (Bug #17780517)
• For full-text queries, a failure to check that num_token is less than max_proximity_item could result in an assertion. (Bug #18233051)

• Certain queries for the INFORMATION_SCHEMA TABLES and COLUMNS tables could lead to excessive memory use when there were large numbers of empty InnoDB tables. (Bug #18592390)

• When committing a transaction, a flag is now used to check whether a thread has been created, rather than checking the thread itself, which uses more resources, particularly when running the server with master_info_repository=TABLE. (Bug #18684222)

• If a client thread on a worker executed FLUSH TABLES WITH READ LOCK while the master executed a DML, executing SHOW SLAVE STATUS in the same client became blocked, causing a deadlock. (Bug #19843808)

• Ordering by a GROUP_CONCAT() result could cause a server exit. (Bug #19880368)

Aurora MySQL database engine updates: 2015-08-24

Version: 1.1

This update includes the following improvements:

• Replication stability improvements when replicating with a MySQL database (binlog replication). For information on Aurora MySQL replication with MySQL, see Replication with Amazon Aurora (p. 69).

• A 1 gigabyte (GB) limit on the size of the relay logs accumulated for an Aurora MySQL DB cluster that is a replication worker. This improves the file management for the Aurora DB clusters.

• Stability improvements in the areas of read ahead, recursive foreign-key relationships, and Aurora replication.

• Integration of MySQL bug fixes.
  • InnoDB databases with names beginning with a digit cause a full-text search (FTS) parser error. (Bug #17607956)
  • InnoDB full-text searches fail in databases whose names began with a digit. (Bug #17161372)
  • For InnoDB databases on Windows, the full-text search (FTS) object ID is not in the expected hexadecimal format. (Bug #16559254)
  • A code regression introduced in MySQL 5.6 negatively impacted DROP TABLE and ALTER TABLE performance. This could cause a performance drop between MySQL Server 5.5.x and 5.6.x. (Bug #16884741)

• Simplified logging to reduce the size of log files and the amount of storage that they require.

Database engine updates for Aurora MySQL Serverless clusters

The following are Aurora MySQL database engine updates for Aurora MySQL Serverless DB clusters. These release notes provide information about bug fixes, updates to the database engine, and other critical information. Aurora Serverless v1 doesn't have its own version number. It shares the version number (and name) of the Aurora database engine that supports Aurora Serverless v1. For more information, see Aurora Serverless v1 and Aurora database engine versions (p. 176).

• Aurora MySQL Serverless 5.7 engine updates 2021-07-16 (version 2.08.3) (p. 1201)
• Aurora MySQL Serverless 5.7 engine updates 2020-06-18 (version 2.07.1) (p. 1201)

• Aurora MySQL Serverless 5.6 engine updates 2021-07-16 (version 1.22.3) (p. 1202)
• Aurora MySQL Serverless 5.6 engine updates 2020-08-14 (version 1.21.0) (p. 1202)
Aurora MySQL Serverless 5.7 engine updates 2021-07-16 (version 2.08.3)

Aurora Serverless 5.7 is generally available. It has the same features and bug fixes as Aurora MySQL 2.08.3.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL Serverless 5.7. By using a snapshot, you can also upgrade an Aurora MySQL-5.6 compatible Aurora Serverless v1 DB cluster to an Aurora MySQL-5.7 compatible Aurora Serverless v1 DB cluster. To do so:

- Create a snapshot from the Aurora MySQL 5.6 Serverless DB cluster. To learn how, see Creating a DB cluster snapshot (p. 491).
- Restore the snapshot to a new Aurora MySQL 5.7 Serverless cluster. For more information, see Restoring an Aurora Serverless v1 DB cluster (p. 165).

Aurora Serverless v1 doesn't have its own version number. It uses the number of the Aurora MySQL version that supports it to distinguish between Aurora MySQL 5.7 and Aurora MySQL 5.6 updates. For more information, see Aurora Serverless v1 and Aurora database engine versions (p. 176).

For general information about Aurora Serverless, see Using Amazon Aurora Serverless v1 (p. 146).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Aurora DB cluster.

Bug fixes:

This Aurora Serverless release includes all bug fixes up to Aurora MySQL version 2.08.3. For details, see Aurora MySQL database engine updates 2020-11-12 (version 2.08.3) (p. 1091) and the release notes for previous Aurora MySQL versions.

Features:

This Aurora Serverless release includes all new features up to Aurora MySQL version 2.08.3. For details, see Aurora MySQL database engine updates 2020-11-12 (version 2.08.3) (p. 1091) and the release notes for previous Aurora MySQL versions.

Aurora MySQL Serverless 5.7 engine updates 2020-06-18 (version 2.07.1)

Aurora Serverless 5.7 is generally available. It has the same features and bug fixes as Aurora MySQL 2.07.1.

You can restore a snapshot from a currently supported Aurora MySQL release into Aurora MySQL Serverless 5.7. By using a snapshot, you can also upgrade an Aurora MySQL-5.6 compatible Aurora Serverless v1 DB cluster to an Aurora MySQL-5.7 compatible Aurora Serverless v1 DB cluster. To do so:

- Create a snapshot from the Aurora MySQL 5.6 Serverless DB cluster. To learn how, see Creating a DB cluster snapshot (p. 491).
- Restore the snapshot to a new Aurora MySQL 5.7 Serverless cluster. For more information, see Restoring an Aurora Serverless v1 DB cluster (p. 165).

Aurora Serverless v1 doesn't have its own version number. It uses the number of the Aurora MySQL version that supports it to distinguish between Aurora MySQL 5.7 and Aurora MySQL 5.6 updates. For more information, see Aurora Serverless v1 and Aurora database engine versions (p. 176).

For general information about Aurora Serverless, see Using Amazon Aurora Serverless v1 (p. 146).
If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Aurora DB cluster.

**Bug fixes:**

This Aurora Serverless release includes all bug fixes up to Aurora MySQL version 2.07.1. For details, see Aurora MySQL database engine updates 2019-12-23 (version 2.07.1) (p. 1110) and the release notes for previous Aurora MySQL versions.

**Features:**

This Aurora Serverless release includes all new features up to Aurora MySQL version 2.07.1. For details, see Aurora MySQL database engine updates 2019-12-23 (version 2.07.1) (p. 1110) and the release notes for previous Aurora MySQL versions. The following features are of particular interest for users of Aurora Serverless or Aurora MySQL with MySQL 5.7 compatibility:

- Aurora MySQL Serverless now supports the hot row contention feature. For more information, see Aurora MySQL database engine updates: 2016-12-14 (p. 1189).
- Aurora MySQL Serverless now supports the hash join feature. To use this feature, you must specify the configuration setting `optimizer_switch='hash_join=on'`. For more information, see Optimizing large Aurora MySQL join queries with hash joins (p. 1003).
- Aurora Serverless 5.7 can use the Data API. For more information, see Using the Data API for Aurora Serverless (p. 177).
- Aurora Serverless 5.7 can use the query editor. For more information, see Using the query editor for Aurora Serverless (p. 203).
- Aurora Serverless 5.7 supports the same JSON features as other Aurora MySQL versions that are compatible with MySQL 5.7.

**Aurora MySQL Serverless 5.6 engine updates 2021-07-16 (version 1.22.3)**

Aurora Serverless 5.6 is generally available. It has the same features and bug fixes as Aurora MySQL 1.22.3.

Aurora Serverless v1 doesn’t have its own version number. It uses the number of the Aurora MySQL version that supports it to distinguish between Aurora MySQL 5.6 and Aurora MySQL 5.7 updates. For more information, see Aurora Serverless v1 and Aurora database engine versions (p. 176). For general information about Aurora Serverless, see Using Amazon Aurora Serverless v1 (p. 146).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Aurora DB cluster.

**Bug fixes:**

This Aurora Serverless release includes all bug fixes up to Aurora MySQL version 1.22.3. For details, see Aurora MySQL database engine updates 2020-11-09 (version 1.22.3) (p. 1158) and the release notes for previous Aurora MySQL versions.

**Aurora MySQL Serverless 5.6 engine updates 2020-08-14 (version 1.21.0)**

Aurora Serverless 5.6 is generally available. It has the same features and bug fixes as Aurora MySQL 1.21.0.

Aurora Serverless v1 doesn’t have its own version number. It uses the number of the Aurora MySQL version that supports it to distinguish between Aurora MySQL 5.6 and Aurora MySQL 5.7 updates. For
more information, see Aurora Serverless v1 and Aurora database engine versions (p. 176). For general information about Aurora Serverless, see Using Amazon Aurora Serverless v1 (p. 146).

If you have any questions or concerns, AWS Support is available on the community forums and through AWS Premium Support. For more information, see Maintaining an Aurora DB cluster.

**Bug fixes:**

This Aurora Serverless release includes all bug fixes up to Aurora MySQL version 1.21.0. For details, see Aurora MySQL database engine updates 2019-11-25 (version 1.21.0) (p. 1163) and the release notes for previous Aurora MySQL versions.

**Features:**

This Aurora Serverless release improves CPU utilization across the Serverless fleet, especially benefitting clusters with one and two Aurora capacity units (ACUs). See Aurora Serverless v1 architecture (p. 151) for more information about ACUs.

### MySQL bugs fixed by Aurora MySQL database engine updates

The following sections identify MySQL bugs that have been fixed by Aurora MySQL database engine updates.

#### Topics

- MySQL bugs fixed by Aurora MySQL 2.x database engine updates (p. 1203)
- MySQL bugs fixed by Aurora MySQL 1.x database engine updates (p. 1213)

### MySQL bugs fixed by Aurora MySQL 2.x database engine updates

MySQL 5.7-compatible version Aurora contains all MySQL bug fixes through MySQL 5.7.12. The following table identifies additional MySQL bugs that have been fixed by Aurora MySQL database engine updates, and which update they were fixed in.

<table>
<thead>
<tr>
<th>Database engine update</th>
<th>Version</th>
<th>MySQL bugs fixed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL database engine updates 2021-10-21 (version 2.10.1) (p. 1072)</td>
<td>2.10.1</td>
<td>CURRENT_TIMESTAMP PRODUCES ZEROS IN TRIGGER. (Bug #25209512)</td>
</tr>
</tbody>
</table>
| Aurora MySQL database engine updates 2021-05-25 (version 2.10.0) (p. 1074) | 2.10.0 | • Interleaved transactions could sometimes deadlock the replica applier when the transaction isolation level was set to REPEATABLE READ. (Bug #25040331)  
  • When a stored procedure contained a statement referring to a view which in turn referred to another view, the procedure could not be invoked successfully more than once. (Bug #87858, Bug #26864199)  
  • For queries with many OR conditions, the optimizer now is more memory-efficient and less likely to exceed the memory limit imposed by the range_optimizer_max_mem_size system variable. |
<table>
<thead>
<tr>
<th>Database engine update</th>
<th>Version</th>
<th>MySQL bugs fixed</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>In addition, the default value for that variable has been raised from 1,536,000 to 8,388,608. (Bug #79450, Bug #22283790)</td>
</tr>
<tr>
<td>•</td>
<td></td>
<td><strong>Replication:</strong> In the <code>next_event()</code> function, which is called by a replica's SQL thread to read the next event from the relay log, the SQL thread did not release the <code>relaylog.log_lock</code> it acquired when it ran into an error (for example, due to a closed relay log), causing all other threads waiting to acquire a lock on the relay log to hang. With this fix, the lock is released before the SQL thread leaves the function under the situation. (Bug #21697821)</td>
</tr>
<tr>
<td>•</td>
<td></td>
<td>Fixing a memory corruption for <code>ALTER TABLE</code> with virtual column. (Bug #24961167; Bug #24960450)</td>
</tr>
<tr>
<td>•</td>
<td></td>
<td><strong>Replication:</strong> Multithreaded replicas could not be configured with small queue sizes using <code>slave_pending_jobs_size_max</code> if they ever needed to process transactions larger than that size. Any packet larger than <code>slave_pending_jobs_size_max</code> was rejected with the error <code>ER_MTS_EVENT_BIGGER_PENDING_JOBS_SIZE_MAX</code>, even if the packet was smaller than the limit set by <code>slave_max_allowed_packet</code>. With this fix, <code>slave_pending_jobs_size_max</code> becomes a soft limit rather than a hard limit. If the size of a packet exceeds <code>slave_pending_jobs_size_max</code> but is less than <code>slave_max_allowed_packet</code>, the transaction is held until all the replica workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed. The queue size for replica workers can therefore be limited while still allowing occasional larger transactions. (Bug #21280753, Bug #77406)</td>
</tr>
<tr>
<td>•</td>
<td></td>
<td><strong>Replication:</strong> When using a multithreaded replica, applier errors displayed worker ID data that was inconsistent with data externalized in Performance Schema replication tables. (Bug #25231367)</td>
</tr>
<tr>
<td>•</td>
<td></td>
<td><strong>Replication:</strong> On a GTID-based replication replica running with <code>--gtid-mode=ON</code>, <code>--log-bin=OFF</code>, and using <code>--slave-skip-errors</code>, when an error was encountered that should be ignored <code>Exec_Master_Log_Pos</code> was not being correctly updated, causing <code>Exec_Master_Log_Pos</code> to lose synchrony with <code>Read_master_log_pos</code>. If a <code>GTID_NEXT</code> was not specified, the replica would never update its GTID state when rolling back from a single statement transaction. The <code>Exec_Master_Log_Pos</code> would not be updated because even though the transaction was finished, its GTID state would show otherwise. The fix removes the restraint of updating the GTID state when a transaction is rolled back only if <code>GTID_NEXT</code> is specified. (Bug #22268777)</td>
</tr>
<tr>
<td>•</td>
<td></td>
<td><strong>Replication:</strong> A partially failed statement was not correctly consuming an auto-generated or specified GTID when binary logging was disabled. The fix ensures that a partially failed <code>DROP TABLE</code>, a partially failed <code>DROP USER</code>, or a partially failed <code>DROP VIEW</code> consume respectively the relevant GTID and save it into <code>@@GLOBAL.GTID_EXECUTED</code> and <code>mysql.gtid_executed</code> table when binary logging is disabled. (Bug #21686749)</td>
</tr>
<tr>
<td>•</td>
<td></td>
<td><strong>Replication:</strong> Replicas running MySQL 5.7 could not connect to a MySQL 5.5 source due to an error retrieving the <code>server_uuid</code>,</td>
</tr>
</tbody>
</table>
MySQL bugs fixed by Aurora MySQL updates

<table>
<thead>
<tr>
<th>Database engine update</th>
<th>Version</th>
<th>MySQL bugs fixed</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>which is not part of MySQL 5.5. This was caused by changes in the method of retrieving the <code>server_uuid</code>. (Bug #22748612)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Binlog replication: GTID transaction skipping mechanism was not working properly for XA transaction before this fix. Server has a mechanism to skip (silently) a GTID transaction if it is already executed that particular transaction in the past. (BUG#25041920)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;XA ROLLBACK&quot; statements that failed because an incorrect transaction ID was given, could be recorded in the binary log with the correct transaction ID, and could therefore be actioned by replication replicas. A check is now made for the error situation before binary logging takes place, and failed XA ROLLBACK statements are not logged. (Bug #26618925)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Replication: If a replica was set up using a CHANGE MASTER TO statement that did not specify the source log file name and source log position, then shut down before START SLAVE was issued, then restarted with the option --relay-log-recovery set, replication did not start. This happened because the receiver thread had not been started before relay log recovery was attempted, so no log rotation event was available in the relay log to provide the source log file name and source log position. In this situation, the replica now skips relay log recovery and logs a warning, then proceeds to start replication. (Bug #28996606, Bug #93397)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Replication: In row-based replication, a message that incorrectly displayed field lengths was returned when replicating from a table with a <code>utf8mb3</code> column to a table of the same definition where the column was defined with a <code>utf8mb4</code> character set. (Bug #25135304, Bug #83918)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Replication: When a RESET SLAVE statement was issued on a replication replica with GTIDs in use, the existing relay log files were purged, but the replacement new relay log file was generated before the set of received GTIDs for the channel had been cleared. The former GTID set was therefore written to the new relay log file as the PREVIOUS_GTIDS event, causing a fatal error in replication stating that the replica had more GTIDs than the source, even though the gtid_executed set for both servers was empty. Now, when RESET SLAVE is issued, the set of received GTIDs is cleared before the new relay log file is generated, so that this situation does not occur. (Bug #27411175)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Replication: With GTIDs in use for replication, transactions including statements that caused a parsing error (ER_PARSE_ERROR) could not be skipped manually by the recommended method of injecting an empty or replacement transaction with the same GTID. This action should result in the replica identifying the GTID as already used, and therefore skipping the unwanted transaction that shared its GTID. However, in the case of a parsing error, because the statement was parsed before the GTID was checked to see if it needed to be skipped, the replication applier thread stopped due to the parsing error, even though the intention was for the transaction to be skipped anyway. With this fix, the replication applier thread now ignores parsing errors if the transaction concerned needs to be skipped because the GTID was already used. Note that this behavior</td>
</tr>

| Aurora MySQL database engine updates 2020-12-11 (version 2.09.1) (p. 1084) | 2.09.1 | - **Replication**: Interleaved transactions could sometimes deadlock the slave applier when the transaction isolation level was set to `REPEATABLE READ`. (Bug #25040331)
- For a table having a `TIMESTAMP` or `DATETIME` column having a default of `CURRENT_TIMESTAMP`, the column could be initialized to `0000-00-00 00:00:00` if the table had a `BEFORE INSERT` trigger. (Bug #25209512, Bug #84077)
- For an `INSERT` statement for which the `VALUES` list produced values for the second or later row using a subquery containing a join, the server could exit after failing to resolve the required privileges. (Bug #23762382) |
| Aurora MySQL database engine updates 2020-11-12 (version 2.08.3) (p. 1091) | 2.08.3 | - Bug #23762382 - INSERT VALUES QUERY WITH JOIN IN A SELECT CAUSES INCORRECT BEHAVIOR.
- Bug #25209512 - CURRENT_TIMESTAMP PRODUCES ZEROS IN TRIGGER. |
| Aurora MySQL database engine updates 2020-06-02 (version 2.08.0) (p. 1096) | 2.08.0 | - Bug #25289359: A full-text cache lock taken when data is synchronized was not released if the full-text cache size exceeded the full-text cache size limit.
- Bug #29138644: Manually changing the system time while the MySQL server was running caused page cleaner thread delays.
- Bug #25222337: A NULL virtual column field name in a virtual index caused a server exit during a field name comparison that occurs while populating virtual columns affected by a foreign key constraint.
- Bug #25053286: Executing a stored procedure containing a query that accessed a view could allocate memory that was not freed until the session ended.
- Bug #25586773: Executing a stored procedure containing a statement that created a table from the contents of certain `SELECT` statements could result in a memory leak.
- Bug #28834208: During log application, after an `OPTIMIZE TABLE` operation, InnoDB did not populate virtual columns before checking for virtual column index updates.
- Bug #26666274: Infinite loop in performance schema buffer container due to 32-bit unsigned integer overflow. |
<p>| Aurora MySQL database engine updates 2021-11-24 (version 2.07.7) (p. 1099) | 2.07.7 | INSERTING 64K SIZE RECORDS TAKE TOO MUCH TIME. (Bug#23031146) |
| Aurora MySQL database engine updates 2021-09-02 (version 2.07.6) (p. 1100) | 2.07.6 | INSERTING 64K SIZE RECORDS TAKE TOO MUCH TIME. (Bug#23031146) |</p>

### Aurora MySQL database engine updates

<table>
<thead>
<tr>
<th>Database engine update</th>
<th>Version</th>
<th>MySQL bugs fixed</th>
</tr>
</thead>
</table>
| Aurora MySQL database engine updates 2020-11-10 (version 2.07.3) (p. 1105) | 2.07.3 | - **InnoDB**: Concurrent XA transactions that ran successfully to the XA prepare stage on the master conflicted when replayed on the slave, resulting in a lock wait timeout in the applier thread. The conflict was due to the GAP lock range which differed when the transactions were replayed serially on the slave. To prevent this type of conflict, GAP locks taken by XA transactions in **READ COMMITTED** isolation level are now released (and no longer inherited) when XA transactions reach the prepare stage. (Bug #27189701, Bug #25866046)
- **InnoDB**: A gap lock was taken unnecessarily during foreign key validation while using the **READ COMMITTED** isolation level. (Bug #25082593)
- **Replication**: When using XA transactions, if a lock wait timeout or deadlock occurred for the applier (SQL) thread on a replication slave, the automatic retry did not work. The cause was that while the SQL thread would do a rollback, it would not roll the XA transaction back. This meant that when the transaction was retried, the first event was XA START which was invalid as the XA transaction was already in progress, leading to an XAER_RMFAIL error. (Bug #24764800)
- **Replication**: Interleaved transactions could sometimes deadlock the slave applier when the transaction isolation level was set to **REPEATABLE READ**. (Bug #25040331)
- **Replication**: The value returned by a **SHOW SLAVE STATUS** statement for the total combined size of all existing relay log files (**Relay_Log_Space**) could become much larger than the actual disk space used by the relay log files. The I/O thread did not lock the variable while it updated the value, so the SQL thread could automatically delete a relay log file and write a reduced value before the I/O thread finished updating the value. The I/O thread then wrote its original size calculation, ignoring the SQL thread’s update and so adding back the space for the deleted file. The **Relay_Log_Space** value is now locked during updates to prevent concurrent updates and ensure an accurate calculation. (Bug #26997096, Bug #87832)
- For an **INSERT** statement for which the VALUES list produced values for the second or later row using a subquery containing a join, the server could exit after failing to resolve the required privileges. (Bug #23762382)
- For a table having a **TIMESTAMP** or **DATETIME** column having a default of **CURRENT_TIMESTAMP**, the column could be initialized to **0000-00-00 00:00:00** if the table had a **BEFORE INSERT** trigger. (Bug #25209512, Bug #84077)
- A server exit could result from simultaneous attempts by multiple threads to register and deregister metadata Performance Schema objects. (Bug #26502135)
- Executing a stored procedure containing a statement that created a table from the contents of certain **SELECT** statements could result in a memory leak. (Bug #25586773) |

### MySQL bugs fixed by Aurora MySQL 1.x database engine updates

MySQL 5.6-compatible version Aurora contains all MySQL bug fixes through MySQL 5.6.10. The following table identifies additional MySQL bugs that have been fixed by Aurora MySQL database engine updates, and which update they were fixed in.

<table>
<thead>
<tr>
<th>Database engine update</th>
<th>Version</th>
<th>MySQL bugs fixed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL database engine updates 2021-03-18 (version 1.23.2) (p. 1151)</td>
<td>1.23.2</td>
<td>- Replication: While a SHOW BINLOG EVENTS statement was executing, any parallel transaction was blocked. The fix ensures that the SHOW BINLOG EVENTS process now only acquires a lock for the duration of calculating the file's end position, therefore parallel transactions are not blocked for long durations. (Bug #76618, Bug #20928790)</td>
</tr>
</tbody>
</table>
| Aurora MySQL database engine updates 2020-09-02 (version 1.23.0) (p. 1153) | 1.23.0 | - Binlog events with ALTER TABLE ADD COLUMN ALGORITHM=QUICK will be rewritten as ALGORITHM=DEFAULT to be compatible with the community edition.  
- BUG #22350047: IF CLIENT KILLED AFTER ROLLBACK TO SAVEPOINT PREVIOUS STMTS COMMITTED  
- Bug #29915479: RUNNING COM_REGISTER_SLAVE WITHOUT COM_BINLOG_DUMP CAN RESULTS IN SERVER EXIT  
- Bug #30441969: BUG #29723340: MYSQL SERVER CRASH AFTER SQL QUERY WITH DATA ?AST  
- Bug #30628268: OUT OF MEMORY CRASH  
- Bug #27081349: UNEXPECTED BEHAVIOUR WHEN DELETE WITH SPATIAL FUNCTION  
- Bug #27230859: UNEXPECTED BEHAVIOUR WHILE HANDLING INVALID POLYGON"  
- Bug #27081349: UNEXPECTED BEHAVIOUR WHEN DELETE WITH SPATIAL"  
- Bug #26935001: ALTER TABLE AUTO_INCREMENT TRIES TO READ INDEX FROM DISCARDED TABLESPACE  
- Bug #29770705: SERVER CRASHED WHILE EXECUTING SELECT WITH SPECIFIC WHERE CLAUSE  
- Bug #27659490: SELECT USING DYNAMIC RANGE AND INDEX MERGE USE TOO MUCH MEMORY(OOM)  
- Bug #24786290: REPLICATION BREAKS AFTER BUG #74145 HAPPENS IN MASTER  
- Bug #27703912: EXCESSIVE MEMORY USAGE WITH MANY PREPARE  
- Bug #20527363: TRUNCATE TEMPORARY TABLE CRASH: ! DICT_TF2_FLAG_IS_SET(TABLE, DICT_TF2_TEMPORARY)  
- Bug#23103937 PS_TRUNCATE_ALL_TABLES() DOES NOT WORK IN SUPER_READ_ONLY MODE  
- Bug #25053286: USE VIEW WITH CONDITION IN PROCEDURE CAUSES INCORRECT BEHAVIOR (fixed in 5.6.36)  
- Bug #25586773: INCORRECT BEHAVIOR FOR CREATE TABLE SELECT IN A LOOP IN SP (fixed in 5.6.39) |

• Bug #16311231: Incorrect results were returned if a query contained a subquery in an IN clause that contained an XOR operation in the WHERE clause. |
| Aurora MySQL database engine updates 2019-02-07 (version 1.19.0) (p. 1170) | 1.19.0  | • BUG #32917: DETECT ORPHAN TEMP-POOL FILES, AND HANDLE GRACEFULLY  
• BUG #63144 CREATE TABLE IF NOT EXISTS METADATA LOCK IS TOO RESTRICTIVE |
<p>| Aurora MySQL database engine updates 2019-01-17 (p. 1172) | 1.17.8  | • BUG #13418638: CREATE TABLE IF NOT EXISTS METADATA LOCK IS TOO RESTRICTIVE |</p>
<table>
<thead>
<tr>
<th>Database engine update</th>
<th>Version</th>
<th>MySQL bugs fixed</th>
</tr>
</thead>
</table>
| Aurora MySQL database engine updates 2018-10-08 (p. 1173)                            | 1.17.7  | - Drop index on a foreign key column leads to missing table. (Bug #16208542)  
- Memory leak in add_derived_key(). (Bug #76349)  
- For partitioned tables, queries could return different results depending on whether Index Merge was used. (Bug #16862316)  
- Queries using the index_merge optimization (see Index merge optimization) could return invalid results when run against tables that were partitioned by HASH. (Bug #17588348) |
| Aurora MySQL database engine updates 2018-09-06 (p. 1174)                            | 1.17.6  | - For an ALTER TABLE statement that renamed or changed the default value of a BINARY column, the alteration was done using a table copy and not in place. (Bug #67141, Bug #14735373, Bug #69580, Bug #17024290)  
- An outer join between a regular table and a derived table that is implicitly groups could cause a server exit. (Bug #16177639) |
| Aurora MySQL database engine updates 2018-03-13 (p. 1177)                            | 1.17.0  | - LAST_INSERT_ID is replicated incorrectly if replication filters are used (Bug #69861)  
- Query returns different results depending on whether INDEX_MERGE setting (Bug #16862316)  
- Query proc re-execute of stored routine, inefficient query plan (Bug #16346367)  
- InnoDB FTS : Assert in FTS_CACHE_APPEND_DELETED_DOC_IDS (Bug #18079671)  
- Assert RBT_EMPTY(INDEX_CACHE->WORDS) in ALTER TABLE CHANGE COLUMN (Bug #17536995)  
- InnoDB fulltext search doesn't find records when savepoints are involved (Bug #70333, Bug #17458835) |
| Aurora MySQL database engine updates 2017-11-20 (p. 1179)                            | 1.15.1  | - Reverted — MySQL instance stalling "doing SYNC index" (Bug #73816)  
- Reverted — Assert RBT_EMPTY(INDEX_CACHE->WORDS) in ALTER TABLE CHANGE COLUMN (Bug #17536995)  
- Reverted — InnoDB Fulltext search doesn't find records when savepoints are involved (Bug #70333) |
| Aurora MySQL database engine updates 2017-10-24 (p. 1180)                            | 1.15.0  | - CREATE USER accepts plugin and password hash, but ignores the password hash (Bug #78033)  
- The partitioning engine adds fields to the read bit set to be able to return entries sorted from a partitioned index. This leads to the join buffer will try to read unneeded fields. Fixed by not adding all partitioning fields to the read_set, but instead only sort on the already set prefix fields in the read_set. Added a DBUG_ASSERT that if doing key_cmp, at least the first field must be read (Bug #16367691).  
- MySQL instance stalling "doing SYNC index" (Bug #73816)  
- Assert RBT_EMPTY(INDEX_CACHE->WORDS) in ALTER TABLE CHANGE COLUMN (Bug #17536995)  
- InnoDB Fulltext search doesn't find records when savepoints are involved (Bug #70333) |

| Aurora MySQL database engine updates: 2017-02-23 (p. 1187) | 1.11.0 | • Running ALTER table DROP foreign key simultaneously with another DROP operation causes the table to disappear. (Bug #16095573)  
• Some INFORMATION_SCHEMA queries that used ORDER BY did not use a filesort optimization as they did previously. (Bug #16423536)  
• FOUND_ROWS () returns the wrong count of rows on a table. (Bug #68458)  
• The server fails instead of giving an error when too many temp tables are open. (Bug #18948649) |
| Aurora MySQL database engine updates: 2016-12-14 (p. 1189) | 1.10.0 | • UNION of derived tables returns wrong results with '1=0/false'-clauses. (Bug #69471)  
• Server crashes in ITEM_FUNC_GROUP_CONCAT::FIX_FIELDS on 2nd execution of stored procedure. (Bug #20755389)  
• Avoid MySQL queries from stalling for too long during FTS cache sync to disk by offloading the cache sync task to a separate thread, as soon as the cache size crosses 10% of the total size. (Bugs #22516559, #73816) |
| Aurora MySQL database engine updates: 2016-10-26 (p. 1191) | 1.8.1 | • OpenSSL changed the Diffie-Hellman key length parameters due to the LogJam issue. (Bug #18367167) |
| Aurora MySQL database engine updates: 2016-10-18 (p. 1191) | 1.8.0 | • When dropping all indexes on a column with multiple indexes, InnoDB failed to block a DROP INDEX operation when a foreign key constraint requires an index. (Bug #16896810)  
• Solve add foreign key constraint crash. (Bug #16413976)  
• Fixed a crash when fetching a cursor in a stored procedure, and analyzing or flushing the table at the same time. (Bug #18158639)  
• Fixed an auto-increment bug when a user alters a table to change the AUTO_INCREMENT value to less than the maximum auto-increment column value. (Bug #16310273) |

<thead>
<tr>
<th>Database engine update</th>
<th>Version</th>
<th>MySQL bugs fixed</th>
</tr>
</thead>
</table>
| Aurora MySQL database engine updates: 2015-10-16 (p. 1198) | 1.2, 1.3 | - Killing a query inside innodb causes it to eventually crash with an assertion. (Bug #1608883)
- For failure to create a new thread for the event scheduler, event execution, or new connection, no message was written to the error log. (Bug #16865959)
- If one connection changed its default database and simultaneously another connection executed SHOW PROCESSLIST, the second connection could access invalid memory when attempting to display the first connection's default database memory. (Bug #11765252)
- PURGE BINARY LOGS by design does not remove binary log files that are in use or active, but did not provide any notice when this occurred. (Bug #13727933)
- For some statements, memory leaks could result when the optimizer removed unneeded subquery clauses. (Bug #15875919)
- During shutdown, the server could attempt to lock an uninitialized mutex. (Bug #16016493)
- A prepared statement that used GROUP_CONCAT() and an ORDER BY clause that named multiple columns could cause the server to exit. (Bug #16075310)
- Performance Schema instrumentation was missing for replica worker threads. (Bug #16083949)
- STOP SLAVE could cause a deadlock when issued concurrently with a statement such as SHOW STATUS that retrieved the values for one or more of the status variables Slave_retried_transactions, Slave_heartbeat_period, Slave_received_heartbeats, Slave_last_heartbeat, or Slave_running. (Bug #16088188)
- A full-text query using Boolean mode could return zero results in some cases where the search term was a quoted phrase. (Bug #16206253)
- The optimizer's attempt to remove redundant subquery clauses raised an assertion when executing a prepared statement with a subquery in the ON clause of a join in a subquery. (Bug #16318585)
- GROUP_CONCAT unstable, crash in ITEM_SUM::CLEAN_UP_AFTER_REMOVAL. (Bug #16347450)
- Attempting to replace the default InnoDB full-text search (FTS) stopword list by creating an InnoDB table with the same structure as INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD would result in an error. (Bug #16373868)
- After the client thread on a worker performed a FLUSH TABLES WITH READ LOCK and was followed by some updates on the master, the worker hung when executing SHOW SLAVE STATUS. (Bug #16387720)
- When parsing a delimited search string such as "abc-def" in a full-text search, InnoDB now uses the same word delimiters as MyISAM. (Bug #16419661)
- Crash in FTS_AST_TERM_SET_WILDCARD. (Bug #16429306)

Security vulnerabilities fixed in Amazon Aurora MySQL

Common Vulnerabilities and Exposures (CVE) is a list of entries for publicly known cybersecurity vulnerabilities. Each entry contains an identification number, a description, and at least one public reference.

You can find on this page a list of security vulnerabilities fixed in Aurora MySQL. For general information about security for Aurora, see Security in Amazon Aurora (p. 1628). For additional security information for Aurora MySQL, see Security with Amazon Aurora MySQL (p. 739).

We recommend that you always upgrade to the latest Aurora release to be protected against known vulnerabilities. You can use this page to verify whether a particular version of Aurora MySQL has a fix for a specific security vulnerability. If your cluster doesn't have the security fix, you can see which Aurora MySQL version you should upgrade to for that fix.

Any CVEs fixed in Aurora MySQL version 1 and 2 are also listed in the release notes for that version:

- Database engine updates for Amazon Aurora MySQL version 1 (p. 1148)
- Database engine updates for Amazon Aurora MySQL version 2 (p. 1071)
Note
The initial release of Aurora MySQL version 3 includes all CVEs fixed up to community MySQL 8.0.23. For future CVEs that are fixed, look for them listed here and in the Aurora MySQL version 3 release notes.

CVEs and minimum fixed Aurora MySQL versions

- CVE-2021-23841: 2.10.0, 2.09.3, 1.23.3
- CVE-2021-3712: 2.09.3
- CVE-2021-3449: 2.10.0, 2.09.3, 1.23.3
- CVE-2021-2307: 2.10.1, 2.09.3, 1.23.4
- CVE-2021-2226: 2.10.1, 2.09.3, 1.23.4
- CVE-2021-2194: 2.10.1
- CVE-2021-2174: 2.10.1, 2.09.3
- CVE-2021-2171: 2.10.1, 2.09.3
- CVE-2021-2169: 2.10.1, 2.09.3

• CVE-2013-1523: 1.22.0
• CVE-2012-5615: 1.22.0
Working with Amazon Aurora PostgreSQL

Amazon Aurora PostgreSQL is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases. Aurora PostgreSQL is a drop-in replacement for PostgreSQL and makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. Amazon RDS provides administration for Aurora by handling routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair. Amazon RDS also provides push-button migration tools to convert your existing Amazon RDS for PostgreSQL applications to Aurora PostgreSQL.

Aurora PostgreSQL can work with many industry standards. For example, you can use Aurora PostgreSQL databases to build HIPAA-compliant applications and to store healthcare related information, including protected health information (PHI), under a completed Business Associate Agreement (BAA) with AWS. Aurora PostgreSQL is FedRAMP HIGH eligible. For details about AWS and compliance efforts, see AWS services in scope by compliance program.

Security with Amazon Aurora PostgreSQL

Security for Amazon Aurora PostgreSQL is managed at three levels:

- To control who can perform Amazon RDS management actions on Aurora PostgreSQL DB clusters and DB instances, you use AWS Identity and Access Management (IAM). When you connect to AWS using IAM credentials, your AWS account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management in Amazon Aurora (p. 1645).

  If you are using IAM to access the Amazon RDS console, you must first sign on to the AWS Management Console with your IAM user credentials. Then go to the Amazon RDS console at https://console.aws.amazon.com/rds/.

- Aurora DB clusters must be created in an Amazon Virtual Private Cloud (VPC). To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora DB clusters in a VPC, you use a VPC security group. These endpoint and port connections can be made using Secure Sockets Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see Amazon Virtual Private Cloud VPCs and Amazon Aurora (p. 1708).

  The supported VPC tenancy depends on the DB instance class used by your Aurora PostgreSQL DB clusters. With default VPC tenancy, the VPC runs on shared hardware. With dedicated VPC tenancy, the VPC runs on a dedicated hardware instance. The burstable performance DB instance classes support default VPC tenancy only. The burstable performance DB instance classes include the db.t3 and db.t4g DB instance classes. All other Aurora PostgreSQL DB instance classes support both default and dedicated VPC tenancy.

  For more information about instance classes, see Aurora DB instance classes (p. 53). For more information about default and dedicated VPC tenancy, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

- To authenticate login and permissions for an Amazon Aurora DB cluster, you can take the same approach as with a stand-alone instance of PostgreSQL.

  Commands such as CREATE ROLE, ALTER ROLE, GRANT, and REVOKE work just as they do in on-premises databases, as does directly modifying database schema tables. For more information, see Client authentication in the PostgreSQL documentation.

  **Note**
  The Salted Challenge Response Authentication Mechanism (SCRAM) is not supported with Aurora PostgreSQL.

  **Note**
  For more information, see Security in Amazon Aurora (p. 1628).

When you create an Amazon Aurora PostgreSQL DB instance, the master user has the following default privileges:

- LOGIN
- NOSUPERUSER
- INHERIT
- CREATEDB
• CREATEROLE
• NOREPLICATION
• VALID UNTIL 'infinity'

To provide management services for each DB cluster, the rdsadmin user is created when the DB cluster is created. Attempting to drop, rename, change the password, or change privileges for the rdsadmin account will result in an error.

Restricting password management

You can restrict who can manage database user passwords to a special role. By doing this, you can have more control over password management on the client side.

You enable restricted password management with the static parameter rds.restrict_password_commands and use a role called rds_password. When the parameter rds.restrict_password_commands is set to 1, only users that are members of the rds_password role can run certain SQL commands. The restricted SQL commands are commands that modify database user passwords and password expiration time.

To use restricted password management, your DB cluster must be running Amazon Aurora for PostgreSQL 10.6 or higher. Because the rds.restrict_password_commands parameter is static, changing this parameter requires a database restart.

When a database has restricted password management enabled, if you try to run restricted SQL commands you get the following error: ERROR: must be a member of rds_password to alter passwords.

Following are some examples of SQL commands that are restricted when restricted password management is enabled.

```
postgres=> CREATE ROLE myrole WITH PASSWORD 'mypassword';
postgres=> CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2020-01-01';
postgres=> ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2020-01-01';
postgres=> ALTER ROLE myrole WITH PASSWORD 'mypassword';
postgres=> ALTER ROLE myrole VALID UNTIL '2020-01-01';
postgres=> ALTER ROLE myrole RENAME TO myrole2;
```

Some ALTER ROLE commands that include RENAME TO might also be restricted. They might be restricted because renaming a PostgreSQL role that has an MD5 password clears the password.

The rds_superuser role has membership for the rds_password role by default, and you can't change this. You can give other roles membership for the rds_password role by using the GRANT SQL command. We recommend that you give membership to rds_password to only a few roles that you use solely for password management. These roles require the CREATEROLE attribute to modify other roles.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. We recommend that you restrict password-related changes by using your own client-side utility. This utility should have a role that is a member of rds_password and has the CREATEROLE role attribute.

Securing Aurora PostgreSQL data with SSL/TLS

Amazon RDS supports Secure Socket Layer (SSL) and Transport Layer Security (TLS) encryption for Aurora PostgreSQL DB clusters. Using SSL/TLS, you can encrypt a connection between your applications and your Aurora PostgreSQL DB clusters. You can also force all connections to your Aurora PostgreSQL
DB cluster to use SSL/TLS. Amazon Aurora PostgreSQL supports Transport Layer Security (TLS) versions 1.1 and 1.2. We recommend using TLS 1.2 for encrypted connections.

For general information about SSL/TLS support and PostgreSQL databases, see SSL support in the PostgreSQL documentation. For information about using an SSL/TLS connection over JDBC, see Configuring the client in the PostgreSQL documentation.

Topics

- Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster (p. 1230)
- Determining the SSL/TLS connection status (p. 1231)

SSL/TLS support is available in all AWS Regions for Aurora PostgreSQL. Amazon RDS creates an SSL/TLS certificate for your Aurora PostgreSQL DB cluster when the DB cluster is created. If you enable SSL/TLS certificate verification, then the SSL/TLS certificate includes the DB cluster endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

To connect to an Aurora PostgreSQL DB cluster over SSL/TLS

1. Download the certificate.
   
   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634).
2. Import the certificate into your operating system.
3. Connect to your Aurora PostgreSQL DB cluster over SSL/TLS.

   When you connect using SSL/TLS, your client can choose to verify the certificate chain or not. If your connection parameters specify sslmode=verify-ca or sslmode=verify-full, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

   When a client, such as psql or JDBC, is configured with SSL/TLS support, the client first tries to connect to the database with SSL/TLS by default. If the client can't connect with SSL/TLS, it reverts to connecting without SSL/TLS. The default sslmode mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to prefer, where JDBC clients default to verify-full.

   Use the sslrootcert parameter to reference the certificate, for example sslrootcert=rds-ssl-ca-cert.pem.

The following is an example of using psql to connect to an Aurora PostgreSQL DB cluster.

```
$ psql -h testpg.cdhmugfdpib.us-east-1.rds.amazonaws.com -p 5432 "dbname=testpg user=testuser sslrootcert=rds-ca-2015-root.pem sslmode=verify-full"
```

Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster

You can require that connections to your Aurora PostgreSQL DB cluster use SSL/TLS by using the rds.force_ssl parameter. By default, the rds.force_ssl parameter is set to 0 (off). You can set the rds.force_ssl parameter to 1 (on) to require SSL/TLS for connections to your DB cluster. Updating the rds.force_ssl parameter also sets the PostgreSQL ssl parameter to 1 (on) and modifies your DB cluster’s pg_hba.conf file to support the new SSL/TLS configuration.

You can set the rds.force_ssl parameter value by updating the DB cluster parameter group for your DB cluster. If the DB cluster parameter group isn't the default one, and the ssl parameter is already set
to 1 when you set `rds.force_ssl` to 1, you don’t need to reboot your DB cluster. Otherwise, you must reboot your DB cluster for the change to take effect. For more information on parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 335).

When the `rds.force_ssl` parameter is set to 1 for a DB cluster, you see output similar to the following when you connect, indicating that SSL/TLS is now required:

```
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
psql (9.3.12, server 9.4.4)
Some psql features might not work.
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
```

**Determining the SSL/TLS connection status**

The encrypted status of your connection is shown in the logon banner when you connect to the DB cluster.

```
Password for user master:
psql (9.3.12)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL/TLS is being used. The function returns `t` if the connection is using SSL/TLS, otherwise it returns `f`.

```
postgres=> create extension sslinfo;
CREATE EXTENSION
postgres=> select ssl_is_used();
ssl_is_used
---------
t
(1 row)
```

You can use the `select ssl_cipher()` command to determine the SSL/TLS cipher:

```
postgres=> select ssl_cipher();
ssl_cipher
-----------------
DHE-RSA-AES256-SHA
(1 row)
```

If you enable `set rds.force_ssl` and restart your DB cluster, non-SSL connections are refused with the following message:

```
1231
```
$ export PGSSLMODE=disable
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser

psql: FATAL: no pg_hba.conf entry for host "host.ip", user "someuser", database "postgres", SSL off

For information about the sslmode option, see Database connection control functions in the PostgreSQL documentation.

Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your Aurora DB clusters using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB clusters. If they do, you can further check whether those applications require certificate verification to connect.

Note
Some applications are configured to connect to Aurora PostgreSQL DB clusters only if they can successfully verify the certificate on the server.
For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB clusters. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 1636). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634). For information about using SSL/TLS with PostgreSQL DB clusters, see Securing Aurora PostgreSQL data with SSL/TLS (p. 1229).

Topics
- Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL (p. 1232)
- Determining whether a client requires certificate verification in order to connect (p. 1233)
- Updating your application trust store (p. 1233)
- Using SSL/TLS connections for different types of applications (p. 1234)

Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL

Check the DB cluster configuration for the value of the rds.force_ssl parameter. By default, the rds.force_ssl parameter is set to 0 (off). If the rds.force_ssl parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 335).
Determining whether a client requires certificate verification in order to connect

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, where JDBC clients default to `verify-full`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `require`, `verify-ca`, or `verify-full`. An error is thrown if the certificate is invalid.

Use `PGSSLROOTCERT` to verify the certificate with the `PGSSLMODE` environment variable, with `PGSSLMODE` set to `require`, `verify-ca`, or `verify-full`.

```bash
```

Use the `sslrootcert` argument to verify the certificate with `sslmode` in connection string format, with `sslmode` set to `require`, `verify-ca`, or `verify-full`.

```bash
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=require sslrootcert=/full/path/rds-ca-2019-root.pem user=primaryuser dbname=postgres"
```

For example, in the preceding case, if you use an invalid root certificate, you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

Updating your application trust store

For information about updating the trust store for PostgreSQL applications, see Secure TCP/IP connections with SSL in the PostgreSQL documentation.

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.
Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

To update the trust store for JDBC applications

1. Download the 2019 root certificate that works for all AWS Regions and put the file in your trust store directory.
   
   For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634).
2. Convert the certificate to .der format using the following command.
   
   ```bash
   ```
   
   Replace the file name with the one that you downloaded.
3. Import the certificate into the key store using the following command.
   
   ```bash
   ```
4. Confirm that the key store was updated successfully.
   
   ```bash
   keytool -list -v -keystore clientkeystore.jks
   ```
   
   Enter the key store password when you are prompted for it.

   Your output should contain the following.

   ```
   rds-root, date, trustedCertEntry,
   Certificate fingerprint (SHA1):
   # This fingerprint should match the output from the below command
   openssl x509 -fingerprint -in rds-ca-2019-root.pem -noout
   ```

Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

  The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).

  For the complete list of options, see Parameter key words in the PostgreSQL documentation. For the complete list of environment variables, see Environment variables in the PostgreSQL documentation.

- **pgAdmin**

  This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

  For information about configuring connections, see the pgAdmin documentation.

- **JDBC**
JDBC enables database connections with Java applications.

For general information about connecting to a PostgreSQL database with JDBC, see Connecting to the database in the PostgreSQL documentation. For information about connecting with SSL/TLS, see Configuring the client in the PostgreSQL documentation.

• Python

A popular Python library for connecting to PostgreSQL databases is psycopg2.

For information about using psycopg2, see the psycopg2 documentation. For a short tutorial on how to connect to a PostgreSQL database, see Psycopg2 tutorial. You can find information about the options the connect command accepts in The psycopg2 module content.

Important
After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 1637).

Migrating data to Amazon Aurora with PostgreSQL compatibility

You have several options for migrating data from your existing database to an Amazon Aurora PostgreSQL-Compatible Edition DB cluster. Your migration options also depend on the database that you are migrating from and the size of the data that you are migrating. Following are your options:

Migrating an RDS for PostgreSQL DB instance using a snapshot (p. 1236)

You can migrate data directly from an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster.

Migrating an RDS for PostgreSQL DB instance using an Aurora read replica (p. 1238)

You can also migrate from an RDS for PostgreSQL DB instance by creating an Aurora PostgreSQL read replica of an RDS for PostgreSQL DB instance. When the replica lag between the RDS for PostgreSQL DB instance and the Aurora PostgreSQL read replica is zero, you can stop replication. At this point, you can make the Aurora read replica a standalone Aurora PostgreSQL DB cluster for reading and writing.

Importing S3 data into Aurora PostgreSQL (p. 1379)

You can migrate data by importing it from Amazon S3 into a table belonging to an Aurora PostgreSQL DB cluster.

Migrating from a database that is not PostgreSQL-compatible

You can use AWS Database Migration Service (AWS DMS) to migrate data from a database that is not PostgreSQL-compatible. For more information on AWS DMS, see What is AWS Database Migration Service? in the AWS Database Migration Service User Guide.

For a list of AWS Regions where Aurora is available, see Amazon Aurora in the AWS General Reference.

Important
If you plan to migrate an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster in the near future, we strongly recommend that you disable auto minor version upgrades for the DB instance early in the migration planning phase. Migration to Aurora PostgreSQL
might be delayed if the RDS for PostgreSQL version isn't yet supported by Aurora PostgreSQL. For information about Aurora PostgreSQL versions, see Engine versions for Amazon Aurora PostgreSQL.

Migrating a snapshot of an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster

To create an Aurora PostgreSQL DB cluster, you can migrate a DB snapshot of an RDS for PostgreSQL DB instance. The new Aurora PostgreSQL DB cluster is populated with the data from the original RDS for PostgreSQL DB instance. For information about creating a DB snapshot, see Creating a DB snapshot.

In some cases, the DB snapshot might not be in the AWS Region where you want to locate your data. If so, use the Amazon RDS console to copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see Copying a DB snapshot.

You can migrate RDS for PostgreSQL snapshots that are compatible with the Aurora PostgreSQL versions available in the given AWS Region. For example, a snapshot from an RDS for PostgreSQL 11.1 DB instance can be migrated to Aurora PostgreSQL version 11.4, 11.7, 11.8, or 11.9 in the US West (N. California) Region. An RDS PostgreSQL 10.11 snapshot can be migrated to Aurora PostgreSQL 10.11, 10.12, 10.13, and 10.14. In other words, the RDS for PostgreSQL snapshot must use the same or a lower minor version as the Aurora PostgreSQL.

When you migrate the DB snapshot by using the console, the console takes the actions necessary to create both the DB cluster and the primary instance.

You can also choose for your new Aurora PostgreSQL DB cluster to be encrypted at rest by using an AWS KMS key. This option is available only for unencrypted DB snapshots.

To migrate a PostgreSQL DB snapshot by using the RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Snapshots.
3. On the Snapshots page, choose the RDS for PostgreSQL snapshot that you want to migrate into an Aurora PostgreSQL DB cluster.
4. Choose Actions then choose Migrate snapshot.
5. Set the following values on the Migrate database page:
   - **DB engine version**: Choose a DB engine version you want to use for the new migrated instance.
   - **DB instance identifier**: Enter a name for the DB cluster that is unique for your account in the AWS Region that you chose. This identifier is used in the endpoint addresses for the instances in your DB cluster. You might choose to add some intelligence to the name, such as including the AWS Region and DB engine that you chose, for example aurora-cluster1.

   The DB instance identifier has the following constraints:
   - It must contain 1–63 alphanumeric characters or hyphens.
   - Its first character must be a letter.
   - It can't end with a hyphen or contain two consecutive hyphens.
   - It must be unique for all DB instances per AWS account, per AWS Region.
   - **DB instance class**: Choose a DB instance class that has the required storage and capacity for your database, for example db.r3.large. Aurora cluster volumes automatically grow as the amount of data in your database increases. 128 tebibytes (TiB) So you only need to choose a DB instance class that meets your current storage requirements. For more information, see Overview of Aurora storage (p. 63).
• **Virtual private cloud (VPC):** If you have an existing VPC, then you can use that VPC with your Aurora PostgreSQL DB cluster by choosing your VPC identifier, for example vpc-a464d1c1. For information on using an existing VPC, see How to create a VPC for use with Amazon Aurora (p. 1714).

Otherwise, you can choose to have Amazon RDS create a VPC for you by choosing **Create new VPC.**

• **Subnet group:** If you have an existing subnet group, then you can use that subnet group with your Aurora PostgreSQL DB cluster by choosing your subnet group identifier, for example gs-subnet-group1.

• **Public access:** Choose **No** to specify that instances in your DB cluster can only be accessed by resources inside of your VPC. Choose **Yes** to specify that instances in your DB cluster can be accessed by resources on the public network.

**Note**
Your production DB cluster might not need to be in a public subnet, because only your application servers require access to your DB cluster. If your DB cluster doesn't need to be in a public subnet, set **Public access to No.**

• **VPC security group:** Choose a VPC security group to allow access to your database.

• **Availability Zone:** Choose the Availability Zone to host the primary instance for your Aurora PostgreSQL DB cluster. To have Amazon RDS choose an Availability Zone for you, choose **No preference.**

• **Database port:** Enter the default port to be used when connecting to instances in the Aurora PostgreSQL DB cluster. The default is **5432.**

**Note**
You might be behind a corporate firewall that doesn't allow access to default ports such as the PostgreSQL default port, 5432. In this case, provide a port value that your corporate firewall allows. Remember that port value later when you connect to the Aurora PostgreSQL DB cluster.

• **Enable Encryption:** Choose **Enable Encryption** for your new Aurora PostgreSQL DB cluster to be encrypted at rest. Also choose a KMS key as the **AWS KMS key** value.

• **Auto minor version upgrade:** Choose **Enable auto minor version upgrade** to enable your Aurora PostgreSQL DB cluster to receive minor PostgreSQL DB engine version upgrades automatically when they become available.

The **Auto minor version upgrade** option only applies to upgrades to PostgreSQL minor engine versions for your Aurora PostgreSQL DB cluster. It doesn't apply to regular patches applied to maintain system stability.

6. Choose **Migrate** to migrate your DB snapshot.

7. Choose **Databases** to see the new DB cluster. Choose the new DB cluster to monitor the progress of the migration. On the **Connectivity & security** tab, you can find the cluster endpoint to use for connecting to the primary writer instance of the DB cluster. For more information on connecting to an Aurora PostgreSQL DB cluster, see Connecting to an Amazon Aurora DB cluster (p. 279).
Migrating data from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster using an Aurora read replica

You can migrate from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster by using an Aurora read replica. When you need to migrate from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster, we recommend using this approach.

In this case, Amazon RDS uses the PostgreSQL DB engine’s streaming replication functionality to create a special type of DB cluster for the source PostgreSQL DB instance. This type of DB cluster is called an Aurora read replica. Updates made to the source RDS for PostgreSQL DB instance are asynchronously replicated to the Aurora read replica.

Topics

• Overview of migrating data by using an Aurora read replica (p. 1238)
• Preparing to migrate data by using an Aurora read replica (p. 1239)
• Creating an Aurora read replica (p. 1239)
• Promoting an Aurora read replica (p. 1245)

Overview of migrating data by using an Aurora read replica

To migrate from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster, we recommend creating an Aurora read replica of your source RDS for PostgreSQL DB instance. When the replica lag between the RDS for PostgreSQL DB instance and the Aurora PostgreSQL Read Replica is zero, you can stop replication. At this point, you can promote the Aurora read replica to be a standalone Aurora PostgreSQL DB cluster. This standalone DB cluster can then accept write loads.

Be prepared for migration to take a while, roughly several hours per terabyte (TiB) of data. While the migration is in progress, your RDS for PostgreSQL instance accumulates write ahead log (WAL) segments. Make sure that your Amazon RDS instance has sufficient storage capacity for these segments.

When you create an Aurora read replica of an RDS for PostgreSQL DB instance, Amazon RDS creates a DB snapshot of your source RDS for PostgreSQL DB instance. This snapshot is private to Amazon RDS and incurs no charges. Amazon RDS then migrates the data from the DB snapshot to the Aurora read replica. After the DB snapshot data is migrated to the new Aurora PostgreSQL DB cluster, RDS starts replication between your RDS for PostgreSQL DB instance and the Aurora PostgreSQL DB cluster.

You can only have one Aurora read replica for an RDS for PostgreSQL DB instance. If you try to create an Aurora read replica for your RDS for PostgreSQL instance and you already have an Aurora read replica or a cross-region read replica, the request is rejected.

Note

Replication issues can arise due to feature differences between Aurora PostgreSQL and the PostgreSQL engine version of your RDS for PostgreSQL DB instance that is the replication source. You can replicate only from an RDS for PostgreSQL instance that is compatible with the Aurora PostgreSQL version. The RDS for PostgreSQL version must be lower than or equal to a supported Aurora PostgreSQL version in the same major version. For example, you can replicate data between an RDS for PostgreSQL version 11.7 DB instance and an Aurora PostgreSQL version 11.7 or higher 11 version DB cluster, but not an Aurora PostgreSQL version 11.6 DB cluster. For information about Aurora PostgreSQL versions, see Aurora PostgreSQL releases and engine versions in the Aurora User Guide. If you encounter an error, you can find help in the Amazon RDS community forum or by contacting AWS Support.

For more information on PostgreSQL read replicas, see Working with read replicas in the Amazon RDS User Guide.
Preparing to migrate data by using an Aurora read replica

Before you migrate data from your RDS for PostgreSQL instance to an Aurora PostgreSQL cluster, make sure that your instance has sufficient storage capacity. This storage capacity is for the write ahead log (WAL) segments that accumulate during the migration. There are several metrics to check for this, described following.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FreeStorageSpace</td>
<td>The available storage space.</td>
</tr>
<tr>
<td></td>
<td>Units: Bytes</td>
</tr>
<tr>
<td>OldestReplicationSlotLag</td>
<td>The size of the lag for WAL data in the replica that is lagging the most.</td>
</tr>
<tr>
<td></td>
<td>Units: Megabytes</td>
</tr>
<tr>
<td>RDSToAuroraPostgreSQLReplicaLag</td>
<td>The amount of time in seconds that an Aurora PostgreSQL DB cluster lags behind the source RDS DB instance.</td>
</tr>
<tr>
<td>TransactionLogsDiskUsage</td>
<td>The disk space used by the transaction logs.</td>
</tr>
<tr>
<td></td>
<td>Units: Megabytes</td>
</tr>
</tbody>
</table>

For more information about monitoring your RDS instance, see Monitoring in the Amazon RDS User Guide.

Creating an Aurora read replica

You can create an Aurora read replica for an RDS for PostgreSQL DB instance by using the console or the AWS CLI.

Console

**To create an Aurora read replica from a source PostgreSQL DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the RDS for PostgreSQL DB instance that you want to use as the source for your Aurora read replica, and choose Create Aurora read replica for Actions.
4. Choose the DB cluster specifications that you want to use for the Aurora read replica, as described in the following table.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB instance class</strong></td>
<td>Choose a DB instance class that defines the processing and memory requirements for the primary instance in the DB cluster. For more information about DB instance class options, see Aurora DB instance classes (p. 53).</td>
</tr>
<tr>

</tr>
</tbody>
</table>
| **DB instance identifier** | Enter a name for the primary instance in your Aurora read replica DB cluster. This identifier is used in the endpoint address for the primary instance of the new DB cluster. The DB instance identifier has the following constraints:  
  - It must contain 1–63 alphanumeric characters or hyphens.  
  - Its first character must be a letter.  
  - It can't end with a hyphen or contain two consecutive hyphens.  
  - It must be unique for all DB instances for each AWS account, for each AWS Region.  
  
  The Aurora read replica DB cluster is created from a snapshot of the source DB instance. Thus, the master user name and master password for the Aurora read replica are

5. Choose **Create read replica**.

**AWS CLI**

To create an Aurora read replica from a source RDS for PostgreSQL DB instance, use the `create-db-cluster` and `create-db-instance` AWS CLI commands to create a new Aurora PostgreSQL DB cluster. When you call the `create-db-cluster` command, include the `--replication-source-identifier` parameter to identify the Amazon Resource Name (ARN) for the source RDS for PostgreSQL DB instance. For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS) in the AWS General Reference.

Don't specify the master user name, master password, or database name. The Aurora read replica uses the same master user name, master password, and database name as the source RDS for PostgreSQL DB instance.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster --db-cluster-identifier sample-replica-cluster --engine aurora-postgresql \
```
Use the `create-db-instance` CLI command with the following parameters:

- **--db-cluster-identifier**
  The name of your DB cluster.
- **--db-instance-class**
  The name of the DB instance class to use for your primary instance.
- **--db-instance-identifier**
  The name of your primary instance.
- **--engine aurora-postgresql**
  The database engine to use.

In the following example, you create a primary instance named `myreadreplicainstance` for the DB cluster named `myreadreplicacluster`. You do this using the DB instance class specified in `myinstanceclass`.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-cluster-identifier myreadreplicacluster \
  --db-instance-class myinstanceclass \
  --db-instance-identifier myreadreplicainstance \
  --engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^
  --db-cluster-identifier myreadreplicacluster ^
  --db-instance-class myinstanceclass ^
  --db-instance-identifier myreadreplicainstance ^
  --engine aurora-postgresql
```
RDS API

To create an Aurora read replica from a source RDS for PostgreSQL DB instance, use the RDS API operations `CreateDBCluster` and `CreateDBInstance` to create a new Aurora DB cluster and primary instance. Don't specify the master user name, master password, or database name. The Aurora read replica uses the same master user name, master password, and database name as the source RDS for PostgreSQL DB instance.

You can create a new Aurora DB cluster for an Aurora read replica from a source RDS for PostgreSQL DB instance. To do so, use the RDS API operation `CreateDBCluster` with the following parameters:

- **DBClusterIdentifier**
  
  The name of the DB cluster to create.

- **DBSubnetGroupName**
  
  The name of the DB subnet group to associate with this DB cluster.

- **Engine=aurora-postgresql**
  
  The name of the engine to use.

- **ReplicationSourceIdentifier**
  
  The Amazon Resource Name (ARN) for the source PostgreSQL DB instance. For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS) in the Amazon Web Services General Reference.

- **VpcSecurityGroupIds**
  
  The list of Amazon EC2 VPC security groups to associate with this DB cluster.

See an example with the RDS API operation `CreateDBCluster`.

If you use the console to create an Aurora read replica, then Amazon RDS automatically creates the primary instance for your DB cluster Aurora Read Replica. If you use the CLI to create an Aurora read replica, you must explicitly create the primary instance for your DB cluster. The primary instance is the first instance that is created in a DB cluster.

You can create a primary instance for your DB cluster by using the RDS API operation `CreateDBInstance` with the following parameters:

- **DBClusterIdentifier**
  
  The name of your DB cluster.

- **DBInstanceClass**
  
  The name of the DB instance class to use for your primary instance.

- **DBInstanceIdentifier**
  
  The name of your primary instance.

- **Engine=aurora-postgresql**
  
  The name of the engine to use.

See an example with the RDS API operation `CreateDBInstance`.
Promoting an Aurora read replica

After migration completes, you can promote the Aurora read replica to a standalone DB cluster. You then direct your client applications to the endpoint for the Aurora read replica. For more information on the Aurora endpoints, see Amazon Aurora connection management (p. 31). Promotion should complete fairly quickly. You can't delete the primary PostgreSQL DB instance or unlink the DB instance and the Aurora read replica until the promotion is complete.

Before you promote your Aurora read replica, stop any transactions from being written to the source RDS for PostgreSQL DB instance. Then wait for the replica lag on the Aurora read replica to reach zero. For more information, see Monitoring Aurora PostgreSQL replication (p. 1373) and Monitoring Amazon Aurora metrics with Amazon CloudWatch (p. 628).

Console

To promote an Aurora read replica to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB instance for the Aurora read replica.
4. For Actions, choose Promote.
5. Choose Promote read replica.

AWS CLI

To promote an Aurora read replica to a stand-alone DB cluster, use the `promote-read-replica-db-cluster` AWS CLI command.

Example

For Linux, macOS, or Unix:

```bash
aws rds promote-read-replica-db-cluster --db-cluster-identifier myreadreplicacluster
```

For Windows:

```bash
aws rds promote-read-replica-db-cluster ^
    --db-cluster-identifier myreadreplicacluster
```

RDS API

To promote an Aurora read replica to a stand-alone DB cluster, use the RDS API operation `PromoteReadReplicaDBCluster`.

After you promote your read replica, confirm that the promotion has completed by using the following procedure.

To confirm that the Aurora read replica was promoted

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Events.
3. On the **Events** page, verify that there is an event, *Promoted read replica cluster to a stand-alone database cluster for the cluster that you promoted.*

After promotion is complete, the primary RDS for PostgreSQL DB instance and the Aurora Read Replica are unlinked. At this point, you can safely delete the DB instance if you want to.
Working with Babelfish for Aurora PostgreSQL

Babelfish for Aurora PostgreSQL extends your Amazon Aurora PostgreSQL-Compatible Edition database with the ability to accept database connections from Microsoft SQL Server clients. Doing this allows applications originally built for SQL Server to work directly with Aurora PostgreSQL with few code changes compared to a traditional migration and without changing database drivers. For more information about migrating, see Using Babelfish to migrate to PostgreSQL (p. 1250).

Babelfish provides an additional endpoint for an Aurora PostgreSQL database cluster that allows it to understand the SQL Server wire-level protocol and commonly used SQL Server statements. This approach allows client applications that use the Tabular Data Stream (TDS) wire protocol to connect natively to the TDS listener port on Aurora PostgreSQL. Babelfish supports TDS versions 7.1 and higher. For more information on the SQL Server wire-level protocol, see [MS-TDS]: Tabular Data Stream Protocol on the Microsoft website.

You can access your data simultaneously using a Babelfish TDS connection from one application and a native PostgreSQL connection from another application. You can customize the ports used for each client connection when you create the cluster, or later in your Aurora PostgreSQL parameter group. For more information about the parameters that control Babelfish, see Configuring a database for Babelfish (p. 1290).

By default, to use the following dialects use the following ports:

- SQL Server dialect, clients connect to port 1433.
- PostgreSQL dialect, clients connect to port 5432.

Babelfish runs the Transact-SQL (T-SQL) language with the exceptions documented in Differences between Aurora PostgreSQL with Babelfish and SQL Server (p. 1271).

Babelfish architecture

When you create an Aurora PostgreSQL cluster with Babelfish turned on, Aurora provisions the cluster with a PostgreSQL database named babelfish_db. This database is where all migrated SQL Server objects and structures reside.

When you connect to the TDS port, the session is placed in the babelfish_db database. From T-SQL, the structure looks similar to being connected to a SQL Server instance. You can see the master and tempdb databases and the sys.databases catalog. You can create additional user databases and switch between databases with the USE statement. When you create a SQL Server user database, it's flattened into the babelfish_db PostgreSQL database. Your database retains cross-database syntax and semantics equal to or similar to those provided by SQL Server.

Using Babelfish with a single database or multiple databases

When you create an Aurora PostgreSQL cluster to use with Babelfish, you choose between using a single SQL Server database on its own or multiple SQL Server databases together. Your choice affects how the names of SQL Server schemas inside the babelfish_db database appear from Aurora PostgreSQL. The migration mode is stored in the migration_mode parameter. You can't change this parameter after creating your cluster.

In single-database mode, the schema names of the user database in the babelfish_db database remain the same as in SQL Server. If you choose to move a single database, schemas are recreated inside of the database and can be referenced with the same name used with SQL Server. For example, the dbo and smith schemas reside inside the dbA database.
When connecting through TDS, you can run `USE dbA` to see schemas `dbo` and `smith` from T-SQL, as you would in SQL Server. The unchanged schema names are also visible from PostgreSQL.

In multiple-database mode, the schema names of user databases become `dbname_schemaname` when seen from PostgreSQL. The schema names remain the same when seen from T-SQL.
When connecting through TDS, you can run `USE dbA`, to see schemas `dbo` and `smith` from T-SQL, as you would in SQL Server. The mapped schema names, such as `dbA_dbo` and `dbA_smith`, are visible from PostgreSQL.

Each database still contains your schemas. The name of each database is prepended to the name of the SQL Server schema, using an underscore as a delimiter, for example:

- `dbA` contains `dbA_dbo` and `dbA_smith`.
- `dbB` contains `dbB_dbo` and `dbB_jones`.
- `dbC` contains `dbC_dbo` and `dbC_miller`.

Inside the `babelfish_db` database, the T-SQL user still needs to run `USE dbname` to change database context, so the look and feel remains similar to SQL Server.

### Choosing a migration mode

Each migration mode has advantages and disadvantages. Choose your migration mode based on the number of user databases you have, and your migration plans. After you create a cluster for use with Babelfish, you can't change the migration mode. When choosing a migration mode, consider the requirements of your user databases and clients.

When you create a cluster for use with Babelfish, Aurora PostgreSQL creates the system databases, `master` and `tempdb`. If you created or modified objects in the system databases (`master` or `tempdb`), make sure to recreate those objects in your new cluster. Unlike SQL Server, Babelfish doesn't reinitialize `tempdb` after a cluster reboot.

Use single database migration mode in the following cases:

- If you are migrating a single SQL Server database. In single database mode, migrated schema names are identical to the original SQL Server schema names. When you migrate your application, you make fewer changes to your SQL code.
- If your end goal is a complete migration to native Aurora PostgreSQL. Before migrating, consolidate your schemas into a single schema (`dbo`) and then migrate into a single cluster to lessen required changes.

Use multiple database migration mode in the following cases:

- If you are trying out Babelfish and you aren't sure of your future needs.
- If multiple user databases need to be migrated together, and the end goal isn't to perform a fully native PostgreSQL migration.
- If you might be migrating multiple databases in the future.
Using Babelfish to migrate to PostgreSQL

You can use Babelfish for Aurora PostgreSQL to ease migration from a SQL Server database to an Amazon Aurora PostgreSQL DB cluster. Before migrating, review Using Babelfish with a single database or multiple databases (p. 1247).

The following high-level overview lists the steps required to make your SQL Server application work with Babelfish:

1. Create a new Aurora PostgreSQL DB cluster with Babelfish turned on, providing support for SQL Server T-SQL syntax and features. For details, see Creating an Aurora PostgreSQL cluster with Babelfish (p. 1252).

2. To connect to the new database, use a native SQL Server tool such as sqlcmd. For details, see Using a SQL Server client to connect to your DB cluster (p. 1262).

3. Export the data definition language (DDL) for your SQL Server databases that you want to migrate. The DDL is SQL code that describes database objects that contain user data (such as tables, indexes, and views) and user-written database code (such as stored procedures, user-defined functions, and triggers).

   You can use SQL Studio Management Studio (SSMS) to export the DDL. After connecting to your existing SQL Server instance, complete the following steps:

   a. Open the context menu (right-click) for a database name.

   b. Choose Tasks, Generate Scripts from the context menu.

   c. On the Choose Objects page, select the entire database or specific objects.

   d. On the Set Scripting Options page, choose Advanced and make sure you turn on triggers, logins, owners, and permissions. These are turned off by default in SSMS.

   e. Save the script.

4. Export the data manipulation language (DML) for your SQL Server databases that you want to migrate. The DML is SQL code that inserts rows into the tables in your database.

   You can use SQL Studio Management Studio (SSMS) to export the DML. After connecting to your existing SQL Server instance, complete the following steps:

   a. Open the context menu (right-click) for a database name.

   b. Choose Tasks, Generate Scripts from the context menu.

   c. On the Choose Objects page, select the entire database or specific objects.

   d. On the Set Scripting Options page, choose Advanced and for Types of data to script, choose Data only.

   e. Save the script.

5. Run an assessment tool.

   For example, you can run the Babelfish Compass tool. You run this tool on the DDL to determine to what extent the T-SQL code is supported by Babelfish. Identify T-SQL code that might require modifications before running on Babelfish.

   Because Babelfish Compass is an open-source tool, report any issues through GitHub. Don't report issues with Babelfish Compass to AWS Support.

6. Run the DDL on your new Babelfish server to recreate your schemas on Babelfish using SSMS or sqlcmd. Make code adjustments as needed. This process might require multiple iterations.

7. Run the DML on your new Babelfish server to insert rows into the tables in your database.

8. Reconfigure your client application to connect to the Babelfish endpoint instead of SQL Server. For details, see Connecting to a DB cluster with Babelfish turned on (p. 1259).

9. Modify your application where necessary and retest. For more information, see Differences between Aurora PostgreSQL with Babelfish and SQL Server (p. 1271).
10 When you're satisfied with your application test results, start using your Babelfish database for production.

When you're ready, stop the original database and redirect live client applications to use the Babelfish TDS port.

11 (Optional) Capture client-side SQL queries, and run these queries through an assessment tool (such as Babelfish Compass). A reverse-engineered schema only converts server-side SQL code. For applications with complex client-side SQL queries, we recommend that you also analyze these for Babelfish compatibility. If the analysis indicates that the client-side SQL statements contain unsupported SQL features, review the SQL aspects in the client application and make modifications if necessary.
Creating an Aurora PostgreSQL cluster with Babelfish

You can use Babelfish on Aurora PostgreSQL. Babelfish is currently supported on Aurora PostgreSQL version 13.4 and higher.

You can use the AWS Management Console or the AWS CLI to create an Aurora PostgreSQL cluster with Babelfish.

**Console**

To create a cluster with Babelfish running with the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/, and choose **Create database**.

2. For **Choose a database creation method**, do one of the following:
   - To specify detailed engine options, choose **Standard create**.
   - To use preconfigured options that support best practices for an Aurora cluster, choose **Easy create**.
3. For **Engine type**, choose **Amazon Aurora**.
4. For **Edition**, choose **Amazon Aurora PostgreSQL**.
5. Choose **Show filters**, and then choose **Show versions that support the Babelfish for PostgreSQL feature** to list the engine types that support Babelfish. Babelfish is currently supported on Aurora PostgreSQL 13.4 and higher.
6. For **Available versions**, choose an Aurora PostgreSQL version.
7. For Templates, choose the template that matches your use case.
8. For DB cluster identifier, enter a name that you can easily find later in the DB cluster list.
9. For Master username, enter an administrator user name.

Unlike SQL Server, Babelfish doesn't create an sa login. To create a login named sa, enter the name in the Master username field.

If you don't create a user named sa at this time, you can create one later with your choice of client. After creating the user, use the ALTER SERVER ROLE command to add it to sysadmin.

10. For Master password, enter a strong password for the administrative user that you just named, and confirm the password.

11. For the options that follow, until the Babelfish settings section, specify your DB cluster settings. For information about each setting, see Settings for Aurora DB clusters (p. 136).

12. To make Babelfish functionality available, select the Turn on Babelfish box.

13. For DB cluster parameter group, do one of the following:

   • Choose Create new to create a new parameter group with Babelfish turned on.
   • Choose Choose existing to use an existing parameter group. If you use an existing group, make sure to modify the group before creating the cluster and add values for Babelfish parameters. For information about Babelfish parameters, see Configuring a database for Babelfish (p. 1290).

   If you use an existing group, provide the group name in the box that follows.

14. For Database migration mode, choose one of the following:

   • Single database to migrate a single SQL Server database.

     In some cases, you might migrate multiple user databases together, with your end goal a complete migration to native Aurora PostgreSQL without Babelfish. If the final applications require consolidated schemas (a single dbo schema), make sure to first consolidate your SQL Server databases into a single SQL server database. Then migrate to Babelfish using Single database mode.

   • Multiple databases to migrate multiple SQL Server databases (originating from a single SQL Server installation). Multiple database mode doesn't consolidate multiple databases that don't originate from a single SQL Server installation. For information about migrating multiple databases, see Using Babelfish with a single database or multiple databases (p. 1247).
15. For **Default collation locale**, enter your server locale. The default is `en-US`. For detailed information about collations, see Babelfish collation support (p. 1294).

16. For **Collation name** field, enter your default collation. The default is `sql_latin1_general_cp1_ci_as`. For detailed information, see Babelfish collation support (p. 1294).

17. For **Babelfish TDS port**, enter the port number for your SQL Server client connect to. The default is 1433.

18. For **DB parameter group**, choose a parameter group or have Aurora create a new group for you with default settings.

19. For **Failover priority**, choose a failover priority for the instance. If you don’t choose a value, the default is `tier-1`. This priority determines the order in which replicas are promoted when recovering from a primary instance failure. For more information, see Fault tolerance for an Aurora DB cluster (p. 68).

20. For **Backup retention period**, choose the length of time (1–35 days) that Aurora retains backup copies of the database. You can use backup copies for point-in-time restores (PITR) of your database down to the second. The default retention period is seven days.
21. Choose **Copy tags to snapshots** to copy any DB instance tags to a DB snapshot when you create a snapshot.

22. Choose **Enable encryption** to turn on encryption at rest (Aurora storage encryption) for this DB cluster.

23. Choose **Enable Performance Insights** to turn on Amazon RDS Performance Insights.

24. Choose **Enable Enhanced monitoring** to start gathering metrics in real time for the operating system that your DB cluster runs on.

25. Choose **PostgreSQL log** to publish the log files to Amazon CloudWatch Logs.

26. Choose **Enable auto minor version upgrade** to automatically update your Aurora DB cluster when a minor version upgrade is available.

27. For **Maintenance window**, do the following:

   - To choose a time for Amazon RDS to make modifications or perform maintenance, choose **Select window**.
28. Select the **Enable deletion protection** box to protect your database from being deleted by accident.

If you turn on this feature, you can't directly delete the database. Instead, you need to modify the database cluster and turn off this feature before deleting the database.

29. Choose **Create database**.

You can find your new database set up for Babelfish in the **Databases** listing. The **Status** column displays **Available** when the deployment is complete.

**AWS CLI**

Before you create an Aurora DB cluster with Babelfish running using the AWS CLI, make sure to fulfill the required prerequisites, such as creating a parameter group. For more information, see [DB cluster prerequisites](p. 124).

Before you can use the AWS CLI to create an Aurora PostgreSQL cluster with Babelfish, do the following:

- Choose your endpoint URL from the list of services at [Amazon Aurora endpoints and quotas](p. 124).
- Create a parameter group for the cluster. For more information about parameter groups, see [Working with DB parameter groups and DB cluster parameter groups](p. 335).
- Modify the parameter group, adding the parameter that turns on Babelfish.
To create an Aurora PostgreSQL DB cluster with Babelfish using the AWS CLI

1. Create a parameter group.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster-parameter-group \
  --endpoint-url my_endpoint_URL \
  --db-cluster-parameter-group-name my_parameter_group \
  --db-parameter-group-family aurora-postgresql13 \
  --description "parameter_group_description"
```

For Windows:

```bash
aws rds create-db-cluster-parameter-group ^
  --endpoint-url my_endpoint_URL ^
  --db-cluster-parameter-group-name my_parameter_group ^
  --db-parameter-group-family aurora-postgresql13 ^
  --description "parameter_group_description"
```

2. Modify your parameter group to turn on Babelfish.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group \
  --endpoint-url my_endpoint_URL \
  --db-cluster-parameter-group-name my_parameter_group \
  --parameters "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group ^
  --endpoint-url my_endpoint_URL ^
  --db-cluster-parameter-group-name my_parameter_group ^
  --parameters "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
```

3. Identify your DB subnet group and the virtual private cloud (VPC) security group ID for your new DB cluster, and then call the `create-db-cluster` command.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster \
  --db-cluster-identifier my_cluster_name \
  --master-username user_name \
  --master-user-password my_password \
  --engine aurora-postgresql \
  --engine-version 13.4 \
  --vpc-security-group-ids my_security_group \
  --db-subnet-group-name my_subnet_group \
  --db-cluster-parameter-group-name my_parameter_group
```

For Windows:

```bash
aws rds create-db-cluster ^
  --db-cluster-identifier my_cluster_name ^
  --master-username user_name ^
  --master-user-password my_password ^
  --engine aurora-postgresql ^
  --engine-version 13.4 ^
  --vpc-security-group-ids my_security_group ^
  --db-subnet-group-name my_subnet_group ^
  --db-cluster-parameter-group-name my_parameter_group
```
Creating an Aurora PostgreSQL cluster with Babelfish

```
--engine aurora-postgresql ^
--engine-version 13.4 ^
--vpc-security-group-ids my_security_group ^
--db-subnet-group-name my_subnet_group ^
--db-cluster-parameter-group-name my_parameter_group
```

4. Explicitly create the primary instance. Use the name of the cluster that you created preceding for the value of the `--db-cluster-identifier` option and run the `create-db-instance` command as shown following.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier my_instance_name \
--db-instance-class db.r5.4xlarge \
--db-subnet-group-name my_subnet_group \
--db-cluster-identifier my_cluster_name \
--engine aurora-postgresql
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier my_instance_name ^
--db-instance-class db.r5.4xlarge ^
--db-subnet-group-name my_subnet_group ^
--db-cluster-identifier my_cluster_name ^
--engine aurora-postgresql
```
Connecting to a DB cluster with Babelfish turned on

To connect to Babelfish, modify your database client configuration to connect to the endpoint of the Aurora PostgreSQL cluster running Babelfish. Your client can use one of the following client drivers compliant with TDS version 7.1 or higher:

- Open Database Connectivity (ODBC)
- OLE DB Driver/MSOLEDBSQL
- Java Database Connectivity (JDBC)
- Microsoft SqlClient Data Provider for SQL Server
- .NET Data Provider for SQL Server
- SQL Server Native Client 11.0 (deprecated)
- OLEDB Provider/SQLOLEDB (deprecated)

With Babelfish, you run the following:

- SQL Server tools, applications, and syntax on the TDS port, by default port 1433.
- PostgreSQL tools, applications, and syntax on the PostgreSQL port, by default port 5432.

If you're new to connecting to an Amazon Aurora PostgreSQL database, see also Connecting to an Amazon Aurora PostgreSQL DB cluster (p. 283).

Finding the DNS writer endpoint and port number

Use the following procedure to find your database endpoint.

**To find your database endpoint**

1. Open the console for Babelfish.
2. Choose Databases from the navigation pane.
   
   Your database should have a status of Available. If it doesn't, wait until it displays as Available. The status updates automatically without requiring you to refresh the page. This process can take up to 20 minutes after creating a DB cluster.
3. Choose your DB cluster that supports Babelfish to show its details.
4. On the Connectivity & security tab, note the available cluster Endpoints values. Use the cluster endpoint for the writer instance in your connection strings for any applications that perform database write or read operations.
Performing client authentication

Aurora PostgreSQL with Babelfish supports password authentication. Passwords are stored in encrypted form on disk. For more information about authentication on an Aurora PostgreSQL cluster, see Security with Amazon Aurora PostgreSQL (p. 1228).

You might be prompted for credentials each time you connect to Babelfish. Any user migrated to or created on Aurora PostgreSQL can use the same credentials on both the SQL Server port and the PostgreSQL port. Babelfish doesn’t enforce password policies, but we recommend you do the following:

- Require a complex password that is at least eight characters long.
- Enforce a password expiration policy.

To review a complete list of database users, use the command `SELECT * FROM pg_user;`. 
Configuring a client to connect to the DB cluster

To see how to connect a client to a DB cluster that supports Babelfish, see the code examples following.

Example Using C# code to connect to a DB cluster

```csharp
string dataSource = 'babelfishServer_11_24';

//Create connection
cConnectionString = "Data Source=+ dataSource
    +";Initial Catalog=your-DB-name
    +";User ID=user-id;Password=password"
SqlConnection cnn = new SqlConnection(connectionString);
cnn.Open();
```

Example Using generic JDBC API classes and interfaces to connect to a DB cluster

```java
String dbServer =
    "database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com";
String connectionUrl = "jdbc:sqlserver://" + dbServer + ":1433;" +
    "databaseName=your-DB-name;user=user-id;password=password"

// Load the SQL Server JDBC driver and establish the connection.
System.out.print("Connecting Babelfish Server ... ");
Connection cnn = DriverManager.getConnection(connectionUrl);
```

Example Using SQL Server-specific JDBC classes and interfaces to connect to a DB cluster

```java
// Create datasource.
SQLServerDataSource ds = new SQLServerDataSource();
ds.setUser("user-id");
ds.setPassword("password");
String babelfishServer =
    "database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com"

ds.setServerName(babelfishServer);
ds.setPortNumber(1433);
ds.setDatabaseName("your-DB-name");

Connection con = ds.getConnection();
```
Using a SQL Server client to connect to your DB cluster

You can use a SQL Server client to connect with Babelfish on the TDS port.

Using sqlcmd to connect to the DB cluster

You can connect to and interact with an Aurora PostgreSQL DB cluster that supports Babelfish by using the SQL Server sqlcmd command line client. Use the following command to connect.

```
sqlcmd -S endpoint,port -U login-id -P password -d your-DB-name
```

The options are as follows:

- `-S` is the endpoint and (optional) TDS port of the DB cluster.
- `-U` is the login name of the user.
- `-P` is the password associated with the user.
- `-d` is the name of your Babelfish database.

After connecting, you can use many of the same commands that you use with SQL Server. For some examples, see Querying a database for object information (p. 1267).

To review a list of exceptions, see Differences between Aurora PostgreSQL with Babelfish and SQL Server (p. 1271).

Using SSMS to connect to the DB cluster

In the following procedure, you connect to your Aurora PostgreSQL database by using Microsoft SQL Server Management Studio (SSMS). You can use the SSMS query editor to connect to a Babelfish database.

You can't currently connect using the SSMS Object Explorer.

To connect to your Babelfish database with SSMS

1. Start SSMS.
2. Open the Connect to Server dialog box by doing one of the following:
   a. Choose New Query.
   b. If the Query Editor is open, choose Query, Connection, Connect.
3. Provide the following information for your database:
   a. For Server type, choose Database Engine.
   b. For Server name, enter the DNS name. For example, your server name should look similar to the following.

   `cluster-name.cluster-123abc456def.us-east-1-rds.amazonaws.com,1433`

   c. For Authentication, choose SQL Server Authentication.
   d. For Login, enter the user name that you chose when you created your database.
   e. For Password, enter the password that you chose when you created your database.
4. (Optional) Choose **Options**, and then choose the **Connection Properties** tab.
5. (Optional) For **Connect to database**, specify the name of the migrated SQL Server database to connect to, and choose **Connect**.

   If a message appears indicating that SSMS can't apply connection strings, choose **OK**.

   If you are having trouble connecting, see **Troubleshooting connections to your SQL Server DB instance** in the *Amazon RDS User Guide*. 

Using a PostgreSQL client to connect to your DB cluster

You can use a PostgreSQL client to connect to Babelfish on the PostgreSQL port.

Using psql to connect to the DB cluster

You can query an Aurora PostgreSQL DB cluster that supports Babelfish with the `psql` command line client. When connecting, use the PostgreSQL port. Use the following command to connect to Babelfish with the psql client:

```
psql "host=hostName port=portNumber dbname=babelfish_db user=userName"
```

The parameters are as follows:

- **host** – The host name of the DB cluster (cluster endpoint) that you want to access
- **port** – The PostgreSQL port number used to connect to your DB instance
- **dbname** – `babelfish_db`
- **user** – The database user account that you want to access
- **password** – The password of the database user

When you run a SQL command on the psql client, you end the command with a semicolon. For example, the following SQL command queries the `pg_tables` system view to return information about each table in the database.

```
SELECT * FROM pg_tables;
```

The psql client also has a set of built-in metacommands. A metacommand is a shortcut that adjusts formatting or provides a shortcut that returns meta-data in an easy-to-use format. For example, the following metacommand returns similar information to the previous SQL command:

```
\d
```

Metacommands don’t need to be terminated with a semicolon (`;`).

To exit the psql client, enter `\q`.

For more information about using the psql client to query an Aurora PostgreSQL cluster, see the PostgreSQL documentation.

Using pgAdmin to connect to the DB cluster

You can use the pgAdmin client to access your data in native PostgreSQL dialect.

To connect to the cluster with the pgAdmin client

1. Download and install the pgAdmin client from the pgAdmin website.
2. Open the client and authenticate with pgAdmin.
3. Open the context (right-click) menu for Servers, and then choose Create, Server.
4. Enter information in the **Create - Server** dialog box.

On the **Connection** tab, add the Aurora PostgreSQL cluster address for **Host** and the PostgreSQL port number (by default, 5432) for **Port**. Provide authentication details, and choose **Save**.

![Create - Server dialog box](image)
After connecting, you can use pgAdmin functionality to monitor and manage your Aurora PostgreSQL cluster on the PostgreSQL port.

For more details about using pgAdmin, visit the pgAdmin web site.

### Querying a database for object information

To return information about database objects that are stored in your Aurora PostgreSQL cluster, you can query many of the same system views that you use on SQL Server. You can access these views from either the TDS port or the PostgreSQL port.

For example, to find a list of schemas in your migrated database on the T-SQL port, connect to the TDS port with `sqlcmd`, and use the following command.

```
SELECT * FROM sys.schemas
```

If you migrate a single-db or multi-db database, Babelfish returns a list of schema names formatted in Babelfish style that includes both the SQL Server and PostgreSQL system schemas:

```
mydb_dbo
public
sys
master_dbo
temp_dbo
```

You get the same result set if you connect with a PostgreSQL client on the database port (by default, 5432). For example, querying the database with pgAdmin returns the following.
Use SQL Server and PostgreSQL views to return information about objects in your Aurora PostgreSQL cluster. A few of the SQL Server views implemented by Babelfish follow:

<table>
<thead>
<tr>
<th>View name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys.all_views</td>
<td>All views in all schemas</td>
</tr>
<tr>
<td>sys.schemas</td>
<td>All schemas</td>
</tr>
<tr>
<td>sys.databases</td>
<td>All databases in all schemas</td>
</tr>
<tr>
<td>sys.server_principals</td>
<td>All logins and roles</td>
</tr>
<tr>
<td>sys.all_objects</td>
<td>All objects in all schemas</td>
</tr>
<tr>
<td>sys.tables</td>
<td>All tables in a schema</td>
</tr>
<tr>
<td>sys.all_columns</td>
<td>All columns in all tables and views</td>
</tr>
<tr>
<td>sys.columns</td>
<td>All columns in user-defined tables and views</td>
</tr>
</tbody>
</table>

PostgreSQL implements system catalogs that are similar to the SQL Server object catalog views. For a complete list of system catalogs, see System Catalogs in the PostgreSQL documentation.

**Querying Babelfish to find Babelfish details**

You can query Babelfish to find details about the Babelfish version, the Aurora PostgreSQL version, and the compatible Microsoft SQL Server version.

Run these queries while connected to the TDS port.
To identify the Babelfish version, run the following query:

```
SELECT CAST(serverproperty('babelfishversion') AS VARCHAR)
```

The query returns results similar to the following:

```
1.0.0
```

To identify the version of the Aurora PostgreSQL DB cluster, run the following query:

```
SELECT aurora_version() AS aurora_version
```

The query returns results similar to the following:

```
13.4.0
```

To identify the compatible Microsoft SQL Server version, run the following query:

```
SELECT @@VERSION AS version
```

The query returns results similar to the following:

```
Babelfish for Aurora Postgres with SQL Server Compatibility - 12.0.2000.8
Sep 28 2021 14:37:26
Copyright (c) Amazon Web Services
PostgreSQL 13.4 on x86_64-pc-linux-gnu
```

In addition, the following query returns 1 when executed on Babelfish, and NULL when executed on Microsoft SQL Server:

```
SELECT CAST(serverproperty('babelfish') AS VARCHAR) AS runs_on_babelfish
```

To query `babelfish_db` the same way using the PostgreSQL port, connect to the `babelfish_db` and run the following.

```
\x
SELECT
  aurora_version() as aurora_version,
  version() as postgresql_version,
  sys.version() as Babelfish_compatibility,
  sys.SERVERPROPERTY('BabelfishVersion') as Babelfish_Version
FROM babelfish_db;
```

The query returns the following.

```
<table>
<thead>
<tr>
<th>aurora_version</th>
<th>postgresql_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>13.4.0</td>
<td>PostgreSQL 13.4 on aarch64-unknown-linux-gnu, compiled by aarch64-unknown-linux-gnu-gcc (GCC) 7.4.0, 64-bit</td>
</tr>
</tbody>
</table>
```

Differences between Aurora PostgreSQL with Babelfish and SQL Server

Babelfish provides support for T-SQL and SQL Server behavior by supporting SQL Server data types, syntax, and functions for Aurora PostgreSQL. This approach allows Aurora to support both Aurora PostgreSQL and SQL Server SQL dialects. Also, Babelfish supports the SQL Server wire-level protocol (TDS), allowing a SQL Server application to communicate natively with Aurora PostgreSQL. Doing this helps migrate database objects, stored procedures, and application code with fewer changes.

Although Babelfish doesn't offer complete support for T-SQL, you can use Aurora PostgreSQL SQL commands to perform many of the tasks normally handled by these commands. For example, if you regularly use a specific T-SQL command that isn't supported by Babelfish, connect to the Aurora PostgreSQL port and use a PostgreSQL SQL command instead. For more information, see SQL Commands in the PostgreSQL documentation.

Aurora PostgreSQL offers functionality to replace many commonly used SQL Server features. Some examples of SQL Server functionality that can be replaced by Aurora functionality follow:

- If you use SQL Server bulk copy, you can use the Aurora PostgreSQL COPY statement. COPY is optimized for fast data loading.
- If you use unsupported SQL Server GROUP BY clauses, you can use Aurora PostgreSQL GROUPING SETS.
- If you use SQL Server JSON support, you can use Aurora PostgreSQL JSON functions and operators.
- If you use SQL Server XML support, you can use Aurora PostgreSQL XML functions.
- If you use SQL Server full-text search, you can use Aurora PostgreSQL full-text search.
- If you use the SQL Server GEOGRAPHY data type, you can use PostGIS to provide support for geographical data and geographical data manipulation.

To help with cluster management in Aurora PostgreSQL, you can use its scalability, high-availability with failover support, and built-in replication. For more information about these capabilities, see Managing performance and scaling for Aurora DB clusters (p. 392), High availability for Amazon Aurora (p. 67), and Replication with Amazon Aurora (p. 69). You also have access to other AWS tools and utilities:

- Amazon CloudWatch is a monitoring and observability service that provides you with data and actionable insights.
- Amazon RDS Performance Insights is a database performance tuning and monitoring feature that helps you quickly assess the load on your database.
- Amazon RDS Multi-AZ deployments provide enhanced availability and durability for your database cluster.
- Amazon RDS global databases allow a single Amazon Aurora database to span multiple AWS Regions, offering scalable, cross-Region replication.
- Automatic software patching keeps your database up-to-date with the latest security and feature patches when they become available.
- Overview of Amazon RDS event notification (p. 646) Amazon RDS events notify you by email or SMS message of important database events, such as an automated failover.

T-SQL limitations and unsupported functionality

The following table lists unsupported or partially supported T-SQL syntax and unsupported functionality for Babelfish.
<table>
<thead>
<tr>
<th>Functionality or syntax</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD SIGNATURE</td>
<td>Functionality related to this command isn't supported.</td>
</tr>
<tr>
<td>CREATE AGGREGATE</td>
<td>Functionality related to this command isn't supported.</td>
</tr>
<tr>
<td>Aggregate functions (partially supported)</td>
<td>APPROX_COUNT_DISCTINCT, CHECKSUM_AGG, GROUPING_ID, ROWCOUNT_BIG, STDEV, STDEVP, VAR, and VARP aren't supported.</td>
</tr>
<tr>
<td>CREATE, ALTER, DROP APPLICATION ROLE</td>
<td>Functionality related to this syntax isn't supported.</td>
</tr>
<tr>
<td>CREATE, ALTER, DROP ASSEMBLY</td>
<td>Functionality related to this syntax isn't supported.</td>
</tr>
<tr>
<td>CREATE, ALTER, DROP ASYMMETRIC KEY</td>
<td>Functionality related to this syntax isn't supported.</td>
</tr>
<tr>
<td>Assembly modules and CLR routines</td>
<td>Functionality related to assembly modules and CLR routines isn't supported.</td>
</tr>
<tr>
<td>CREATE, ALTER, DROP AUTHORIZATION</td>
<td>Functionality related to these commands isn't supported.</td>
</tr>
<tr>
<td>CREATE, ALTER, DROP AVAILABILITY GROUP</td>
<td>Functionality related to these commands isn't supported.</td>
</tr>
<tr>
<td>BACKUP statement</td>
<td>Aurora PostgreSQL snapshots of a database are dissimilar to backup files created in SQL Server. Also, the granularity of when a backup and restore occurs might be different between SQL Server and Aurora PostgreSQL.</td>
</tr>
<tr>
<td>BEGIN DISTRIBUTED TRANSACTION</td>
<td>Functionality related to this syntax isn't supported.</td>
</tr>
<tr>
<td>CREATE, ALTER, DROP BROKER PRIORITY</td>
<td>Functionality related to these commands isn't supported.</td>
</tr>
<tr>
<td>Bulk copy in and out</td>
<td>Functionality related to bulk copy isn't supported.</td>
</tr>
<tr>
<td>BULK INSERT</td>
<td>This syntax isn't supported.</td>
</tr>
<tr>
<td>CERTENCODED function</td>
<td>This function isn't supported.</td>
</tr>
<tr>
<td>CERTID function</td>
<td>This function isn't supported.</td>
</tr>
<tr>
<td>CERTPRIVATEKEY function</td>
<td>This function isn't supported.</td>
</tr>
<tr>
<td>CERTPROPERTY function</td>
<td>This function isn't supported.</td>
</tr>
<tr>
<td>SQL keywords CLUSTERED and NONCLUSTERED for indexes and constraints</td>
<td>Babelfish accepts and ignores the CLUSTERED and NONCLUSTERED keywords.</td>
</tr>
<tr>
<td>Collation, index on type dependant on the ICU library</td>
<td>An index on a user-defined type that depends on the ICU collation library (the library used by Babelfish) isn't invalidated when the version of the library is changed. For more information about collations, see Babelfish collation support (p. 1294).</td>
</tr>
<tr>
<td>Functionality or syntax</td>
<td>Notes</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>COLLATIONPROPERTY function</td>
<td>Collation properties are only implemented for the supported Babelfish BBF collations. For more information about collations, see Babelfish collation support (p. 1294).</td>
</tr>
<tr>
<td>Column default</td>
<td>When creating a column default, the constraint name is ignored. To drop a column default, use the following syntax: ALTER TABLE...ALTER COLUMN..DROP DEFAULT...</td>
</tr>
<tr>
<td>Column name: IDENTITYCOL</td>
<td>This column name isn't supported.</td>
</tr>
<tr>
<td>Column name: $IDENTITY</td>
<td>This column name isn't supported.</td>
</tr>
<tr>
<td>Column name: $ROWGUID</td>
<td>This column name isn't supported.</td>
</tr>
<tr>
<td>COLUMNPROPERTY</td>
<td>This function isn't supported.</td>
</tr>
<tr>
<td>Blank column names with no column alias</td>
<td>The sqlcmd and psql utilities handle columns with blank names differently:</td>
</tr>
<tr>
<td></td>
<td>• SQL Server sqlcmd returns a blank column name.</td>
</tr>
<tr>
<td></td>
<td>• PostgreSQL psql returns a generated column name.</td>
</tr>
<tr>
<td>Column name case</td>
<td>Column names are stored as lowercase in the PostgreSQL catalogs and are returned to the client in lowercase if you run a SELECT statement. In general, all schema identifiers are stored in lowercase in the PostgreSQL catalogs. For more information, see SQL-SYNTAX-IDENTIFIERS in the PostgreSQL documentation.</td>
</tr>
<tr>
<td>Virtual computed columns (non-persistent)</td>
<td>Virtual computed columns are created as persistent.</td>
</tr>
<tr>
<td>Column attributes</td>
<td>ROWGUIDCOL, SPARSE, FILESTREAM, MASKED aren't supported.</td>
</tr>
<tr>
<td>CREATE, ALTER, DROP COLUMN ENCRYPTION KEY</td>
<td>Functionality related to these commands isn't supported.</td>
</tr>
<tr>
<td>COLUMN MASTER KEY</td>
<td>Functionality related to this object type isn't supported.</td>
</tr>
<tr>
<td>sysdatabases.cmptlevel</td>
<td>sysdatabases.cmptlevel are always NULL.</td>
</tr>
<tr>
<td>CREATE CONTRACT</td>
<td>All functionality related to this command isn't supported.</td>
</tr>
<tr>
<td>CREATE, ALTER, DROP, BACKUP CERTIFICATE</td>
<td>Functionality related to these commands isn't supported.</td>
</tr>
<tr>
<td>CONNECTIONPROPERTY function</td>
<td>The unsupported properties include local_net_address, client_net_address, and physical_net_transport.</td>
</tr>
<tr>
<td>Constraints</td>
<td>PostgreSQL doesn't support turning on and turning off individual constraints. The statement is ignored and a warning is raised.</td>
</tr>
<tr>
<td>Constraints created with DESC (descending) columns</td>
<td>Constraints are created with ASC (ascending) columns.</td>
</tr>
<tr>
<td>Constraints with IGNORE_DUP_KEY</td>
<td>Constraints are created without this property.</td>
</tr>
<tr>
<td>BEGIN CONVERSATION TIMER</td>
<td>This syntax isn't supported.</td>
</tr>
<tr>

Managing Babelfish error handling

Babelfish mimics SQL behavior in terms of control flow and transaction state whenever possible. If Babelfish encounters an error, it returns an error code similar to the SQL Server error code if possible. If Babelfish can't map the error, it returns a fixed error code (33557097). If an unmapped error is one of the following, the indicated result happens:

- If it's a compile time error, Babelfish rolls back the transaction.
- If it's a runtime error, Babelfish ends the batch and rolls back the transaction.
- If it's a protocol error between the client and server, the transaction isn't rolled back.

If an error code can't be mapped to an equivalent code and the code for a similar error is available, the error code is mapped to the alternative code. For example, the behaviors that cause SQL Server codes 8143 and 8144 are both mapped to 8143.

Errors that can't be mapped don't respect a TRY... CATCH construct.

You can use @@ERROR to return a SQL Server error code, or the @@PGERROR function to return a PostgreSQL error code. You can also use the fn_mapped_system_error_list function to return a list of mapped error codes. For information about PostgreSQL error codes, see the PostgreSQL website.

Babelfish escape hatches

To better deal with statements that might fail, Babelfish defines certain options called escape hatches. An escape hatch is an option that specifies Babelfish behavior when it encounters an unsupported feature or syntax.

You can use the sp_babelfish_configure stored procedure to control the settings of an escape hatch. Use the script to set the escape hatch to ignore or strict. If it's set to strict, Babelfish returns an error that you need to correct before continuing.

Include the server keyword to apply the changes to the current session and on a cluster level.

The usage is as follows:

- To list all escape hatches and their status, plus usage information, run sp_babelfish_configure.
- To list the named escape hatches and their values, for the current session or cluster-wide, run the command sp_babelfish_configure 'hatch_name' where hatch_name is the identifier of one or more escape hatches. hatch_name can use SQL wildcards, such as '%'.
- To set one or more escape hatches to the value specified, run sp_babelfish_configure ['hatch_name' [, 'strict'|'ignore' [, 'server']]]. To make the settings permanent on a cluster-wide level, include the server keyword. To set them for the current session only, don't use server.

The string identifying the hatch (or hatches) might contain SQL wildcards. For example, the following sets all syntax escape hatches to ignore for the Aurora PostgreSQL cluster.

```
EXECUTE sp_babelfish_configure '%', 'ignore', 'server'
```

The Babelfish predefined escape hatches are as follows.

<table>
<thead>
<tr>
<th>Escape hatch</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>escape_hatch_storage</td>
<td>Escape hatch on any storage option used in CREATE, ALTER DATABASE, TABLE, INDEX. This is ignored.</td>
<td>ignore</td>

Configuring a database for Babelfish

When you create a Babelfish for Aurora PostgreSQL DB cluster, you can use a parameter group in one of two ways. You can create a new parameter group that configures a cluster with Babelfish running. Or you can use a pre-existing Amazon Aurora parameter group.

To use an existing parameter group, edit the group and set the `babelfish_status` parameter to `on`. Specify any Babelfish options before creating your Aurora PostgreSQL cluster. For information about modifying your parameter group, see Working with DB parameter groups and DB cluster parameter groups (p. 335).

The following parameters control Babelfish preferences.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Default value</th>
<th>Values allowed</th>
<th>Description</th>
<th>Modifiable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds.babelfish_status</td>
<td>String</td>
<td>off</td>
<td>on, off, datatypesonly</td>
<td>Sets the state of Babelfish for Aurora PostgreSQL; functionality. When this parameter is set to datatypesonly, Babelfish is turned off but SQL Server data types are still available.</td>
<td>Yes</td>
</tr>
<tr>
<td>babelfishpg_tds.default_server_name</td>
<td>String</td>
<td>Microsoft SQL Server</td>
<td>null</td>
<td>The default name of the Babelfish server.</td>
<td>Yes</td>
</tr>
<tr>
<td>babelfishpg_tds.port</td>
<td>Integer</td>
<td>1433</td>
<td>1-65535</td>
<td>Sets the TCP port used for requests in SQL Server syntax.</td>
<td>Yes</td>
</tr>
<tr>
<td>babelfishpg_tds.tds_default_protocol_version</td>
<td>Integer</td>
<td>TDSv7.0, TDSv7.1, TDSv7.1.1, TDSv7.2, TDSv7.3A, TDSv7.3B, TDSv7.4, DEFAULT</td>
<td>Sets a default TDS protocol version for connecting clients.</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>babelfishpg_tds.tds_ssl_encrypt</td>
<td>Boolean</td>
<td>0</td>
<td>0/1</td>
<td>Turns encryption on (0) or off (1) for data traversing the TDS listener port. For detailed information about using SSL for client connections, see How Babelfish interprets SSL settings (p. 1293).</td>
<td>Yes</td>
</tr>
<tr>
<td>babelfishpg_tds.tds_ssl_max_protocol_version</td>

</tbody>
</table>
How Babelfish interprets SSL settings

When a client connects to port 1433, Babelfish compares the Secure Sockets Layer (SSL) setting sent during the client handshake to the Babelfish SSL parameter setting (tds_ssl_encrypt). Babelfish then determines if a connection is allowed. If a connection is allowed, encryption behavior is either enforced or not, depending on your parameter settings and the support for encryption offered by the client.

The table following shows how Babelfish behaves for each combination.

<table>
<thead>
<tr>
<th>Client SSL setting</th>
<th>Babelfish SSL setting</th>
<th>Connection allowed?</th>
<th>Value returned to client</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENCRYPT_OFF</td>
<td>tds_ssl_encrypt=false</td>
<td>Allowed, the login packet is encrypted</td>
<td>ENCRYPT_OFF</td>
</tr>
<tr>
<td>ENCRYPT_OFF</td>
<td>tds_ssl_encrypt=true</td>
<td>Allowed, the entire connection is encrypted</td>
<td>ENCRYPT_REQ</td>
</tr>
<tr>
<td>ENCRYPT_ON</td>
<td>tds_ssl_encrypt=false</td>
<td>Allowed, the entire connection is encrypted</td>
<td>ENCRYPT_ON</td>
</tr>
<tr>
<td>ENCRYPT_ON</td>

</tr>
</tbody>
</table>
Babelfish collation support

A *collation* specifies the sort order and presentation format of data. Babelfish maps SQL Server collations to comparable collations provided by Babelfish. Babelfish predefines Unicode collations with culturally sensitive string comparisons and sort orders. Babelfish also provides a way to translate the collations in your SQL Server DB to the closest-matching Babelfish collation. Locale-specific collations are provided for different languages and regions.

Some collations specify a code page that corresponds to a client-side encoding. Babelfish automatically translates from the server encoding to the client encoding depending on the collation of each output column.

Babelfish uses version 153.80 of the ICU collation library. For detailed information about PostgreSQL collation behavior, see the PostgreSQL documentation.

Babelfish supports deterministic and nondeterministic collations:

- A **deterministic collation** considers two characters as equal if they have the exact same byte sequence. A deterministic collation evaluates \( x \) and \( X \) as not equal. Collations that are deterministic are case-sensitive (CS) and accent-sensitive (AS).
- A **nondeterministic collation** doesn't require an identical match. A nondeterministic collation evaluates \( x \) and \( X \) as equal. Nondeterministic collations are case-insensitive (CI) and accent-insensitive (AI).

Babelfish and SQL Server follow a naming convention for collations that describe the collation attributes, as shown in the table following.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AI</td>
<td>Accent-insensitive.</td>
</tr>
<tr>
<td>AS</td>
<td>Accent-sensitive.</td>
</tr>
<tr>
<td>BIN2</td>
<td>BIN2 requests data to be sorted in code point order. Unicode code point order is the same character order for UTF-8, UTF-16, and UCS-2 encodings. Code point order is a fast deterministic collation.</td>
</tr>
<tr>
<td>CI</td>
<td>Case-insensitive.</td>
</tr>
<tr>
<td>CS</td>
<td>Case-sensitive.</td>
</tr>
<tr>
<td>PREF</td>
<td>To sort uppercase letters before lowercase letters, use a PREF collation. If comparison is case-insensitive, the uppercase version of a letter sorts before the lowercase version, if there is no other distinction. The ICU library supports uppercase preference with <code>colCaseFirst=upper</code>, but not for CI_AS collations. PREF can be applied only to CS_AS deterministic collations.</td>
</tr>
</tbody>
</table>

PostgreSQL doesn't support the LIKE clause on nondeterministic collations, but Babelfish supports it for CI_AS collations. Babelfish doesn't support the LIKE clause on AI collations. Pattern matching operations on nondeterministic collations also aren't supported.

To establish Babelfish collation behavior, set the following parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default_locale</td>
<td>The <code>default_locale</code> parameter is used in combination with the collation attributes in the table preceding to customize</td>
</tr>
</tbody>
</table>
Babelfish collation support

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The default locale applies to all Babelfish collations that start with the letters BBF, and to all SQL Server collations that are mapped to Babelfish collations. You can change this parameter after initial Babelfish database creation, but it doesn't affect the locale of existing collations.</td>
</tr>
<tr>
<td>server_collation_name</td>
<td>The collation used as the default collation at both the server level and the database level. The default value is <code>sql_latin1_general_cp1_ci_as</code>. The <code>server_collation_name</code> has to be a <code>CI_AS</code> collation because in T-SQL, the server collation determines how identifiers are compared.</td>
</tr>
<tr>
<td></td>
<td>You can choose from the collations in the table that follows for the <code>Collation name</code> field when you create your Aurora PostgreSQL cluster for use with Babelfish. Don't modify the <code>server_collation_name</code> after the Babelfish database is created.</td>
</tr>
</tbody>
</table>

Use the following collations as a server collation or an object collation.

<table>
<thead>
<tr>
<th>Collation ID</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>BBF_Unicode_General_CI_AS</td>
<td>Supports case-insensitive comparison and the LIKE operator.</td>
</tr>
<tr>
<td>BBF_Unicode_CP1_CI_AS</td>
<td>Non-deterministic collation also known as CP1252.</td>
</tr>
<tr>
<td>BBF_Unicode_CP1250_CI_AS</td>
<td>Non-deterministic collation used to represent texts in Central European and Eastern European languages that use Latin script.</td>
</tr>
<tr>
<td>BBF_Unicode_CP1251_CI_AS</td>
<td>Non-deterministic collation for languages that use the Cyrillic script.</td>
</tr>
<tr>
<td>BBF_Unicode_CP1253_CI_AS</td>
<td>Non-deterministic collation used to represent modern Greek.</td>
</tr>
<tr>
<td>BBF_Unicode_CP1254_CI_AS</td>
<td>Non-deterministic collation that supports Turkish.</td>
</tr>
<tr>
<td>BBF_Unicode_CP1255_CI_AS</td>
<td>Non-deterministic collation that supports Hebrew.</td>
</tr>
<tr>
<td>BBF_Unicode_CP1256_CI_AS</td>
<td>Non-deterministic collation used to write languages that use Arabic script.</td>
</tr>
<tr>
<td>BBF_Unicode_CP1257_CI_AS</td>
<td>Non-deterministic collation used to support Estonian, Latvian, and Lithuanian languages.</td>
</tr>
<tr>
<td>BBF_Unicode_CP1258_CI_AS</td>
<td>Non-deterministic collation used to write Vietnamese characters.</td>
</tr>
<tr>
<td>BBF_Unicode_CP874_CI_AS</td>
<td>Non-deterministic collation used to write Thai characters.</td>

<td>Chinese</td>
<td>Chinese_CS_AS</td>
<td>Chinese_CI_AS, Chinese_CI_AI</td>
</tr>
<tr>
<td>Cyrillic_General</td>
<td>Cyrillic_General_CS_AS</td>
<td>Cyrillic_General_CI_AS, Cyrillic_General_CI_AI</td>
</tr>
<tr>
<td>Estonian</td>
<td>Estonian_CS_AS</td>
<td>Estonian_CI_AS, Estonian_CI_AI</td>
</tr>
<tr>
<td>Finnish_Swedish</td>
<td>Finnish_Swedish_CS_AS</td>
<td>Finnish_Swedish_CI_AS, Finnish_Swedish_CI_AI</td>
</tr>
<tr>
<td>French</td>
<td>French_CS_AS</td>
<td>French_CI_AS, French_CI_AI</td>
</tr>
<tr>
<td>Greek</td>
<td>Greek_CS_AS</td>
<td>Greek_CI_AS, Greek_CI_AI</td>
</tr>
<tr>
<td>Hebrew</td>
<td>Hebrew_CS_AS</td>
<td>Hebrew_CI_AS, Hebrew_CI_AI</td>
</tr>
</tbody>
</table>
Managing collations

The ICU library provides collation version tracking to ensure that indexes that depend on collations can be reindexed when a new version of ICU becomes available. You can use the following query to identify all collations in the current database that need to be refreshed and the objects that depend on them.

```
SELECT pg_describe_object(refclascid, refobjid, refobjsubid) AS "Collation",
       pg_describe_object(classid, objid, objsubid) AS "Object" FROM pg_depend d JOIN
       pg_collation c ON refclascid = 'pg_collation'::regclass AND refobjid = c.oid WHERE
       c.collversion <> pg_collation_actual_version(c.oid) ORDER BY 1, 2;
```

Predefined collations are stored in the `sys.fn_helpcollations` table. You can use the following command to display information about a collation (such as its lcid, style, and collate flags). To retrieve the list, connect a psql client to the Aurora PostgreSQL port (by default, 5432) and enter the following.

```
postgres=# set search_path = public, pg_temp, sys;
SET
postgres=# \dO

Connect to the T-SQL port (by default 1433) and enter the following.

```
SELECT * FROM fn_helpcollation()
```

Collation limitations and behaviors

Babelfish uses the ICU library for collation support. The following section lists some of the known limitations and behavior variations of Babelfish collations:

- **Unicode sorting rules**

  SQL Server SQL collations sort Unicode-encoded data (nchar and nvarchar) one way, but data that isn’t Unicode-encoded (char and varchar) a different way. Babelfish databases are always UTF-8 encoded and always apply Unicode sorting rules consistently, regardless of data type. Thus, the sort order is the same for char or varchar as it is for nchar or nvarchar.

### Dialects

<table>
<thead>
<tr>
<th>Dialect</th>
<th>Deterministic options</th>
<th>Nondeterministic options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Korean_Wamsung</td>
<td>Korean_Wamsung_CS_AS</td>
<td>Korean_Wamsung_CI_AS, Korean_Wamsung_CI_AI</td>
</tr>
<tr>
<td>Modern_Spanish</td>
<td>Modern_Spanish_CS_AS</td>
<td>Modern_Spanish_CI_AS, Modern_Spanish_CI_AI</td>
</tr>
<tr>
<td>Mongolian</td>
<td>Mongolian_CS_AS</td>
<td>Mongolian_CI_AS, Mongolian_CI_AI</td>
</tr>
<tr>
<td>Polish</td>
<td>Polish_CS_AS</td>
<td>Polish_CI_AS, Polish_CI_AI</td>
</tr>
<tr>
<td>Thai</td>
<td>Thai_CS_AS</td>
<td>Thai_CI_AS, Thai_CI_AI</td>
</tr>
<tr>
<td>Traditional_Spanish</td>
<td>Traditional_Spanish_CS_AS</td>
<td>Traditional_Spanish_CI_AS, Traditional_Spanish_CI_AI</td>
</tr>
<tr>
<td>Turkish</td>
<td>Turkish_CS_AS</td>
<td>Turkish_CI_AS, Turkish_CI_AI</td>
</tr>
<tr>
<td>Ukranian</td>
<td>Ukranian_CS_AS</td>
<td>Ukranian_CI_AS, Ukranian_CI_AI</td>
</tr>
<tr>
<td>Vietnamese</td>
<td>Vietnamese_CS_AS</td>
<td>Vietnamese_CI_AS, Vietnamese_CI_AI</td>
</tr>
</tbody>
</table>
• **Secondary-equal collations**

The default ICU Unicode secondary-equal (CI_AS) collation sorts punctuation marks and other nonalphanumeric characters before numeric characters, and numeric characters before alphabetic characters. However, the order of punctuation and other special characters is different.

• **Tertiary collations**

SQL collations, such as `SQL_Latin1_General_Pref_CP1_CI_AS`, support the `TERTIARY_WEIGHTS` function and the ability to sort strings that compare equally in a CI_AS collation to be sorted uppercase first: `ABC`, `AbC`, `Abc`, `abc`, `ABC`, `abc`, and finally `abc`. Thus, the `DENSE_RANK OVER (ORDER BY column)` analytic function assesses these strings as having the same rank but orders them uppercase first within a partition.

You can get a similar result with Babelfish by adding a `COLLATE` clause to the `ORDER BY` clause that specifies a tertiary CS_AS collation that specifies `@colCaseFirst=upper`. However, the `colCaseFirst` modifier applies only to strings that are tertiary-equal (rather than secondary-equal like a CI_AS collation). Thus, you can’t emulate tertiary SQL collations using a single ICU collation.

As a workaround, we recommend that you modify applications that use the `SQL_Latin1_General_Pref_CP1_CI_AS` collation to use the `BBF_SQL_Latin1_General_CP1_CI_AS` collation first. Then add `COLLATE BBF_SQL_Latin1_General_Pref_CP1_CS_AS` to any `ORDER BY` clause for this column.

• **PostgreSQL** is built with a specific version of ICU and can match at most one version of a collation. Variations across versions are unavoidable, as are minor variations across time as languages evolve.

• **Character expansion**

A character expansion treats a single character as equal to a sequence of characters at the primary level. SQL Server’s default CI_AS collation supports character expansion; ICU collations support character expansion only for accent-insensitive collations.

When character expansion is required, then use a AI collation for comparisons. However, such collations aren’t currently supported by the LIKE operator.

• **char and varchar encoding**

When collations that begin with SQL are used for char or varchar data types, the sort order for characters preceding ASCII 127 is determined by the specific code page for that SQL collation. For SQL collations, strings declared as char or varchar might sort differently than strings declared as nchar or nvarchar.

PostgreSQL encodes all strings with the database encoding so converts all characters to UTF-8 and sorts using Unicode rules.

Because SQL collations sort nchar and nvarchar data types using Unicode rules, Babelfish encodes all strings on the server using UTF-8. Babelfish sorts nchar and nvarchar strings the same way it sorts char and varchar strings, using Unicode rules.

• **Supplementary character**

The SQL Server functions `NCHAR`, `UNICODE`, and `LEN` support characters for code-points outside the Unicode Basic Multilingual Plane (BMP). In contrast, non-SC collations use surrogate pair characters to handle supplementary characters. For Unicode data types, SQL Server can represent up to 65,535 characters using UCS-2, or the full Unicode range (1,114,111 characters) if supplementary characters are used.

• **Kana-sensitive**

When Japanese Kana characters Hiragana and Katakana are treated differently, the collation is called Kana-sensitive (KS). ICU supports the Japanese collation standard JIS X 4061. The now deprecated `colhiraganaQ [on | off]` locale modifier might provide the same functionality as
KS collations. However, KS collations of the same name as SQL Server aren't currently supported by Babelfish.

- **Width-Sensitive**

  When a single-byte character (half-width) and the same character represented as a double-byte character (full-width) are treated differently, the collation is called *width-sensitive (WS)*. WS collations with the same name as SQL Server aren't currently supported by Babelfish.

- **Variation-Selector Sensitivity**

  Variation-Selector Sensitivity (VSS) collations distinguish between ideographic variation selectors in Japanese collations `Japanese_Bushu_Kakusu_140` and `Japanese_XJIS_140`. A variation sequence is made up of a base character plus an additional variation selector. If you don't select the `VSS` option, the variation selector isn't considered in the comparison.

  VSS collations aren't currently supported by Babelfish.

- **BIN and BIN2**

  A BIN2 collation sorts characters according to code point order. The byte-by-byte binary order of UTF-8 preserves Unicode code point order, so this is also likely to be the best-performing collation. If Unicode code point order works for an application, consider using a BIN2 collation. However, using a BIN2 collation can result in data being displayed on the client in an order that is culturally unexpected. New mappings to lowercase characters are added to Unicode as time progresses, so the `LOWER` function might perform differently on different versions of ICU. This is a special case of the more general collation versioning problem rather than as something specific to the BIN2 collation.

  Babelfish provides the `BBF_Latin1_General_BIN2` collation with the Babelfish distribution to collate in Unicode code point order. In a BIN collation only the first character is sorted as a wchar. Remaining characters are sorted byte-by-byte, effectively in code point order according to its encoding. This approach doesn't follow Unicode collation rules and isn't supported by Babelfish.
Babelfish troubleshooting

Common causes of connection failures to a new Aurora DB cluster with Babelfish include the following:

- **Security group doesn't allow access** – If you're having trouble connecting to a Babelfish, make sure that you added your IP address to the default Amazon EC2 security group. You can use https://checkip.amazonaws.com/ to determine your IP address and then add it to your in-bound rule for the TDS port and the PostgreSQL port. For more information, see Add rules to a security group in the Amazon EC2 User Guide.

For more information about troubleshooting Aurora connection issues, see Can't connect to Amazon RDS DB instance (p. 1735).
Turning off Babelfish

When you no longer need Babelfish, you can turn off Babelfish functionality.

Be aware of some considerations:

- In some cases, you might turn off Babelfish before completing a migration to Aurora PostgreSQL. If you do and your DDL depends on SQL Server data types or you use any T-SQL functionality in your code, your code fails.
- If after provisioning a Babelfish instance you turn off the Babelfish extension, you can't provision that same database again on the same cluster.

To turn off Babelfish, modify your parameter group, setting `rds.babelfish_status` to OFF. You can continue to use your SQL Server data types with Babelfish off, by setting `rds.babelfish_status` to `datatypeonly`.

If you turn off Babelfish in parameter group, all clusters that use that parameter group lose Babelfish functionality.

For more information about modifying parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 335).
Managing Amazon Aurora PostgreSQL

The following sections discuss managing performance and scaling for an Amazon Aurora PostgreSQL DB cluster. It also includes other maintenance tasks.

Topics
- Scaling Aurora PostgreSQL DB instances (p. 1302)
- Maximum connections to an Aurora PostgreSQL DB instance (p. 1302)
- Temporary storage limits for Aurora PostgreSQL (p. 1303)
- Testing Amazon Aurora PostgreSQL by using fault injection queries (p. 1305)
- Displaying volume status for an Aurora PostgreSQL DB cluster (p. 1308)
- Specifying the RAM disk for the stats_temp_directory (p. 1309)
- Scheduling maintenance with the PostgreSQL pg_cron extension (p. 1311)

Scaling Aurora PostgreSQL DB instances

You can scale Aurora PostgreSQL DB instances in two ways, instance scaling and read scaling. For more information about read scaling, see Read scaling (p. 396).

You can scale your Aurora PostgreSQL DB cluster by modifying the DB instance class for each DB instance in the DB cluster. Aurora PostgreSQL supports several DB instance classes optimized for Aurora. Don't use db.t2 or db.t3 instance classes for larger Aurora clusters of size greater than 40 terabytes (TB). For detailed specifications of the DB instance classes supported by Aurora PostgreSQL, see Supported DB engines for DB instance classes (p. 53).

Maximum connections to an Aurora PostgreSQL DB instance

The maximum number of connections allowed to an Aurora PostgreSQL DB instance is determined by the `max_connections` parameter in the instance-level parameter group for the DB instance. By default, this value is set to the following equation:

\[ \text{LEAST}\left(\frac{\text{DBInstanceClassMemory}}{9531392},5000\right) \]

Setting the `max_connections` parameter to this equation makes sure that the number of allowed connection scales well with the size of the instance. For example, suppose your DB instance class is `db.r5.large`, which has 16 gibibytes (GiB) of memory. Then the maximum connections allowed is around 1802, as shown in the following equation:

\[ \text{LEAST}\left(\frac{16*1073741824}{9531392},5000\right) = 1802 \]

**Note**

The `DBInstanceClassMemory` value represents the memory capacity, in bytes, available for the DB instance. It's a number that Aurora computes internally and isn't directly available for you to query. Aurora reserves some memory in each DB instance for the Aurora management components. This adjustment to the available memory produces a lower `max_connections` value than if the formula used the full memory for the associated DB instance class. You can tune the maximum number of connections to support your workload.

The following table lists the resulting default value of `max_connections` for each DB instance class available to Aurora PostgreSQL. You can increase the maximum number of connections to your Aurora PostgreSQL DB instance by scaling the instance up to a DB instance class with more memory, or by setting a larger value for the `max_connections` parameter, up to 262,143.
## Temporary storage limits for Aurora PostgreSQL

Aurora PostgreSQL stores tables and indexes in the Aurora storage subsystem. Aurora PostgreSQL uses separate temporary storage for non-persistent temporary files. This includes files that are used for such purposes as:

<table>
<thead>
<tr>
<th>Instance class</th>
<th>max_connections default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.r6g.16xlarge</td>
<td>5000</td>
</tr>
<tr>
<td>db.r6g.12xlarge</td>
<td>5000</td>
</tr>
<tr>
<td>db.r6g.8xlarge</td>
<td>5000</td>
</tr>
<tr>
<td>db.r6g.4xlarge</td>
<td>5000</td>
</tr>
<tr>
<td>db.r6g.2xlarge</td>
<td>5000</td>
</tr>
<tr>
<td>db.r6g.xlarge</td>
<td>3479</td>
</tr>
<tr>
<td>db.r6g.large</td>
<td>1722</td>

<tr>
<td>db.t3.medium</td>
<td>7.5</td>
</tr>
</tbody>
</table>

You can monitor the temporary storage available for a DB instance with the `FreeLocalStorage` CloudWatch metric, described in Amazon Aurora metrics (p. 628).
For some workloads, you can reduce the amount of temporary storage by allocating more memory to the processes that are performing the operation. To increase the memory available to an operation, increasing the values of the `work_mem` or `maintenance_work_mem` PostgreSQL parameters.

**Testing Amazon Aurora PostgreSQL by using fault injection queries**

You can test the fault tolerance of your Aurora PostgreSQL DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance. Fault injection queries enable you to schedule simulated tests of the following events:

**Topics**
- Testing an instance crash (p. 1305)
- Testing an Aurora Replica failure (p. 1306)
- Testing a disk failure (p. 1307)
- Testing disk congestion (p. 1307)

When a fault injection query specifies a crash, it forces a crash of the Aurora PostgreSQL DB instance. The other fault injection queries result in simulations of failure events, but don’t cause the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see Amazon Aurora connection management (p. 31).

**Note**
Fault injection queries for Aurora PostgreSQL are currently supported for the following versions:
- Version 2.4, which is compatible with PostgreSQL version 10.11.
- Version 3.2, which is compatible with PostgreSQL version 11.7.

**Testing an instance crash**

You can force a crash of an Aurora PostgreSQL instance by using the fault injection query function `aurora_inject_crash()`.

For this fault injection query, a failover does not occur. If you want to test a failover, then you can choose the `Failover` instance action for your DB cluster in the RDS console, or use the `failover-db-cluster` AWS CLI command or the `FailoverDBCluster` RDS API operation.

**Syntax**

```sql
SELECT aurora_inject_crash ('instance' | 'dispatcher' | 'node');
```

**Options**

This fault injection query takes one of the following crash types. The crash type is not case sensitive:

- `'instance'`
  
  A crash of the PostgreSQL-compatible database for the Amazon Aurora instance is simulated.
A crash of the dispatcher on the primary instance for the Aurora DB cluster is simulated. The dispatcher writes updates to the cluster volume for an Amazon Aurora DB cluster.

A crash of both the PostgreSQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated.

Testing an Aurora Replica failure

You can simulate the failure of an Aurora Replica by using the fault injection query function aurora_inject_replica_failure().

An Aurora Replica failure blocks replication to the Aurora Replica or all Aurora Replicas in the DB cluster by the specified percentage for the specified time interval. When the time interval completes, the affected Aurora Replicas are automatically synchronized with the primary instance.

### Syntax

```sql
SELECT aurora_inject_replica_failure(
    percentage_of_failure,
    time_interval,
    'replica_name'
);
```

### Options

This fault injection query takes the following parameters:

- **percentage_of_failure**
  
  The percentage of replication to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no replication is blocked. If you specify 100, then all replication is blocked.

- **time_interval**
  
  The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

  **Note**
  
  Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long an interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.

- **replica_name**
  
  The Aurora Replica in which to inject the failure simulation. Specify the name of an Aurora Replica to simulate a failure of the single Aurora Replica. Specify an empty string to simulate failures for all Aurora Replicas in the DB cluster.

To identify replica names, see the `server_id` column from the `aurora_replica_status()` function. For example:

```sql
postgres=> SELECT server_id FROM aurora_replica_status();
```
Testing a disk failure

You can simulate a disk failure for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_failure()`. During a disk failure simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as faulting. Requests to those segments are blocked for the duration of the simulation.

Syntax

```
SELECT aurora_inject_disk_failure(
    percentage_of_failure,
    index,
    is_disk,
    time_interval
);
```

Options

This fault injection query takes the following parameters:

- **percentage_of_failure**
  
  The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.

- **index**
  
  A specific logical block of data in which to simulate the failure event. If you exceed the range of available logical blocks or storage nodes data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see Displaying volume status for an Aurora PostgreSQL DB cluster (p. 1308).

- **is_disk**
  
  Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

- **time_interval**
  
  The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

Testing disk congestion

You can simulate a disk failure for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_congestion()`. During a disk congestion simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as congested. Requests to those segments are delayed between the specified minimum and maximum delay time for the duration of the simulation.

Syntax

```
SELECT aurora_inject_disk_congestion(
    percentage_of_failure,
    index,
    is_disk,
    time_interval,
    1307
);
```
Options

This fault injection query takes the following parameters:

percentage_of_failure

The percentage of the disk to mark as congested during the failure event. This is a double value between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.

index

A specific logical block of data or storage node to use to simulate the failure event.

If you exceed the range of available logical blocks or storage nodes of data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see Displaying volume status for an Aurora PostgreSQL DB cluster (p. 1308).

is_disk

Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

time_interval

The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

minimum, maximum

The minimum and maximum amount of congestion delay, in milliseconds. Valid values range from 0.0 to 100.0 milliseconds. Disk segments marked as congested are delayed for a random amount of time within the minimum and maximum range for the duration of the simulation. The maximum value must be greater than the minimum value.

Displaying volume status for an Aurora PostgreSQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called protection groups.

The data in each protection group is replicated across six physical storage devices, called storage nodes. These storage nodes are allocated across three Availability Zones (AZs) in the region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see Introducing the Aurora storage engine on the AWS Database Blog.

Use the `aurora_show_volume_status()` function to return the following server status variables:

- Disks — The total number of logical blocks of data for the DB cluster volume.
- Nodes — The total number of storage nodes for the DB cluster volume.

You can use the `aurora_show_volume_status()` function to help avoid an error when using the `aurora_inject_disk_failure()` fault injection function. The `aurora_inject_disk_failure()`
fault injection function simulates the failure of an entire storage node, or a single logical block of data within a storage node. In the function, you specify the index value of a specific logical block of data or storage node. However, the statement returns an error if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume. For more information about fault injection queries, see Testing Amazon Aurora PostgreSQL by using fault injection queries (p. 1305).

**Note**
The `aurora_show_volume_status()` function is available for Aurora PostgreSQL version 10.11. For more information about Aurora PostgreSQL versions, see Amazon Aurora PostgreSQL releases and engine versions (p. 1524).

**Syntax**

```sql
SELECT * FROM aurora_show_volume_status();
```

**Example**

```
customer_database=> SELECT * FROM aurora_show_volume_status();
disks | nodes
-------+-------
96 | 45
```

### Specifying the RAM disk for the stats_temp_directory

You can use the Aurora PostgreSQL parameter, `rds.pg_stat_ramdisk_size`, to specify the system memory allocated to a RAM disk for storing the PostgreSQL `stats_temp_directory`. The RAM disk parameter is available for all Aurora PostgreSQL versions.

Under certain workloads, setting this parameter can improve performance and decrease IO requirements. For more information about the `stats_temp_directory`, see the PostgreSQL documentation.

To enable a RAM disk for your `stats_temp_directory`, set the `rds.pg_stat_ramdisk_size` parameter to a non-zero value in the DB cluster parameter group used by your DB cluster. The parameter value is in MB. You must restart the DB cluster before the change takes effect. For information about setting parameters, see Working with DB parameter groups and DB cluster parameter groups (p. 335).

For example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```bash
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name db-cl-pg-ramdisk-testing \
  --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256, ApplyMethod=pending-reboot"
```

After you restart the DB cluster, run the following command to see the status of the `stats_temp_directory`:

```
postgres=>show stats_temp_directory;
```

The command should return the following:

```
stats_temp_directory
```
Specifying the RAM disk for the stats_temp_directory

```
--------------------------
/rdsdbramdisk/pg_stat_tmp
(1 row)
```
Scheduling maintenance with the PostgreSQL pg_cron extension

You can use the PostgreSQL pg_cron extension to schedule maintenance commands within a PostgreSQL database. For a complete description, see What is pg_cron? in the pg_cron documentation.

The pg_cron extension is supported on Aurora PostgreSQL engine version 12.6 and higher 12 versions, and all 13 versions.

Topics

- Enabling the pg_cron extension (p. 1311)
- Granting permissions to pg_cron (p. 1311)
- Scheduling pg_cron jobs (p. 1312)
- pg_cron reference (p. 1314)

Enabling the pg_cron extension

Enable the pg_cron extension as follows:

1. Modify the parameter group associated with your PostgreSQL DB instance and add pg_cron to the shared_preload_libraries parameter value. This change requires a PostgreSQL DB instance restart to take effect. For more information, see Modifying parameters in a DB parameter group (p. 343).

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has the rds_superuser permissions.

   ```sql
   CREATE EXTENSION pg_cron;
   ```

3. Either use the default settings, or schedule jobs to run in other databases within your PostgreSQL DB instance. The pg_cron scheduler is set in the default PostgreSQL database named postgres. The pg_cron objects are created in this postgres database and all scheduling actions run in this database.

To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than postgres (p. 1314).

Granting permissions to pg_cron

As the rds_superuser role, you can create the pg_cron extension and then grant permissions to other users. For other users to be able to schedule jobs, grant them permissions to objects in the cron schema.

**Important**

We recommend that you grant access to the cron schema sparingly.

To grant others permission to the cron schema, run the following command.

```sql
postgres=> GRANT USAGE ON SCHEMA cron TO other-user;
```

This permission provides other-user with access to the cron schema to schedule and unschedule cron jobs. However, for the cron jobs to run successfully, the user also needs permission to access the objects in the cron jobs. If the user doesn't have permission, the job fails and errors such as the
following appears in the postgresql.log. In this example, the user doesn't have permission to access the pgbench_accounts table.

```
2020-12-08 16:41:00 UTC::@:[30647]:ERROR: permission denied for table pgbench_accounts
2020-12-08 16:41:00 UTC::@:[30647]:STATEMENT: update pgbench_accounts set abalance = abalance + 1
2020-12-08 16:41:00 UTC::@:[27071]:LOG: background worker "pg_cron" (PID 30647) exited with exit code 1
```

Other messages in the cron.job_run_details table appear like the following.

```
postgres=> select jobid, username, status, return_message, start_time from cron.job_run_details where status = 'failed';
  jobid |  username  | status |                   return_message                   |
        +-----------------------------+--------+--------------------------------------------------|
        | unprivuser | failed | ERROR: permission denied for table pgbench_accounts |
  start_time
        +-----------------------------+--------+--------------------------------------------------|
        | 2020-12-08 16:41:00.036268+00 |          |                                                  |
        | 2020-12-08 16:40:00.050844+00 |          |                                                  |
        | 2020-12-08 16:42:00.175644+00 |          |                                                  |
        | 2020-12-08 16:43:00.069174+00 |          |                                                  |
        | 2020-12-08 16:44:00.059466+00 |          |                                                  |
(5 rows)
```

For more information, see The pg_cron tables (p. 1316).

### Scheduling pg_cron jobs

The following sections demonstrate scheduling pg_cron jobs to perform management tasks.

**Note**

When creating pg_cron jobs, make sure that the number of max_worker_processes is always greater than the number of cron.max_running_jobs. A pg_cron job will fail if it runs out of background worker processes. The default number of pg_cron jobs is 5; for more information, see The pg_cron parameters (p. 1314).

**Topics**

- Vacuuming a table (p. 1312)
- Purging the pg_cron history table (p. 1313)
- Disabling logging of pg_cron history (p. 1313)
- Scheduling a cron job for a database other than postgres (p. 1314)

**Vacuuming a table**

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

Following is an example of using the cron.schedule function to set up a job to use VACUUM FREEZE on a specific table every day at 22:00 (GMT).

```
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
```
After the preceding example runs, you can check the history in the `cron.job_run_details` table as follows.

```
postgres=> select * from cron.job_run_details;
jobid | runid | job_pid | database | username | command | status | return_message | start_time | end_time
-------+-------+---------+----------+----------+----------------------------------------+---------+----------------+------------+------------
 1 | 1 | 3395 | postgres | adminuser| vacuum freeze pgbench_accounts | succeeded | VACUUM | 2020-12-04 21:10:00.050386+00 | 2020-12-04 21:10:00.072028+00
(1 row)
```

Following is an example of viewing the history in the `cron.job_run_details` table to investigate why a job failed.

```
postgres=> select * from cron.job_run_details where status = 'failed';
jobid | runid | job_pid | database | username | command | status | return_message | start_time | end_time
-------+-------+---------+----------+----------+---------------------------------------+---------+----------------+------------+------------
 5 | 4 | 30339 | postgres | adminuser| vacuum freeze pgbench_account | failed | ERROR: relation "pgbench_account" does not exist | 2020-12-04 21:48:00.015145+00 | 2020-12-04 21:48:00.029567+00
(1 row)
```

For more information, see The pg_cron tables (p. 1316).

### Purging the pg_cron history table

The `cron.job_run_details` table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the `cron.schedule` function to schedule a job that runs every day at midnight to purge the `cron.job_run_details` table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```
SELECT cron.schedule('0 0 * * *', $$DELETE FROM cron.job_run_details
WHERE end_time < now() - interval '7 days'$$);
```

For more information, see The pg_cron tables (p. 1316).

### Disabling logging of pg_cron history

To completely disable writing anything to the `cron.job_run_details` table, modify the parameter group associated with the PostgreSQL DB instance and set the `cron.log_run` parameter to off. If you do this, the pg_cron extension no longer writes to the table and produces errors only in the `postgresql.log` file. For more information, see Modifying parameters in a DB parameter group (p. 343).
Use the following command to check the value of the `cron.log_run` parameter.

```
postgres=> SHOW cron.log_run;
```

For more information, see The pg_cron parameters (p. 1314).

**Scheduling a cron job for a database other than postgres**

The metadata for `pg_cron` is all held in the PostgreSQL default database named `postgres`. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the `cron.schedule` (p. 1315).

   ```
   postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum freeze test_table');
   ```

2. As a user with the `rds_superuser` role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

   ```
   postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
   ```

3. Verify by querying the `cron.job` table.

   ```
   postgres=> select * from cron.job;
   | jobid | schedule | command | nodename | nodeport | database | username | active |
   |-------+-----------+----------------------------------------+-----------+----------|
   |       | 29 03 * * * | vacuum freeze test_table | localhost | 8192 | database1 | adminuser | t |
   |       | t | database1 manual vacuum |
   | 1 | 59 23 * * * | vacuum freeze pgbench_accounts | localhost | 8192 | postgres | adminuser | t | manual vacuum |
   (2 rows)
   ```

**Note**

In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (`postgres`) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

**pg_cron reference**

You can use the following parameters, functions, and tables with the `pg_cron` extension. For more information, see What is pg_cron? in the pg_cron documentation.

**Topics**

- The `pg_cron` parameters (p. 1314)
- The `cron.schedule()` function (p. 1315)
- The `cron. unschedule()` function (p. 1316)
- The `pg_cron` tables (p. 1316)

**The pg_cron parameters**

Following is a list of parameters that control the `pg_cron` extension behavior.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.database_name</td>
<td>The database in which pg_cron metadata is kept.</td>
</tr>
<tr>
<td>cron.host</td>
<td>The hostname to connect to PostgreSQL. You can't modify this value.</td>
</tr>
<tr>
<td>cron.log_run</td>
<td>Log all the jobs that run into the job_run_details table. Values are on or off. For more information, see The pg_cron tables (p. 1316).</td>
</tr>
<tr>
<td>cron.log_statement</td>
<td>Log all cron statements before running them. Values are on or off.</td>
</tr>
<tr>
<td>cron.max_running_jobs</td>
<td>The maximum number of jobs that can run concurrently.</td>
</tr>
<tr>
<td>cron.use_background_workers</td>
<td>Use background workers instead of client sessions. You can't modify this value.</td>
</tr>
</tbody>
</table>

Use the following SQL command to display these parameters and their values.

```
pagres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%' ORDER BY name;
```

**The cron.schedule() function**

This function schedules a cron job. The job is initially scheduled in the default postgres database. The function returns a bigint value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than postgres (p. 1314).

The function has two syntax formats.

**Syntax**

```
cron.schedule (job_name, schedule, command
                        );
```

```
cron.schedule (schedule, command
                        );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the cron job.</td>
</tr>
<tr>
<td>schedule</td>
<td>Text indicating the schedule for the cron job. The format is the standard cron format.</td>
</tr>
<tr>
<td>command</td>
<td>Text of the command to run.</td>
</tr>
</tbody>
</table>
Examples

```
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');
schedule  
----------
 145   
(1 row)
```

```
postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
schedule  
----------
 146   
(1 row)
```

**The cron.unschedule() function**

This function deletes a cron job. You can either pass in the `job_name` or the `job_id`. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

**Syntax**

```
cron.unschedule (job_id);
cron.unschedule (job_name);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>job_id</code></td>
<td>A job identifier that was returned from the <code>cron.schedule</code> function when the cron job was scheduled.</td>
</tr>
<tr>
<td><code>job_name</code></td>
<td>The name of a cron job that was scheduled with the <code>cron.schedule</code> function.</td>
</tr>
</tbody>
</table>

**Examples**

```
postgres=> select cron.unschedule(108);
unschedule 
-----------
t    
(1 row)
```

```
postgres=> select cron.unschedule('test');
unschedule 
-----------
t    
(1 row)
```

**The pg_cron tables**

The following tables are used to schedule the cron jobs and record how the jobs completed.
### Table

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.job</td>
<td>Contains the metadata about each scheduled job. Most interactions with this</td>
</tr>
<tr>
<td></td>
<td>table should be done by using the <code>cron.schedule</code> and <code>cron.unschedule</code></td>
</tr>
<tr>
<td></td>
<td>functions.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>We don't recommend giving update or insert privileges directly to this</td>
</tr>
<tr>
<td></td>
<td>table. Doing so would allow the user to update the <code>username</code> column to</td>
</tr>
<tr>
<td></td>
<td>run as <code>rds-superuser</code>.</td>
</tr>
<tr>
<td>cron.job_run_details</td>
<td>Contains historic information about past scheduled jobs that ran. This is</td>
</tr>
<tr>
<td></td>
<td>useful to investigate the status, return messages, and start and end time</td>
</tr>
<tr>
<td></td>
<td>from the job that ran.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To prevent this table from growing indefinitely, purge it on a regular</td>
</tr>
<tr>
<td></td>
<td>basis. For an example, see Purging the pg_cron history table (p. 1313).</td>
</tr>
</tbody>
</table>

---

## Tuning with wait events for Aurora PostgreSQL

Wait events are an important tuning tool for Aurora PostgreSQL. If you can find out why sessions are waiting for resources and what they are doing, you are better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions.

**Important**

The wait events in this chapter are specific to Aurora PostgreSQL. Use the information in this chapter to tune only Amazon Aurora, not RDS for MySQL. Some wait events in this chapter have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently. For example, Amazon Aurora storage works differently from open source storage, so storage-related wait events indicate different resource conditions.

**Topics**

- Essential concepts for Aurora PostgreSQL tuning (p. 1318)
- Aurora PostgreSQL wait events (p. 1321)
- Client:ClientRead (p. 1322)
- Client:ClientWrite (p. 1325)
- CPU (p. 1326)
- IO:BufFileRead and IO:BufFileWrite (p. 1330)
- IO:DataFileRead (p. 1336)
- IO:XactSync (p. 1342)
- ipc:damrecordtxack (p. 1344)
- Lock:advisory (p. 1344)
- Lock:extend (p. 1346)
- Lock:Relation (p. 1348)
- Lock:transactionid (p. 1351)
Essential concepts for Aurora PostgreSQL tuning

Before you tune your Aurora PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of Aurora PostgreSQL. For a helpful architecture diagram, see the PostgreSQL wikibook.

Topics
- Aurora PostgreSQL wait events (p. 1318)
- Aurora PostgreSQL memory (p. 1318)
- Aurora PostgreSQL processes (p. 1320)

Aurora PostgreSQL wait events

A wait event indicates a resource for which a session is waiting. For example, the wait event `Client:ClientRead` occurs when Aurora PostgreSQL is waiting to receive data from the client. Typical resources that a session waits for include the following:

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

Aurora PostgreSQL memory

Aurora PostgreSQL memory is divided into shared and local.

Topics
Shared memory in Aurora PostgreSQL

Aurora PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

Topics
• Shared buffers (p. 1319)
• Write ahead log (WAL) buffers (p. 1319)

Shared buffers

The shared buffer pool is an Aurora PostgreSQL memory area that holds all pages that are or were being used by application connections. A page is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn’t in memory, and no more memory exists, Aurora PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The shared_buffers parameter determines how much memory the server dedicates to caching data.

Write ahead log (WAL) buffers

A write-ahead log (WAL) buffer holds transaction data that Aurora PostgreSQL later writes to persistent storage. Using the WAL mechanism, Aurora PostgreSQL can do the following:

• Recover data after a failure
• Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, Aurora PostgreSQL writes the changes to the WAL buffer. When the client issues a COMMIT, the WAL writer process writes transaction data to the WAL file.

The wal_level parameter determines how much information is written to the WAL.

Local memory in Aurora PostgreSQL

Every backend process allocates local memory for query processing.

Topics
• Work memory area (p. 1319)
• Maintenance work memory area (p. 1320)
• Temporary buffer area (p. 1320)

Work memory area

The work memory area holds temporary data for queries that performs sorts and hashes. For example, a query with an ORDER BY clause performs a sort. Queries use hash tables in hash joins and aggregations.
The `work_mem` parameter the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

**Maintenance work memory area**

The *maintenance work memory area* caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

**Temporary buffer area**

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session.

Before the first use of temporary tables within a session, you can change the `temp_buffers` value.

**Aurora PostgreSQL processes**

Aurora PostgreSQL uses multiple processes.

**Topics**
- Postmaster process (p. 1320)
- Backend processes (p. 1320)
- Background processes (p. 1320)

**Postmaster process**

The *postmaster process* is the first process started when you start Aurora PostgreSQL. The postmaster process has the following primary responsibilities:

- Fork and monitor background processes
- Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

**Backend processes**

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a postgres process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

**Background processes**

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

- WAL writer
Aurora PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows Aurora PostgreSQL to use the logs to recover the database after a failure.

- **Background writer**

  This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.

- **Autovacuum daemon**

  The daemon consists of the following:
  - The autovacuum launcher
  - The autovacuum worker processes

  When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:
  - Recover or reuse disk space occupied by updated or deleted rows
  - Update statistics used by the planner
  - Protect against loss of old data because of transaction ID wraparound

  The autovacuum feature automates the execution of VACUUM and ANALYZE commands. VACUUM has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. VACUUM FULL requires an exclusive lock on the table it is working on. Thus, it can't run in parallel with operations that access the same table. VACUUM creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

### Aurora PostgreSQL wait events

The following table lists the wait events for Aurora PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions. The following wait events are a subset of the list in Amazon Aurora PostgreSQL wait events (p. 1495).

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client:ClientRead (p. 1322)</td>
<td>This event occurs when Aurora PostgreSQL is waiting to receive data from the client.</td>
</tr>
<tr>
<td>Client:ClientWrite (p. 1325)</td>
<td>This event occurs when Aurora PostgreSQL is waiting to write data to the client.</td>
</tr>
<tr>
<td>CPU (p. 1326)</td>
<td>This event occurs when a thread is active in CPU or is waiting for CPU.</td>
</tr>
<tr>
<td>IO:BufFileRead and IO:BufFileWrite (p. 1330)</td>
<td>These events occur when Aurora PostgreSQL creates temporary files.</td>
</tr>
<tr>
<td>IO:DataFileRead (p. 1336)</td>
<td>This event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.</td>
</tr>
<tr>
<td>IO:XactSync (p. 1342)</td>
<td>This event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction.</td>
</tr>
</tbody>
</table>
### Wait event

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipc:damrecordtxack (p. 1344)</td>
<td>This event occurs when Aurora PostgreSQL in a session using database activity streams generates an activity stream event, then waits for that event to become durable.</td>
</tr>
<tr>
<td>Lock:advisory (p. 1344)</td>
<td>This event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.</td>
</tr>
<tr>
<td>Lock:extend (p. 1346)</td>
<td>This event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.</td>
</tr>
<tr>
<td>Lock:Relation (p. 1348)</td>
<td>This event occurs when a query is waiting to acquire a lock on a table or view that’s currently locked by another transaction.</td>
</tr>
<tr>
<td>Lock:transactionid (p. 1351)</td>
<td>This event occurs when a transaction is waiting for a row-level lock.</td>
</tr>
<tr>
<td>Lock:tuple (p. 1354)</td>
<td>This event occurs when a backend process is waiting to acquire a lock on a tuple.</td>
</tr>
<tr>
<td>lwlock:buffer_content (BufferContent) (p. 1356)</td>
<td>This event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing.</td>
</tr>
<tr>
<td>LWLock:buffer_mapping (p. 1358)</td>
<td>This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.</td>
</tr>
<tr>
<td>LWLock:BufferIO (p. 1359)</td>
<td>This event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page.</td>
</tr>
<tr>
<td>LWLock:lock_manager (p. 1361)</td>
<td>This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.</td>
</tr>
<tr>
<td>Timeout:PgSleep (p. 1364)</td>
<td>This event occurs when a server process has called the pg_sleep function and is waiting for the sleep timeout to expire.</td>
</tr>
</tbody>
</table>

### Client:ClientRead

The **Client:ClientRead** event occurs when Aurora PostgreSQL is waiting to receive data from the client.

**Topics**

- Supported engine versions (p. 1323)
- Context (p. 1323)
- Likely causes of increased waits (p. 1323)
- Actions (p. 1323)
Supported engine versions

This wait event information is supported for Aurora PostgreSQL version 10 and higher.

Context

An Aurora PostgreSQL DB cluster is waiting to receive data from the client. The Aurora PostgreSQL DB cluster must receive the data from the client before it can send more data to the client. The time that the cluster waits before receiving data from the client is a Client:ClientRead event.

Likely causes of increased waits

Common causes for the Client:ClientRead event to appear in top waits include the following:

Increased network latency

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for DB cluster to receive data from the client.

Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.

Excessive network round trips

A large number of network round trips between the Aurora PostgreSQL DB cluster and the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.

Large copy operation

During a copy operation, the data is transferred from the client's file system to the Aurora PostgreSQL DB cluster. Sending a large amount of data to the DB cluster can delay transmission of data from the client to the DB cluster.

Idle client connection

When a client connects to the Aurora PostgreSQL DB cluster in an idle in transaction state, the DB cluster might wait for the client to send more data or issue a command. A connection in this state can lead to an increase in Client:ClientRead events.

PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called pkt_buf, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the pkt_buf setting to 8,192. If the new setting doesn't decrease the number of Client:ClientRead events, we recommend increasing the pkt_buf setting to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Place the clients in the same Availability Zone and VPC subnet as the cluster (p. 1324)
- Scale your client (p. 1324)
- Use current generation instances (p. 1324)
- Increase network bandwidth (p. 1324)
• Monitor maximums for network performance (p. 1324)
• Monitor for transactions in the "idle in transaction" state (p. 1324)

Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster. Make sure that the clients are as geographically close to the DB cluster as possible.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the Amazon EC2 User Guide for Linux Instances.

For information about DB instance classes, see Aurora DB instance classes (p. 53). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place db. before the Amazon EC2 instance type name. For example, the r5.8xlarge Amazon EC2 instance is equivalent to the db.r5.8xlarge DB instance class.

Increase network bandwidth

Use NetworkReceiveThroughput and NetworkTransmitThroughput Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon Aurora metrics (p. 628).

Monitor maximums for network performance

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Linux Instances and Monitor network performance for your Amazon EC2 instance in the Amazon EC2 User Guide for Windows Instances.

Monitor for transactions in the "idle in transaction" state

Check whether you have an increasing number of idle in transaction connections. To do this, monitor the state column in the pg_stat_activity table. You might be able to identify the connection source by running a query similar to the following.

```
select client_addr, state, count(1) from pg_stat_activity
```
where state like 'idle in transaction%'
group by 1,2
order by 3 desc

Client:ClientWrite

The Client:ClientWrite event occurs when Aurora PostgreSQL is waiting to write data to the client.

Topics
- Supported engine versions (p. 1325)
- Context (p. 1325)
- Likely causes of increased waits (p. 1325)
- Actions (p. 1325)

Supported engine versions

This wait event information is supported for Aurora PostgreSQL version 10 and higher.

Context

A client process must read all of the data received from an Aurora PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a Client:ClientWrite event.

Reduced network throughput between the Aurora PostgreSQL DB cluster and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. CPU pressure is when the CPU is fully utilized and there are tasks waiting for CPU time. Network saturation is when the network between the database and client is carrying more data than it can handle.

Likely causes of increased waits

Common causes for the Client:ClientWrite event to appear in top waits include the following:

Increased network latency

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora PostgreSQL DB cluster.

Large volume of data sent to the client

The Aurora PostgreSQL DB cluster might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in Client:ClientWrite events.

Actions

We recommend different actions depending on the causes of your wait event.

Topics
- Place the clients in the same Availability Zone and VPC subnet as the cluster (p. 1326)
• Use current generation instances (p. 1326)
• Reduce the amount of data sent to the client (p. 1326)
• Scale your client (p. 1326)

Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster.

Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see Jumbo frames (9001 MTU) in the Amazon EC2 User Guide for Linux Instances.

For information about DB instance classes, see Aurora DB instance classes (p. 53). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place db. before the Amazon EC2 instance type name. For example, the r5.8xlarge Amazon EC2 instance is equivalent to the db.r5.8xlarge DB instance class.

Reduce the amount of data sent to the client

When possible, adjust your application to reduce the amount of data that the Aurora PostgreSQL DB cluster sends to the client. Making such adjustments relieves CPU and network contention on the client.

Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

Topics

• Supported engine versions (p. 1326)
• Context (p. 1326)
• Likely causes of increased waits (p. 1328)
• Actions (p. 1328)

Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

Context

The central processing unit (CPU) is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time spent running the query increases. CPU scheduling is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.
Topics

• How to tell when this wait occurs (p. 1327)
• DBLoadCPU metric (p. 1327)
• os.cpuUtilization metrics (p. 1327)
• Likely cause of CPU scheduling (p. 1327)

How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

• The `pg_stat_activity.state` column has the value `active`.
• The `wait_event_type` and `wait_event` columns in `pg_stat_activity` are both null.

To see the backend processes that are using or waiting on CPU, run the following query.

```sql
SELECT * FROM pg_stat_activity WHERE state = 'active' AND wait_event_type IS NULL AND wait_event IS NULL;
```

DBLoadCPU metric

The Performance Insights metric for CPU is `DBLoadCPU`. The value for `DBLoadCPU` can differ from the value for the Amazon CloudWatch metric `CPUUtilization`. The latter metric is collected from the HyperVisor for a database instance.

os.cpuUtilization metrics

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

• `os.cpuUtilization.nice.avg`
• `os.cpuUtilization.total.avg`
• `os.cpuUtilization.wait.avg`
• `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

 Likely cause of CPU scheduling

From an operating system perspective, the CPU is active when it isn't running the idle thread. The CPU is active while it performs a computation, but it's also active when it waits on memory I/O. This type of I/O dominates a typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

• The CloudWatch `CPUUtilization` metric is near 100 percent.
• The average load is greater than the number of vCPUs, indicating a heavy load. You can find the `loadAverageMinute` metric in the OS metrics section in Performance Insights.
Likely causes of increased waits

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

Topics
- Likely causes of sudden spikes (p. 1328)
- Likely causes of long-term high frequency (p. 1328)
- Corner cases (p. 1328)

Likely causes of sudden spikes

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a “connection storm.”
- Your application workload changed in any of the following ways:
  - New queries
  - An increase in the size of your dataset
  - Index maintenance or creation
  - New functions
  - New operators
  - An increase in parallel query execution
- Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

- Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
- Queries are performing suboptimally because they need a large number of buffers.

Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

- The CPU is swapping processes in and out.
- CPU context switching has increased.
- Aurora PostgreSQL code is missing wait events.

Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Topics
- Investigate whether the database is causing the CPU increase (p. 1329)
Investigate whether the database is causing the CPU increase

Examine the `os.cpuUtilization.nice.avg` metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

Determine whether the number of connections increased

Examine the `DatabaseConnections` metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

- The number of backend processes consuming CPU is less than the number of vCPUs.
  
  In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.

- The number of backend processes consuming CPU is greater than the number of vCPUs.
  
  In this case, consider the following options:
  
  - Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see Using Amazon RDS Proxy (p. 286).
  - Upgrade your instance size to get a higher number of vCPUs.
  - Redirect some read-only workloads to reader nodes, if applicable.

The connections didn't increase

Examine the `blks_hit` metrics in Performance Insights. Look for a correlation between an increase in `blks_hit` and CPU usage. The following scenarios are possible:

- CPU usage and `blks_hit` are correlated.
  
  In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:
  
  - Explain the plans manually and compare them to the expected execution plan.
  - Look for an increase in block hits per second and local block hits per second. In the Top SQL section of Performance Insights dashboard, choose Preferences.

- CPU usage and `blks_hit` aren't correlated.
  
  In this case, determine whether any of the following occurs:
  
  - The application is rapidly connecting to and disconnecting from the database.

    Diagnose this behavior by turning on log_connections and log_disconnections, then analyzing the PostgreSQL logs. Consider using the pgbadger log analyzer. For more information, see https://github.com/darold/pgbadger.

  - The OS is overloaded.

    In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights `os.cpuUtilization` metrics or the CloudWatch CPUUtilization metric. If the operating system is overloaded, look at Enhanced
Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.

- Top SQL statements are consuming too much CPU.

Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an EXPLAIN command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see http://explain.dalibo.com/.

**Respond to workload changes**

If your workload has changed, look for the following types of changes:

**New queries**

Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

**An increase in the size of the data set**

Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

**Index maintenance or creation**

Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

**New functions**

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

**New operators**

Check whether they perform as expected during the testing.

**An increase in running parallel queries**

Determine whether any of the following situations has occurred:

- The relations or indexes involved have suddenly grown in size so that they differ significantly from `min_parallel_table_scan_size` or `min_parallel_index_scan_size`.
- Recent changes have been made to `parallel_setup_cost` or `parallel_tuple_cost`.
- Recent changes have been made to `max_parallel_workers` or `max_parallel_workers_per_gather`.

**IO:BufFileRead and IO:BufFileWrite**

The `IO:BufFileRead` and `IO:BufFileWrite` events occur when Aurora PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called "spilling to disk."

**Topics**

- Supported engine versions (p. 1331)
- Context (p. 1331)
- Likely causes of increased waits (p. 1331)
- Actions (p. 1331)
Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

IO:BufFileRead and IO:BufFileWrite relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see Work memory area (p. 1319) and Maintenance work memory area (p. 1320).

The default value for work_mem is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set work_mem carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, Aurora PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a “chainsaw” pattern. This pattern can indicate that your database is creating small files constantly.

Likely causes of increased waits

In general, these wait events are caused by operations that consume more memory than the work_mem or maintenance_work_mem parameters allocate. To compensate, the operations write to temporary files. Common causes for the IO:BufFileRead and IO:BufFileWrite events include the following:

Queries that need more memory than exists in the work memory area

Queries with the following characteristics use the work memory area:

• Hash joins
• ORDER BY clause
• GROUP BY clause
• DISTINCT
• Window functions
• CREATE TABLE AS SELECT
• Materialized view refresh

Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:

• CREATE INDEX
• CLUSTER

Actions

We recommend different actions depending on the causes of your wait event.

Topics

• Identify the problem (p. 1332)
• Examine your join queries (p. 1332)
• Examine your ORDER BY and GROUP BY queries (p. 1333)
• Avoid using the DISTINCT operation (p. 1333)
• Consider using window functions instead of GROUP BY functions (p. 1334)
• Investigate materialized views and CTAS statements (p. 1334)
• Use pg_repack when you create indexes (p. 1334)
• Increase maintenance_work_mem when you cluster tables (p. 1335)
• Tune memory to prevent IO:BufFileRead and IO:BufFileWrite (p. 1335)

Identify the problem

Assume a situation in which Performance Insights isn't turned on and you suspect that IO:BufFileRead and IO:BufFileWrite are occurring more frequently than is normal. Do the following:

1. Examine the FreeStorageAvailable metric in Amazon CloudWatch.
2. Look for a chainsaw pattern, which is a series of jagged spikes.

A chainsaw pattern indicates a quick consumption and release of storage, often associated with temporary files. If you notice this pattern, turn on Performance Insights. When using Performance Insights, you can identify when the wait events occur and which queries are associated with them. Your solution depends on the specific query causing the events.

Or set the parameter log_temp_files. This parameter logs all queries generating more than threshold KB of temporary files. If the value is 0, Aurora PostgreSQL logs all temporary files. If the value is 1024, Aurora PostgreSQL logs all queries that produces temporary files larger than 1 MB. For more information about log_temp_files, see Error Reporting and Logging in the PostgreSQL documentation.

Examine your join queries

Your application probably use joins. For example, the following query joins four tables.

```
SELECT *
FROM order
INNER JOIN order_item
    ON (order.id = order_item.order_id)
INNER JOIN customer
    ON (customer.id = order.customer_id)
INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND
        order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```
SELECT *
FROM order
INNER JOIN order_item
    ON (order.id = order_item.order_id)
INNER JOIN customer
    ON (customer.id = order_item.order_id)
INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND
        order.customer_address_id = customer_address_id)
WHERE customer.id = 1234567890;
```
The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.
- No `CREATE TABLE FROM SELECT` statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

**Examine your ORDER BY and GROUP BY queries**

In some cases, an `ORDER BY` clause can result in excessive temporary files. Consider the following guidelines:

- Only include columns in an `ORDER BY` clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the `ORDER BY` clause.
- Considering creating indexes to accelerate `ORDER BY` clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.
- If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use `WITH` clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.

- If you don't need to obtain the full result set, use the `LIMIT` clause. For example, if you only want the top five rows, a query using the `LIMIT` clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a `GROUP BY` clause can also require temporary files. `GROUP BY` queries summarize values by using functions such as the following:

- `COUNT`
- `AVG`
- `MIN`
- `MAX`
- `SUM`
- `STDDEV`

To tune `GROUP BY` queries, follow the recommendations for `ORDER BY` queries.

**Avoid using the DISTINCT operation**

If possible, avoid using the `DISTINCT` operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the `DISTINCT` operation becomes. If possible, add filters in the `WHERE` clause even if you use the same filters for different tables. Filtering
the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use DISTINCT for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use Amazon Aurora PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the CREATE STATISTICS command.

**Consider using window functions instead of GROUP BY functions**

Using GROUP BY, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the OVER clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the GROUP BY functions in window functions, but also use functions such as the following:

- RANK
- ARRAY_AGG
- ROW_NUMBER
- LAG
- LEAD

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```sql
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary,
       avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
FROM empsalary;
```

You can rewrite the query with the WINDOW clause as follows.

```sql
SELECT sum(salary) OVER w as sum_salary,
       avg(salary) OVER w as avg_salary
FROM empsalary
WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the Aurora PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

**Investigate materialized views and CTAS statements**

When a materialized view refreshes, it runs a query. This query can contain an operation such as GROUP BY, ORDER BY, or DISTINCT. During a refresh, you might observe large numbers of temporary files and the wait events IO:BufFileWrite and IO:BufFileRead. Similarly, when you create a table based on a SELECT statement, the CREATE TABLE statement runs a query. To reduce the temporary files needed, optimize the query.

**Use pg_repack when you create indexes**

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information, see Maintenance work memory area (p. 1320).

A possible workaround when recreating a large index is to use the pg_repack tool. For more information, see Reorganize tables in PostgreSQL databases with minimal locks in the pg_repack documentation.
Increase maintenance_work_mem when you cluster tables

The CLUSTER command clusters the table specified by table_name based on an existing index specified by index_name. Aurora PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the CLUSTER command and observe the wait events IO:BufFileWrite and IO:BufFileRead, tune maintenance_work_mem. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

In some situation, you need to tune memory. Your goal is to balance the following requirements:

- The work_mem value (see Work memory area (p. 1319))
- The memory remaining after discounting the shared_buffers value (see Buffer pool (p. 805))
- The maximum connections opened and in use, which is limited by max_connections

Increase the size of the work memory area

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the work_mem value. For more information, see Work memory area (p. 1319).

To find out how many temporary files a query generates, set log_temp_files to 0. If you increase the work_mem value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, work_mem sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

Reserve sufficient memory for the shared buffer pool

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase work_mem. For more information about the buffer pool, see Buffer pool (p. 805).

For example, assume that your Aurora PostgreSQL instance class is db.r5.2xlarge. This class has 64 GiB of memory. By default, 75 percent of the memory is reserved for the shared buffer pool. After you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to work_mem depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the Aurora PostgreSQL automation services automatically restart.

Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of work_mem. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
• Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of work_mem. In this way, you reduce the occurrence of the IO:BufFileRead and IO:BufFileWrite wait events. Also, the queries waiting for the work memory area speed up significantly.

**IO:DataFileRead**

The IO:DataFileRead event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

**Topics**
- Supported engine versions (p. 1336)
- Context (p. 1336)
- Likely causes of increased waits (p. 1336)
- Actions (p. 1337)

**Supported engine versions**

This wait event information is supported for all versions of Aurora PostgreSQL.

**Context**

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include `SELECT`, `UPDATE`, and `DELETE`. For example, an `UPDATE` can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the IO:DataFileRead event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the IO:DataFileRead event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for `SELECT` queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see Buffer pool (p. 805).

**Likely causes of increased waits**

Common causes for the IO:DataFileRead event include the following:

**Connection spikes**

You might find multiple connections generating the same number of IO:DataFileRead wait events. In this case, a spike (sudden and large increase) in IO:DataFileRead events can occur.

**SELECT and DML statements performing sequential scans**

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater `seq_scan` value. Find them by querying `pg_stat_user_tables`. To track queries that are generating more read operations, use the extension `pg_stat_statements`.

**CTAS and CREATE INDEX for large data sets**

A CTAS is a `CREATE TABLE AS SELECT` statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the IO:DataFileRead event can occur. When you
create an index, the database might need to read the entire object using a sequential scan. A CTAS generates `IO:DataFileRead` events when pages aren't in memory.

**Multiple vacuum workers running at the same time**

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows, the `IO:DataFileRead` waits increase. After space is reclaimed, the vacuum time spent on `IO:DataFileRead` decreases.

**Ingesting large amounts of data**

When your application ingests large amounts of data, `ANALYZE` operations might occur more often. The `ANALYZE` process can be triggered by an autovacuum launcher or invoked manually.

The `ANALYZE` operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the `default_statistics_target` value. For more information, see the [PostgreSQL documentation](https://www.postgresql.org/docs/current). The `default_statistics_target` parameter accepts values between 1 and 10,000, where the default is 100.

**Resource starvation**

If instance network bandwidth or CPU are consumed, the `IO:DataFileRead` event might occur more frequently.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- **Check predicate filters for queries that generate waits** *(p. 1337)*
- **Minimize the effect of maintenance operations** *(p. 1338)*
- **Respond to high numbers of connections** *(p. 1342)*

**Check predicate filters for queries that generate waits**

Assume that you identify specific queries that are generating `IO:DataFileRead` wait events. You might identify them using the following techniques:

- **Performance Insights**
- **Catalog views such as the one provided by the extension `pg_stat_statements`**
- **The catalog view `pg_stat_all_tables`, if it periodically shows an increased number of physical reads**
- **The `pg_statio_all_tables` view, if it shows that _read counters are increasing**

We recommend that you determine which filters are used in the predicate (`WHERE` clause) of these queries. Follow these guidelines:

- **Run the `EXPLAIN` command.** In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more `IO:DataFileRead` events when compared to queries that use filters.

Find out whether the column listed in the `WHERE` clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the `IO:DataFileRead` events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.

- **Find out whether the query is accessing a very large table.** In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.
• Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you’re passing in the filters for your \texttt{WHERE} clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

**Minimize the effect of maintenance operations**

Maintenance operations such as \texttt{VACUUM} and \texttt{ANALYZE} are important. We recommend that you don’t turn them off because you find \texttt{IO:DataFileRead} wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

• Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
• For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.
• When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

\[
\text{pg\_stat\_user\_tables.n\_dead\_tup} > (\text{pg\_class.reltuples} \times \text{autovacuum\_vacuum\_scale\_factor}) + \text{autovacuum\_vacuum\_threshold}
\]

The view \texttt{pg\_stat\_user\_tables} and catalog \texttt{pg\_class} have multiple rows. One row can correspond to one row in your table. This formula assumes that the \texttt{reltuples} are for a specific table. The parameters \texttt{autovacuum\_vacuum\_scale\_factor} (0.20 by default) and \texttt{autovacuum\_vacuum\_threshold} (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

**Topics**

• Find tables consuming unnecessary space (p. 1338)
• Find indexes consuming unnecessary space (p. 1339)
• Find tables that are eligible to be autovacuumed (p. 1341)

**Find tables consuming unnecessary space**

To find tables consuming unnecessary space, run the following query.

```sql
/* WARNING: Run with a nonsuperuser role, the query inspects only tables */
/* that you have the permission to read. */
/* This query is compatible with PostgreSQL 9.0 and later. */

SELECT current_database(), schemaname, tablename, bs*tblpages AS real_size,
       (tblpages-est_tblpages)*bs AS extra_size,
       CASE WHEN tblpages - est_tblpages > 0
             THEN 100 * (tblpages - est_tblpages)/tblpages::float
             ELSE 0
       END AS extra_ratio,
       fillfactor,
       (tblpages-est_tblpages_ff)*bs AS bloat_size,
       CASE WHEN tblpages - est_tblpages_ff > 0
             THEN 100 * (tblpages - est_tblpages_ff)/tblpages::float
             ELSE 0
       END AS bloat_ratio,
       is_na
       -- , (pst).free_percent + (pst).dead_tuple_percent AS real_frag
FROM (SELECT
       ceil( reltuples / ( (bs-page_hdr)/tpl_size ) ) + ceil( toasttuples / 4 ) AS est_tblpages,
```
Find indexes consuming unnecessary space

To find indexes consuming unnecessary space, run the following query.

```sql
-- WARNING: run with a nonsuperuser role, the query inspects
-- only indexes on tables you have permissions to read.
-- WARNING: rows with is_na = 't' are known to have bad statistics ("name" type is not
-- supported).
-- This query is compatible with PostgreSQL 8.2 and later.
SELECT current_database(), nspname AS schemaname, tblname, idxname, bs*(relpages)::bigint
AS real_size,
bs*(relpages-est_pages)::bigint AS extra_size,
FROM pg_attribute AS att
JOIN pg_class AS tbl ON att.attrelid = tbl.oid
JOIN pg_namespace AS ns ON ns.oid = tbl.relnamespace
LEFT JOIN pg_stats AS s ON s.schemaname=ns.nspname
  AND s.tablename = tbl.relname AND s.inherited=false AND s.attname=att.attname
LEFT JOIN pg_class AS toast ON tbl.reltoastrelid = toast.oid
WHERE att.attnum > 0 AND NOT att.attisdropped
  AND tbl.relkind = 'r'
GROUP BY 1,2,3,4,5,6,7,8,9,10, tbl.relhasoids
ORDER BY 2,3
) AS s
) AS s2
) AS s3 ;
-- WHERE NOT is_na
-- AND tblpages*((pst).free_percent + (pst).dead_tuple_percent)::float4/100 >= 1
```

n_dead_tup

-- or 1 = 1
)
ORDER BY age(relfrozenxid) DESC;

Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the DatabaseConnections metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

  If your application doesn't use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see Using Amazon RDS Proxy (p. 286).

- Whenever possible, take advantage of reader nodes for Aurora PostgreSQL and read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the reader-only endpoint. This technique spreads application requests across all reader nodes, reducing the I/O pressure on the writer node.

- Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives Aurora PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating IO:DataFileRead wait events are writes.

IO:XactSync

The IO:XactSync event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. A prepared transaction is part of PostgreSQL's support for a two-phase commit.

Topics
- Supported engine versions (p. 1342)
- Context (p. 1342)
- Likely causes of increased waits (p. 1343)
- Actions (p. 1343)

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

The event IO:XactSync indicates that the instance is spending time waiting for the Aurora storage subsystem to confirm that transaction data was processed.
Likely causes of increased waits

When the IO:XactSync event appears more than normal, possibly indicating a performance problem, typical causes include the following:

**Network saturation**

Traffic between clients and the DB instance or traffic to the storage subsystem might be too heavy for the network bandwidth.

**CPU pressure**

A heavy workload might be preventing the Aurora storage daemon from getting sufficient CPU time.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Monitor your resources (p. 1343)
- Scale up the CPU (p. 1343)
- Increase network bandwidth (p. 1343)
- Reduce the number of commits (p. 1344)

Monitor your resources

To determine the cause of the increased IO:XactSync events, check the following metrics:

- **WriteThroughput** and **CommitThroughput** – Changes in write throughput or commit throughput can show an increase in workload.
- **WriteLatency** and **CommitLatency** – Changes in write latency or commit latency can show that the storage subsystem is being asked to do more work.
- **CPUUtilization** – If the instance's CPU utilization is above 90 percent, the Aurora storage daemon might not be getting sufficient time on the CPU. In this case, I/O performance degrades.

For information about these metrics, see Instance-level metrics for Amazon Aurora (p. 633).

Scale up the CPU

To address CPU starvation issues, consider changing to an instance type with more CPU capacity. For information about CPU capacity for a DB instance class, see Hardware specifications for DB instance classes for Aurora (p. 61).

Increase network bandwidth

To determine whether the instance is reaching its network bandwidth limits, check for the following other wait events:

- **IO:DataFileRead**, **IO:BufferRead**, **IO:BufferWrite**, and **IO:XactWrite** – Queries using large amounts of I/O can generate more of these wait events.
- **Client:ClientRead** and **Client:ClientWrite** – Queries with large amounts of client communication can generate more of these wait events.
If network bandwidth is an issue, consider changing to an instance type with more network bandwidth. For information about network performance for a DB instance class, see Hardware specifications for DB instance classes for Aurora (p. 61).

**Reduce the number of commits**

To reduce the number of commits, combine statements into transaction blocks.

**ipc:damrecordtxack**

The `ipc:damrecordtxack` event occurs when Aurora PostgreSQL in a session using database activity streams generates an activity stream event, then waits for that event to become durable.

**Topics**

- Relevant engine versions (p. 1344)
- Context (p. 1344)
- Causes (p. 1344)
- Actions (p. 1344)

**Relevant engine versions**

This wait event information is relevant for all Aurora PostgreSQL 10.7 and higher 10 versions, 11.4 and higher 11 versions, and all 12 and 13 versions.

**Context**

In synchronous mode, durability of activity stream events is favored over database performance. While waiting for a durable write of the event, the session blocks other database activity, causing the `ipc:damrecordtxack` wait event.

**Causes**

The most common cause for the `ipc:damrecordtxack` event to appear in top waits is that the Database Activity Streams (DAS) feature is a holistic audit. Higher SQL activity generates activity stream events that need to be recorded.

**Actions**

We recommend different actions depending on the causes of your wait event:

- Reduce the number of SQL statements or turn off database activity streams. Doing this reduces the number of events that require durable writes.
- Change to asynchronous mode. Doing this helps to reduce contention on the `ipc:damrecordtxack` wait event.

However, the DAS feature can't guarantee the durability of every event in asynchronous mode.

**Lock:advisory**

The `Lock:advisory` event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

**Topics**

- Relevant engine versions (p. 1345)
Relevant engine versions

This wait event information is relevant for Aurora PostgreSQL versions 9.6 and higher.

Context

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user’s application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see Advisory Locks in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a CREATE INDEX statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see Advisory Lock Functions in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the pg_locks system view.

Causes

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from Advisory Locks in the PostgreSQL documentation.

```sql
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```

In this example, the LIMIT clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls `pg_advisory_unlock` for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

Actions

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.
A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```sql
SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
       blocked_activity.usename AS blocked_user,
       blocking_activity.usename AS blocking_user,
       now() - blocked_activity.xact_start AS blocked_transaction_duration,
       now() - blocking_activity.xact_start AS blocking_transaction_duration,
       concat(blocked_activity.wait_event_type,':',blocked_activity.wait_event) AS blocked_wait_event,
       concat(blocking_activity.wait_event_type,':',blocking_activity.wait_event) AS blocking_wait_event,
       blocked_activity.state AS blocked_state,
       blocking_activity.state AS blocking_state,
       blocked_locks.locktype AS blocked_locktype,
       blocking_locks.locktype AS blocking_locktype,
       blocked_activity.query AS blocked_statement,
       blocking_activity.query AS blocking_statement
FROM pg_catalog.pg_locks blocked_locks
JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid = blocked_locks.pid
JOIN pg_catalog.pg_locks blocking_locks ON blocking_locks.locktype = blocked_locks.locktype
AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
AND blocking_locks.transactionid IS NOT DISTINCT FROM blocked_locks.transactionid
AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid = blocking_locks.pid
WHERE NOT blocked_locks.GRANTED;
```

All of the advisory lock API functions have two sets of arguments, either one `bigint` argument or two integer arguments:

- For the API functions with one `bigint` argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.
- For the API functions with two integer arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one `bigint` argument; 2 means two integer arguments.

**Lock:extend**

The `Lock:extend` event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

**Topics**
- Supported engine versions (p. 1347)
• Context (p. 1347)
• Likely causes of increased waits (p. 1347)
• Actions (p. 1347)

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

The event `Lock:extend` indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a `Lock:extend` wait event. INSERT, COPY, and UPDATE operations can generate this event.

Likely causes of increased waits

When the `Lock:extend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Surge in concurrent inserts or updates to the same table

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

Insufficient network bandwidth

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in `Lock:extend` events.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

• Reduce concurrent inserts and updates to the same relation (p. 1347)
• Increase network bandwidth (p. 1348)

Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in `tup_inserted` and `tup_updated` metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the `pg_stat_all_tables` view for the values in `n_tup_ins` and `n_tup_upd` fields. For information about the `pg_stat_all_tables` view, see `pg_stat_all_tables` in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query `pg_stat_activity` as in the following example:

```sql
SELECT blocked.pid, blocked.usename,
```
After you identify relations that contribute to increase Lock:extend events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see Managing PostgreSQL partitions with the pg_partman extension (p. 1469).
- If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see CREATE TABLE in the PostgreSQL documentation.

  **Important**
  We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

**Increase network bandwidth**

To see whether there's an increase in write latency, check the WriteLatency metric in CloudWatch. If there is, use the WriteThroughput and ReadThroughput Amazon CloudWatch metrics to monitor the storage related traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon Aurora metrics (p. 628). For information about network performance for each DB instance class, see Hardware specifications for DB instance classes for Aurora (p. 61).

**Lock:Relation**

The Lock:Relation event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

**Topics**

- Supported engine versions (p. 1349)
- Context (p. 1349)
- Likely causes of increased waits (p. 1349)
Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the LOCK command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, Aurora PostgreSQL generates a Lock:Relation event. Some common examples are the following:

- Exclusive locks such as ACCESS EXCLUSIVE can block all concurrent access. Data definition language (DDL) operations such as DROP TABLE, TRUNCATE, VACUUM FULL, and CLUSTER acquire ACCESS EXCLUSIVE locks implicitly. ACCESS EXCLUSIVE is also the default lock mode for LOCK TABLE statements that don't specify a mode explicitly.
- Using CREATE INDEX (without CONCURRENT) on a table conflicts with data manipulation language (DML) statements UPDATE, DELETE, and INSERT, which acquire ROW EXCLUSIVE locks.

For more information about table-level locks and conflicting lock modes, see Explicit Locking in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.
- Blocking transaction – A transaction stops blocking when it runs a ROLLBACK or COMMIT statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.

Likely causes of increased waits

When the Lock:Relation event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Increased concurrent sessions with conflicting table locks

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

Maintenance operations

Health maintenance operations such as VACUUM and ANALYZE can significantly increase the number of conflicting locks. VACUUM FULL acquires an ACCESS EXCLUSIVE lock, and ANALYZE acquires a SHARE UPDATE EXCLUSIVE lock. Both types of locks can cause a Lock:Relation wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

Locks on reader instances

There might be an increase in locks acquired on reader instances. From the standpoint of locking, Aurora PostgreSQL treats the writer and reader instances as a single unit. Thus, locks acquired on
a reader instance can block queries on the writer. Similarly, locks on the writer can block reader queries.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Reduce the impact of blocking SQL statements (p. 1350)
- Minimize the effect of maintenance operations (p. 1350)
- Check for reader locks (p. 1350)

**Reduce the impact of blocking SQL statements**

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- **Use the NOWAIT option** – Some SQL commands, such as `SELECT` and `LOCK` statements, support this option. The `NOWAIT` directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

  For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that's locked by transaction C, transaction A might be blocked until transaction C completes. But if transaction B uses a `NOWAIT` when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- **Use SET lock_timeout** – Set a `lock_timeout` value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

**Minimize the effect of maintenance operations**

Maintenance operations such as `VACUUM` and `ANALYZE` are important. We recommend that you don't turn them off because you find `Lock:Relation` wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.
- **To reduce `Lock:Relation` waits caused by autovacuum tasks**, perform any needed autovacuum tuning. For information about tuning autovacuum, see *Working with PostgreSQL autovacuum on Amazon RDS* in the *Amazon RDS User Guide*.

**Check for reader locks**

You can see how concurrent sessions on a writer and readers might be holding locks that block each other. One way to do this is to run a query that returns the lock type and relation, as in the following example.

<table>
<thead>
<tr>
<th>Writer session</th>
<th>Reader session</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>export</td>
<td>export</td>
<td>This example shows two concurrent sessions. The first column shows the writer session.</td>
</tr>
</tbody>
</table>
### Writer session

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>psql -h $WRITER</code></td>
<td>The writer session creates table t1 on the writer instance.</td>
</tr>
<tr>
<td><code>psql (15devel, server 10.14)</code></td>
<td>Type &quot;help&quot; for help.</td>
</tr>
<tr>
<td><code>create_table</code></td>
<td>The reader session sets a lock timeout interval of 100 milliseconds.</td>
</tr>
<tr>
<td><code>set lock_timeout=100;</code></td>
<td>The reader session tries to read data from table t1 on the reader instance.</td>
</tr>
<tr>
<td><code>begin;</code></td>
<td>The writer session drops t1.</td>
</tr>
<tr>
<td><code>drop_table</code></td>
<td>The query times out and is canceled on the reader.</td>
</tr>
<tr>
<td><code>select * from t1;</code></td>
<td>The reader session queries pg_locks and pg_stat_activity to determine the cause of the error. The result indicates that the aurora wal replay process is holding an ACCESS EXCLUSIVE lock on table t1.</td>
</tr>
<tr>
<td><code>error: canceling statement due to lock timeout</code></td>
<td>The Lock:transactionid event occurs when a transaction is waiting for a row-level lock.</td>
</tr>
</tbody>
</table>
Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

The event Lock:transactionid occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that shows the Lock:transactionid wait event is blocked because of this lock. After the blocking transaction ends in either a COMMIT or ROLLBACK statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of Aurora PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- UPDATE
- SELECT ... FOR UPDATE
- SELECT ... FOR KEY SHARE

The statement SELECT ... FOR KEY SHARE is a special case. The database uses the clause FOR KEY SHARE to optimize the performance of referential integrity. A row-level lock on a row can block INSERT, UPDATE, and DELETE commands on other tables that reference the row.

Likely causes of increased waits

When this event appears more than normal, the cause is typically UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements combined with the following conditions.

High concurrency

Aurora PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:

- A highly concurrent workload contends for the same rows.
- Concurrency increases.

Idle in transaction

Sometimes the pg_stat_activity.state column shows the value idle in transaction. This value appears for sessions that have started a transaction, but haven't yet issued a COMMIT or ROLLBACK. If the pg_stat_activity.state value isn't active, the query shown in pg_stat_activity is the
most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event Lock:transactionid. To diagnose the issue, examine the output from `pg_stat_activity` and `pg_locks`.

### Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

### Actions

Row-locking is a conflict among `UPDATE`, `SELECT ... FOR UPDATE`, or `SELECT ... FOR KEY SHARE` statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

**Topics**

- Respond to high concurrency (p. 1353)
- Respond to idle transactions (p. 1353)
- Respond to long-running transactions (p. 1353)

### Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

- Lower the concurrency in the application. For example, decrease the number of active sessions.
- Implement a connection pool. To learn how to pool connections with RDS Proxy, see Using Amazon RDS Proxy (p. 286).
- Design the application or data model to avoid contending `UPDATE` and `SELECT ... FOR UPDATE` statements. You can also decrease the number of foreign keys accessed by `SELECT ... FOR KEY SHARE` statements.

### Respond to idle transactions

If `pg_stat_activity.state` shows `idle in transaction`, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a `COMMIT` or `ROLLBACK`.
- Search for code paths that are missing `COMMIT`, `ROLLBACK`, or `END`.
- Make sure that the exception handling logic in your application always has a path to a valid end of transaction.
- Make sure that your application processes query results after ending the transaction with `COMMIT` or `ROLLBACK`.

### Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of `Lock:transactionid`, try the following strategies:

- Keep row locks out of long-running transactions.
- Limit the length of queries by implementing autocommit whenever possible.
**Lock:tuple**

The **Lock:tuple** event occurs when a backend process is waiting to acquire a lock on a tuple.

**Topics**
- Supported engine versions (p. 1354)
- Context (p. 1354)
- Likely causes of increased waits (p. 1354)
- Actions (p. 1355)

**Supported engine versions**

This wait event information is supported for all versions of Aurora PostgreSQL.

**Context**

The event **Lock:tuple** indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the **Lock:tuple** event.

<table>
<thead>
<tr>
<th>Time</th>
<th>Session 1</th>
<th>Session 2</th>
<th>Session 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>Starts a transaction.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t2</td>
<td>Updates row 1.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>t3</td>
<td></td>
<td>Updates row 1. The session acquires an exclusive lock on the tuple and then waits for session 1 to release the lock by committing or rolling back.</td>
<td></td>
</tr>
<tr>
<td>t4</td>
<td></td>
<td></td>
<td>Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.</td>
</tr>
</tbody>
</table>

Or you can simulate this wait event by using the benchmarking tool **pgbench**. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see Explicit Locking in the PostgreSQL documentation. To learn more about **pgbench**, see pgbench in the PostgreSQL documentation.

**Likely causes of increased waits**

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running **UPDATE** or **DELETE** statements.
- Highly concurrent sessions are running a **SELECT** statement using the **FOR UPDATE** or **FOR NO KEY UPDATE** lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and **Lock:tuple** can appear.
For more information, see Row-Level Locks in the PostgreSQL documentation.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- Investigate your application logic (p. 1355)
- Find the blocker session (p. 1355)
- Reduce concurrency when it is high (p. 1356)
- Troubleshoot bottlenecks (p. 1356)

**Investigate your application logic**

Find out whether a blocker session has been in the `idle in transaction` state for long time. If so, consider ending the blocker session as a short-term solution. You can use the `pg_terminate_backend` function. For more information about this function, see Server Signaling Functions in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the `idle_in_transaction_session_timeout` parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see Client Connection Defaults in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see SET AUTOCOMMIT in the PostgreSQL documentation.

**Find the blocker session**

While the `Lock:tuple` wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see Lock dependency information in the PostgreSQL wiki. To analyze past `Lock:tuple` events, use the Aurora function `aurora_stat_backend_waits`.

The following example queries all sessions, filtering on `tuple` and ordering by `wait_time`.

```sql
--AURORA_STAT_BACKEND_WAITS
SELECT a.pid, a.usename, a.app_name, a.current_query, a.current_wait_type, a.current_wait_event, a.current_state, wt.type_name AS wait_type, we.event_name AS wait_event, a.waits, a.wait_time
FROM (SELECT pid, usename, left(application_name,16) AS app_name, coalesce(wait_event_type,'CPU') AS current_wait_type, coalesce(wait_event,'CPU') AS current_wait_event, state AS current_state, left(query,80) as current_query, (aurora_stat_backend_waits(pid)).*
FROM pg_stat_activity
```
WHERE pid <> pg_backend_pid()
    AND usename<>'rdsadmin') a
NATURAL JOIN aurora_stat_wait_type() wt
NATURAL JOIN aurora_stat_wait_event() we
WHERE we.event_name = 'tuple'
ORDER BY a.wait_time;

pid | usename | app_name | current_query                  | current_wait_type | current_wait_event | current_state | wait_type | wait_event | waits | wait_time
-------+---------+----------+------------------------------------------------ |-------------------+--------------------+---------------+-----------+------------+-------+-----------
32136 | sys     | psql     | /*session3*/ update tab set col=1 where col=1; | Lock              | tuple              | active        | Lock      | tuple      |     1 |   1000018
11999 | sys     | psql     | /*session4*/ update tab set col=1 where col=1; | Lock              | tuple              | active        | Lock      | tuple      |     1 |   1000024

Reduce concurrency when it is high

The Lock:tuple event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.

You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.
- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the NOWAIT clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

Troubleshoot bottlenecks

The Lock:tuple can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

- Scale up your instance class type.
- Optimize resource-intensive queries.
- Change the application logic.
- Archive data that is rarely accessed.

lwlock:buffer_content (BufferContent)

The lwlock:buffer_content event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In Aurora PostgreSQL 13 and higher, this wait event is called BufferContent.

Topics
- Supported engine versions (p. 1357)
- Context (p. 1357)
- Likely causes of increased waits (p. 1357)
- Actions (p. 1357)
Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The `lwlock:buffer_content` event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

Likely causes of increased waits

When the `lwlock:buffer_content` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

Actions

We recommend different actions depending on the causes of your wait event. You might identify `lwlock:buffer_content` events by using Amazon RDS Performance Insights or by querying the view `pg_stat_activity`.

Topics

- Improve in-memory efficiency (p. 1357)
- Reduce usage of foreign key constraints (p. 1357)
- Remove unused indexes (p. 1358)

Improve in-memory efficiency

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see Aurora DB instance classes (p. 53).

Reduce usage of foreign key constraints

Investigate workloads experiencing high numbers of `lwlock:buffer_content` wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.
Remove unused indexes

For workloads experiencing high numbers of `lwlock:buffer_content` (BufferContent) wait events, identify unused indexes and remove them.

**LWLock:buffer_mapping**

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

*Note*
This event appears as `LWLock:buffer_mapping` in Aurora PostgreSQL version 12 and lower, and `LWLock:BufferMapping` in version 13 and higher.

**Topics**
- Supported engine versions (p. 1358)
- Context (p. 1358)
- Causes (p. 1358)
- Actions (p. 1358)

**Supported engine versions**

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

**Context**

The *shared buffer pool* is an Aurora PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The `shared_buffers` parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database. For more information, see *Shared buffers* (p. 1319).

The `LWLock:buffer_mapping` wait event occurs in the following scenarios:

- A process searches the buffer table for a page and acquires a shared buffer mapping lock.
- A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
- A process removes a page from the pool and acquires an exclusive buffer mapping lock.

**Causes**

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

**Actions**

We recommend different actions depending on the causes of your wait event.
Topics

- Monitor buffer-related metrics (p. 1359)
- Assess your indexing strategy (p. 1359)
- Reduce the number of buffers that must be allocated quickly (p. 1359)

Monitor buffer-related metrics

When `LWLock:buffer_mapping` waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

BufferCacheHitRatio

This Amazon CloudWatch metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. You might see this metric decrease in the lead-up to the `LWLock:buffer_mapping` wait event.

`blks_hit`

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the `LWLock:buffer_mapping` wait event appears, you might observe a spike in `blks_hit`.

`blks_read`

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in `blks_read` in the lead-up to the `LWLock:buffer_mapping` wait event.

Assess your indexing strategy

To confirm that your indexing strategy is not degrading performance, check the following:

Index bloat

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The `tup_returned` metric shows the number of rows read. The `tup_fetched` metric shows the number of rows returned to the client. If `tup_returned` is significantly larger than `tup_fetched`, the data might not be properly indexed. Also, your table statistics might not be current.

Reduce the number of buffers that must be allocated quickly

To reduce the `LWLock:buffer_mapping` wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

`LWLock:BufferIO`

The `LWLock:BufferIO` event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.
Topics

- Relevant engine versions (p. 1360)
- Context (p. 1360)
- Causes (p. 1360)
- Actions (p. 1360)

Relevant engine versions

This wait event information is relevant for all Aurora PostgreSQL 13 versions.

Context

Each shared buffer has an I/O lock that is associated with the LWLock:BufferIO wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the shared_buffers parameter.

As soon as the page is read inside the shared buffer pool, the LWLock:BufferIO lock is released.

Note
The LWLock:BufferIO wait event precedes the IO:DataFileRead (p. 1336) wait event. The IO:DataFileRead wait event occurs while data is being read from storage.

For more information on lightweight locks, see Locking Overview.

Causes

Common causes for the LWLock:BufferIO event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the shared_buffers parameter) and the number of buffers needed by the current workload
- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Checkpoints occurring too frequently or needing to flush too many modified pages
- Sudden spikes for database connections trying to perform operations on the same page

Actions

We recommend different actions depending on the causes of your wait event:

- Observe Amazon CloudWatch metrics for correlation between sharp decreases in the BufferCacheHitRatio and LWLock:BufferIO wait events. This effect can mean that you have a small shared buffers setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
- Tune max_wal_size and checkpoint_timeout based on your workload peak time if you see LWLock:BufferIO coinciding with BufferCacheHitRatio metric dips. Then identify which query might be causing it.
- Verify whether you have unused indexes, then remove them.
- Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
- Avoid indexing columns unnecessarily.
- Prevent sudden database connection spikes by using a connection pool.
- Restrict the maximum number of connections to the database as a best practice.

**LWLock:lock_manager**

This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

**Topics**
- Supported engine versions (p. 1361)
- Context (p. 1361)
- Likely causes of increased waits (p. 1362)
- Actions (p. 1362)

**Supported engine versions**

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

**Context**

When you issue a SQL statement, Aurora PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.

**Fast path locking**

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

- They use the DEFAULT lock method.
- They represent a lock on a database relation rather than a shared relation.
- They are weak locks that are unlikely to conflict.
- The engine can quickly verify that no conflicting locks can possibly exist.

The engine can't use fast path locking when either of the following conditions is true:

- The lock doesn't meet the preceding criteria.
- No more slots are available for the backend process.

For more information about fast path locking, see fast path in the PostgreSQL lock manager README and pg-locks in the PostgreSQL documentation.

**Example of a scaling problem for the lock manager**

In this example, a table named `purchases` stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:
1. You query many days worth of data, which requires the database to read many partitions.

2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.

3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of `FP_LOCK_SLOTS_PER_BACKEND`, the lock manager uses the non–fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non–fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the LWLock:lock_manager wait event appears.

**Note**
The LWLock:lock_manager wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non–fast path locks that the database must control.

### Likely causes of increased waits

When the LWLock:lock_manager wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.
- A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

### Actions

If the CPU wait event occurs, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades and this wait event is dominating DB load.

### Topics

- Use partition pruning (p. 1362)
- Remove unnecessary indexes (p. 1363)
- Tune your queries for fast path locking (p. 1363)
- Tune for other wait events (p. 1363)
- Reduce hardware bottlenecks (p. 1363)
- Use a connection pooler (p. 1363)
- Upgrade your Aurora PostgreSQL version (p. 1364)

### Use partition pruning

*Partition pruning* is a query optimization strategy that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.
Queries can take advantage of partition pruning when their WHERE clause contains the column used for the partitioning. For more information, see Partition Pruning in the PostgreSQL documentation.

Remove unnecessary indexes

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading Unused Indexes in the PostgreSQL wiki.
- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see pg-collector in the AWS Labs GitHub repository.

Tune your queries for fast path locking

To find out whether your queries use fast path locking, query the fastpath column in the pg_locks table. If your queries aren't using fast path locking, try to reduce number of relations per query to fewer than 16.

Tune for other wait events

If LWLock:lock_manager is first or second in the list of top waits, check whether the following wait events also appear in the list:

- Lock:Relation
- Lock:transactionid
- Lock:tuple

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for LWLock:lock_manager.

Reduce hardware bottlenecks

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.
- Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see Amazon RDS Instance Types.

Use a connection pooler

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see Amazon RDS Instance Types.

For more information about connection pooling, see the following resources:

- Using Amazon RDS Proxy (p. 286)
• `pgbouncer`
• `Connection Pools and Data Sources` in the *PostgreSQL Documentation*

**Upgrade your Aurora PostgreSQL version**

If your current version of Aurora PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and 13 have an improved partition mechanism. For more information about version 12, see *PostgreSQL 12.0 Release Notes*. For more information about upgrading Aurora PostgreSQL, see *Amazon Aurora PostgreSQL updates* (p. 1522).

**Timeout::PgSleep**

The `Timeout::PgSleep` event occurs when a server process has called the `pg_sleep` function and is waiting for the sleep timeout to expire.

**Topics**

• Supported engine versions (p. 1364)
• Likely causes of increased waits (p. 1364)
• Actions (p. 1364)

**Supported engine versions**

This wait event information is supported for all versions of Aurora PostgreSQL.

**Likely causes of increased waits**

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

• `pg_sleep`
• `pg_sleep_for`
• `pg_sleep_until`

The preceding functions delay execution until the specified number of seconds have elapsed. For example, `SELECT pg_sleep(1)` pauses for 1 second. For more information, see *Delaying Execution* in the PostgreSQL documentation.

**Actions**

Identify the statement that was running the `pg_sleep` function. Determine if the use of the function is appropriate.

**Best practices with Amazon Aurora PostgreSQL**

This topic includes information on best practices and options for using or migrating data to an Amazon Aurora PostgreSQL DB cluster.

**Fast failover with Amazon Aurora PostgreSQL**

There are several things you can do to make a failover perform faster with Aurora PostgreSQL. This section discusses each of the following ways:
• Aggressively set TCP keepalives to ensure that longer running queries that are waiting for a server response will be stopped before the read timeout expires in the event of a failure.

• Set the Java DNS caching timeouts aggressively to ensure the Aurora read-only endpoint can properly cycle through read-only nodes on subsequent connection attempts.

• Set the timeout variables used in the JDBC connection string as low as possible. Use separate connection objects for short and long running queries.

• Use the provided read and write Aurora endpoints to establish a connection to the cluster.

• Use RDS APIs to test application response on server side failures and use a packet dropping tool to test application response for client-side failures.

• Use the AWS JDBC Driver for PostgreSQL (preview) to take full advantage of the failover capabilities of Aurora PostgreSQL. For more information about the AWS JDBC Driver for PostgreSQL and complete instructions for using it, see the AWS JDBC Driver for PostgreSQL GitHub repository.

Contents
• Setting TCP keepalives parameters (p. 1365)
• Configuring your application for fast failover (p. 1366)
  • Reducing DNS cache timeouts (p. 1366)
  • Setting an Aurora PostgreSQL connection string for fast failover (p. 1366)
  • Other options for obtaining the host string (p. 1368)
    • Java example to list instances using the DescribeDBClusters API (p. 1369)
• Testing failover (p. 1369)
• Fast failover Java example (p. 1370)

Setting TCP keepalives parameters

The TCP keepalive process is simple: when you set up a TCP connection, you associate a set of timers. When the keepalive timer reaches zero, you send a keepalive probe packet. If you receive a reply to your keepalive probe, you can assume that the connection is still up and running.

Enabling TCP keepalive parameters and setting them aggressively ensures that if your client is no longer able to connect to the database, then any active connections are quickly closed. This action allows the application to react appropriately, such as by picking a new host to connect to.

You need to set the following TCP keepalive parameters:

• tcp_keepalive_time controls the time, in seconds, after which a keepalive packet is sent when no data has been sent by the socket (ACKs are not considered data). We recommend the following setting:

  tcp_keepalive_time = 1

• tcp_keepalive_intvl controls the time, in seconds, between sending subsequent keepalive packets after the initial packet is sent (set using the tcp_keepalive_time parameter). We recommend the following setting:

  tcp_keepalive_intvl = 1

• tcp_keepalive_probes is the number of unacknowledged keepalive probes that occur before the application is notified. We recommend the following setting:

  tcp_keepalive_probes = 5

These settings should notify the application within five seconds when the database stops responding. A higher tcp_keepalive_probes value can be set if keepalive packets are often dropped within the
application's network. This subsequently increases the time it takes to detect an actual failure, but allows for more buffer in less reliable networks.

**Setting TCP keepalive parameters on Linux**

1. When testing how to configure the TCP keepalive parameters, we recommend doing so via the command line with the following commands: This suggested configuration is system wide, meaning that it affects all other applications that create sockets with the SO_KEEPALIVE option on.

   ```
sudo sysctl net.ipv4.tcp_keepalive_time=1
sudo sysctl net.ipv4.tcp_keepalive_intvl=1
sudo sysctl net.ipv4.tcp_keepalive_probes=5
   ```

2. After you've found a configuration that works for your application, persist these settings by adding the following lines to `/etc/sysctl.conf`, including any changes you made:

   ```
tcp_keepalive_time = 1
tcp_keepalive_intvl = 1
tcp_keepalive_probes = 5
   ```

For information on setting TCP keepalive parameters on Windows, see [Things you May want to know about TCP keepalive](#).

**Configuring your application for fast failover**

This section discusses several Aurora PostgreSQL specific configuration changes you can make. To learn more about PostgreSQL JDBC driver setup and configuration, see the [PostgreSQL JDBC Driver documentation](#).

**Topics**

- [Reducing DNS cache timeouts (p. 1366)](#)
- [Setting an Aurora PostgreSQL connection string for fast failover (p. 1366)](#)
- [Other options for obtaining the host string (p. 1368)](#)

**Reducing DNS cache timeouts**

When your application tries to establish a connection after a failover, the new Aurora PostgreSQL writer will be a previous reader, which can be found using the Aurora read only endpoint before DNS updates have fully propagated. Setting the java DNS TTL to a low value helps cycle between reader nodes on subsequent connection attempts.

```java
// Sets internal TTL to match the Aurora RO Endpoint TTL
java.security.Security.setProperty("networkaddress.cache.ttl" , "1");
// If the lookup fails, default to something like small to retry
java.security.Security.setProperty("networkaddress.cache.negative.ttl" , "3");
```

**Setting an Aurora PostgreSQL connection string for fast failover**

To make use of Aurora PostgreSQL fast failover, your application's connection string should have a list of hosts (highlighted in bold in the following example) instead of just a single host. Here is an example connection string you could use to connect to an Aurora PostgreSQL cluster:

```
jdbc:postgresql://myauroracluster.cluster-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432
```
For more information about PostgreSQL JDBC driver parameters, see Connecting to the Database.

For best availability and to avoid a dependency on the RDS API, the best option for connecting is to maintain a file with a host string that your application reads from when you establish a connection to the database. This host string would have all the Aurora endpoints available for the cluster. For more information about Aurora endpoints, see Amazon Aurora connection management (p. 31). For example, you could store the endpoints in a file locally like the following:

```
myauroracluster.cluster-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432
```

Your application would read from this file to populate the host section of the JDBC connection string. Renaming the DB cluster causes these endpoints to change; ensure that your application handles that event should it occur.

Another option is to use a list of DB instance nodes:

```
my-node1.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node2.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node3.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node4.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432
```

The benefit of this approach is that the PostgreSQL JDBC connection driver will loop through all nodes on this list to find a valid connection, whereas when using the Aurora endpoints only two nodes will be tried per connection attempt. The downside of using DB instance nodes is that if you add or remove nodes from your cluster and the list of instance endpoints becomes stale, the connection driver may never find the correct host to connect to.

Set the following parameters aggressively to help ensure that your application doesn't wait too long to connect to any one host.

- **targetServerType** – Use this parameter to control whether the driver connects to a write or read node. To ensure your applications will reconnect only to a write node, set the `targetServerType` value to `primary`.

  Values for the `targetServerType` parameter include `primary`, `secondary`, `any`, and `preferSecondary`. The `preferSecondary` value attempts to establish a connection to a reader first but connects to the writer if no reader connection can be established.

- **loginTimeout** – Controls how long your application waits to login to the database *after* a socket connection has been established.

- **connectTimeout** – Controls how long the socket waits to establish a connection to the database.

You can modify other application parameters to speed up the connection process, depending on how aggressive you want your application to be.

- **cancelSignalTimeout** – In some applications, you may want to send a "best effort" cancel signal on a query that has timed out. If this cancel signal is in your failover path, you should consider setting it aggressively to avoid sending this signal to a dead host.

- **socketTimeout** – This parameter controls how long the socket waits for read operations. This parameter can be used as a global “query timeout” to ensure no query waits longer than this value. A good practice is to have one connection handler that runs short lived queries and sets this value lower, and to have another connection handler for long running queries with this value set much higher. Then, you can rely on TCP keepalive parameters to stop long running queries if the server goes down.
• **tcpKeepAlive** – Enable this parameter to ensure the TCP keepalive parameters that you set are respected.

• **loadBalanceHosts** – When set to true, this parameter has the application connect to a random host chosen from a list of candidate hosts.

**Other options for obtaining the host string**

You can get the host string from several sources, including the `aurora_replica_status` function and by using the Amazon RDS API.

Your application can connect to any DB instance in the DB cluster and query the `aurora_replica_status` function to determine who the writer of the cluster is, or to find any other reader nodes in the cluster. You can use this function to reduce the amount of time it takes to find a host to connect to, though in certain scenarios the `aurora_replica_status` function may show out of date or incomplete information in certain network failure scenarios.

A good way to ensure your application can find a node to connect to is to attempt to connect to the **cluster writerendpoint** and then the **cluster readerendpoint** until you can establish a readable connection. These endpoints do not change unless you rename your DB cluster, and thus can generally be left as static members of your application or stored in a resource file that your application reads from.

After you establish a connection using one of these endpoints, you can call the `aurora_replica_status` function to get information about the rest of the cluster. For example, the following command retrieves information with the `aurora_replica_status` function.

```
postgres=> SELECT server_id, session_id, highest_lsn_rcvd, cur_replay_latency_in_usec, now(), last_update_timestamp
FROM aurora_replica_status();
```

<table>
<thead>
<tr>
<th>server_id</th>
<th>session_id</th>
<th>highest_lsn_rcvd</th>
<th>cur_replay_latency_in_usec</th>

(3 rows)

So for example, the hosts section of your connection string could start with both the writer and reader cluster endpoints:

```
myauroracluster.cluster-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432
```

If the return value of the query is **OFF**, then you've successfully connected to the primary node. If the return value is **ON**, and your application requires a read/write connection, you can then call the `aurora_replica_status` function to determine the `server_id` that has `session_id='MASTER_SESSION_ID'`. This function gives you the name of the primary node. You can use this in conjunction with the 'endpointPostfix' described below.

One thing to be aware of is when you connect to a replica that has stale data. When this happens, the `aurora_replica_status` function might show out-of-date information. A threshold for staleness
can be set at the application level and examined by looking at the difference between the server time and the last_update_timestamp. In general, your application should avoid flipping between two hosts due to conflicting information returned by the aurora_replica_status function. Your application should try all known hosts first instead of blindly following the data returned by the aurora_replica_status function.

Java example to list instances using the DescribeDBClusters API

You can programmatically find the list of instances by using the AWS SDK for Java, specifically the DescribeDBClusters API. Here's a small example of how you might do this in java 8:

```java
AmazonRDS client = AmazonRDSClientBuilder.defaultClient();
DescribeDBClustersRequest request = new DescribeDBClustersRequest()
    .withDBClusterIdentifier(clusterName);
DescribeDBClustersResult result =
rdsClient.describeDBClusters(request);

DBCluster singleClusterResult = result.getDBClusters().get(0);

String pgJDBCEndpointStr =
singleClusterResult.getDBClusterMembers().stream()
    .sorted(Comparator.comparing(DBClusterMember::getIsClusterWriter)
    .reversed()) // This puts the writer at the front of the list
    .map(m -> m.getDBInstanceIdentifier() + endpointPostfix + ":" +
    singleClusterResult.getPort())
    .collect(Collectors.joining(",");
```

pgJDBCEndpointStr will contain a formatted list of endpoints. For example:

```
my-node1.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node2.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432
```

The variable endpointPostfix can be a constant that your application sets, or can be obtained by querying the DescribeDBInstances API for a single instance in your cluster. This value remains constant within a region and for an individual customer, so it would save an API call to simply keep this constant in a resource file that your application reads from. In the example above, it would be set to:

```
.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com
```

For availability purposes, a good practice is to default to using the Aurora endpoints of your DB cluster if the API is not responding, or is taking too long to respond. The endpoints are guaranteed to be up to date within the time it takes to update the DNS record. This is typically less than 30 seconds. You can store this in a resource file that your application consumes.

Testing failover

In all cases you must have a DB cluster with two or more DB instances in it.

From the server side, certain APIs can cause an outage that can be used to test how your applications responds:

- **FailoverDBCluster** - Will attempt to promote a new DB instance in your DB cluster to writer.

  The following code sample shows how you can use failoverDBCluster to cause an outage. For more details about setting up an Amazon RDS client, see Using the AWS SDK for Java.

```java
public void causeFailover() {
    final AmazonRDS rdsClient = AmazonRDSClientBuilder.defaultClient();
}```
FailoverDBClusterRequest request = new FailoverDBClusterRequest();
request.setDBClusterIdentifier("cluster-identifier");

rdsClient.failoverDBCluster(request);

- **RebootDBInstance** – Failover is not guaranteed in this API. It will shutdown the database on the
  writer, though, and can be used to test how your application responds to connections dropping (note that
  the `ForceFailover` parameter is not applicable for Aurora engines and instead should use the
  `FailoverDBCluster` API).

- **ModifyDBCluster** – Modifying the `Port` will cause an outage when the nodes in the cluster begin
  listening on a new port. In general your application can respond to this failure by ensuring that only
  your application controls port changes and can appropriately update the endpoints it depends on,
  by having someone manually update the port when they make modifications at the API level, or by
  querying the RDS API in your application to determine if the port has changed.

- **ModifyDBInstance** – Modifying the `DBInstanceClass` will cause an outage.

- **DeleteDBInstance** – Deleting the primary/writer will cause a new DB instance to be promoted to writer
  in your DB cluster.

From the application/client side, if using Linux, you can test how the application responds to sudden
packet drops based on port, host, or if tcp keepalive packets are not sent or received by using iptables.

**Fast failover Java example**

The following code sample shows how an application might set up an Aurora PostgreSQL driver
manager. The application would call `getConnection()` when it needs a connection. A call to this
function can fail to find a valid host, such as when no writer is found but the `targetServerType`
parameter was set to `primary`. The calling application should simply retry calling the function. This can
easily be wrapped into a connection pooler to avoid pushing the retry behavior onto the application.
Most connection poolers allow you to specify a JDBC connection string, so your application could call
into `getJdbcConnectionString()` and pass that to the connection pooler to make use of faster
failover on Aurora PostgreSQL.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.util.ArrayList;
import java.util.List;
import java.util.stream.Collectors;
import java.util.stream.IntStream;
import org.joda.time.Duration;

public class FastFailoverDriverManager {
    private static Duration LOGIN_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CONNECT_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CANCEL_SIGNAL_TIMEOUT = Duration.standardSeconds(1);
    private static Duration DEFAULT_SOCKET_TIMEOUT = Duration.standardSeconds(5);

    public FastFailoverDriverManager() {
        try {
            Class.forName("org.postgresql.Driver");
        } catch (ClassNotFoundException e) {
            e.printStackTrace();
        }
    }

    /*
```
* RO endpoint has a TTL of 1s, we should honor that here. Setting this aggressively makes sure that when
* the PG JDBC driver creates a new connection, it will resolve a new different RO endpoint on subsequent attempts
* (assuming there is > 1 read node in your cluster)
*/
java.security.Security.setProperty("networkaddress.cache.ttl" , "1");
// If the lookup fails, default to something like small to retry
java.security.Security.setProperty("networkaddress.cache.negative.ttl" , "3");

public Connection getConnection(String targetServerType) throws SQLException {
    return getConnection(targetServerType, DEFAULT_SOCKET_TIMEOUT);
}

public Connection getConnection(String targetServerType, Duration queryTimeout) throws SQLException {
    Connection conn = DriverManager.getConnection(getJdbcConnectionString(targetServerType, queryTimeout));

    /*
     * A good practice is to set socket and statement timeout to be the same thing
     * since both
     * the client AND server will stop the query at the same time, leaving no running
     * queries
     * on the backend
     */
    Statement st = conn.createStatement();
    st.execute("set statement_timeout to " + queryTimeout.getMillis());
    st.close();

    return conn;
}

private static String urlFormat = "jdbc:postgresql://%s" + "/postgres" + "?user=%s" + "&password=%s" + "&loginTimeout=%d" + "&connectTimeout=%d" + "&cancelSignalTimeout=%d" + "&socketTimeout=%d" + "&targetServerType=%s" + "&tcpKeepAlive=true" + "&ssl=true" + "&loadBalanceHosts=true";

public String getJdbcConnectionString(String targetServerType, Duration queryTimeout) {
    return String.format(urlFormat,
        getFormattedEndpointList(getLocalEndpointList()),
        CredentialManager.getUsername(),
        CredentialManager.getPassword(),
        LOGIN_TIMEOUT.getStandardSeconds(),
        CONNECT_TIMEOUT.getStandardSeconds(),
        CANCEL_SIGNAL_TIMEOUT.getStandardSeconds(),
        queryTimeout.getStandardSeconds(),
        targetServerType
    );
}

private List<String> getLocalEndpointList() {
    /*
     * As mentioned in the best practices doc, a good idea is to read a local resource
     * file and parse the cluster endpoints.
     * For illustration purposes, the endpoint list is hardcoded here
     */
    List<String> newEndpointList = new ArrayList<>();
Troubleshooting storage issues

If the amount of memory required by a sort or index creation operation exceeds the amount of memory available, Aurora PostgreSQL writes the excess data to storage. When it writes the data it uses the same storage space it uses for storing error and message logs. If your sorts or index creation functions exceed the memory available, you could develop a local storage shortage. If you experience issues with Aurora PostgreSQL running out of storage space, you can either reconfigure your data sorts to use more memory, or reduce the data retention period for your PostgreSQL log files. For more information about changing the log retention period see, PostgreSQL database log files (p. 675).

If your Aurora cluster is larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes.

Replication with Amazon Aurora PostgreSQL

Following, you can find a description of replication with Amazon Aurora PostgreSQL, including how to monitor replication.

Topics

• Using Aurora Replicas (p. 1372)
• Monitoring Aurora PostgreSQL replication (p. 1373)
• Using PostgreSQL logical replication with Aurora (p. 1373)

Using Aurora Replicas

An Aurora Replica is an independent endpoint in an Aurora DB cluster, best used for scaling read operations and increasing availability. An Aurora DB cluster can include up to 15 Aurora Replicas located throughout the Availability Zones of the Aurora DB cluster's AWS Region. The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary writer DB instance and to Aurora Replicas in the DB cluster. For more information about Aurora Replicas, see Aurora Replicas (p. 69).

Aurora Replicas work well for read scaling because they're fully dedicated to read operations on your cluster volume. The writer DB instance manages write operations. The cluster volume is shared among all instances in your Aurora PostgreSQL DB cluster. Thus, no extra work is needed to replicate a copy of the data for each Aurora Replica.

With Aurora PostgreSQL, when an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements
running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing
statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica
is shut down and deleted.

Aurora PostgreSQL DB clusters don't support Aurora Replicas in different AWS Regions. That means you
can't use Aurora Replicas for cross-Region replication. However, you can scale reads and achieve high
availability for an Aurora PostgreSQL DB cluster by using the Aurora global database feature. Aurora
global databases have a single read/write primary DB cluster in one AWS Region and up to five read-
only secondary DB clusters in different Regions. For more information, see Using Amazon Aurora global
databases (p. 223).

**Note**
Rebooting the writer DB instance of an Amazon Aurora DB cluster also automatically reboots
the Aurora Replicas for that DB cluster. The automatic reboot re-establishes an entry point that
guarantees read/write consistency across the DB cluster.

### Monitoring Aurora PostgreSQL replication

Read scaling and high availability depend on minimal lag time. You can monitor how far an Aurora
Replica is lagging behind the writer DB instance of your Aurora PostgreSQL DB cluster by monitoring the
Amazon CloudWatch *ReplicaLag* metric. Because Aurora Replicas read from the same cluster volume
as the writer DB instance, the *ReplicaLag* metric has a different meaning for an Aurora PostgreSQL DB
cluster. The *ReplicaLag* metric for an Aurora Replica indicates the lag for the page cache of the Aurora
Replica compared to that of the writer DB instance.

For more information on monitoring RDS instances and CloudWatch metrics, see Monitoring an Amazon
Aurora DB cluster (p. 537).

### Using PostgreSQL logical replication with Aurora

PostgreSQL logical replication provides fine-grained control over replicating and synchronizing parts of a
database. For example, you can use logical replication to replicate an individual table of a database.

Following, you can find information about how to work with PostgreSQL logical replication and Amazon
Aurora. For more detailed information about the PostgreSQL implementation of logical replication, see
Logical replication and Logical decoding concepts in the PostgreSQL documentation.

**Note**
Logical replication is available with Aurora PostgreSQL version 2.2.0 (compatible with
PostgreSQL 10.6) and later.

Following, you can find information about how to work with PostgreSQL logical replication and Amazon
Aurora.

**Topics**
- Configuring logical replication (p. 1373)
- Example of logical replication of a database table (p. 1375)
- Logical replication using the AWS Database Migration Service (p. 1376)
- Stopping logical replication (p. 1378)

### Configuring logical replication

To use logical replication, you first set the *rds.logical_replication* parameter for a cluster
parameter group. You then set up the publisher and subscriber.

Logical replication uses a publish and subscribe model. *Publishers* and *subscribers* are the nodes. A
*publication* is a set of changes generated from one or more database tables. You specify a publication on
a publisher. A subscription defines the connection to another database and one or more publications to which it subscribes. You specify a subscription on a subscriber. The publication and subscription make the connection between the publisher and subscriber.

**Note**
Following are requirements for logical replication:

- To perform logical replication for a PostgreSQL database, your AWS user account needs the rds_superuser role.
- The RDS for PostgreSQL DB instance that you use as the source must have automated backups enabled. For instructions on how to enable automated backups for an RDS for PostgreSQL DB instance, see Enabling automated backups in the *Amazon RDS User Guide*.

To enable PostgreSQL logical replication with Aurora

1. Create a new DB cluster parameter group to use for logical replication, as described in Creating a DB cluster parameter group (p. 339). Use the following settings:
   - For Parameter group family, choose your version of Aurora PostgreSQL, such as aurora-postgresql12.
   - For Type, choose DB Cluster Parameter Group.
2. Modify the DB cluster parameter group, as described in Modifying parameters in a DB cluster parameter group (p. 345). Set the rds.logical_replication static parameter to 1.
   
   Enabling the rds.logical_replication parameter affects the DB cluster's performance.
3. Review the max_replication_slots, max_wal_senders, max_logical_replication_workers, and max_worker_processes parameters in your DB cluster parameter group based on your expected usage. If necessary, modify the DB cluster parameter group to change the settings for these parameters, as described in Modifying parameters in a DB cluster parameter group (p. 345).

   Follow these guidelines for setting the parameters:
   - max_replication_slots – Ensure that max_replication_slots is at least as high as the combined number of logical replication publications and subscriptions you plan to create. If you are using AWS DMS, make sure max_replication_slots is at least as high as the number of AWS DMS tasks you plan to use for change data capture from this DB cluster, plus any logical replication publications and subscriptions.
   - max_wal_senders and max_logical_replication_workers – Ensure that max_wal_senders and max_logical_replication_workers are each set at least as high as the number of logical replication slots that you intend to be active, or the number of active AWS DMS tasks for change data capture. Leaving a logical replication slot inactive prevents vacuum from removing obsolete tuples from tables, so we recommend that you don't keep inactive replication slots for long periods of time.
   - max_worker_processes – Ensure that max_worker_processes is at least as high as the combined values of max_logical_replication_workers, autovacuum_max_workers, and max_parallel_workers. Having a high number of background worker processes might affect application workloads on small DB instance classes, so monitor the performance of your database if you set max_worker_processes higher than the default value.

To configure a publisher for logical replication

1. Set the publisher's cluster parameter group:
   - To use an existing Aurora PostgreSQL DB cluster for the publisher, the engine version must be 10.6 or later. Do the following:
1. Modify the DB cluster parameter group to set it to the group that you created when you enabled logical replication. For details about modifying an Aurora PostgreSQL DB cluster, see Modifying an Amazon Aurora DB cluster (p. 368).

2. Restart the DB cluster for static parameter changes to take effect. The DB cluster parameter group includes a change to the static parameter rds.logical_replication.

- To use a new Aurora PostgreSQL DB cluster for the publisher, create the DB cluster using the following settings. For details about creating an Aurora PostgreSQL DB cluster, see Creating a DB cluster (p. 125).
  1. Choose the Amazon Aurora engine and choose the PostgreSQL-compatible edition.
  2. For Engine version, choose an Aurora PostgreSQL engine that is compatible with PostgreSQL 10.6 or greater.
  3. For DB cluster parameter group, choose the group that you created when you enabled logical replication.

2. Modify the inbound rules of the security group for the publisher to allow the subscriber to connect. Usually, you do this by including the IP address of the subscriber in the security group. For details about modifying a security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

Example of logical replication of a database table

To implement logical replication, use the PostgreSQL commands CREATE PUBLICATION and CREATE SUBSCRIPTION.

For this example, table data is replicated from an Aurora PostgreSQL database as the publisher to a PostgreSQL database as the subscriber. Note that a subscriber database can be an RDS PostgreSQL database or an Aurora PostgreSQL database. A subscriber can also be an application that uses PostgreSQL logical replication. After the logical replication mechanism is set up, changes on the publisher are continually sent to the subscriber as they occur.

To set up logical replication for this example, do the following:

1. Configure an Aurora PostgreSQL DB cluster as the publisher. To do so, create a new Aurora PostgreSQL DB cluster, as described when configuring the publisher in Configuring logical replication (p. 1373).

2. Set up the publisher database.

   For example, create a table using the following SQL statement on the publisher database.

   ```sql
   CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);
   ```

3. Insert data into the publisher database by using the following SQL statement.

   ```sql
   INSERT INTO LogicalReplicationTest VALUES (generate_series(1,10000));
   ```

4. Create a publication on the publisher by using the following SQL statement.

   ```sql
   CREATE PUBLICATION testpub FOR TABLE LogicalReplicationTest;
   ```

5. Create your subscriber. A subscriber database can be either of the following:

   - Aurora PostgreSQL database version 2.2.0 (compatible with PostgreSQL 10.6) or later.
   - Amazon RDS for PostgreSQL database with the PostgreSQL DB engine version 10.4 or later.

   For this example, we create an Amazon RDS for PostgreSQL database as the subscriber. For details on creating a DB instance, see Creating a DB instance in the Amazon RDS User Guide.
6. Set up the subscriber database.

For this example, create a table like the one created for the publisher by using the following SQL statement.

```
CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);
```

7. Verify that there is data in the table at the publisher but no data yet at the subscriber by using the following SQL statement on both databases.

```
SELECT count(*) FROM LogicalReplicationTest;
```

8. Create a subscription on the subscriber.

Use the following SQL statement on the subscriber database and the following settings from the publisher cluster:

- **host** – The publisher cluster's writer DB instance.
- **port** – The port on which the writer DB instance is listening. The default for PostgreSQL is 5432.
- **dbname** – The DB name of the publisher cluster.

```
CREATE SUBSCRIPTION testsub CONNECTION
  'host=publisher-cluster-writer-endpoint port=5432 dbname=db-name user=user
password=password'
  PUBLICATION testpub;
```

After the subscription is created, a logical replication slot is created at the publisher.

9. To verify for this example that the initial data is replicated on the subscriber, use the following SQL statement on the subscriber database.

```
SELECT count(*) FROM LogicalReplicationTest;
```

Any further changes on the publisher are replicated to the subscriber.

## Logical replication using the AWS Database Migration Service

You can use the AWS Database Migration Service (AWS DMS) to replicate a database or a portion of a database. Use AWS DMS to migrate your data from an Aurora PostgreSQL database to another open source or commercial database. For more information about AWS DMS, see the AWS Database Migration Service User Guide.

The following example shows how to set up logical replication from an Aurora PostgreSQL database as the publisher and then use AWS DMS for migration. This example uses the same publisher and subscriber that were created in Example of logical replication of a database table (p. 1375).

To set up logical replication with AWS DMS, you need details about your publisher and subscriber from Amazon RDS. In particular, you need details about the publisher's writer DB instance and the subscriber's DB instance.

Get the following information for the publisher's writer DB instance:

- The virtual private cloud (VPC) identifier
- The subnet group
- The Availability Zone (AZ)
- The VPC security group
• The DB instance ID

Get the following information for the subscriber’s DB instance:
• The DB instance ID
• The source engine

**To use AWS DMS for logical replication with Aurora PostgreSQL**

1. Prepare the publisher database to work with AWS DMS.

   To do this, PostgreSQL 10.x and later databases require that you apply AWS DMS wrapper functions to the publisher database. For details on this and later steps, see the instructions in *Using PostgreSQL version 10.x and later as a source for AWS DMS* in the *AWS Database Migration Service User Guide*.

2. Sign in to the AWS Management Console and open the AWS DMS console at `https://console.aws.amazon.com/dms/v2`. At top right, choose the same AWS Region in which the publisher and subscriber are located.

3. Create an AWS DMS replication instance.

   Choose values that are the same as for your publisher's writer DB instance. These include the following settings:
   - For **VPC**, choose the same VPC as for the writer DB instance.
   - For **Replication Subnet Group**, choose a subnet group with the same values as the writer DB instance. Create a new one if necessary.
   - For **Availability zone**, choose the same zone as for the writer DB instance.
   - For **VPC Security Group**, choose the same group as for the writer DB instance.

4. Create an AWS DMS endpoint for the source.

   Specify the publisher as the source endpoint by using the following settings:
   - For **Endpoint type**, choose **Source endpoint**.
   - Choose **Select RDS DB Instance**.
   - For **RDS Instance**, choose the DB identifier of the publisher's writer DB instance.
   - For **Source engine**, choose **postgres**.

5. Create an AWS DMS endpoint for the target.

   Specify the subscriber as the target endpoint by using the following settings:
   - For **Endpoint type**, choose **Target endpoint**.
   - Choose **Select RDS DB Instance**.
   - For **RDS Instance**, choose the DB identifier of the subscriber DB instance.
   - Choose a value for **Source engine**. For example, if the subscriber is an RDS PostgreSQL database, choose **postgres**. If the subscriber is an Aurora PostgreSQL database, choose **aurora-postgresql**.

6. Create an AWS DMS database migration task.

   You use a database migration task to specify what database tables to migrate, to map data using the target schema, and to create new tables on the target database. At a minimum, use the following settings for **Task configuration**:
   - For **Replication instance**, choose the replication instance that you created in an earlier step.
   - For **Source database endpoint**, choose the publisher source that you created in an earlier step.
• For **Target database endpoint**, choose the subscriber target that you created in an earlier step.

The rest of the task details depend on your migration project. For more information about specifying all the details for DMS tasks, see Working with AWS DMS tasks in the *AWS Database Migration Service User Guide*.

After AWS DMS creates the task, it begins migrating data from the publisher to the subscriber.

**Stopping logical replication**

You can stop using logical replication.

**To stop using logical replication**

1. Drop all replication slots.

   To drop all of the replication slots, connect to the publisher and run the following SQL command

   ```sql
   SELECT pg_drop_replication_slot(slot_name) FROM pg_replication_slots
   WHERE slot_name IN (SELECT slot_name FROM pg_replication_slots);
   ``

   The replication slots can't be active when you run this command.

2. Modify the DB cluster parameter group associated with the publisher, as described in Modifying parameters in a DB cluster parameter group (p. 345). Set the `rds.logical_replication` static parameter to 0.

3. Restart the publisher DB cluster for the change to the `rds.logical_replication` static parameter to take effect.

**Integrating Amazon Aurora PostgreSQL with other AWS services**

Amazon Aurora integrates with other AWS services so that you can extend your Aurora PostgreSQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora PostgreSQL DB cluster can use AWS services to do the following:

• Quickly collect, view, and assess performance for your Aurora PostgreSQL DB instances with Amazon RDS Performance Insights. Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database’s performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information about Performance Insights, see Monitoring DB load with Performance Insights on Amazon Aurora (p. 561).

• Automatically add or remove Aurora Replicas with Aurora Auto Scaling. For more information, see Using Amazon Aurora Auto Scaling with Aurora replicas (p. 423).

• Configure your Aurora PostgreSQL DB cluster to publish log data to Amazon CloudWatch Logs. CloudWatch Logs provide highly durable storage for your log records. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. For more information, see Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs (p. 1428).

• Import data from an Amazon S3 bucket to an Aurora PostgreSQL DB cluster, or export data from an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. For more information, see Importing Amazon S3 data into an Aurora PostgreSQL DB cluster (p. 1379) and Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 (p. 1391).
Importing S3 data into an Aurora PostgreSQL DB cluster

You can import data from Amazon S3 into a table belonging to an Aurora PostgreSQL DB cluster. To do this, you use the aws_s3 PostgreSQL extension that Aurora PostgreSQL provides. Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into Aurora PostgreSQL.

If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can't import data from a bucket that is encrypted with a customer managed key.

For more information on storing data with Amazon S3, see Create a bucket in the Amazon Simple Storage Service User Guide. For instructions on how to upload a file to an Amazon S3 bucket, see Add an object to a bucket in the Amazon Simple Storage Service User Guide.

Topics

- Overview of importing Amazon S3 data (p. 1379)
- Setting up access to an Amazon S3 bucket (p. 1380)
- Using the aws_s3.table_import_from_s3 function to import Amazon S3 data (p. 1385)
- Function reference (p. 1387)

Overview of importing Amazon S3 data

To import data stored in an Amazon S3 bucket to a PostgreSQL database table, follow these steps.

To import S3 data into Aurora PostgreSQL

1. Install the required PostgreSQL extensions. These include the aws_s3 and aws_commons extensions. To do so, start psql and use the following command.

   ```
   psql> CREATE EXTENSION aws_s3 CASCADE;
   NOTICE: installing required extension "aws_commons"
   ```

   The aws_s3 extension provides the aws_s3.table_import_from_s3 (p. 1387) function that you use to import Amazon S3 data. The aws_commons extension provides additional helper functions.

2. Identify the database table and Amazon S3 file to use.

   The aws_s3.table_import_from_s3 (p. 1387) function requires the name of the PostgreSQL database table that you want to import data into. The function also requires that you identify the Amazon S3 file to import. To provide this information, take the following steps.
a. Identify the PostgreSQL database table to put the data in. For example, the following is a sample `t1` database table used in the examples for this topic.

```
psql> CREATE TABLE t1 (col1 varchar(80), col2 varchar(80), col3 varchar(80));
```

b. Get the following information to identify the Amazon S3 file that you want to import:

- **Bucket name** – A bucket is a container for Amazon S3 objects or files.
- **File path** – The file path locates the file in the Amazon S3 bucket.
- **AWS Region** – The AWS Region is the location of the Amazon S3 bucket. For example, if the S3 bucket is in the US East (N. Virginia) Region, use `us-east-1`. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 11).

To find how to get this information, see View an object in the Amazon Simple Storage Service User Guide. You can confirm the information by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

```bash
aws s3 cp s3://sample_s3_bucket/sample_file_path ./
```

c. Use the `aws_commons.create_s3_uri (p. 1390)` function to create an `aws_commons._s3_uri_1` structure to hold the Amazon S3 file information. You provide this `aws_commons._s3_uri_1` structure as a parameter in the call to the `aws_s3.table_import_from_s3 (p. 1387)` function.

For a psql example, see the following.

```
psql> SELECT aws_commons.create_s3_uri('sample_s3_bucket', 'sample.csv', 'us-east-1') AS s3_uri \\
          \gset
```

3. Provide permission to access the Amazon S3 file.

To import data from an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket the file is in. To do this, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see Setting up access to an Amazon S3 bucket (p. 1380).

4. Import the Amazon S3 data by calling the `aws_s3.table_import_from_s3` function.

After you complete the previous preparation tasks, use the `aws_s3.table_import_from_s3 (p. 1387)` function to import the Amazon S3 data. For more information, see Using the `aws_s3.table_import_from_s3` function to import Amazon S3 data (p. 1385).

### Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

**Topics**

- Using an IAM role to access an Amazon S3 bucket (p. 1381)
- Using security credentials to access an Amazon S3 bucket (p. 1384)
- Troubleshooting access to Amazon S3 (p. 1385)
Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket the file is in. This way, you don’t have to manage additional credential information or provide it in the `aws_s3.table_import_from_s3` (p. 1387) function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB cluster.

**To give an Aurora PostgreSQL DB cluster access to Amazon S3 through an IAM role**

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your Aurora PostgreSQL DB cluster to access Amazon S3.

   Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Aurora PostgreSQL:
   
   • `s3:GetObject`
   • `s3:ListBucket`

   Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

   • `arn:aws:s3:::your-s3-bucket`
   • `arn:aws:s3:::your-s3-bucket/*`

   For more information on creating an IAM policy for Aurora PostgreSQL, see Creating and using an IAM policy for IAM database access (p. 1664). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named `your-s3-bucket`.

   **Note**
   
   Note the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN when you attach the policy to an IAM role, in a subsequent step.

   **Example**

   For Linux, macOS, or Unix:

   ```sh
   aws iam create-policy \
   --policy-name rds-s3-import-policy \
   --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
     "Sid": "s3import",
     "Action": [
     "s3:GetObject",
     "s3:ListBucket"
     ],
     "Effect": "Allow",
     "Resource": [n
     "arn:aws:s3:::your-s3-bucket",
     "arn:aws:s3:::your-s3-bucket/*"
     ]
   ]}
   '}
   ```
For Windows:

```
aws iam create-policy --policy-name rds-s3-import-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3import",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3:::your-s3-bucket",
        "arn:aws:s3:::your-s3-bucket/*"
      ]
    }
  ]
}'
```

2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

**Example**

For Linux, macOS, or Unix:

```
aws iam create-role --role-name rds-s3-import-role --assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      }
    }
  ]
}'
```

```
aws iam create-policy --policy-name rds-s3-import-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3import",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3:::your-s3-bucket",
        "arn:aws:s3:::your-s3-bucket/*"
      ]
    }
  ]
}'
```
Setting up access to an Amazon S3 bucket

For Windows:

```bash
aws iam create-role ^
  --role-name rds-s3-import-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
      }
    ]
  }'

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created in the previous step to the role named rds-s3-import-role. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam attach-role-policy \
  --policy-arn your-policy-arn \
  --role-name rds-s3-import-role
```

For Windows:

```bash
aws iam attach-role-policy ^
  --policy-arn your-policy-arn ^
  --role-name rds-s3-import-role
```

4. Add the IAM role to the DB cluster.

You do so by using the AWS Management Console or AWS CLI, as described following.
Note
You can't associate an IAM role with an Aurora Serverless DB cluster. For more information, see Using Amazon Aurora Serverless v1 (p. 146).
Also, be sure the database you use doesn't have any restrictions noted in Importing Amazon S3 data into an Aurora PostgreSQL DB cluster (p. 1379).

Console

To add an IAM role for a PostgreSQL DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this cluster.
4. Under Feature, choose s3Import.
5. Choose Add role.

AWS CLI

To add an IAM role for a PostgreSQL DB cluster using the CLI

- Use the following command to add the role to the PostgreSQL DB cluster named my-db-cluster. Replace your-role-arn with the role ARN that you noted in a previous step. Use s3Import for the value of the --feature-name option.

  Example

  For Linux, macOS, or Unix:

  ```bash
  aws rds add-role-to-db-cluster \
  --db-cluster-identifier my-db-cluster \
  --feature-name s3Import \n  --role-arn your-role-arn \n  --region your-region
  ```

  For Windows:

  ```bash
  aws rds add-role-to-db-cluster ^
  --db-cluster-identifier my-db-cluster ^
  --feature-name s3Import ^
  --role-arn your-role-arn ^
  --region your-region
  ```

RDS API

To add an IAM role for a PostgreSQL DB cluster using the Amazon RDS API, call the AddRoleToDBCluster operation.

Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. To do this, use the credentials parameter in the aws_s3.table_import_from_s3 (p. 1387) function call.
The credentials parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the `aws_commons.create_aws_credentials` (p. 1390) function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```
psql=> SELECT aws_commons.create_aws_credentials(
  'sample_access_key', 'sample_secret_key', '')
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the `aws_s3.table_import_from_s3` (p. 1387) function with the credentials parameter to import the data, as shown following.

```
psql=> SELECT aws_s3.table_import_from_s3(
  't', '', '(format csv)',
  s3_uri',
  'creds' );
```

Or you can include the `aws_commons.create_aws_credentials` (p. 1390) function call inline within the `aws_s3.table_import_from_s3` function call.

```
psql=> SELECT aws_s3.table_import_from_s3(
  't', '', '(format csv)',
  s3_uri',
  aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', ''));
```

## Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import Amazon S3 file data, see the following for recommendations:

- Troubleshooting Amazon Aurora identity and access (p. 1690)
- Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide
- Troubleshooting Amazon S3 and IAM in the IAM User Guide

## Using the `aws_s3.table_import_from_s3` function to import Amazon S3 data

Import your Amazon S3 data by calling the `aws_s3.table_import_from_s3` (p. 1387) function.

**Note**

The following examples use the IAM role method for providing access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don’t include credential parameters.

The following shows a typical PostgreSQL example using `psql`.

```
psql=> SELECT aws_s3.table_import_from_s3(
  't1',
  '',
  '(format csv)',
  s3_uri'
) ;
```

The parameters are the following:
• `t1` – The name for the table in the PostgreSQL DB cluster to copy the data into.

• `' '` – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see Importing an Amazon S3 file that uses a custom delimiter (p. 1386).

• `{format csv}` – PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command. In the preceding example, the COPY command uses the comma-separated value (CSV) file format to copy the data.

• `s3_uri` – A structure that contains the information identifying the Amazon S3 file. For an example of using the `aws_commons.create_s3_uri` (p. 1390) function to create an `s3_uri` structure, see Overview of importing Amazon S3 data (p. 1379).

The return value is text. For the full reference of this function, see `aws_s3.table_import_from_s3` (p. 1387).

The following examples show how to specify different kinds of files when importing Amazon S3 data.

**Topics**

- Importing an Amazon S3 file that uses a custom delimiter (p. 1386)
- Importing an Amazon S3 compressed (gzip) file (p. 1387)
- Importing an encoded Amazon S3 file (p. 1387)

**Importing an Amazon S3 file that uses a custom delimiter**

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the `aws_s3.table_import_from_s3` (p. 1387) function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
```

To import a file that uses a custom delimiter

1. Create a table in the database for the imported data.

   ```
   psql=> CREATE TABLE test (a text, b text, c text, d text, e text);
   ```

2. Use the following form of the `aws_s3.table_import_from_s3` (p. 1387) function to import data from the Amazon S3 file.

   You can include the `aws_commons.create_s3_uri` (p. 1390) function call inline within the `aws_s3.table_import_from_s3` function call to specify the file.

   ```
   psql=> SELECT aws_s3.table_import_from_s3('test',
          'a,b,d,e',
          'DELIMITER ''|''',
          aws_commons.create_s3_uri('sampleBucket', 'pipeDelimitedSampleFile', 'us-east-2'))
   ```
The data is now in the table in the following columns.

```
<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>foo1</td>
<td></td>
<td>bar1</td>
<td>elephant1</td>
</tr>
<tr>
<td>2</td>
<td>foo2</td>
<td></td>
<td>bar2</td>
<td>elephant2</td>
</tr>
<tr>
<td>3</td>
<td>foo3</td>
<td></td>
<td>bar3</td>
<td>elephant3</td>
</tr>
<tr>
<td>4</td>
<td>foo4</td>
<td></td>
<td>bar4</td>
<td>elephant4</td>
</tr>
</tbody>
</table>
```

Importing an Amazon S3 compressed (gzip) file

The following example shows how to import a file from Amazon S3 that is compressed with gzip.

Ensure that the file contains the following Amazon S3 metadata:

- **Key:** Content-Encoding
- **Value:** gzip

For more about adding these values to Amazon S3 metadata, see [How do I add metadata to an S3 object?](https://docs.aws.amazon.com/AmazonS3/latest/userguide/s3-object-metadata.html) in the [Amazon Simple Storage Service User Guide](https://docs.aws.amazon.com/AmazonS3/latest/userguide/).

Import the gzip file into your Aurora PostgreSQL DB cluster as shown following.

```
psql>= CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
psql=> SELECT aws_s3.table_import_from_s3('test_gzip', '', '(format csv)', 'myS3Bucket', 'test-data.gz', 'us-east-2');
```

Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```
psql>= SELECT aws_s3.table_import_from_s3('test_table', '', 'encoding 'WIN1252''', aws_commons.create_s3_uri('sampleBucket', 'SampleFile', 'us-east-2'));
```

**Function reference**

**Functions**

- `aws_s3.table_import_from_s3` (p. 1387)
- `aws_commons.create_s3_uri` (p. 1390)
- `aws_commons.create_aws_credentials` (p. 1390)

**aws_s3.table_import_from_s3**

Imports Amazon S3 data into an Aurora PostgreSQL table. The `aws_s3` extension provides the `aws_s3.table_import_from_s3` function. The return value is text.
Syntax

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB cluster.

```python
aws_s3.table_import_from_s3 (
    table_name text,
    column_list text,
    options text,
    s3_info aws_commons._s3_uri_1
)
```

- The `credentials` parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```python
aws_s3.table_import_from_s3 (
    table_name text,
    column_list text,
    options text,
    s3_info aws_commons._s3_uri_1,
    credentials aws_commons._aws_credentials_1
)
```

Parameters

table_name

A required text string containing the name of the PostgreSQL database table to import the data into.

column_list

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see Importing an Amazon S3 file that uses a custom delimiter (p. 1386).

options

A required text string containing arguments for the PostgreSQL `COPY` command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the PostgreSQL `COPY` documentation.

s3_info

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket containing the file.
- `file_path` – The Amazon S3 file name including the path of the file.
- `region` – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 11).

credentials

An `aws_commons._aws_credentials_1` composite type containing the following credentials to use for the import operation:

- Access key
Alternate syntax

To help with testing, you can use an expanded set of parameters instead of the `s3_info` and `credentials` parameters. Following are additional syntax variations for the `aws_s3.table_import_from_s3` function:

- Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```sql
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text
)
```

- Instead of using the `credentials` parameter to specify Amazon S3 access, use the combination of the `access_key`, `secret_key`, and `session_token` parameters.

```sql
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text,  
    access_key text,  
    secret_key text,  
    session_token text
)
```

Alternate parameters

- **bucket**
  
  A text string containing the name of the Amazon S3 bucket that contains the file.

- **file_path**
  
  A text string containing the Amazon S3 file name including the path of the file.

- **region**
  
  A text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions and Availability Zones](p. 11).

- **access_key**
  
  A text string containing the access key to use for the import operation. The default is NULL.

- **secret_key**
  
  A text string containing the secret key to use for the import operation. The default is NULL.
session_token

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

aws_commons.create_s3_uri

Creates an aws_commons._s3_uri_1 structure to hold Amazon S3 file information. Use the results of the aws_commons.create_s3_uri function in the s3_info parameter of the aws_s3.table_import_from_s3 (p. 1387) function.

Syntax

```plaintext
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

Parameters

- **bucket**
  
  A required text string containing the Amazon S3 bucket name for the file.

- **file_path**
  
  A required text string containing the Amazon S3 file name including the path of the file.

- **region**
  
  A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 11).

aws_commons.create_aws_credentials

Sets an access key and secret key in an aws_commons._aws_credentials_1 structure. Use the results of the aws_commons.create_aws_credentials function in the credentials parameter of the aws_s3.table_import_from_s3 (p. 1387) function.

Syntax

```plaintext
aws_commons.create_aws_credentials(
    access_key text,
    secret_key text,
    session_token text
)
```

Parameters

- **access_key**
  
  A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

- **secret_key**
  
  A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.
Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3

You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 bucket. To do this, you use the `aws_s3` PostgreSQL extension that Aurora PostgreSQL provides.

For more information on storing data with Amazon S3, see *Create a bucket* in the *Amazon Simple Storage Service User Guide*.

The upload to Amazon S3 uses server-side encryption by default. If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can’t export data to a bucket that is encrypted with a customer managed key.

**Note**
You can save DB and DB cluster snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see *Exporting DB snapshot data to Amazon S3* (p. 514).

**Topics**
- Overview of exporting data to Amazon S3 (p. 1391)
- Verify that your Aurora PostgreSQL version supports exports (p. 1392)
- Specifying the Amazon S3 file path to export to (p. 1392)
- Setting up access to an Amazon S3 bucket (p. 1393)
- Exporting query data using the `aws_s3.query_export_to_s3` function (p. 1396)
- Troubleshooting access to Amazon S3 (p. 1398)
- Function reference (p. 1398)

**Overview of exporting data to Amazon S3**

To export data stored in an Aurora PostgreSQL database to an Amazon S3 bucket, use the following procedure.

**To export Aurora PostgreSQL data to S3**

1. Install the required PostgreSQL extensions. These include the `aws_s3` and `aws_commons` extensions. To do so, start `psql` and use the following commands.

   ```sql
   CREATE EXTENSION IF NOT EXISTS aws_s3 CASCADE;
   ```

   The `aws_s3` extension provides the `aws_s3.query_export_to_s3` function that you use to export data to Amazon S3. The `aws_commons` extension is included to provide additional helper functions.

2. Identify an Amazon S3 file path to use for exporting data. For details about this process, see *Specifying the Amazon S3 file path to export to* (p. 1392).

3. Provide permission to access the Amazon S3 bucket.
To export data to an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
2. Create an IAM role.
3. Attach the policy you created to the role you created.
4. Add this IAM role to your DB cluster.

For details about this process, see Setting up access to an Amazon S3 bucket (p. 1393).

4. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

After you complete the preceding preparation tasks, use the `aws_s3.query_export_to_s3` function to export query results to Amazon S3. For details about this process, see Exporting query data using the `aws_s3.query_export_to_s3` function (p. 1396).

## Verify that your Aurora PostgreSQL version supports exports

Currently, Amazon S3 exports are supported for the following versions of Aurora PostgreSQL:

- 10.11 and higher 10 versions
- 11.6 and higher 11 versions
- 12.4 and higher 12 versions
- 13.3 and higher 13 versions

You can also verify support by using the `describe-db-engine-versions` command. The following example verify support for version 10.14.

```bash
aws rds describe-db-engine-versions --region us-east-1 --engine aurora-postgresql --engine-version 10.14 --engine-version 10.14 | grep s3Export
```

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

### Specifying the Amazon S3 file path to export to

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- **Bucket name** – A *bucket* is a container for Amazon S3 objects or files.

For more information on storing data with Amazon S3, see Create a bucket and View an object in the Amazon Simple Storage Service User Guide.

- **File path** – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on.
For example, a file path with an `exports` folder and a `query-1-export` file prefix is `/exports/query-1-export`.

- AWS Region (optional) – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Aurora saves your files into Amazon S3 in the same AWS Region as the exporting DB cluster.

  **Note**
  
  Currently, the AWS Region must be the same as the region of the exporting DB cluster.

For a listing of AWS Region names and associated values, see [Regions and Availability Zones](#p.11).

To hold the Amazon S3 file information about where the export is to be stored, you can use the `aws_commons.create_s3_uri` function to create an `aws_commons._s3_uri_1` composite structure as follows.

```sql
psql-- SELECT aws_commons.create_s3_uri(  
'sample-bucket',  
'sample-filepath',  
'us-west-2'  
) AS s3_uri_1 \gset
```

You later provide this `s3_uri_1` value as a parameter in the call to the `aws_s3.query_export_to_s3` function. For examples, see Exporting query data using the `aws_s3.query_export_to_s3` function (p. 1396).

### Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB cluster permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

**To give a PostgreSQL DB cluster access to Amazon S3 through an IAM role**

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your PostgreSQL DB cluster to access Amazon S3.

   As part of creating this policy, take the following steps:

   a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB cluster to an Amazon S3 bucket:

      - `s3:PutObject`
      - `s3:AbortMultipartUpload`

   b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: `arn:aws:s3:::your-s3-bucket/*`

   For more information on creating an IAM policy for Aurora PostgreSQL, see [Creating and using an IAM policy for IAM database access](p. 1664). See also Tutorial: Create and attach your first customer managed policy in the [IAM User Guide](#).

   The following AWS CLI command creates an IAM policy named `rds-s3-export-policy` with these options. It grants access to a bucket named `your-s3-bucket`. 

---

1393
Warning
We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see Using endpoint policies for Amazon S3 in the Amazon VPC User Guide. We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives S3:PutObject access to all resources using "Resource":"*", then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to any publicly writable bucket within your AWS Region.

After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name rds-s3-export-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3export",
      "Action": [
        "S3:PutObject"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3:::your-s3-bucket/*"
      ]
    }
  ]
}
```

2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the aws:SourceArn and aws:SourceAccount global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the aws:SourceArn value contains the account ID, the aws:SourceAccount value and the account in the aws:SourceArn value must use the same account ID when used in the same policy statement.

- Use aws:SourceArn if you want cross-service access for a single resource.
- Use aws:SourceAccount if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the aws:SourceArn global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named rds-s3-export-role.

**Example**

For Linux, macOS, or Unix:

```
aws iam create-role \
  --role-name rds-s3-export-role \
  --assume-role-policy-document '{
```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
    "Condition": {
      "StringEquals": {
        "aws:SourceAccount": 111122223333,
        "aws:SourceArn": arn:aws:rds:us-east-1:111122223333db:dbname
      }
    }
  }
]
}

For Windows:

aws iam create-role  ^
  --role-name rds-s3-export-role  ^
  --assume-role-policy-document '{
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
    "Condition": {
      "StringEquals": {
        "aws:SourceAccount": 111122223333,
        "aws:SourceArn": arn:aws:rds:us-east-1:111122223333db:dbname
      }
    }
  }
]
}

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace your-policy-arn with the policy ARN that you noted in an earlier step.

aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role

4. Add the IAM role to the DB cluster. You do so by using the AWS Management Console or AWS CLI, as described following.

Console

To add an IAM role for a PostgreSQL DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this instance.

4. Under Feature, choose s3Export.

5. Choose Add role.

AWS CLI

To add an IAM role for a PostgreSQL DB cluster using the CLI

- Use the following command to add the role to the PostgreSQL DB cluster named my-db-cluster. Replace your-role-arn with the role ARN that you noted in a previous step. Use s3Export for the value of the --feature-name option.

Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-cluster \
--db-cluster-identifier my-db-cluster \
--feature-name s3Export \
--role-arn your-role-arn \
--region your-region
```

For Windows:

```
aws rds add-role-to-db-cluster ^
--db-cluster-identifier my-db-cluster ^
--feature-name s3Export ^
--role-arn your-role-arn ^
--region your-region
```

Exporting query data using the aws_s3.query_export_to_s3 function

Export your PostgreSQL data to Amazon S3 by calling the aws_s3.query_export_to_s3 function.

Topics

- Prerequisites (p. 1396)
- Calling aws_s3.query_export_to_s3 (p. 1397)
- Exporting to a CSV file that uses a custom delimiter (p. 1398)
- Exporting to a binary file with encoding (p. 1398)

Prerequisites

Before you use the aws_s3.query_export_to_s3 function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in Overview of exporting data to Amazon S3 (p. 1391).
• Determine where to export your data to Amazon S3 as described in Specifying the Amazon S3 file path to export to (p. 1392).
• Make sure that the DB cluster has export access to Amazon S3 as described in Setting up access to an Amazon S3 bucket (p. 1393).

The examples following use a database table called `sample_table`. These examples export the data into a bucket called `sample-bucket`. The example table and data are created with the following SQL statements in `psql`.

```
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid, name) VALUES (1, 'Monday'), (2, 'Tuesday'), (3, 'Wednesday');
```

Calling `aws_s3.query_export_to_s3`

The following shows the basic ways of calling the `aws_s3.query_export_to_s3` function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the `aws_commons.create_s3_uri` function to create the structure.

```
psql=> SELECT aws_commons.create_s3_uri('sample-bucket', 'sample-filepath', 'us-west-2') AS s3_uri_1 \gset
```

Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called `sample-bucket`.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1', options :='format text');
```

The parameters are described as follows:

• `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
• `:'s3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

```
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',
    aws_commons.create_s3_uri('sample-bucket', 'sample-filepath', 'us-west-2'))
```

• `options :='format text'` – The options parameter is an optional text string containing PostgreSQL COPY arguments. The copy process uses the arguments and format of the `PostgreSQL COPY` command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.
Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with _part XX appended. The XX represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://my-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://my-bucket/my-prefix
s3-us-west-2://my-bucket/my-prefix_part2
s3-us-west-2://my-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see `aws_s3.query_export_to_s3 (p. 1399)`. For more about accessing files in Amazon S3, see View an object in the Amazon Simple Storage Service User Guide.

### Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the `aws_s3.query_export_to_s3 (p. 1399)` function to export data to a file that uses a custom delimiter. The example uses arguments of the PostgreSQL COPY command to specify the comma-separated value (CSV) format and a colon (:) delimiter.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
options :='format csv, delimiter $$:$$');
```

### Exporting to a binary file with encoding

The following example shows how to call the `aws_s3.query_export_to_s3 (p. 1399)` function to export data to a binary file that has Windows-1253 encoding.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
options :='format binary, encoding WIN1253');
```

### Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, they must allow access to port 443 for SSL connections. For more information, see Provide access to the DB cluster in the VPC by creating a security group (p. 86).

See also the following for recommendations:

- Troubleshooting Amazon Aurora identity and access (p. 1690)
- Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide
- Troubleshooting Amazon S3 and IAM in the IAM User Guide

### Function reference

**Functions**

- `aws_s3.query_export_to_s3 (p. 1399)`
aws_s3.query_export_to_s3

Exports a PostgreSQL query result to an Amazon S3 bucket. The aws_s3 extension provides the aws_s3.query_export_to_s3 function.

The two required parameters are query and s3_info. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called options provides for defining various export parameters. For examples of using the aws_s3.query_export_to_s3 function, see Exporting query data using the aws_s3.query_export_to_s3 function (p. 1396).

Syntax

```python
aws_s3.query_export_to_s3(
    query text,
    s3_info aws_commons._s3_uri_1,
    options text
)
```

Input parameters

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the s3_info parameter.

s3_info

An aws_commons._s3_uri_1 composite type containing the following information about the S3 object:

- **bucket** – The name of the Amazon S3 bucket to contain the file.
- **file_path** – The Amazon S3 file name and path.
- **region** – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 11).

Currently, this value must be the same AWS Region as that of the exporting DB cluster. The default is the AWS Region of the exporting DB cluster.

To create an aws_commons._s3_uri_1 composite structure, see the aws_commons.create_s3_uri (p. 1401) function.

options

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the s3_info parameter. Following are additional syntax variations for the aws_s3.query_export_to_s3 function.

Instead of using the s3_info parameter to identify an Amazon S3 file, use the combination of the bucket, file_path, and region parameters.

```python
aws_s3.query_export_to_s3(
    query text,
    bucket text,
    file_path text,
    region text
)
```
### Output parameters

```sql
aws_s3.query_export_to_s3(
    OUT rows_uploaded bigint,
    OUT files_uploaded bigint,
    OUT bytes_uploaded bigint
)
```

- **rows_uploaded**
  The number of table rows that were successfully uploaded to Amazon S3 for the given query.

- **files_uploaded**
  The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has _partXX appended to the name. The XX represents 2, then 3, and so on as needed.

- **bytes_uploaded**
  The total number of bytes uploaded to Amazon S3.

### Examples

```sql
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'sample-bucket', 'sample-filepath','us-west-2','format text');
```
aws_commons.create_s3_uri

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. You use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the `aws_s3.query_export_to_s3` function. For an example of using the `aws_commons.create_s3_uri` function, see Specifying the Amazon S3 file path to export to (p. 1392).

Syntax

```java
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

**Input parameters**

- **bucket**
  
  A required text string containing the Amazon S3 bucket name for the file.

- **file_path**
  
  A required text string containing the Amazon S3 file name including the path of the file.

- **region**
  
  A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 11).

Managing query execution plans for Aurora PostgreSQL

With query plan management for Amazon Aurora PostgreSQL-Compatible Edition, you can control how and when query execution plans change. Query plan management has two main objectives:

- Preventing plan regressions when the database system changes
- Controlling when the query optimizer can use new plans

The quality and consistency of query optimization have a major impact on the performance and stability of any relational database management system (RDBMS). Query optimizers create a query execution plan for a SQL statement at a specific point in time. As conditions change, the optimizer might pick a different plan that makes performance better or worse. In some cases, a number of changes can all cause the query optimizer to choose a different plan and lead to performance regression. These changes include changes in statistics, constraints, environment settings, query parameter bindings, and software upgrades. Regression is a major concern for high-performance applications.

With query plan management, you can control execution plans for a set of statements that you want to manage. You can do the following:

- Improve plan stability by forcing the optimizer to choose from a small number of known, good plans.
- Optimize plans centrally and then distribute the best plans globally.
- Identify indexes that aren't used and assess the impact of creating or dropping an index.
- Automatically detect a new minimum-cost plan discovered by the optimizer.
• Try new optimizer features with less risk, because you can choose to approve only the plan changes that improve performance.

**Topics**

• Enabling query plan management for Aurora PostgreSQL (p. 1402)
• Upgrading query plan management (p. 1403)
• Basics of query plan management (p. 1403)
• Best practices for query plan management (p. 1406)
• Examining plans in the apg_plan_mgmt.dba_plans view (p. 1407)
• Capturing execution plans (p. 1410)
• Using managed plans (p. 1411)
• Maintaining execution plans (p. 1414)
• Parameter reference for query plan management (p. 1418)
• Function reference for query plan management (p. 1421)

**Enabling query plan management for Aurora PostgreSQL**

Query plan management is available with the following Aurora PostgreSQL versions:

• All Aurora PostgreSQL 13 versions
• Aurora PostgreSQL version 12.4 and higher
• Aurora PostgreSQL version 11.6 and higher
• Aurora PostgreSQL version 10.5 and higher
• Aurora PostgreSQL version 9.6.11 and higher

Only users with the `rds_superuser` role can complete the following procedure. The `rds_superuser` is required for creating the apg_plan_mgmt extension and its `apg_plan_mgmt` role. Users must be granted the `apg_plan_mgmt` role to administer the apg_plan_mgmt extension.

**To enable query plan management**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Create a new instance-level parameter group to use for query plan management parameters. For more information, see Creating a DB parameter group (p. 338). Associate the new parameter group with the DB instances in which you want to use query plan management. For more information, see Modify a DB instance in a DB cluster (p. 369).
3. Create a new cluster-level parameter group to use for query plan management parameters. For more information, see Creating a DB cluster parameter group (p. 339). Associate the new cluster-level parameter group with the DB clusters in which you want to use query plan management. For more information, see Modifying the DB cluster by using the console, CLI, and API (p. 368).
4. Open your cluster-level parameter group and set the `rds.enable_plan_management` parameter to 1. For more information, see Modifying parameters in a DB cluster parameter group (p. 345).
5. Restart your DB instance to enable this new setting.
6. Connect to your DB instance with a SQL client such as psql.
7. Create the `apg_plan_mgmt` extension for your DB instance. The following shows an example.

```sql
psql my-database
```
If you create the `apg_plan_mgmt` extension in the `template1` default database, then the query plan management extension is available in each new database that you create.

You can disable query plan management at any time by turning off the `apg_plan_mgmt.use_plan_baselines` and `apg_plan_mgmt.capture_plan_baselines`:

```sql
my-database=> CREATE EXTENSION apg_plan_mgmt;

my-database=> SET apg_plan_mgmt.use_plan_baselines = off;
my-database=> SET apg_plan_mgmt.capture_plan_baselines = off;
```

### Upgrading query plan management

The latest version of query plan management is 2.0. If you installed an earlier version of query plan management, we strongly recommend that you upgrade to version 2.0. For version details, see Extension versions for Amazon Aurora PostgreSQL (p. 1589).

To upgrade, run the following commands at the cluster or DB instance level.

```sql
ALTER EXTENSION apg_plan_mgmt UPDATE TO '2.0';
SELECT apg_plan_mgmt.validate_plans('update_plan_hash');
SELECT apg_plan_mgmt.reload();
```

### Basics of query plan management

You can manage any SELECT, INSERT, UPDATE, or DELETE statement with query plan management, regardless of how complex the statement is. Prepared, dynamic, embedded, and immediate-mode SQL statements are all supported. All PostgreSQL language features can be used, including partitioned tables, inheritance, row-level security, and recursive common table expressions (CTEs).

### Performing a manual plan capture

To capture plans for specific statements, use the manual capture mode as in the following example.

```sql
/* Turn on manual capture */
SET apg_plan_mgmt.capture_plan_baselines = manual;
EXPLAIN SELECT COUNT(*) from pg_class;       -- capture the plan baseline
SET apg_plan_mgmt.capture_plan_baselines = off;    -- turn off capture
SET apg_plan_mgmt.use_plan_baselines = true;   -- turn on plan usage
```

You can either execute SELECT, INSERT, UPDATE, or DELETE statements, or you can include the EXPLAIN statement as shown above. Use EXPLAIN to capture a plan without the overhead or potential side-effects of executing the statement. For more about manual capture, see Manually capturing plans for specific
SQL statements (p. 1410). Note that query plan management doesn’t save the plans for statements that refer to system tables such as `pg_class`.

Viewing captured plans

When EXPLAIN SELECT runs in the previous example, the optimizer saves the plan. To do so, it inserts a row into the `apg_plan_mgmt.dba_plans` view and commits the plan in an autonomous transaction. You can see the contents of the `apg_plan_mgmt.dba_plans` view if you’ve been granted the `apg_plan_mgmt` role. The following query displays some important columns of the `dba_plans` view.

```sql
SELECT sql_hash, plan_hash, status, enabled, plan_outline, sql_text::varchar(40)
FROM apg_plan_mgmt.dba_plans
ORDER BY sql_text, plan_created;
```

Each row displayed represents a managed plan. The preceding example displays the following information.

- `sql_hash` – The ID of the managed statement that the plan is for.
- `plan_hash` – The ID of the managed plan.
- `status` – The status of the plan. The optimizer can run an approved plan.
- `enabled` – A value that indicates whether the plan is enabled for use or disabled and not for use.
- `plan_outline` – Details of the managed plan.

For more about the `apg_plan_mgmt.dba_plans` view, see Examining plans in the `apg_plan_mgmt.dba_plans` view (p. 1407).

Working with managed statements and the SQL hash

A managed statement is a SQL statement captured by the optimizer under query plan management. You specify which SQL statements to capture as managed statements using either manual or automatic capture:

- For manual capture, you provide the specific statements to the optimizer as shown in the previous example.
- For automatic capture, the optimizer captures plans for statements that run multiple times. Automatic capture is shown in a later example.

In the `apg_plan_mgmt.dba_plans` view, you can identify a managed statement with a SQL hash value. The SQL hash is calculated on a normalized representation of the SQL statement that removes some differences such as the literal values. Using normalization means that when multiple SQL statements differ only in their literal or parameter values, they are represented by the same SQL hash in the `apg_plan_mgmt.dba_plans` view. Therefore, there can be multiple plans for the same SQL hash where each plan is optimal under different conditions.

When the optimizer processes any SQL statement, it uses the following rules to create the normalized SQL statement:

- Removes any leading block comment
- Removes the EXPLAIN keyword and EXPLAIN options, if present
- Removes trailing spaces
- Removes all literals
- Preserves space and case for readability

For example, take the following statement.
/*Leading comment*/ EXPLAIN SELECT /* Query 1 */ * FROM t WHERE x > 7 AND y = 1;

The optimizer normalizes this statement as the following.

SELECT /* Query 1 */ * FROM t WHERE x > CONST AND y = CONST;

## Working with automatic plan capture

Use automatic plan capture if you want to capture plans for all SQL statements in your application, or if you can’t use manual capture. With automatic plan capture, the optimizer captures plans for statements that run at least two times. To use automatic plan capture, do the following.

1. Create a custom DB parameter group based on the default DB parameter group for the version of Aurora PostgreSQL that you're running.
2. Edit the custom DB parameter group, by changing the `apg_plan_mgmt.capture_plan_baselines` setting to `automatic`.
3. Save your customized DB parameter group.
4. Apply your custom DB parameter group to an Aurora DB instance that is already running as follows:
   - Choose your Aurora PostgreSQL DB instance from the list in the navigation pane, and then choose Modify.
   - In the **Additional configuration** section of the Modify DB instance page, for the **DB parameter group**, choose your custom DB parameter group.
   - Choose Continue. Confirm the Summary of modifications and choose **Apply immediately**.
   - Choose Modify DB instance to apply your custom DB parameter group.

You can also use your custom DB parameter group when you create a new Aurora PostgreSQL DB instance. For more information about parameter groups, see [Modifying parameters in a DB parameter group](p. 343).

As your application runs, the optimizer captures plans for any statement that runs more than once. The optimizer always sets the status of a managed statement’s first captured plan to approved. A managed statement’s set of approved plans is known as its **plan baseline**.

As your application continues to run, the optimizer might find additional plans for the managed statements. The optimizer sets additional captured plans to a status of Unapproved.

The set of all captured plans for a managed statement is known as the **plan history**. Later, you can decide if the Unapproved plans perform well and change them to Approved, Rejected, or Preferred by using the `apg_plan_mgmt.evolve_plan_baselines` function or the `apg_plan_mgmt.set_plan_status` function.

To turn off automatic plan capture, set `apg_plan_mgmt.capture_plan_baselines` to `off` in the parameter group for the DB instance. Follow the same general process as outlined above, modifying your custom DB parameter group value for `apg_plan_mgmt.capture_plan_baselines` and then applying the custom DB parameter group to your Aurora DB instance.

For more about plan capture, see [Capturing execution plans](p. 1410).

## Validating plans

Managed plans can become invalid ("stale") when objects that they depend on are removed, such as an index. To find and delete all plans that are stale, use the `apg_plan_mgmt.validate_plans` function.

```sql
SELECT apg_plan_mgmt.validate_plans('delete');
```
For more information, see Validating plans (p. 1415).

**Approving new plans that improve performance**

While using your managed plans, you can verify whether newer, lower-cost plans discovered by the optimizer are faster than the minimum-cost plan already in the plan baseline. To do the performance comparison and optionally approve the faster plans, call the `apg_plan_mgmt.evolve_plan_baselines` function.

The following example automatically approves any unapproved plan that is enabled and faster by at least 10 percent than the minimum-cost plan in the plan baseline.

```sql
SELECT apg_plan_mgmt.evolve_plan_baselines(
    sql_hash,
    plan_hash,
    1.1,
    'approve'
) FROM apg_plan_mgmt.dba_plans
WHERE status = 'Unapproved' AND enabled = true;
```

When the `apg_plan_mgmt.evolve_plan_baselines` function runs, it collects performance statistics and saves them in the `apg_plan_mgmt.dba_plans` view in the columns `planning_time_ms`, `execution_time_ms`, `cardinality_error`, `total_time_benefit_ms`, and `execution_time_benefit_ms`. The `apg_plan_mgmt.evolve_plan_baselines` function also updates the columns `last_verified` or `last_validated` timestamps, in which you can see the most recent time the performance statistics were collected.

```sql
SELECT sql_hash, plan_hash, status, last_verified, sql_text::varchar(40) FROM apg_plan_mgmt.dba_plans
ORDER BY last_verified DESC; -- value updated by evolve_plan_baselines()
```

For more information about verifying plans, see Evaluating plan performance (p. 1414).

**Deleting plans**

The optimizer deletes plans automatically if they have not been executed or chosen as the minimum-cost plan for the plan retention period. By default, the plan retention period is 32 days. To change the plan retention period, set the `apg_plan_mgmt.plan_retention_period` parameter.

You can also review the contents of the `apg_plan_mgmt.dba_plans` view and delete any plans you don't want by using the `apg_plan_mgmt.delete_plan` function. For more information, see Deleting plans (p. 1417).

**Best practices for query plan management**

Consider using a plan management style that is either proactive or reactive. These plan management styles contrast in how and when new plans get approved for use.

**Proactive plan management to help prevent performance regression**

With proactive plan management, you manually approve new plans after you have verified that they are faster. Do this to prevent plan performance regressions. Follow these steps for proactive plan management:

1. In a development environment, identify the SQL statements that have the greatest impact on performance or system throughput. Then capture the plans for these statements as described
Examine plans in the DBA plans view

With reactive plan management, you monitor your application as it runs to detect plans that cause performance regressions. When you detect regressions, you manually reject or fix the bad plans. Follow these steps for reactive plan management:

1. While your application runs, enforce the use of managed plans and automatically add newly discovered plans as unapproved. For more information, see Using managed plans (p. 1411) and Automatically capturing plans (p. 1411).
3. When you discover a plan regression, set the plan’s status to rejected. The next time the optimizer runs the SQL statement, it automatically ignores the rejected plan and uses a different approved plan instead. For more information, see Rejecting or disabling slower plans (p. 1415).

In some cases, you might prefer to fix a bad plan rather than reject, disable, or delete it. Use the pg_hint_plan extension to experiment with improving a plan. With pg_hint_plan, you use special comments to tell the optimizer to override how it normally creates a plan. For more information, see Fixing plans using pg_hint_plan (p. 1416).

Examine plans in the apg_plan_mgmt.dba_plans view

Query plan management provides a new SQL view for database administrators (DBAs) to use called apg_plan_mgmt.dba_plans. This one view contains the plan history for all of the databases in the DB instance.

This view contains the plan history for all of your managed statements. Each managed plan is identified by the combination of a SQL hash value and a plan hash value. With these identifiers, you can use tools such as Amazon RDS Performance Insights to track individual plan performance. For more information on Performance Insights, see Using Amazon RDS performance insights.

Note
Access to the apg_plan_mgmt.dba_plans view is restricted to users that hold the apg_plan_mgmt role.

Listing managed plans

To list the managed plans, use a SELECT statement on the apg_plan_mgmt.dba_plans view. The following example displays some columns in the dba_plans view such as the status, which identifies the approved and unapproved plans.
Reference for the `apg_plan_mgmt.dba_plans` view

The columns of plan information in the `apg_plan_mgmt.dba_plans` view include the following.

<table>
<thead>
<tr>
<th><code>dba_plans</code> column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cardinality_error</code></td>
<td>A measure of the error between the estimated cardinality versus the actual cardinality. Cardinality is the number of table rows that the plan is to process. If the cardinality error is large, then it increases the likelihood that the plan isn't optimal. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td><code>compatibility_level</code></td>
<td>The feature level of the Aurora PostgreSQL optimizer.</td>
</tr>
<tr>
<td><code>created_by</code></td>
<td>The authenticated user (<code>session_user</code>) who created the plan.</td>
</tr>
<tr>
<td><code>enabled</code></td>
<td>An indicator of whether the plan is enabled or disabled. All plans are enabled by default. You can disable plans to prevent them from being used by the optimizer. To modify this value, use the <code>apg_plan_mgmt.set_plan_enabled</code> function.</td>
</tr>
<tr>
<td><code>environment_variables</code></td>
<td>The PostgreSQL Grand Unified Configuration (GUC) parameters and values that the optimizer has overridden at the time the plan was captured.</td>
</tr>
<tr>
<td><code>estimated_startup_cost</code></td>
<td>The estimated optimizer setup cost before the optimizer delivers rows of a table.</td>
</tr>
<tr>
<td><code>estimated_total_cost</code></td>
<td>The estimated optimizer cost to deliver the final table row.</td>
</tr>
<tr>
<td><code>execution_time_benefit_ms</code></td>
<td>The execution time benefit in milliseconds of enabling the plan. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td><code>execution_time_ms</code></td>
<td>The estimated time in milliseconds that the plan would run. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td><code>has_side_effects</code></td>
<td>A value that indicates that the SQL statement is a data manipulation language (DML) statement or a SELECT statement that contains a VOLATILE function.</td>
</tr>
<tr>
<td><code>last_used</code></td>
<td>This value is updated to the current date whenever the plan is either executed or when the plan is the query optimizer's minimum-cost plan. This value is stored in shared memory and periodically flushed to disk. To get the most up-to-date value, read the date from shared memory by calling the function <code>apg_plan_mgmt.plan_last_used(sql_hash, plan_hash)</code> instead of reading the <code>last_used</code> value. For additional information, see the <code>apg_plan_mgmt.plan_retention_period</code> parameter.</td>
</tr>
<tr>
<td><code>last_validated</code></td>
<td>The most recent date and time when it was verified that the plan could be recreated by either the <code>apg_plan_mgmt.validate_plans</code> function or the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td><strong>dba_plans column</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>last_verified</td>
<td>The most recent date and time when a plan was verified to be the best-performing plan for the specified parameters by the <code>apg_plan_mgmt.evolve_plan_baselines (p. 1422)</code> function.</td>
</tr>
<tr>
<td>origin</td>
<td>How the plan was captured with the <code>apg_plan_mgmt.capture_plan_baselines (p. 1419)</code> parameter. Valid values include the following:</td>
</tr>
<tr>
<td></td>
<td>M – The plan was captured with manual plan capture.</td>
</tr>
<tr>
<td></td>
<td>A – The plan was captured with automatic plan capture.</td>
</tr>
<tr>
<td>param_list</td>
<td>The parameter values that were passed to the statement if this is a prepared statement.</td>
</tr>
<tr>
<td>plan_created</td>
<td>The date and time the plan that was created.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The plan identifier. The combination of <code>plan_hash</code> and <code>sql_hash</code> uniquely identifies a specific plan.</td>
</tr>
<tr>
<td>plan_outline</td>
<td>A representation of the plan that is used to recreate the actual execution plan, and that is database-independent. Operators in the tree correspond to operators that appear in the EXPLAIN output.</td>
</tr>
<tr>
<td>planning_time_ms</td>
<td>The actual time to run the planner, in milliseconds. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines (p. 1422)</code> function.</td>
</tr>
<tr>
<td>queryId</td>
<td>A statement hash, as calculated by the <code>pg_stat_statements</code> extension. This isn't a stable or database-independent identifier because it depends on object identifiers (OIDs).</td>
</tr>
<tr>
<td>sql_hash</td>
<td>A hash value of the SQL statement text, normalized with literals removed.</td>
</tr>
<tr>
<td>sql_text</td>
<td>The full text of the SQL statement.</td>
</tr>
<tr>
<td>status</td>
<td>A plan's status, which determines how the optimizer uses a plan. Valid values include the following.</td>
</tr>
<tr>
<td></td>
<td>• Approved – A usable plan that the optimizer can choose to run. The optimizer runs the least-cost plan from a managed statement's set of approved plans (baseline). To reset a plan to approved, use the <code>apg_plan_mgmt.evolve_plan_baselines (p. 1422)</code> function.</td>
</tr>
<tr>
<td></td>
<td>• Unapproved – A captured plan that you have not verified for use. For more information, see Evaluating plan performance (p. 1414).</td>
</tr>
<tr>
<td></td>
<td>• Rejected – A plan that the optimizer won't use. For more information, see Rejecting or disabling slower plans (p. 1415).</td>
</tr>
<tr>
<td></td>
<td>• Preferred – A plan that you have determined is a preferred plan to use for a managed statement.</td>
</tr>
<tr>
<td></td>
<td>If the optimizer's minimum-cost plan isn't an approved or preferred plan, you can reduce plan enforcement overhead. To do so, make a subset of the approved plans Preferred. When the optimizer's minimum cost isn't an Approved plan, a Preferred plan is chosen before an Approved plan.</td>
</tr>
<tr>
<td></td>
<td>To reset a plan to Preferred, use the <code>apg_plan_mgmt.set_plan_status (p. 1425)</code> function.</td>
</tr>
</tbody>
</table>
Capturing execution plans

You can capture execution plans for specific SQL statements by using manual plan capture. Alternatively, you can capture all (or the slowest) plans that are executed two or more times as your application runs by using automatic plan capture.

When capturing plans, the optimizer sets the status of a managed statement's first captured plan to approved. The optimizer sets the status of any additional plans captured for a managed statement to unapproved. However, more than one plan might occasionally be saved with the approved status. This can happen when multiple plans are created for a statement in parallel and before the first plan for the statement is committed.

To control the maximum number of plans that can be captured and stored in the `dba_plans` view, set the `apg_plan_mgmt.max_plans` parameter in your DB instance-level parameter group. A change to the `apg_plan_mgmt.max_plans` parameter requires a DB instance restart for a new value to take effect. For more information, see the `apg_plan_mgmt.max_plans` (p. 1419) parameter.

Topics

- Manually capturing plans for specific SQL statements (p. 1410)
- Automatically capturing plans (p. 1411)

Manually capturing plans for specific SQL statements

If you have a known set of SQL statements to manage, put the statements into a SQL script file and then manually capture plans. The following shows a `psql` example of how to capture query plans manually for a set of SQL statements.

```
psql> SET apg_plan_mgmt.capture_plan_baselines = manual;
psql> \i my-statements.sql
psql> SET apg_plan_mgmt.capture_plan_baselines = off;
```

After capturing a plan for each SQL statement, the optimizer adds a new row to the `apg_plan_mgmt.dba_plans` view.

We recommend that you use either EXPLAIN or EXPLAIN EXECUTE statements in the SQL script file. Make sure that you include enough variations in parameter values to capture all the plans of interest.

If you know of a better plan than the optimizer's minimum cost plan, you might be able to force the optimizer to use the better plan. To do so, specify one or more optimizer hints. For more information, see Fixing plans using `pg_hint_plan` (p. 1416). To compare the performance of the unapproved and approved plans and approve, reject, or delete them, see Evaluating plan performance (p. 1414).
Automatically capturing plans

Use automatic plan capture for situations such as the following:

- You don't know the specific SQL statements that you want to manage.
- You have hundreds or thousands of SQL statements to manage.
- Your application uses a client API. For example, JDBC uses unnamed prepared statements or bulk-mode statements that can't be expressed in psql.

To capture plans automatically

1. Turn on automatic plan capture by setting `apg_plan_mgmt.capture_plan_baselines` to `automatic` in the DB instance-level parameter group. For more information, see Modifying parameters in a DB parameter group (p. 343).
2. Restart your DB instance.
3. As the application runs, the optimizer captures plans for each SQL statement that runs at least twice.

As the application runs with default query plan management parameter settings, the optimizer captures plans for each SQL statement that runs at least twice. Capturing all plans while using the defaults has very little run-time overhead and can be enabled in production.

To turn off automatic plan capture

- Set the `apg_plan_mgmt.capture_plan_baselines` parameter to `off` from the DB instance-level parameter group.

To measure the performance of the unapproved plans and approve, reject, or delete them, see Evaluating plan performance (p. 1414).

Using managed plans

To get the optimizer to use captured plans for your managed statements, set the parameter `apg_plan_mgmt.use_plan_baselines` to `true`. The following is a local instance example.

```
SET apg_plan_mgmt.use_plan_baselines = true;
```

While the application runs, this setting causes the optimizer to use the minimum-cost, preferred, or approved plan that is valid and enabled, for each managed statement.

How the optimizer chooses which plan to run

The cost of an execution plan is an estimate that the optimizer makes to compare different plans. Optimizer cost is a function of several factors that include the CPU and I/O operations that the plan uses. For more information about PostgreSQL query planner costs, see the PostgreSQL documentation on query planning.

The following flowchart shows how the query plan management optimizer chooses which plan to run.
The flow is as follows:

1. When the optimizer processes every SQL statement, it generates a minimum-cost plan.
2. Without query plan management, the optimizer simply runs its generated plan. The optimizer uses query plan management if you set one or both of the following parameter settings:

   - use_plan_baselines=false
   - capture_plan_baselines=off
• `apg_plan_mgmt.capture_plan_baselines` to manual or automatic
• `apg_plan_mgmt.use_plan_baselines` to true

3. The optimizer immediately runs the generated plan if the following are both true:
   • The optimizer's plan is already in the `apg_plan_mgmt.dba_plans` view for the SQL statement.
   • The plan's status is either approved or preferred.

4. The optimizer goes through the capture plan processing if the parameter
   `apg_plan_mgmt.capture_plan_baselines` is manual or automatic.

   For details on how the optimizer captures plans, see Capturing execution plans (p. 1410).

5. The optimizer runs the generated plan if `apg_plan_mgmt.use_plan_baselines` is false.

6. If the optimizer's plan isn't in the `apg_plan_mgmt.dba_plans` view, the optimizer captures the plan
   as a new unapproved plan.

7. The optimizer runs the generated plan if the following are both true:
   • The optimizer's plan isn't a rejected or disabled plan.
   • The plan's total cost is less than the unapproved execution plan threshold.

   The optimizer doesn't run disabled plans or any plans that have the rejected status. In most cases,
   the optimizer doesn't execute unapproved plans. However, the optimizer runs an unapproved plan if
   you set a value for the parameter `apg_plan_mgmt.unapproved_plan_execution_threshold` and
   the plan's total cost is less than the threshold. For more information, see the
   `apg_plan_mgmt.unapproved_plan_execution_threshold` (p. 1420) parameter.

8. If the managed statement has any enabled and valid preferred plans, the optimizer runs the
   minimum-cost one.

   A valid plan is one that the optimizer can run. Managed plans can become invalid for various reasons.
   For example, plans become invalid when objects that they depend on are removed, such as an index or
   a partition of a partitioned table.

9. The optimizer determines the minimum-cost plan from the managed statement's approved plans that
   are both enabled and valid. The optimizer then runs the minimum-cost approved plan.

**Analyzing which plan the optimizer will use**

When the `apg_plan_mgmt.use_plan_baselines` parameter is set to true, you can use EXPLAIN
ANALYZE SQL statements to cause the optimizer to show the plan it would use if it were to run the
statement. The following is an example.

```
EXPLAIN ANALYZE EXECUTE rangeQuery (1,10000);
```

```
QUERY PLAN
--------------------------------------------------------------------------
Aggregate  (cost=393.29..393.30 rows=1 width=8) (actual time=7.251..7.251 rows=1 loops=1)
   ->  Index Only Scan using t1_pkey on t1  (cost=0.29..368.29 rows=10000 width=0)
         (actual time=0.061..4.859 rows=10000 loops=1)
         Index Cond: ((id >= 1) AND (id <= 10000))
Heap Fetches: 10000
Planning time: 1.408 ms
Execution time: 7.291 ms
Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1984047223, Plan Hash: 512153379
```

The optimizer indicates which plan it will run, but notice that in this example that it found a lower-cost
plan. In this case, you capture this new minimum cost plan by turning on automatic plan capture as
described in Automatically capturing plans (p. 1411).
Maintaining execution plans

Query plan management provides techniques and functions to add, maintain, and improve execution plans.

Topics
- Evaluating plan performance (p. 1414)
- Validating plans (p. 1415)
- Fixing plans using pg_hint_plan (p. 1416)
- Deleting plans (p. 1417)
- Exporting and importing plans (p. 1417)

Evaluating plan performance

After the optimizer captures plans as unapproved, use the `apg_plan_mgmt.evolve_plan_baselines` function to compare plans based on their actual performance. Depending on the outcome of your performance experiments, you can change a plan's status from unapproved to either approved or rejected. You can instead decide to use the `apg_plan_mgmt.evolve_plan_baselines` function to temporarily disable a plan if it does not meet your requirements.

Topics
- Approving better plans (p. 1414)
- Rejecting or disabling slower plans (p. 1415)

Approving better plans

The following example demonstrates how to change the status of managed plans to approved using the `apg_plan_mgmt.evolve_plan_baselines` function.

```
SELECT apg_plan_mgmt.evolve_plan_baselines (sql_hash, plan_hash, min_speedup_factor := 1.0, action := 'approve')
FROM apg_plan_mgmt.dba_plans WHERE status = 'Unapproved';
```

```
NOTICE: rangequery (1,10000)
NOTICE: Baseline [ Planning time 0.761 ms, Execution time 13.261 ms]
NOTICE: Baseline+1 [ Planning time 0.204 ms, Execution time 8.956 ms]
NOTICE: Total time benefit: 4.862 ms, Execution time benefit: 4.305 ms
NOTICE: Unapproved -> Approved
```

The output shows a performance report for the `rangequery` statement with parameter bindings of 1 and 10,000. The new unapproved plan (Baseline+1) is better than the best previously approved plan.
(Baseline). To confirm that the new plan is now Approved, check the `apg_plan_mgmt.dba_plans` view.

```sql
SELECT sql_hash, plan_hash, status, enabled, stmt_name
FROM apg_plan_mgmt.dba_plans;
```

<table>
<thead>
<tr>
<th>sql_hash</th>
<th>plan_hash</th>
<th>status</th>
<th>enabled</th>
<th>stmt_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1984047223</td>
<td>512153379</td>
<td>Approved</td>
<td>t</td>
<td>rangequery</td>
</tr>
<tr>
<td>1984047223</td>
<td>512284451</td>
<td>Approved</td>
<td>t</td>
<td>rangequery</td>
</tr>
</tbody>
</table>

(2 rows)

The managed plan now includes two approved plans that are the statement's plan baseline. You can also call the `apg_plan_mgmt.set_plan_status` function to directly set a plan's status field to 'Approved', 'Rejected', 'Unapproved', or 'Preferred'.

### Rejecting or disabling slower plans

To reject or disable plans, pass 'reject' or 'disable' as the action parameter to the `apg_plan_mgmt.evolve_plan_baselines` function. This example disables any captured Unapproved plan that is slower by at least 10 percent than the best Approved plan for the statement.

```sql
SELECT apg_plan_mgmt.evolve_plan_baselines(
    sql_hash, -- The managed statement ID
    plan_hash, -- The plan ID
    1.1, -- number of times faster the plan must be
    'disable', -- The action to take. This sets the enabled field to false.
) FROM apg_plan_mgmt.dba_plans
WHERE status = 'Unapproved' AND -- plan is Unapproved
    origin = 'Automatic'; -- plan was auto-captured
```

You can also directly set a plan to rejected or disabled. To directly set a plan's enabled field to true or false, call the `apg_plan_mgmt.set_plan_enabled` function. To directly set a plan's status field to 'Approved', 'Rejected', 'Unapproved', or 'Preferred', call the `apg_plan_mgmt.set_plan_status` function.

### Validating plans

Use the `apg_plan_mgmt.validate_plans` function to delete or disable plans that are invalid.

Plans can become invalid or stale when objects that they depend on are removed, such as an index or a table. However, a plan might be invalid only temporarily if the removed object gets recreated. If an invalid plan can become valid later, you might prefer to disable an invalid plan or do nothing rather than delete it.

To find and delete all plans that are invalid and haven't been used in the past week, use the `apg_plan_mgmt.validate_plans` function as follows.

```sql
SELECT apg_plan_mgmt.validate_plans(sql_hash, plan_hash, 'delete')
FROM apg_plan_mgmt.dba_plans
WHERE last_used < (current_date - interval '7 days');
```

To enable or disabled a plan directly, use the `apg_plan_mgmt.set_plan_enabled` function.
Fixing plans using pg_hint_plan

The query optimizer is well-designed to find an optimal plan for all statements, and in most cases the optimizer finds a good plan. However, occasionally you might know that a much better plan exists than that generated by the optimizer. Two recommended ways to get the optimizer to generate a desired plan include using the pg_hint_plan extension or setting Grand Unified Configuration (GUC) variables in PostgreSQL:

- **pg_hint_plan extension** – Specify a "hint" to modify how the planner works by using PostgreSQL's pg_hint_plan extension. To install and learn more about how to use the pg_hint_plan extension, see the pg_hint_plan documentation.
- **GUC variables** – Override one or more cost model parameters or other optimizer parameters, such as the from_collapse_limit or GEQO_threshold.

When you use one of these techniques to force the query optimizer to use a plan, you can also use query plan management to capture and enforce use of the new plan.

You can use the pg_hint_plan extension to change the join order, the join methods, or the access paths for a SQL statement. You use a SQL comment with special pg_hint_plan syntax to modify how the optimizer creates a plan. For example, assume the problem SQL statement has a two-way join.

```
SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
```

Then suppose that the optimizer chooses the join order (t1, t2), but we know that the join order (t2, t1) is faster. The following hint forces the optimizer to use the faster join order, (t2, t1). Include EXPLAIN so that the optimizer generates a plan for the SQL statement but does not run the statement. (Output not shown.)

```
/*+ Leading ((t2 t1)) */ EXPLAIN SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
```

The following steps show how to use pg_hint_plan.

**To modify the optimizer's generated plan and capture the plan using pg_hint_plan**

1. Turn on the manual capture mode.
```
SET apg_plan_mgmt.capture_plan_baselines = manual;
```

2. Specify a hint for the SQL statement of interest.
```
/*+ Leading ((t2 t1)) */ EXPLAIN SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
```

After this runs, the optimizer captures the plan in the apg_plan_mgmt.dba_plans view. The captured plan doesn't include the special pg_hint_plan comment syntax because query plan management normalizes the statement by removing leading comments.

3. View the managed plans by using the apg_plan_mgmt.dba_plans view.
```
SELECT sql_hash, plan_hash, status, sql_text, plan_outline
FROM apg_plan_mgmt.dba_plans;
```
4. Set the status of the plan to Preferred. Doing so makes sure that the optimizer chooses to run it, instead of selecting from the set of approved plans, when the minimum-cost plan isn't already Approved or Preferred.

   ```sql
   SELECT apg_plan_mgmt.set_plan_status(sql_hash, plan_hash, 'preferred');
   ```

5. Turn off manual plan capture and enforce the use of managed plans.

   ```sql
   SET apg_plan_mgmt.capture_plan_baselines = false;
   SET apg_plan_mgmt.use_plan_baselines = true;
   ```

Now, when the original SQL statement runs, the optimizer chooses either an Approved or Preferred plan. If the minimum-cost plan isn't Approved or Preferred, then the optimizer chooses the Preferred plan.

### Deleting plans

Delete plans that have not been used for a long time or that are no longer relevant. Each plan has a `last_used` date that the optimizer updates each time it executes a plan or picks it as the minimum-cost plan for a statement. Use the `last_used` date to determine if a plan has been used recently and is still relevant.

For example, you can use the `apg_plan_mgmt.delete_plan` function as follows. Doing this deletes all plans that haven't been chosen as the minimum-cost plan or haven't run in at least 31 days. However, this example doesn't delete plans that have been explicitly rejected.

```sql
SELECT SUM(apg_plan_mgmt.delete_plan(sql_hash, plan_hash))
FROM apg_plan_mgmt.dba_plans
WHERE last_used < (current_date - interval '31 days')
AND status <> 'Rejected';
```

To delete any plan that is no longer valid and that you expect not to become valid again, use the `apg_plan_mgmt.validate_plans` function. For more information, see Validating plans (p. 1415).

You can implement your own policy for deleting plans. Plans are automatically deleted when the `current_date` `last_used` is greater than the value of the `apg_plan_mgmt.plan_retention_period` parameter, which defaults to 32 days. You can specify a longer interval, or you can implement your own plan retention policy by calling the `delete_plan` function directly. The `last_used` date is the most recent date that either the optimizer chose a plan as the minimum cost plan or that the plan was executed.

**Important**

If you don't clean up plans, you might eventually run out of shared memory that is set aside for query plan management. To control how much memory is available for managed plans, use the `apg_plan_mgmt.max_plans` parameter. Set this parameter in your DB instance-level parameter group and restart your DB instance for changes to take effect. For more information, see the `apg_plan_mgmt.max_plans` (p. 1419) parameter.

### Exporting and importing plans

You can export your managed plans and import them into another DB instance.

**To export managed plans**

An authorized user can copy any subset of the `apg_plan_mgmt.plans` table to another table, and then save it using the `pg_dump` command. The following is an example.
CREATE TABLE plans_copy AS SELECT * 
FROM apg_plan_mgmt.plans [ WHERE predicates ] ;

% pg_dump --table apg_plan_mgmt.plans_copy -Ft mysourcedatabase > plans_copy.tar

DROP TABLE apg_plan_mgmt.plans_copy;

To import managed plans

1. Copy the .tar file of the exported managed plans to the system where the plans are to be restored.
2. Use the pg_restore command to copy the tar file into a new table.

% pg_restore --dbname mytargetdatabase -Ft plans_copy.tar

3. Merge the plans_copy table with the apg_plan_mgmt.plans table, as shown in the following example.

   Note
   In some cases, you might dump from one version of the apg_plan_mgmt extension and restore into a different version. In these cases, the columns in the plans table might be different. If so, name the columns explicitly instead of using SELECT *.

   INSERT INTO apg_plan_mgmt.plans SELECT * FROM plans_copy
   ON CONFLICT ON CONSTRAINT plans_pkey
   DO UPDATE SET
   status = EXCLUDED.status,
   enabled = EXCLUDED.enabled,
   -- Save the most recent last_used date
   last_used = CASE WHEN EXCLUDED.last_used > plans.last_used
   THEN EXCLUDED.last_used ELSE plans.last_used END,
   -- Save statistics gathered by evolve_plan_baselines, if it ran:
   estimated_startup_cost = EXCLUDED.estimated_startup_cost,
   estimated_total_cost = EXCLUDED.estimated_total_cost,
   planning_time_ms = EXCLUDED.planning_time_ms,
   execution_time_ms = EXCLUDED.execution_time_ms,
   total_time_benefit_ms = EXCLUDED.total_time_benefit_ms,
   execution_time_benefit_ms = EXCLUDED.execution_time_benefit_ms;

4. Reload the managed plans into shared memory and remove the temporary plans table.

SELECT apg_plan_mgmt.reload(); -- refresh shared memory
DROP TABLE plans_copy;

Parameter reference for query plan management

The apg_plan_mgmt extension provides the following parameters.

Parameters
- apg_plan_mgmt.capture_plan_baselines (p. 1419)
- apg_plan_mgmt.max_databases (p. 1419)
- apg_plan_mgmt.max_plans (p. 1419)
- apg_plan_mgmt.plan_retention_period (p. 1420)
Set the query plan management parameters at the appropriate level:

- Set at the cluster-level to provide the same settings for all DB instances. For more information, see Modifying parameters in a DB cluster parameter group (p. 345).
- Set at the DB instance level to isolate the settings to an individual DB instance. For more information, see Modifying parameters in a DB parameter group (p. 343).
- Set in a specific client session such as in psql, to isolate the values to only that session.

You must be set the parameters `apg_plan_mgmt.max_databases` and `apg_plan_mgmt.max_plans` at the cluster or DB instance level.

**apg_plan_mgmt.capture_plan_baselines**

Enable execution plan capture for SQL statements.

```sql
SET apg_plan_mgmt.capture_plan_baselines = [off | automatic | manual];
```

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Disable plan capture. This is the default.</td>
</tr>
<tr>
<td>automatic</td>
<td>Enable plan capture for subsequent SQL statements that satisfy the eligibility criteria.</td>
</tr>
<tr>
<td>manual</td>
<td>Enable plan capture for subsequent SQL statements.</td>
</tr>
</tbody>
</table>

**apg_plan_mgmt.max_databases**

Sets the maximum number of database objects that might use query plan management. A database object is what gets created with the CREATE DATABASE SQL statement.

**Important**

Set `apg_plan_mgmt.max_databases` at the cluster or DB instance level. It requires a DB instance restart for a new value to take effect.

```sql
SET apg_plan_mgmt.max_databases = integer-value;
```

<table>
<thead>
<tr>
<th>Value</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive integer</td>
<td>10</td>
<td>A positive integer value.</td>
</tr>
</tbody>
</table>

**apg_plan_mgmt.max_plans**

Sets the maximum number of plans that might be captured in the `apg_plan_mgmt.dba_plans` view.

**Important**

Set `apg_plan_mgmt.max_plans` at the cluster or DB instance level. It requires a DB instance restart for a new value to take effect. We recommend setting this parameter to 10000 or higher for all Aurora PostgreSQL versions.
SET `apg_plan_mgmt.max_plans` = integer-value;

<table>
<thead>
<tr>
<th>Value</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>10000 for Aurora PostgreSQL version 11 and higher 1000 for Aurora PostgreSQL version 10 and lower</td>
<td>A positive integer value greater or equal to 10.</td>
</tr>
</tbody>
</table>

`apg_plan_mgmt.plan_retention_period`  
The number of days plans are kept in the `apg_plan_mgmt.dba_plans` view before being automatically deleted. A plan is deleted when the current date is this many days since the plan’s `last_used` date. The `last_used` date is the most recent date that either the optimizer chose a plan as the minimum cost plan or that the plan was executed.

SET `apg_plan_mgmt.plan_retention_period` = integer-value;

<table>
<thead>
<tr>
<th>Value</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive integer</td>
<td>32</td>
<td>A positive integer value greater or equal to 32, representing days.</td>
</tr>
</tbody>
</table>

`apg_plan_mgmt.unapproved_plan_execution_threshold`  
An estimated total plan cost threshold, below which the optimizer runs an unapproved plan. By default, the optimizer does not run unapproved plans. However, you can set an execution threshold for your fastest unapproved plans. With this setting, the optimizer bypasses the overhead of enforcing only approved plans.

SET `apg_plan_mgmt.unapproved_plan_execution_threshold` = integer-value;

<table>
<thead>
<tr>
<th>Value</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive integer</td>
<td>0</td>
<td>A positive integer value greater or equal to 0. A value of 0 means no unapproved plans run when <code>use_plan_baselines</code> is true.</td>
</tr>
</tbody>
</table>

With the following example, the optimizer runs an unapproved plan if the estimated cost is less than 550, even if `use_plan_baselines` is true.

SET `apg_plan_mgmt.unapproved_plan_execution_threshold` = 550;
### apg_plan_mgmt.use_plan_baselines

Enforce the optimizer to use managed plans for managed statements.

```sql
SET apg_plan_mgmt.use_plan_baselines = [true | false];
```

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>Enforce the use of managed plans. When a SQL statement runs and it is a managed statement in the <code>apg_plan_mgmt.dba_plans</code> view, the optimizer chooses a managed plan in the following order.</td>
</tr>
<tr>
<td></td>
<td>1. The minimum-cost preferred plan that is valid and enabled.</td>
</tr>
<tr>
<td></td>
<td>2. The minimum cost approved plan that is valid and enabled.</td>
</tr>
<tr>
<td></td>
<td>3. The minimum cost unapproved plan that is valid, enabled, and that meets the threshold, if set with the <code>apg_plan_mgmt.unapproved_plan_execution_threshold</code> parameter.</td>
</tr>
<tr>
<td></td>
<td>4. The optimizer's generated minimum-cost plan.</td>
</tr>
<tr>
<td>false</td>
<td>(Default) Do not use managed plans. The optimizer uses its generated minimum-cost plan.</td>
</tr>
</tbody>
</table>

**Usage notes**

When `use_plan_baselines` is true, then the optimizer makes the following execution decisions:

1. If the estimated cost of the optimizer's plan is below the `unapproved_plan_execution_threshold`, then execute it, else
2. If the plan is approved or preferred, then execute it, else
3. Execute a minimum-cost preferred plan, if possible, else
4. Execute a minimum-cost approved plan, if possible, else
5. Execute the optimizer's minimum-cost plan.

### Function reference for query plan management

The `apg_plan_mgmt` extension provides the following functions.

**Functions**

- `apg_plan_mgmt.delete_plan` (p. 1422)
- `apg_plan_mgmt.evolve_plan_baselines` (p. 1422)
- `apg_plan_mgmt.get_explain_plan` (p. 1423)
- `apg_plan_mgmt.plan_last_used` (p. 1424)
- `apg_plan_mgmt.reload` (p. 1424)
- `apg_plan_mgmt.set_plan_enabled` (p. 1425)
- `apg_plan_mgmt.set_plan_status` (p. 1425)
- `apg_plan_mgmt.update_plans_last_used` (p. 1426)
- `apg_plan_mgmt.validate_plans` (p. 1427)
### apg_plan_mgmt.delete_plan

Delete a managed plan.

**Syntax**

```python
apg_plan_mgmt.delete_plan(
    sql_hash,
    plan_hash
)
```

**Return value**

Returns 0 if the delete was successful or -1 if the delete failed.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
</tbody>
</table>

### apg_plan_mgmt.evolve_plan_baselines

Verifies whether an already approved plan is faster or whether a plan identified by the query optimizer as a minimum cost plan is faster.

**Syntax**

```python
apg_plan_mgmt.evolve_plan_baselines(
    sql_hash,
    plan_hash,
    min_speedup_factor,
    action
)
```

**Return value**

The number of plans that were not faster than the best approved plan.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID. Use NULL to mean all plans that have the same sql_hash ID value.</td>
</tr>
<tr>
<td>min_speedup_factor</td>
<td>The minimum speedup factor can be the number of times faster that a plan must be than the best of the already approved plans to approve it. Alternatively, this factor can be the number of times slower that a plan must be to reject or disable it. This is a positive float value.</td>
</tr>
<tr>
<td>action</td>
<td></td>
</tr>
</tbody>
</table>
### Function reference for query plan management

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>The action the function is to perform. Valid values include the following. Case does not matter.</td>
</tr>
<tr>
<td></td>
<td>• 'disable' – Disable each matching plan that does not meet the minimum speedup factor.</td>
</tr>
<tr>
<td></td>
<td>• 'approve' – Enable each matching plan that meets the minimum speedup factor and set its status to approved.</td>
</tr>
<tr>
<td></td>
<td>• 'reject' – For each matching plan that does not meet the minimum speedup factor, set its status to rejected.</td>
</tr>
<tr>
<td></td>
<td>• NULL – The function simply returns the number of plans that have no performance benefit because they do not meet the minimum speedup factor.</td>
</tr>
</tbody>
</table>

**Usage notes**

Set specified plans to approved, rejected, or disabled based on whether the planning plus execution time is faster than the best approved plan by a factor that you can set. The action parameter might be set to 'approve' or 'reject' to automatically approve or reject a plan that meets the performance criteria. Alternatively, it might be set to '' (empty string) to do the performance experiment and produce a report, but take no action.

You can avoid pointlessly rerunning of the `apg_plan_mgmt.evolve_plan_baselines` function for a plan on which it was recently run. To do so, restrict the plans to just the recently created unapproved plans. Alternatively, you can avoid running the `apg_plan_mgmt.evolve_plan_baselines` function on any approved plan that has a recent `last_verified` timestamp.

Conduct a performance experiment to compare the planning plus execution time of each plan relative to the other plans in the baseline. In some cases, there is only one plan for a statement and the plan is approved. In such a case, compare the planning plus execution time of the plan to the planning plus execution time of using no plan.

The incremental benefit (or disadvantage) of each plan is recorded in the `apg_plan_mgmt.dba_plans` view in the `total_time_benefit_ms` column. When this value is positive, there is a measurable performance advantage to including this plan in the baseline.

In addition to collecting the planning and execution time of each candidate plan, the `last_verified` column of the `apg_plan_mgmt.dba_plans` view is updated with the `current_timestamp`. The `last_verified` timestamp might be used to avoid running this function again on a plan that recently had its performance verified.

**apg_plan_mgmt.get_explain_plan**

Generates the text of an `EXPLAIN` statement for the specified SQL statement.

**Syntax**

```sql
apg_plan_mgmt.get_explain_plan(
    sql_hash,
    plan_hash,
    [explainOptionList]
)
```

**Return value**

Returns runtime statistics for the specified SQL statements. Use without `explainOptionList` to return a simple `EXPLAIN` plan.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
<tr>
<td>explainOptionList</td>
<td>A comma-separated list of explain options. Valid values include 'analyze', 'verbose', 'buffers', 'hashes', and 'format json'. If the explainOptionList is NULL or an empty string (''), this function generates an EXPLAIN statement, without any statistics.</td>
</tr>
</tbody>
</table>

Usage notes

For the explainOptionList, you can use any of the same options that you would use with an EXPLAIN statement. The Aurora PostgreSQL optimizer concatenates the list of options you provide to the EXPLAIN statement, so you can request any option that EXPLAIN supports.

### `apg_plan_mgmt.plan_last_used`

Returns the last_used date of the specified plan from shared memory.

**Note**

The value in shared memory is always current on the primary DB instance in the DB cluster. The value is only periodically flushed to the last_used column of the `apg_plan_mgmt.dba_plans` view.

**Syntax**

```sql
apg_plan_mgmt.plan_last_used(
    sql_hash,
    plan_hash
)
```

**Return value**

Returns the last_used date.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
</tbody>
</table>

### `apg_plan_mgmt.reload`

Reload plans into shared memory from the `apg_plan_mgmt.dba_plans` view.
Syntax

```python
apg_plan_mgmt.reload()
```

Return value

None.

Parameters

None.

Usage notes

Call `reload` for the following situations:

- Use it to refresh the shared memory of a read-only replica immediately, rather than wait for new plans to propagate to the replica.
- Use it after importing managed plans.

### apg_plan_mgmt.set_plan_enabled

Enable or disable a managed plan.

Syntax

```python
apg_plan_mgmt.set_plan_enabled(
    sql_hash,
    plan_hash,
    [true | false]
)
```

Return value

Returns 0 if the setting was successful or -1 if the setting failed.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The <code>sql_hash</code> ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's <code>plan_hash</code> ID.</td>
</tr>
<tr>
<td>enabled</td>
<td>Boolean value of true or false:</td>
</tr>
<tr>
<td></td>
<td>• A value of <code>true</code> enables the plan.</td>
</tr>
<tr>
<td></td>
<td>• A value of <code>false</code> disables the plan.</td>
</tr>
</tbody>
</table>

### apg_plan_mgmt.set_plan_status

Set a managed plan's status to **Approved**, **Unapproved**, **Rejected**, or **Preferred**.

Syntax

```python
apg_plan_mgmt.set_plan_status()
```
```sql
sql_hash,
plan_hash,
status
)

Return value

Returns 0 if the setting was successful or -1 if the setting failed.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
<tr>
<td>status</td>
<td>A string with one of the following values:</td>
</tr>
<tr>
<td></td>
<td>• 'Approved'</td>
</tr>
<tr>
<td></td>
<td>• 'Unapproved'</td>
</tr>
<tr>
<td></td>
<td>• 'Rejected'</td>
</tr>
<tr>
<td></td>
<td>• 'Preferred'</td>
</tr>
</tbody>
</table>

The case you use does not matter, however the status value is set to initial uppercase in the `apg_plan_mgmt.dba_plans` view. For more information about these values, see `status` in Reference for the `apg_plan_mgmt.dba_plans` view (p. 1408).

**apg_plan_mgmt.update_plans_last_used**

Immediately updates the plans table with the last_used date stored in shared memory.

**Syntax**

```sql
apg_plan_mgmt.update_plans_last_used()
```

**Return value**

None.

**Parameters**

None.

**Usage notes**

Call `update_plans_last_used` to make sure queries against the `dba_plans.last_used` column use the most current information. If the `last_used` date isn't updated immediately, a background process updates the plans table with the `last_used` date once every hour (by default).

For example, if a statement with a certain `sql_hash` begins to run slowly, you can determine which plans for that statement were executed since the performance regression began. To do that, first flush the data in shared memory to disk so that the `last_used` dates are current, and then query for all plans of the `sql_hash` of the statement with the performance regression. In the query, make sure the `last_used` date is greater than or equal to the date on which the performance regression began. The query identifies the plan or set of plans that might be responsible for the performance regression. You
can use `apg_plan_mgmt.get_explain_plan` with `explainOptionList` set to `verbose`, `hashes`. You can also use `apg_plan_mgmt.evolve_plan_baselines` to analyze the plan and any alternative plans that might perform better.

The `update_plans_last_used` function has an effect only on the primary DB instance of the DB cluster.

### `apg_plan_mgmt.validate_plans`

Validate that the optimizer can still recreate plans. The optimizer validates Approved, Unapproved, and Preferred plans, whether the plan is enabled or disabled. Rejected plans are not validated. Optionally, you can use the `apg_plan_mgmt.validate_plans` function to delete or disable invalid plans.

#### Syntax

```python
apg_plan_mgmt.validate_plans(
    sql_hash,
    plan_hash,
    action)

apg_plan_mgmt.validate_plans(
    action)
```

#### Return value

The number of invalid plans.

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sql_hash</code></td>
<td>The <code>sql_hash</code> ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td><code>plan_hash</code></td>
<td>The managed plan's <code>plan_hash</code> ID. Use NULL to mean all plans for the same <code>sql_hash</code> ID value.</td>
</tr>
<tr>
<td><code>action</code></td>
<td>The action the function is to perform for invalid plans. Valid string values include the following. Case does not matter.</td>
</tr>
<tr>
<td></td>
<td>- 'disable' – Each invalid plan is disabled.</td>
</tr>
<tr>
<td></td>
<td>- 'delete' – Each invalid plan is deleted.</td>
</tr>
<tr>
<td></td>
<td>- 'update_plan_hash' – Updates the <code>plan_hash</code> ID for plans that can't be reproduced exactly. It also allows you to fix a plan by rewriting the SQL. You can then register the good plan as an Approved plan for the original SQL.</td>
</tr>
<tr>
<td></td>
<td>- NULL – The function simply returns the number of invalid plans. No other action is performed.</td>
</tr>
<tr>
<td></td>
<td>- '' – An empty string produces a message indicating the number of both valid and invalid plans.</td>
</tr>
<tr>
<td></td>
<td>Any other value is treated like the empty string.</td>
</tr>
</tbody>
</table>

#### Usage notes

Use the form `validate_plans(action)` to validate all the managed plans for all the managed statements in the entire `apg_plan_mgmt.dba_plans` view.
Use the form `validate_plans(sql_hash, plan_hash, action)` to validate a managed plan specified with `plan_hash`, for a managed statement specified with `sql_hash`.

Use the form `validate_plans(sql_hash, NULL, action)` to validate all the managed plans for the managed statement specified with `sql_hash`.

### Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs

You can configure your Aurora PostgreSQL DB cluster to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage. Unlike with RDS for PostgreSQL which lets you publish both upgrade and postgresql logs, Aurora PostgreSQL supports uploading postgresql logs only to CloudWatch Logs.

Aurora PostgreSQL supports publishing logs to CloudWatch Logs for the following versions:

- 13.3 and higher 13 versions
- 12.4 and higher 12 versions
- 11.6 and higher 11 versions
- 10.11 and higher 10 versions
- 9.6.16 and higher 9 versions

**Note**

Be aware of the following:

- If exporting log data is disabled, Aurora doesn't delete existing log groups or log streams.
- If exporting log data is disabled, existing log data remains available in CloudWatch Logs based on log retention settings, which means you still incur charges for stored audit log data. You can delete log streams and log groups using the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API.
- If you don't want to export audit logs to CloudWatch Logs, make sure that all methods of exporting audit logs are disabled. These methods are the AWS Management Console, the AWS CLI, and the RDS API.

### Publishing logs to Amazon CloudWatch

You can use the AWS Management Console, the AWS CLI, or the RDS API to publish Aurora PostgreSQL logs to Amazon CloudWatch Logs.

**Console**

You can publish Aurora PostgreSQL logs to CloudWatch Logs with the console.

**To publish Aurora PostgreSQL logs from the console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora PostgreSQL DB cluster that you want to publish the log data for.
4. Choose **Modify**.
5. In the **Log exports** section, choose **Postgresql log**.
6. Choose **Continue**, and then choose **Modify cluster** on the summary page.

**AWS CLI**

You can publish Aurora PostgreSQL logs with the AWS CLI. You can run the `modify-db-cluster` AWS CLI command with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--cloudwatch-logs-export-configuration`—The configuration setting for the log types to be set for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora PostgreSQL logs by running one of the following AWS CLI commands:

- `create-db-cluster`
- `restore-db-cluster-from-s3`
- `restore-db-cluster-from-snapshot`
- `restore-db-cluster-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--engine`—The database engine.
- `--enable-cloudwatch-logs-exports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the AWS CLI command that you run.

**Example**

The following command creates an Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster --db-cluster-identifier my-db-cluster --engine aurora-postgresql --enable-cloudwatch-logs-exports postgresql
```

For Windows:

```bash
aws rds create-db-cluster ^
   --db-cluster-identifier my-db-cluster ^
   --engine aurora-postgresql ^
   --enable-cloudwatch-logs-exports postgresql
```

**Example**

The following command modifies an existing Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is `postgresql`. 
For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
  --db-cluster-identifier my-db-cluster \
  --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql"]}'
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier my-db-cluster ^
  --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql"]}'
```

**Note**

When using the Windows command prompt, make sure to escape double quotation marks ("”) in JSON code by prefixing them with a backslash (\).

**Example**

The following example modifies an existing Aurora PostgreSQL DB cluster to disable publishing log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `DisableLogTypes`, and its value is `postgresql`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
  --db-cluster-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"DisableLogTypes":["postgresql"]}'
```

For Windows:

```
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration "{"DisableLogTypes":["postgresql"]}"
```

**Note**

When using the Windows command prompt, you must escape double quotes ("”) in JSON code by prefixing them with a backslash (\).

**RDS API**

You can publish Aurora PostgreSQL logs with the RDS API. You can run the `ModifyDBCluster` operation with the following options:

- `DBClusterIdentifier` – The DB cluster identifier.
- `CloudwatchLogsExportConfiguration` – The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora PostgreSQL logs with the RDS API by running one of the following RDS API operations:

- `CreateDBCluster`
- `RestoreDBClusterFromS3`
- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`
Run the RDS API action with the following parameters:

- **DBClusterIdentifier**—The DB cluster identifier.
- **Engine**—The database engine.
- **EnableCloudwatchLogsExports**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the AWS CLI command that you run.

### Monitoring log events in Amazon CloudWatch

After enabling Aurora PostgreSQL log events, you can monitor the events in Amazon CloudWatch Logs. For more information about monitoring, see [View log data sent to CloudWatch Logs](#).

A new log group is automatically created for the Aurora DB cluster under the following prefix. In this prefix, `cluster-name` represents the DB cluster name and `log_type` represents the log type.

```
/aws/rds/cluster/cluster-name/log_type
```

For example, suppose that you configure the export function to include the postgresql log for a DB cluster named `my-db-cluster`. In this case, PostgreSQL log data is stored in the `/aws/rds/cluster/my-db-cluster/postgresql` log group.

All of the events from all of the DB instances in a DB cluster are pushed to a log group using different log streams.

If a log group with the specified name exists, Aurora uses that log group to export log data for the Aurora DB cluster. You can use automated configuration, such as AWS CloudFormation, to create log groups with predefined log retention periods, metric filters, and customer access. Otherwise, a new log group is automatically created using the default log retention period, **Never Expire**, in CloudWatch Logs. You can use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API to change the log retention period. For more information about changing log retention periods in CloudWatch Logs, see [Change log data retention in CloudWatch Logs](#).

You can use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API to search for information within the log events for a DB cluster. For more information about searching and filtering log data, see [Searching and filtering log data](#).

### Analyze Aurora PostgreSQL logs using CloudWatch Logs Insights

After publishing Aurora PostgreSQL logs to CloudWatch Logs, you can analyze logs graphically and create dashboards using CloudWatch Logs Insights.

#### To analyze Aurora PostgreSQL logs with CloudWatch Logs Insights

2. In the navigation pane, open **Logs** and choose **Log insights**.
3. In **Select log group(s)**, select the log group for your DB cluster.
4. In the query editor, delete the query that is currently shown, enter the following, and then choose Run query.

```sql
# Autovacuum execution time in seconds per 5 minute fields @message
| parse @message "elapsed: * s" as @duration_sec
| filter @message like / automatic vacuum /
| display @duration_sec
| sort @timestamp
| stats avg(@duration_sec) as avg_duration_sec,
max(@duration_sec) as max_duration_sec
by bin(5 min)
```

5. Choose the Visualization tab.
6. Choose **Add to dashboard**.
7. In **Select a dashboard**, either select a dashboard or enter a name to create a new dashboard.
8. In **Widget type**, choose a widget type for your visualization.

9. (Optional) Add more widgets based on your log query results.
a. Choose **Add widget**.

b. Choose a widget type, such as **Line**.

c. In the **Add to this dashboard** window, choose **Logs**.

d. In **Select log group(s)**, select the log group for your DB cluster.

e. In the query editor, delete the query that is currently shown, enter the following, and then choose **Run query**.

```sql
## Autovacuum tuples statistics per 5 min
fields @timestamp, @message
| parse @message "tuples: " as @tuples_temp
| parse @tuples_temp "* removed," as @tuples_removed
| parse @tuples_temp "remain, * are dead but not yet removable, " as @tuples_not_removable
| filter @message like / automatic vacuum /
| sort @timestamp
| stats avg(@tuples_removed) as avg_tuples_removed,
  avg(@tuples_not_removable) as avg_tuples_not_removable
by bin(5 min)
```
Using machine learning with Aurora PostgreSQL

With Aurora machine learning, you can add machine learning–based predictions to database applications using the SQL language. Aurora machine learning uses a highly optimized integration between the Aurora database and the AWS machine learning (ML) services SageMaker and Amazon Comprehend.

Benefits of Aurora machine learning include the following:

- You can add ML–based predictions to your existing database applications. You don't need to build custom integrations or learn separate tools. You can embed machine learning processing directly into your SQL query as calls to functions.
- The ML integration is a fast way to enable ML services to work with transactional data. You don't have to move the data out of the database to perform the machine learning operations. You don't have to convert or reimport the results of the machine learning operations to use them in your database application.
- You can use your existing governance policies to control who has access to the underlying data and to the generated insights.

AWS machine learning services are managed services that you set up and run in their own production environments. Currently, Aurora machine learning integrates with Amazon Comprehend for sentiment analysis and SageMaker for a wide variety of ML algorithms.
For general information about Amazon Comprehend, see Amazon Comprehend. For details about using Aurora and Amazon Comprehend together, see Using Amazon Comprehend for natural language processing (p. 1438).

For general information about SageMaker, see SageMaker. For details about using Aurora and SageMaker together, see Using SageMaker to run your own ML models (p. 1440).

**Note**

Aurora machine learning for PostgreSQL connects an Aurora cluster to SageMaker or Amazon Comprehend services only within the same AWS Region.

### Prerequisites for Aurora machine learning

Aurora machine learning is available on any Aurora cluster that's running a supported Aurora PostgreSQL 10 or higher major version in an AWS Region that supports Aurora machine learning. You can upgrade an Aurora cluster that's running a lower version of Aurora PostgreSQL to a supported higher version if you want to use Aurora machine learning with that cluster. For more information, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605).

For more information about Regions and Aurora version availability, see Aurora machine learning (p. 23).

### Enabling Aurora machine learning

Enabling the ML capabilities involves the following steps.

### Setting up IAM access to AWS machine learning services

Before you can access SageMaker and Amazon Comprehend services, you set up AWS Identity and Access Management (IAM) roles. You then add the IAM roles to the Aurora PostgreSQL cluster. These roles authorize the users of your Aurora PostgreSQL database to access AWS ML services.

You can do IAM setup automatically by using the AWS Management Console as shown here. To use the AWS CLI to set up IAM access, see Manually setting up IAM roles for SageMaker and Amazon Comprehend using the AWS CLI (p. 1450).
Automatically connecting an Aurora DB cluster to AWS services using the console

Aurora machine learning requires that your DB cluster use some combination of Amazon S3, SageMaker, and Amazon Comprehend. Amazon Comprehend is for sentiment analysis. SageMaker is for a wide variety of machine learning algorithms.

For Aurora machine learning, you use Amazon S3 only for training SageMaker models. You only need to use Amazon S3 with Aurora machine learning if you don't already have a trained model available and the training is your responsibility.

To connect a DB cluster to these services requires that you set up an AWS Identity and Access Management (IAM) role for each Amazon service. The IAM role enables users of your DB cluster to authenticate with the corresponding service.

To generate the IAM roles for SageMaker, Amazon Comprehend, or Amazon S3, repeat the following steps for each service that you need.

To connect a DB cluster to an Amazon service

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the Aurora PostgreSQL DB cluster that you want to use.
3. Choose the Connectivity & security tab.
4. Choose Select a service to connect to this cluster in the Manage IAM roles section.
5. Choose the service that you want to connect to from the list:
   - Amazon S3
   - Amazon Comprehend
   - SageMaker
6. Choose Connect service.
7. Enter the required information for the specific service on the Connect cluster window:
   - For SageMaker, enter the Amazon Resource Name (ARN) of a SageMaker endpoint.
     From the navigation pane of the SageMaker console, choose Endpoints and copy the ARN of the endpoint you want to use. For details about what the endpoint represents, see Deploy a Model in Amazon SageMaker.
   - For Amazon Comprehend, you don't specify any additional parameters.
   - For Amazon S3, enter the ARN of an Amazon S3 bucket to use.

The format of an Amazon S3 bucket ARN is `arn:aws:s3:::bucket_name`. Ensure that the Amazon S3 bucket you use is set up with the requirements for training SageMaker models. When you train a model, your Aurora DB cluster requires permission to export data to the Amazon S3 bucket, and also to import data from the bucket.

For more about an Amazon S3 bucket ARN, see Specifying resources in a policy in the Amazon Simple Storage Service User Guide. For more about using an Amazon S3 bucket with SageMaker, see Step 1: Create an Amazon S3 bucket in the Amazon SageMaker Developer Guide.
8. Choose Connect service.
9. Aurora creates a new IAM role and adds it to the DB cluster's list of Current IAM roles for this cluster. The IAM role's status is initially In progress. The IAM role name is autogenerated with the following pattern for each connected service:
• The Amazon S3 IAM role name pattern is rds-\texttt{cluster\_ID-S3\_role-timestamp}.
• The SageMaker IAM role name pattern is rds-\texttt{cluster\_ID-SageMaker\_role-timestamp}.
• The Amazon Comprehend IAM role name pattern is rds-\texttt{cluster\_ID-Comprehend\_role-timestamp}.

Aurora also creates a new IAM policy and attaches it to the role. The policy name follows a similar naming convention and also has a timestamp.

Installing the aws_ml extension for model inference

After you create the required IAM roles and associate them with the Aurora PostgreSQL DB cluster, install the functions that use the SageMaker and Amazon Comprehend functionality. The \texttt{aws\_ml} Aurora PostgreSQL extension provides the \texttt{aws\_sagemaker.invoke_endpoint} function that communicates directly with SageMaker. The \texttt{aws\_ml} extension also provides the \texttt{aws\_comprehend.detect\_sentiment} function that communicates directly with Amazon Comprehend.

To install these functions in a specific database, enter the following SQL command at a psql prompt.

```sql
psql>CREATE EXTENSION IF NOT EXISTS aws_ml CASCADE;
```

If you create the \texttt{aws\_ml} extension in the \texttt{template1} default database, then the functions are available in each new database that you create.

To verify the installation, enter the following at a psql prompt.

```sql
psql>\dx
```

If you set up an IAM role for Amazon Comprehend, you can verify the setup as follows.

```
SELECT sentiment FROM aws_comprehend.detect_sentiment(null, 'I like it!', 'en');
```

When you install the \texttt{aws\_ml} extension, the \texttt{aws\_ml} administrative role is created and granted to the \texttt{rds\_superuser} role. Separate schemas are also created for the \texttt{aws\_sagemaker} service and for the \texttt{aws\_comprehend} service. The \texttt{rds\_superuser} role is made the OWNER of both of these schemas.

For users or roles to obtain access to the functions in the \texttt{aws\_ml} extension, grant EXECUTE privilege on those functions. You can subsequently REVOKE the privileges, if needed. EXECUTE privileges are revoked from PUBLIC on the functions of these schemas by default. In a multi-tenant database configuration, to prevent tenants from accessing the functions use REVOKE USAGE on one or more of the ML service schemas.

For a reference to the installed functions of the \texttt{aws\_ml} extension, see PostgreSQL function reference for Aurora machine learning (p. 1448).

Using Amazon Comprehend for natural language processing

Amazon Comprehend uses machine learning to find insights and relationships in text. Amazon Comprehend uses natural language processing to extract insights about the content of documents. It
develops insights by recognizing the entities, key phrases, language, sentiments, and other common elements in a document. You can use this Aurora machine learning service with very little machine learning experience.

Aurora machine learning uses Amazon Comprehend for sentiment analysis of text that is stored in your database. A sentiment is an opinion expressed in text. Sentiment analysis identifies and categorizes sentiments to determine if the attitude towards something (such as a topic or product) is positive, negative, or neutral.

**Note**

Amazon Comprehend is currently available only in some AWS Regions. To check in which AWS Regions you can use Amazon Comprehend, see the AWS Region table page on the AWS site.

For example, using Amazon Comprehend you can analyze contact center call-in documents to detect caller sentiment and better understand caller-agent dynamics. You can find a further description in the post Analyzing contact center calls on the AWS Machine Learning blog.

You can also combine sentiment analysis with the analysis of other information in your database using a single query. For example, you can detect the average sentiment of call-in center documents for issues that combine the following:

- Open for more than 30 days.
- About a specific product or feature.
- Made by the customers who have the greatest social media influence.

Using Amazon Comprehend from Aurora machine learning is as easy as calling a SQL function. When you installed the `aws_ml` extension (Installing the `aws_ml` extension for model inference (p. 1438)), it provides the `aws_comprehend.detect_sentiment` function to perform sentiment analysis through Amazon Comprehend.

For each text fragment that you analyze, this function helps you determine the sentiment and the confidence level. A typical Amazon Comprehend query looks for table rows where the sentiment has a certain value (POSITIVE or NEGATIVE), with a confidence level greater than a certain percent.

For example, the following query shows how to determine the average sentiment of documents in a database table, `myTable.document`. The query considers only documents where the confidence of the assessment is at least 80 percent. In the following example, English (`en`) is the language of the sentiment text.

```sql
SELECT AVG(CASE s.sentiment WHEN 'POSITIVE' then 1 WHEN 'NEGATIVE' then -1 ELSE 0 END) as avg_sentiment, COUNT(*) AS total
FROM myTable, aws_comprehend.detect_sentiment (myTable.document, 'en') s
WHERE s.confidence >= 0.80;
```

To avoid your being charged for sentiment analysis more than once per table row, you can materialize the results of the analysis once per row. Do this on the rows of interest. In the following example, French (`fr`) is the language of the sentiment text.

```sql
-- *Example:* Update the sentiment and confidence of French text.
--
UPDATE clinician_notes
SET sentiment = (aws_comprehend.detect_sentiment (french_notes, 'fr')).sentiment,
    confidence = (aws_comprehend.detect_sentiment (french_notes, 'fr')).confidence
WHERE clinician_notes.french_notes IS NOT NULL AND
```

1439
For more information on optimizing your function calls, see Best practices with Aurora machine learning (p. 1443).

For information about parameters and return types for the sentiment detection function, see aws_comprehend.detect_sentiment (p. 1448).

**Exporting data to Amazon S3 for SageMaker model training**

Depending on how your team divides the machine learning tasks, you might not perform model training. If someone else provides the SageMaker model for you, you can skip this section.

To train SageMaker models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by SageMaker to train your model before it is deployed. You can query data from an Aurora PostgreSQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then SageMaker consumes the data from the Amazon S3 bucket for training. For more about SageMaker model training, see Train a model with Amazon SageMaker.

**Note**

When you create an S3 bucket for SageMaker model training or batch scoring, always include the text sagemaker in the S3 bucket name. For more information about creating an S3 bucket for SageMaker, see Step 1: Create an Amazon S3 bucket.

For more information about exporting your data, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 (p. 1391).

**Using SageMaker to run your own ML models**

SageMaker is a fully managed machine learning service. With SageMaker, data scientists and developers build and train machine learning models. Then they can directly deploy the models into a production-ready hosted environment.

SageMaker provides access to your data sources so that you can perform exploration and analysis without managing the hardware infrastructure for servers. SageMaker also provides common machine learning algorithms that are optimized to run efficiently against extremely large datasets in a distributed environment. With native support for bring-your-own-algorithms and frameworks, SageMaker offers flexible distributed training options that adjust to your specific workflows.

**Note**

Currently, Aurora machine learning supports any SageMaker endpoint that can read and write the comma-separated value (CSV) format, through a `ContentType` value of `text/csv`. The built-in SageMaker algorithms that currently accept this format are Random Cut Forest, Linear Learner, and XGBoost.

Be sure to deploy the model you are using in the same AWS Region as your Aurora PostgreSQL cluster. Aurora machine learning always invokes SageMaker endpoints in the same AWS Region as your Aurora cluster.

When you install the `aws_ml` extension (as described in Installing the aws_ml extension for model inference (p. 1438)), it provides the `aws_sagemaker.invoke_endpoint` function. You use this function to invoke your SageMaker model and perform model inference directly from within your SQL database application.
Creating a user-defined function to invoke a SageMaker model

Create a separate user-defined function to call `aws_sagemaker.invoke_endpoint` for each of your SageMaker models. Your user-defined function represents the SageMaker endpoint hosting the model. The `aws_sagemaker.invoke_endpoint` function runs within the user-defined function. User-defined functions provide many advantages:

• You can give your ML model its own name instead of only calling `aws_sagemaker.invoke_endpoint` for all of your ML models.
• You can specify the model endpoint URL in just one place in your SQL application code.
• You can control EXECUTE privileges to each ML function independently.
• You can declare the model input and output types using SQL types. SQL enforces the number and type of arguments passed to your ML model and performs type conversion if necessary. Using SQL types will also translate `SQL NULL` to the appropriate default value expected by your ML model.
• You can reduce the maximum batch size if you want to return the first few rows a little faster.

To specify a user-defined function, use the SQL data definition language (DDL) statement `CREATE FUNCTION`. When you define the function, you specify the following:

• The input parameters to the model.
• The specific SageMaker endpoint to invoke.
• The return type.

The user-defined function returns the inference computed by the SageMaker endpoint after running the model on the input parameters. The following example creates a user-defined function for an SageMaker model with two input parameters.

```sql
CREATE FUNCTION classify_event (IN arg1 INT, IN arg2 DATE, OUT category INT)
AS $$
    SELECT aws_sagemaker.invoke_endpoint (  
        'sagemaker_model_endpoint_name', NULL,  
        arg1, arg2 -- model inputs are separate arguments  
    )::INT -- cast the output to INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

• The `aws_sagemaker.invoke_endpoint` function input can be one or more parameters of any data type.

For more details about parameters, see the `aws_sagemaker.invoke_endpoint` function reference.

• This example uses an INT output type. If you cast the output from a `varchar` type to a different type, then it must be cast to a PostgreSQL builtin scalar type such as `INTEGER`, `REAL`, `FLOAT`, or `NUMERIC`. For more information about these types, see Data types in the PostgreSQL documentation.
• Specify PARALLEL SAFE to enable parallel query processing. For more information, see Exploiting parallel query processing (p. 1445).
• Specify COST 5000 to estimate the cost of running the function. Use a positive number giving the estimated run cost for the function, in units of cpu_operator_cost.

Passing an array as input to a SageMaker model

The aws_sagemaker.invoke_endpoint (p. 1449) function can have up to 100 input parameters, which is the limit for PostgreSQL functions. If the SageMaker model requires more than 100 parameters of the same type, pass the model parameters as an array.

The following example creates a user-defined function that passes an array as input to the SageMaker regression model.

```sql
CREATE FUNCTION regression_model (params REAL[], OUT estimate REAL)
AS $$
SELECT aws_sagemaker.invoke_endpoint (
    'sagemaker_model_endpoint_name', NULL,
    params                            -- model input parameters as an array
)::REAL                           -- cast output to REAL
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Specifying batch size when invoking a SageMaker model

The following example creates a user-defined function for a SageMaker model that sets the batch size default to NULL. The function also allows you to provide a different batch size when you invoke it.

```sql
CREATE FUNCTION classify_event (
    IN event_type INT, IN event_day DATE, IN amount REAL, -- model inputs
    max_rows_per_batch INT DEFAULT NULL,  -- optional batch size limit
    OUT category INT)                     -- model output
AS $$
SELECT aws_sagemaker.invoke_endpoint (
    'sagemaker_model_endpoint_name', max_rows_per_batch,
    event_type, event_day, COALESCE(amount, 0.0)
)::INT              -- casts output to type INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

• Use the optional max_rows_per_batch parameter to provide control of the number of rows for a batch-mode function invocation. If you use a value of NULL, then the query optimizer automatically chooses the maximum batch size. For more information, see Optimizing batch-mode execution for Aurora machine learning function calls (p. 1443).
• By default, passing NULL as a parameter's value is translated to an empty string before passing to SageMaker. For this example the inputs have different types.
• If you have a non-text input, or text input that needs to default to some value other than an empty string, use the COALESCE statement. Use COALESCE to translate NULL to the desired null replacement value in the call to aws_sagemaker.invoke_endpoint. For the amount parameter in this example, a NULL value is converted to 0.0.

Invoking a SageMaker model that has multiple outputs

The following example creates a user-defined function for a SageMaker model that returns multiple outputs. Your function needs to cast the output of the aws_sagemaker.invoke_endpoint function to
a corresponding data type. For example, you could use the built-in PostgreSQL point type for (x,y) pairs or a user-defined composite type.

This user-defined function returns values from a model that returns multiple outputs by using a composite type for the outputs.

```sql
CREATE TYPE company_forecasts AS (
    six_month_estimated_return real,
    one_year_bankruptcy_probability float);

CREATE FUNCTION analyze_company (
    IN free_cash_flow NUMERIC(18, 6),
    IN debt NUMERIC(18,6),
    IN max_rows_per_batch INT DEFAULT NULL,
    OUT prediction company_forecasts)
AS $$
SELECT (aws_sagemaker.invoke_endpoint('endpt_name', max_rows_per_batch,
    free_cash_flow, debt))::company_forecasts;
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

For the composite type, use fields in the same order as they appear in the model output and cast the output of `aws_sagemaker.invoke_endpoint` to your composite type. The caller can extract the individual fields either by name or with PostgreSQL ".*" notation.

### Best practices with Aurora machine learning

Most of the work in an `aws_ml` function call happens within the external Aurora machine learning service. This separation allows you to scale the resources for the machine learning service independent of your Aurora cluster. Within Aurora, you mostly focus on making the user-defined function calls themselves as efficient as possible. Some aspects that you can influence from your Aurora cluster include:

- The `max_rows_per_batch` setting for calls to the `aws_ml` functions.
- The number of virtual CPUs of the database instance, which determines the maximum degree of parallelism that the database might use when running your ML functions.
- the PostgreSQL parameters that control parallel query processing.

#### Topics
- Optimizing batch-mode execution for Aurora machine learning function calls (p. 1443)
- Exploiting parallel query processing (p. 1445)
- Using materialized views and materialized columns (p. 1446)

### Optimizing batch-mode execution for Aurora machine learning function calls

Typically PostgreSQL runs functions one row at a time. Aurora machine learning can minimize this overhead by combining the calls to the external Aurora machine learning service for many rows into batches with an approach called **batch-mode execution**. In batch mode, Aurora machine learning receives the responses for a batch of input rows, and then delivers the responses back to the running query one row at a time. This optimization improves the throughput of your Aurora queries without limiting the PostgreSQL query optimizer.

Aurora automatically uses batch mode if the function is referenced from the `SELECT` list, a `WHERE` clause, or a `HAVING` clause. Note that top-level simple `CASE` expressions are eligible for batch-mode execution.
Top-level searched CASE expressions are also eligible for batch-mode execution provided that the first WHEN clause is a simple predicate with a batch-mode function call.

Your user-defined function must be a LANGUAGE SQL function and should specify PARALLEL SAFE and COST 5000.

**Topics**
- Function migration from the SELECT statement to the FROM clause (p. 1444)
- Using the max_rows_per_batch parameter (p. 1444)
- Verifying batch-mode execution (p. 1445)

**Function migration from the SELECT statement to the FROM clause**

Usually, an `aws_ml` function that is eligible for batch-mode execution is automatically migrated by Aurora to the FROM clause.

The migration of eligible batch-mode functions to the FROM clause can be examined manually on a per-query level. To do this, you use EXPLAIN statements (and ANALYZE and VERBOSE) and find the "Batch Processing" information below each batch-mode Function Scan. You can also use EXPLAIN (with VERBOSE) without running the query. You then observe whether the calls to the function appear as a Function Scan under a nested loop join that was not specified in the original statement.

In the following example, the presence of the nested loop join operator in the plan shows that Aurora migrated the `anomaly_score` function. It migrated this function from the SELECT list to the FROM clause, where it's eligible for batch-mode execution.

```sql
EXPLAIN (VERBOSE, COSTS false)
SELECT anomaly_score(ts.R.description) from ts.R;
```

```
QUERY PLAN
-------------------------------------------------------------
Nested Loop
  Output: anomaly_score((r.description)::text)
  ->  Seq Scan on ts.r
       Output: r.id, r.description, r.score
  ->  Function Scan on public.anomaly_score
       Output: anomaly_score.anomaly_score
       Function Call: anomaly_score((r.description)::text)
```

To disable batch-mode execution, set the `apg_enable_function_migration` parameter to false. This prevents the migration of `aws_ml` functions from the SELECT to the FROM clause. The following shows how.

```sql
SET apg_enable_function_migration = false;
```

The `apg_enable_function_migration` parameter is a Grand Unified Configuration (GUC) parameter that is recognized by the Aurora PostgreSQL `apg_plan_mgmt` extension for query plan management. To disable function migration in a session, use query plan management to save the resulting plan as an approved plan. At runtime, query plan management enforces the approved plan with its `apg_enable_function_migration` setting. This enforcement occurs regardless of the `apg_enable_function_migration` GUC parameter setting. For more information, see Managing query execution plans for Aurora PostgreSQL (p. 1401).

**Using the max_rows_per_batch parameter**

The `max_rows_per_batch` parameter of the `aws_sagemaker.invoke_endpoint` (p. 1449) and `aws_comprehend.detect_sentiment` (p. 1448) functions influences how many rows are transferred to
the Aurora machine learning service. The larger the dataset processed by the user-defined function, the larger you can make the batch size.

Batch-mode functions improve efficiency by building batches of rows that spread the cost of the Aurora machine learning function calls over a large number of rows. However, if a SELECT statement finishes early due to a LIMIT clause, then the batch can be constructed over more rows than the query uses. This approach can result in additional charges to your AWS account. To gain the benefits of batch-mode execution but avoid building batches that are too large, use a smaller value for the max_rows_per_batch parameter in your function calls.

If you do an EXPLAIN (VERBOSE, ANALYZE) of a query that uses batch-mode execution, you see a FunctionScan operator that is below a nested loop join. The number of loops reported by EXPLAIN tells you the number of times a row was fetched from the FunctionScan operator. If a statement uses a LIMIT clause, the number of fetches is consistent. To optimize the size of the batch, set the max_rows_per_batch parameter to this value. However, if the batch-mode function is referenced in a predicate in the WHERE clause or HAVING clause, then you probably can't know the number of fetches in advance. In this case, use the loops as a guideline and experiment with max_rows_per_batch to find a setting that optimizes performance.

Verifying batch-mode execution

To see if a function ran in batch mode, use EXPLAIN ANALYZE. If batch-mode execution was used, then the query plan will include the information in a "Batch Processing" section.

```
EXPLAIN ANALYZE SELECT user-defined-function();
Batch Processing: num batches=1 avg/min/max batch size=3333.000/3333.000/3333.000
                  avg/min/max batch call time=146.273/146.273/146.273
```

In this example, there was 1 batch that contained 3,333 rows, which took 146.273 ms to process. The "Batch Processing" section shows the following:

- How many batches there were for this function scan operation
- The batch size average, minimum, and maximum
- The batch execution time average, minimum, and maximum

Typically the final batch is smaller than the rest, which often results in a minimum batch size that is much smaller than the average.

To return the first few rows more quickly, set the max_rows_per_batch parameter to a smaller value.

To reduce the number of batch mode calls to the ML service when you use a LIMIT in your user-defined function, set the max_rows_per_batch parameter to a smaller value.

Exploiting parallel query processing

To dramatically increase performance when processing a large number of rows, you can combine parallel query processing with batch mode processing. You can use parallel query processing for SELECT, CREATE TABLE AS SELECT, and CREATE MATERIALIZED VIEW statements.

Note
PostgreSQL doesn't yet support parallel query for data manipulation language (DML) statements.

Parallel query processing occurs both within the database and within the ML service. The number of cores in the instance class of the database limits the degree of parallelism that can be used when running a query. The database server can construct a parallel query execution plan that partitions the
task among a set of parallel workers. Then each of these workers can build batched requests containing
tens of thousands of rows (or as many as are allowed by each service).

The batched requests from all of the parallel workers are sent to the endpoint for the AWS service
(SageMaker, for example). Thus, the number and type of instances behind the AWS service endpoint also
limits the degree of parallelism that can be usefully exploited. Even a two-core instance class can benefit
significantly from parallel query processing. However, to fully exploit parallelism at higher K degrees, you
need a database instance class that has at least K cores. You also need to configure the AWS service so
that it can process K batched requests in parallel. For SageMaker, you need to configure the SageMaker
endpoint for your ML model to have K initial instances of a sufficiently high-performing instance class.

To exploit parallel query processing, you can set the parallel_workers storage parameter of the table
that contains the data that you plan to pass. You set parallel_workers to a batch-mode function
such as aws_comprehend.detect_sentiment. If the optimizer chooses a parallel query plan, the AWS
ML services can be called both in batch and in parallel. You can use the following parameters with the
aws_comprehend.detect_sentiment function to get a plan with four-way parallelism.

```
-- If you change either of the following two parameters, you must restart
-- the database instance for the changes to take effect.
--
-- SET max_worker_processes to 8;  -- default value is 8
-- SET max_parallel_workers to 8;  -- not greater than max_worker_processes
--
SET max_parallel_workers_per_gather to 4;  -- not greater than max_parallel_workers
-- You can set the parallel_workers storage parameter on the table that the data
-- for the ML function is coming from in order to manually override the degree of
-- parallelism that would otherwise be chosen by the query optimizer
--
ALTER TABLE yourTable SET (parallel_workers = 4);
-- Example query to exploit both batch-mode execution and parallel query
--
EXPLAIN (verbose, analyze, buffers, hashes)
SELECT aws_comprehend.detect_sentiment(description, 'en')).*
FROM yourTable
WHERE id < 100;
```

For more about controlling parallel query, see Parallel plans in the PostgreSQL documentation.

**Using materialized views and materialized columns**

When you invoke an AWS service such as SageMaker or Amazon Comprehend from your database,
your account is charged according to the pricing policy of that service. To minimize charges to your
account, you can materialize the result of calling the AWS service into a materialized column so that
the AWS service is not called more than once per input row. If desired, you can add a materializedAt
timestamp column to record the time at which the columns were materialized.

The latency of an ordinary single-row INSERT statement is typically much less than the latency
of calling a batch-mode function. Thus, you might not be able to meet the latency requirements
of your application if you invoke the batch-mode function for every single-row INSERT that your
application performs. To materialize the result of calling an AWS service into a materialized column,
high-performance applications generally need to populate the materialized columns. To do this, they
periodically issue an UPDATE statement that operates on a large batch of rows at the same time.

UPDATE takes a row-level lock that can impact a running application. So you might need to use
SELECT ... FOR UPDATE SKIP LOCKED, or use MATERIALIZED VIEW.

Analytics queries that operate on a large number of rows in real time can combine batch-mode
materialization with real-time processing. To do this, these queries assemble a UNION ALL of the pre-
materialized results with a query over the rows that don't yet have materialized results. In some cases, such a UNION ALL is needed in multiple places, or the query is generated by a third-party application. If so, you can create a VIEW to encapsulate the UNION ALL operation so this detail isn't exposed to the rest of the SQL application.

You can use a materialized view to materialize the results of an arbitrary SELECT statement at a snapshot in time. You can also use it to refresh the materialized view at any time in the future. Currently PostgreSQL doesn't support incremental refresh, so each time the materialized view is refreshed the materialized view is fully recomputed.

You can refresh materialized views with the CONCURRENTLY option, which updates the contents of the materialized view without taking an exclusive lock. Doing this allows a SQL application to read from the materialized view while it's being refreshed.

**Monitoring Aurora machine learning**

To monitor the functions in the aws_ml package, set the track_functions parameter and then query the PostgreSQL pg_stat_user_functions view.

For information about monitoring the performance of the SageMaker operations called from Aurora machine learning functions, see Monitor Amazon SageMaker.

To set track_functions at the session level, run the following.

```
SET track_functions = 'all';
```

Use one of the following values:

- **all** – Track C language functions and SQL language functions that aren't placed inline. To track the aws_ml functions, use all because these functions are implemented in C.
- **pl** – Track only procedural-language functions.
- **none** – Disable function statistics tracking.

After enabling track_functions and running your user-defined ML function, query the pg_stat_user_functions view to get information. The view includes the number of calls, total_time and self_time for each function. To view the statistics for the aws_sagemaker.invoke_endpoint and aws_comprehend.detect_sentiment functions, filter the results by schema names starting with aws_.

```
run your statement
SELECT * FROM pg_stat_user_functions WHERE schemaname LIKE 'aws_%';
SELECT pg_stat_reset();  -- To clear statistics
```

To find the names of your SQL functions that call the aws_sagemaker.invoke_endpoint function, query the source code of the functions in the PostgreSQL pg_proc catalog table.

```
SELECT proname FROM pg_proc WHERE prosrc LIKE '%invoke_endpoint%';
```

**Using query plan management to monitor ML functions**

If you captured plans using the apg_plan_mgmt extension of query plan management, you can then search through all the statements in your workload that refer to these function names. In your search, you can check plan_outline to see if batch-mode execution was used. You can also list statement
statistics such as execution time and plan cost. Plans that use batch-mode function scans contain a `FuncScan` operator in the plan outline. Functions that aren't run as a join don't contain a `FuncScan` operator.

For more about query plan management, see Managing query execution plans for Aurora PostgreSQL (p. 1401).

To find calls to the `aws_sagemaker.invoke_endpoint` function that don't use batch mode, use the following statement.

```sql
\dx apg_plan_mgmt

SELECT sql_hash, plan_hash, status, environment_variables,
       sql_text::varchar(50), plan_outline
FROM pg_proc, apg_plan_mgmt.dba_plans
WHERE
  prosrc LIKE '%invoke_endpoint%' AND
  sql_text LIKE '% ' || proname || ' '% AND
  plan_outline NOT LIKE '%"FuncScan"%';
```

The example preceding searches all statements in your workload that call SQL functions that in turn call the `aws_sagemaker.invoke_endpoint` function.

To obtain detailed runtime statistics for each of these statements, call the `apg_plan_mgmt.get_explain_stmt` function.

```sql
SELECT apg_plan_mgmt.get_explain_stmt(sql_hash, plan_hash, 'analyze,verbose,buffers')
FROM pg_proc, apg_plan_mgmt.dba_plans
WHERE
  prosrc LIKE '%invoke_endpoint%' AND
  sql_text LIKE '% ' || proname || ' '% AND
  plan_outline NOT LIKE '%"FuncScan"%';
```

### PostgreSQL function reference for Aurora machine learning

**Functions**

- `aws_comprehend.detect_sentiment` (p. 1448)
- `aws_sagemaker.invoke_endpoint` (p. 1449)

**aws_comprehend.detect_sentiment**

Performs sentiment analysis using Amazon Comprehend. For more about usage, see Using Amazon Comprehend for natural language processing (p. 1438).

**Syntax**

```sql
aws_comprehend.detect_sentiment (  
    IN input_text varchar,
    IN language_code varchar,
    IN max_rows_per_batch int,
    OUT sentiment varchar,
    OUT confidence real)
)```

1448
Input Parameters

**input_text**

The text to detect sentiment on.

**language_code**

The language of the input_text. For valid values, see Languages supported in Amazon Comprehend.

**max_rows_per_batch**

The maximum number of rows per batch for batch-mode processing. For more information, see Optimizing batch-mode execution for Aurora machine learning function calls (p. 1443).

Output Parameters

**sentiment**

The sentiment of the text. Valid values are POSITIVE, NEGATIVE, NEUTRAL, or MIXED.

**confidence**

The degree of confidence in the sentiment value. Values range between 1.0 for 100% to 0.0 for 0%.

**aws_sagemaker.invoke_endpoint**

After you train a model and deploy it into production using SageMaker services, your client applications use the aws_sagemaker.invoke_endpoint function to get inferences from the model. The model must be hosted at the specified endpoint and must be in the same AWS Region as the database instance. For more about usage, see Using SageMaker to run your own ML models (p. 1440).

**Syntax**

```sql
aws_sagemaker.invoke_endpoint(
    IN endpoint_name varchar,
    IN max_rows_per_batch int,
    VARIADIC model_input "any",
    OUT model_output varchar
)
```

Input Parameters

**endpoint_name**

An endpoint URL that is AWS Region-independent.

**max_rows_per_batch**

The maximum number of rows per batch for batch-mode processing. For more information, see Optimizing batch-mode execution for Aurora machine learning function calls (p. 1443).

**model_input**

One or more input parameters for the ML model. These can be any data type.

PostgreSQL allows you to specify up to 100 input parameters for a function. Array data types must be one-dimensional, but can contain as many elements as are expected by the SageMaker model.
The number of inputs to a SageMaker model is bounded only by the SageMaker 5 MB message size limit.

**Output Parameters**

`model_output`

The SageMaker model's output parameter, as text.

**Usage Notes**

The `aws_sagemaker.invoke_endpoint` function connects only to a model endpoint in the same AWS Region. If your database instance has replicas in multiple AWS Regions, always deploy each Amazon SageMaker model to all of those AWS Regions.

Calls to `aws_sagemaker.invoke_endpoint` are authenticated using the SageMaker IAM role for the database instance.

SageMaker model endpoints are scoped to an individual account and are not public. The `endpoint_name` URL doesn't contain the account ID. SageMaker determines the account ID from the authentication token that is supplied by the SageMaker IAM role of the database instance.

**Manually setting up IAM roles for SageMaker and Amazon Comprehend using the AWS CLI**

**Note**

If you use the AWS Management Console, AWS does the IAM setup for you automatically. In this case, you can skip the following information and follow the procedure in [Automatically connecting an Aurora DB cluster to AWS services using the console](p. 1437).

Setting up the IAM roles for SageMaker or Amazon Comprehend using the AWS CLI or the RDS API consists of the following steps:

1. Create an IAM policy to specify which SageMaker endpoints can be invoked by your Aurora PostgreSQL cluster or to enable access to Amazon Comprehend.
2. Create an IAM role to permit your Aurora PostgreSQL database cluster to access AWS ML services. Also attach the IAM policy created preceding to the IAM role created here.
3. Associate the IAM role that you created preceding to the Aurora PostgreSQL database cluster to permit access to AWS ML services.

**Topics**

- Creating an IAM policy to access SageMaker using the AWS CLI (p. 1450)
- Creating an IAM policy to access Amazon Comprehend using the AWS CLI (p. 1451)
- Creating an IAM role to access SageMaker and Amazon Comprehend (p. 1452)
- Associating an IAM role with an Aurora PostgreSQL DB cluster using the AWS CLI (p. 1452)

**Creating an IAM policy to access SageMaker using the AWS CLI**

**Note**

Aurora can create the IAM policy for you automatically. You can skip the following information and use the procedure in [Automatically connecting an Aurora DB cluster to AWS services using the console](p. 1437).
The following policy adds the permissions required by Aurora PostgreSQL to invoke a SageMaker function on your behalf. You can specify all of your SageMaker endpoints that you need your database applications to access from your Aurora PostgreSQL cluster in a single policy.

Note
This policy enables you to specify the AWS Region for a SageMaker endpoint. However, an Aurora PostgreSQL cluster can only invoke SageMaker models deployed in the same AWS Region as the cluster.

```json
```

The following AWS CLI command creates an IAM policy with these options.

```bash
```

For the next step, see Creating an IAM role to access SageMaker and Amazon Comprehend (p. 1452).

Creating an IAM policy to access Amazon Comprehend using the AWS CLI

Note
Aurora can create the IAM policy for you automatically. You can skip the following information and use the procedure in Automatically connecting an Aurora DB cluster to AWS services using the console (p. 1437).

The following policy adds the permissions required by Aurora PostgreSQL to invoke Amazon Comprehend on your behalf.

```json
```

To create an IAM policy to grant access to Amazon Comprehend

1. Open the IAM management console.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **Comprehend**.
5. For **Actions**, choose **Detect Sentiment** and **BatchDetectSentiment**.
6. Choose **Review policy**.
7. For **Name**, enter a name for your IAM policy. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.
8. Choose **Create policy**.

For the next step, see Creating an IAM role to access SageMaker and Amazon Comprehend (p. 1452).

### Creating an IAM role to access SageMaker and Amazon Comprehend

**Note**
Aurora can create the IAM role for you automatically. You can skip the following information and use the procedure in Automatically connecting an Aurora DB cluster to AWS services using the console (p. 1437).

After you create the IAM policies, create an IAM role that the Aurora PostgreSQL DB cluster can assume for your database users to access ML services. To create an IAM role, follow the steps described in Creating a role to delegate permissions to an IAM user.

Attach the preceding policies to the IAM role you create. For more information, see Attaching an IAM policy to an IAM user or role (p. 1667).

For more information about IAM roles, see IAM roles in the IAM User Guide.

For the next step, see Associating an IAM role with an Aurora PostgreSQL DB cluster using the AWS CLI (p. 1452).

### Associating an IAM role with an Aurora PostgreSQL DB cluster using the AWS CLI

**Note**
Aurora can associate an IAM role with your DB cluster for you automatically. You can skip the following information and use the procedure in Automatically connecting an Aurora DB cluster to AWS services using the console (p. 1437).

The last process in setting up IAM access is to associate the IAM role and its IAM policy with your Aurora PostgreSQL DB cluster. Do the following:

1. Add the role to the list of associated roles for a DB cluster.

To associate the role with your DB cluster, use the AWS Management Console or the **add-role-to-db-cluster** AWS CLI command.

- **To add an IAM role for a PostgreSQL DB cluster using the console**

  1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
  2. Choose the PostgreSQL DB cluster name to display its details.
  3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this cluster**.
  4. Under **Feature**, choose **SageMaker** or **Comprehend**.
5. Choose *Add role*.

- **To add an IAM role for a PostgreSQL DB cluster using the CLI**

Use the following command to add the role to the PostgreSQL DB cluster named *my-db-cluster*. Replace *your-role-arn* with the role ARN that you noted in a previous step. For the value of the `--feature-name` option, use SageMaker, Comprehend, or s3Export depending on which service you want to use.

**Example**

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-cluster \
    --db-cluster-identifier my-db-cluster \
    --feature-name external-service \
    --role-arn your-role-arn \
    --region your-region
```

For Windows:

```
aws rds add-role-to-db-cluster ^
    --db-cluster-identifier my-db-cluster ^
    --feature-name external-service ^
    --role-arn your-role-arn ^
    --region your-region
```

2. Set the cluster-level parameter for each AWS ML service to the ARN for the associated IAM role.

Use the electroencephalographic, miscomprehended, or both parameters depending on which AWS ML services you intend to use with your Aurora cluster.

Cluster-level parameters are grouped into DB cluster parameter groups. To set the preceding cluster parameters, use an existing custom DB cluster group or create a new one. To create a new DB cluster parameter group, call the `create-db-cluster-parameter-group` command from the AWS CLI, for example:

```
aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccessToExternalServices \
    --db-parameter-group-family aurora-postgresql-group --description "Allow access to Amazon S3, Amazon SageMaker, and Amazon Comprehend"
```

Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group. Do the following.

```
aws rds modify-db-cluster-parameter-group \
    --db-cluster-parameter-group-name AllowAWSAccessToExternalServices \
    --parameters "ParameterName=aws_default_s3_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraS3Role,ApplyMethod=pending-reboot" \
    --parameters "ParameterName=aws_default_sagemaker_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraSageMakerRole,ApplyMethod=pending-reboot" \
    --parameters "ParameterName=aws_default_comprehend_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraComprehendRole,ApplyMethod=pending-reboot"
```

Modify the DB cluster to use the new DB cluster parameter group. Then, reboot the cluster. The following shows how.
When the instance has rebooted, your IAM roles are associated with your DB cluster.

Fast recovery after failover with cluster cache management for Aurora PostgreSQL

For fast recovery of the writer DB instance in your Aurora PostgreSQL clusters if there's a failover, use cluster cache management for Amazon Aurora PostgreSQL. Cluster cache management ensures that application performance is maintained if there's a failover.

In a typical failover situation, you might see a temporary but large performance degradation after failover. This degradation occurs because when the failover DB instance starts, the buffer cache is empty. An empty cache is also known as a **cold cache**. A cold cache degrades performance because the DB instance has to read from the slower disk, instead of taking advantage of values stored in the buffer cache.

With cluster cache management, you set a specific reader DB instance as the failover target. Cluster cache management ensures that the data in the designated reader's cache is kept synchronized with the data in the writer DB instance's cache. The designated reader's cache with prefilled values is known as a **warm cache**. If a failover occurs, the designated reader uses values in its warm cache immediately when it's promoted to the new writer DB instance. This approach provides your application much better recovery performance.

Cluster cache management requires that the designated reader instance have the same instance class type and size (db.r5.2xlarge or db.r5.xlarge, for example) as the writer. Keep this in mind when you create your Aurora PostgreSQL DB clusters so that your cluster can recover during a failover. For a listing of instance class types and sizes, see [Hardware specifications for DB instance classes for Aurora](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraPostgreSQLGuide/DB-class.html).

**Note**
Cluster cache management is not supported for Aurora PostgreSQL DB clusters that are part of Aurora global databases.

### Contents
- Configuring cluster cache management (p. 1454)
  - Enabling cluster cache management (p. 1455)
  - Setting the promotion tier priority for the writer DB instance (p. 1455)
  - Setting the promotion tier priority for a reader DB instance (p. 1456)
- Monitoring the buffer cache (p. 1457)

### Configuring cluster cache management

To configure cluster cache management, do the following processes in order.

**Topics**
- Enabling cluster cache management (p. 1455)
- Setting the promotion tier priority for the writer DB instance (p. 1455)
• Setting the promotion tier priority for a reader DB instance (p. 1456)

**Note**
Allow at least 1 minute after completing these steps for cluster cache management to be fully operational.

### Enabling cluster cache management

To enable cluster cache management, take the steps described following.

#### Console

**To enable cluster cache management**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group for your Aurora PostgreSQL DB cluster.
   - The DB cluster must use a parameter group other than the default, because you can't change values in a default parameter group.
4. For **Parameter group actions**, choose **Edit**.
5. Set the value of the `apg_ccm_enabled` cluster parameter to `1`.
6. Choose **Save changes**.

#### AWS CLI

To enable cluster cache management for an Aurora PostgreSQL DB cluster, use the AWS CLI `modify-db-cluster-parameter-group` command with the following required parameters:

- `--db-cluster-parameter-group-name`
- `--parameters`

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name my-db-cluster-parameter-group \
  --parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name my-db-cluster-parameter-group ^
  --parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

### Setting the promotion tier priority for the writer DB instance

For cluster cache management, make sure that the promotion priority is `tier-0` for the writer DB instance of the Aurora PostgreSQL DB cluster. The **promotion tier priority** is a value that specifies the order in
which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where 0 is the first priority and 15 is the last priority. For more information about the promotion tier, see Fault tolerance for an Aurora DB cluster (p. 68).

**Console**

**To set the promotion priority for the writer DB instance to tier-0**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Writer DB instance of the Aurora PostgreSQL DB cluster.
5. On the Additional configuration panel, choose tier-0 for the Failover priority.
6. Choose Continue and check the summary of modifications.
7. To apply the changes immediately after you save them, choose Apply immediately.
8. Choose Modify DB Instance to save your changes.

**AWS CLI**

To set the promotion tier priority to 0 for the writer DB instance using the AWS CLI, call the `modify-db-instance` command with the following required parameters:

- `--db-instance-identifier`
- `--promotion-tier`
- `--apply-immediately`

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier writer-db-instance \
--promotion-tier 0 \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier writer-db-instance ^
--promotion-tier 0 ^
--apply-immediately
```

**Setting the promotion tier priority for a reader DB instance**

You set one reader DB instance for cluster cache management. To do so, choose a reader from the Aurora PostgreSQL cluster that is the same instance class and size as the writer DB instance. For example, if the writer uses `db.r5.xlarge`, choose a reader that uses this same instance class type and size. Then set its promotion tier priority to 0.
The promotion tier priority is a value that specifies the order in which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where 0 is the first priority and 15 is the last priority.

Console

To set the promotion priority of the reader DB instance to tier-0

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose a Reader DB instance of the Aurora PostgreSQL DB cluster that is the same instance class as the writer DB instance.
5. On the Additional configuration panel, choose tier-0 for the Failover priority.
6. Choose Continue and check the summary of modifications.
7. To apply the changes immediately after you save them, choose Apply immediately.
8. Choose Modify DB Instance to save your changes.

AWS CLI

To set the promotion tier priority to 0 for the reader DB instance using the AWS CLI, call the modify-db-instance command with the following required parameters:

- --db-instance-identifier
- --promotion-tier
- --apply-immediately

Example

For Linux, macOS, or Unix:

`aws rds modify-db-instance \ 
--db-instance-identifier reader-db-instance \ 
--promotion-tier 0 \ 
--apply-immediately`

For Windows:

`aws rds modify-db-instance ^ 
--db-instance-identifier reader-db-instance ^ 
--promotion-tier 0 ^ 
--apply-immediately`

Monitoring the buffer cache

After setting up cluster cache management, you can monitor the state of synchronization between the writer DB instance's buffer cache and the designated reader's warm buffer cache. To examine the buffer cache contents on both the writer DB instance and the designated reader DB instance, use the PostgreSQL pg_buffercache module. For more information, see the PostgreSQL pg_buffercache documentation.
Using the `aurora_ccm_status` Function

Cluster cache management also provides the `aurora_ccm_status` function. Use the `aurora_ccm_status` function on the writer DB instance to get the following information about the progress of cache warming on the designated reader:

- **buffers_sent_last_minute** – How many buffers have been sent to the designated reader in the last minute.
- **buffers_sent_last_scan** – How many buffers have been sent to the designated reader during the last complete scan of the buffer cache.
- **buffers_found_last_scan** – How many buffers have been identified as frequently accessed and needed to be sent during the last complete scan of the buffer cache. Buffers already cached on the designated reader aren't sent.
- **buffers_sent_current_scan** – How many buffers have been sent so far during the current scan.
- **buffers_found_current_scan** – How many buffers have been identified as frequently accessed in the current scan.
- **current_scan_progress** – How many buffers have been visited so far during the current scan.

The following example shows how to use the `aurora_ccm_status` function to convert some of its output into a warm rate and warm percentage.

```sql
SELECT buffers_sent_last_minute*8/60 AS warm_rate_kbps,
       100*(1.0-buffers_sent_last_scan/buffers_found_last_scan) AS warm_percent
FROM aurora_ccm_status();
```

Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster

You can invoke AWS Lambda functions from an Aurora PostgreSQL DB cluster. To do this, use the `aws_lambda` PostgreSQL extension provided with Aurora PostgreSQL.

AWS Lambda is a compute service that you can use to run code. For example, you can use Lambda functions to process event notifications from a DB instance. For more information about Lambda, see What is AWS Lambda? in the AWS Lambda Developer Guide.

**Note**

Invoking an AWS Lambda function is supported in Aurora PostgreSQL 11.9 and later.

**Topics**

- Overview of using a Lambda function (p. 1458)
- Specifying the Lambda function to use (p. 1459)
- Giving Aurora access to Lambda (p. 1460)
- Invoking Lambda functions (p. 1461)
- Function reference (p. 1463)

**Overview of using a Lambda function**

You can invoke a Lambda function from an Aurora PostgreSQL database with the following procedure.
To invoke a Lambda function from an Aurora PostgreSQL database

1. Install the required PostgreSQL extensions. These include the `aws_lambda` and `aws_commons` extensions. To do so, start psql and run the following commands.

   ```
   CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;
   ```

   The `aws_lambda` extension provides the `aws_lambda.invoke` function that you use to invoke functions in Lambda. The `aws_commons` extension is included to provide additional helper functions.

2. Identify the name or Amazon Resource Name (ARN) for the Lambda function to use. For details about this process, see Specifying the Lambda function to use (p. 1459).

3. Provide permission to access the Lambda function.

   To invoke a Lambda function, give the Aurora PostgreSQL DB cluster permission to access the Lambda invoke API operation. Doing this includes the following steps:

   1. Create an AWS Identity and Access Management (IAM) policy that provides access to a Lambda function that you want to invoke.
   2. Create an IAM role.
   3. Attach the IAM policy that you created to the role that you created.
   4. Add this IAM role to your DB cluster.

   For details about this process, see Giving Aurora access to Lambda (p. 1460).

4. Use the `aws_lambda.invoke` function to run the Lambda function. For details about this process, see Invoking Lambda functions (p. 1461).

Specifying the Lambda function to use

To identify the Lambda function to use, specify the following information:

- **Function name** – The name of the Lambda function, ARN, version, or alias. For a listing of possible formats, see Lambda function name formats.
- **AWS Region** – (Optional) The AWS Region where the Lambda function is located. If you don't specify a Region value and it's not specified in the function ARN, Aurora uses the same Region as the DB cluster.

For a listing of AWS Region names and associated values, see Regions and Availability Zones (p. 11).

To hold the Lambda function name information, you can use the `aws_commons.create_lambda_function_arn` function. This function creates an `aws_commons._lambda_function_arn_1` composite structure to store the name information, as shown following.

```sql
psql=> SELECT aws_commons.create_lambda_function_arn(
    'my-function',
    'us-west-2' ) AS aws_lambda_arn_1 \gset
psql=> SELECT aws_commons.create_lambda_function_arn(
    '123456789012:function:my-function',
    'us-west-2' ) AS lambda_partial_arn_1 \gset
psql=> SELECT aws_commons.create_lambda_function_arn(
```
Giving Aurora access to Lambda

To use a Lambda function, give your PostgreSQL DB cluster permission to access Lambda. To do this, use the following procedure.

To give a PostgreSQL DB cluster access to Lambda

1. Create an IAM policy.

   This policy provides the permissions that allow your PostgreSQL DB cluster to invoke Lambda functions.

   As part of creating this policy, take the following steps:
   
   a. Include in the policy the required action `lambda:InvokeFunction` to allow Lambda invocation from your Aurora PostgreSQL DB cluster.
   
   b. Include the Amazon Resource Name (ARN) that identifies the Lambda function. The ARN format for accessing Lambda is: `arn:aws:lambda::<region>:<123456789012>:function:example_function/*`

   For more information on creating an IAM policy for Aurora PostgreSQL, see Creating and using an IAM policy for IAM database access. See also IAM Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named `rds-lambda-policy` with these options. It grants access to a function named `example_function`.

   ```bash
   aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "AllowAccessToExampleFunction",
   "Effect": "Allow",
   "Action": "lambda:InvokeFunction",
   "Resource": "arn:aws:lambda::<region>:<123456789012>:function:example_function"
   }
   ]
   '}
   
   After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

2. Create an IAM role.

   You do this so that Aurora PostgreSQL can assume this IAM role on your behalf to access your Lambda function. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

   The following example shows using the AWS CLI command to create a role named `rds-lambda-role`.

   ```bash
   aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
   }'
3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named `rds-lambda-role`. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-lambda-role
```

4. Add the IAM role to the DB cluster. You do so by using the AWS CLI, as described following.

Use the following CLI command to add the IAM role to the Aurora PostgreSQL DB cluster named `my-db-cluster`. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `Lambda` for the value of the `--feature-name` option, as shown following.

```
aws rds add-role-to-db-cluster \
--db-cluster-identifier my-db-cluster \
--feature-name Lambda \
--role-arn your-role-arn \
--region your-region
```

## Invoking Lambda functions

Following, you can find some examples of calling the `aws_lambda.invoke` function. Before you use the `aws_lambda.invoke` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in Overview of using a Lambda function (p. 1458).
- Determine which Lambda function to invoke as described in Specifying the Lambda function to use (p. 1459).
- Make sure that the DB cluster has invoke access to Lambda as described in Giving Aurora access to Lambda (p. 1460).

You can invoke a Lambda function synchronously or asynchronously. You control this with the following values for the `aws_lambda.invoke` function's `invocation_type` parameter:

- The `RequestResponse` type of invocation for a Lambda function is synchronous and returns a response payload in the result of the `aws_lambda.invoke` function. Use the `RequestResponse` invocation type when your workflow depends on receiving the Lambda function result immediately. Most of the following examples use synchronous invocation.

  The `RequestResponse` type of invocation is the default.

- The `Event` type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the `Event` type of invocation when you don't need to know the result of the Lambda function before your workflow moves on. For an example of asynchronous invocation, see Asynchronous event invocation of Lambda functions (p. 1462).
The following `aws_lambda.invoke` examples use a `aws_lambda_arn_1` structure, which contains the identifying information for the Lambda function. To create the structure, use the `aws_commons.create_lambda_function_arn` function. For an example of using the `aws_commons.create_lambda_function_arn` function, see Specifying the Lambda function to use (p. 1459).

**Topics**
- Synchronous RequestResponse invocation of Lambda functions (p. 1462)
- Asynchronous event invocation of Lambda functions (p. 1462)
- Requesting a Lambda execution log in a function response (p. 1462)
- Including client context in a Lambda function (p. 1463)
- Invoking a specific version of a Lambda function (p. 1463)
- Lambda function error handling (p. 1463)

### Synchronous RequestResponse invocation of Lambda functions

Following is an example of a synchronous Lambda function invocation. The following two `aws_lambda.invoke` function call results are the same.

```sql
psql=> SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json);
psql=> SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'RequestResponse');
```

The parameters are described as follows:

- `'aws_lambda_arn_1'` – This parameter is a structure that identifies the Lambda function to call. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_lambda_function_arn` function call inline within the `aws_lambda.invoke` function call as follows.

```sql
psql=> SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'us-west-2'),
                                          '{"body": "Hello from Postgres!"}'::json, 'RequestResponse');
```

- `{"body": "Hello from PostgreSQL!"}`::json – The JSON payload to pass to the Lambda function.
- `'RequestResponse'` – The Lambda invocation type.

### Asynchronous event invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The `Event` invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the `Event` invocation type in certain workflows that don't depend on the results of the Lambda function.

```sql
psql=> SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'Event');
```

### Requesting a Lambda execution log in a function response

You can request to include the last 4 KB of the execution log in the function response, as shown following.
Set the `aws_lambda.invoke` function's `log_type` parameter to `Tail` to include the execution log in the response. The default value for the `log_type` parameter is `None`.

The `log_result` that's returned is a base64 encoded string. You can decode the contents using a combination of the `decode` and `convert_from` PostgreSQL functions.

### Including client context in a Lambda function

You can pass in client context information that is separate from the payload, as shown following.

```sql
psql=> SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke(':aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the `aws_lambda.invoke` function's `context` parameter.

### Invoking a specific version of a Lambda function

For an example of invoking a specific version of a Lambda function, see the following.

```sql
psql=> SELECT * FROM aws_lambda.invoke(':aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'None', NULL, 'custom_version');
```

To identify a Lambda function's version, use the `aws_lambda.invoke` function's `qualifier` parameter. In this example, 'custom_version' is an alias or version that identifies the version of the function to invoke.

You can instead supply a Lambda function qualifier with the function name information as follows.

```sql
psql=> SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function:custom_version', 'us-west-2'), '{"body": "Hello from Postgres!"}':json)
```

### Lambda function error handling

If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

```sql
psql=> SELECT * FROM aws_lambda.invoke(':aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json);
ERROR:  lambda invocation failed
```

### Function reference

Following is the reference for the functions to use for invoking Lambda functions with Aurora PostgreSQL.

**Functions**
aws_lambda.invoke

Runs a Lambda function for an Aurora PostgreSQL DB cluster.

For more details about invoking Lambda functions, see also `invoke` in the AWS Lambda Developer Guide.

Syntax

**JSON**

```sql
aws_lambda.invoke(
    IN function_name TEXT,
    IN payload JSON,
    IN region TEXT DEFAULT NULL,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSON DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSON,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```

**JSONB**

```sql
aws_lambda.invoke(
    IN function_name TEXT,
    IN payload JSONB,
    IN region TEXT DEFAULT NULL,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSON DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSONB,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT
)

Input parameters

function_name

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see Lambda function name formats in the AWS Lambda Developer Guide.

payload

The input for the Lambda function. The format can be JSON or JSONB. For more information, see JSON Types in the PostgreSQL documentation.

region

(Optional) The Lambda Region for the function. By default, Aurora resolves the AWS Region from the full ARN in the function_name or it uses the Aurora PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the function_name ARN, an error is raised.

invocation_type

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- RequestResponse – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the RequestResponse invocation type when your workflow depends on receiving the Lambda function result immediately.
- Event – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the Event invocation type when you don't need results of the Lambda function before your workflow moves on.
- DryRun – This type of invocation tests access without running the Lambda function.

log_type

The type of Lambda log to return in the log_result output parameter. The value is case-sensitive. Possible values include the following:

- Tail – The returned log_result output parameter will include the last 4 KB of the execution log.
- None – No Lambda log information is returned.

context

Client context in JSON or JSONB format. Fields to use include than custom and env.

qualifier

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the function_name ARN, an error is raised.

Output parameters

status_code

An HTTP status response code. For more information, see Lambda Invoke response elements in the AWS Lambda Developer Guide.

payload

The information returned from the Lambda function that ran. The format is in JSON or JSONB.
executed_version

The version of the Lambda function that ran.

log_result

The execution log information returned if the log_type value is Tail when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

aws_commons.create_lambda_function_arn

Creates an aws_commons._lambda_function_arn_1 structure to hold Lambda function name information. You can use the results of the aws_commons.create_lambda_function_arn function in the function_name parameter of the aws_lambda.invoke function.

Syntax

```sql
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
) RETURNS aws_commons._lambda_function_arn_1
```

**Input parameters**

**function_name**

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

**region**

An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see Regions and Availability Zones (p. 11).

Using the oracle_fdw extension to access foreign data in Aurora PostgreSQL

For easy and efficient access to Oracle databases for Aurora PostgreSQL, you can use the PostgreSQL oracle_fdw extension, which provides a foreign data wrapper. For a complete description of this extension, see the oracle_fdw documentation.

The oracle_fdw extension is supported on Amazon RDS for PostgreSQL versions 12.7, 13.3, and higher that use x86-based DB instance classes.

Turning on the oracle_fdw extension

To use the oracle_fdw extension, perform the following procedure.

**To turn on the oracle_fdw extension**

- Run the following command using an account that has rds_superuser permissions.

  ```sql
  CREATE EXTENSION oracle_fdw;
  ```
Example using a foreign server linked to an RDS for Oracle database

The following example demonstrates using a foreign server linked to an RDS for Oracle database.

To create a foreign server linked to an RDS for Oracle database

1. Note the following for the RDS for Oracle DB instance:
   - Endpoint
   - Port
   - Database name

2. Create a foreign server.
   ```sql
   test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS ('//endpoint:port/DB_name');
   CREATE SERVER
   ```

3. Grant usage to a user who doesn't have rds_superuser permissions, for example user1.
   ```sql
   test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
   GRANT
   ```

4. Connect as user1 and create a mapping to an Oracle user.
   ```sql
   test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS ('oracleuser', 'mypassword');
   CREATE USER MAPPING
   ```

5. Create a foreign table linked to an Oracle table.
   ```sql
   test=> create foreign table mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
   CREATE FOREIGN TABLE
   ```

6. Query the foreign table.
   ```sql
   test=> select * from mytab;
   a
   ---
   1
   (1 row)
   ```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```
Considerations for DB instances from non–Intel-based classes

The oracle_fdw foreign data wrapper relies on the Oracle client. The Oracle client isn't supported on Graviton2-based DB instances, such as the db.m6g instance class. Any calls to Graviton2-based DB instances result in the following error.

```
ERROR: oracle_fdw is not supported on this instance type, please refer to the documentation for more details
```

The following considerations apply to DB instances from non–Intel-based DB classes:

- Migrating from an x86-based DB instance to a Graviton2-based one succeeds, but produces the previous error message when oracle_fdw uses the Oracle client.
- Reverting to an x86-based instance makes oracle_fdw work again.
- If you have a read replica on x86 and the primary DB instance is on Graviton2, calls that require the Oracle client succeed on the read replica if they don't generate write activity. Any calls that don't require the Oracle client succeed on the primary. Therefore, you can successfully perform the steps in the previous example (except the query) on the primary DB instance and run the query on the read replica.

Working with encryption in transit

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see About the Values for Negotiating Encryption and Integrity in the Oracle documentation. The client used for oracle_fdw on RDS is configured with ACCEPTED, meaning that the encryption depends on the Oracle database server configuration.

pg_user_mapping and pg_user_mappings permissions

In the following table, you can find an illustration of user mapping permissions using the example roles. The rdssu1 and rdssu2 users have the rds_superuser role, and the user1 user doesn't.

**Note**

You can use the `\du` metacommand in psql to list existing roles.

```
test=> \du
List of roles

<table>
<thead>
<tr>
<th>Role name</th>
<th>Attributes</th>
<th>Member of</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdssu1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>{rds_superuser}</td>
<td></td>
</tr>
<tr>
<td>rdssu2</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>{rds_superuser}</td>
<td></td>
</tr>
<tr>
<td>user1</td>
<td></td>
<td>{}</td>
</tr>
</tbody>
</table>
```

Users with the rds_superuser role can't query the pg_user_mapping table. The following example uses rdssu1,

```
test=> SET SESSION AUTHORIZATION rdssu1;
```
On RDS for PostgreSQL, all users—even ones with the `rds_superuser` role—can see only their own umoptions values in the `pg_user_mappings` table. The following example demonstrates.

```
<table>
<thead>
<tr>
<th>umid</th>
<th>srvid</th>
<th>srvname</th>
<th>umuser</th>
<th>usename</th>
<th>umoptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>16414</td>
<td>16411</td>
<td>oradb</td>
<td>16412</td>
<td>user1</td>
<td></td>
</tr>
<tr>
<td>16423</td>
<td>16411</td>
<td>oradb</td>
<td>16421</td>
<td>rdssu1</td>
<td>{user=oracleuser,password=mypwd}</td>
</tr>
<tr>
<td>16424</td>
<td>16411</td>
<td>oradb</td>
<td>16422</td>
<td>rdssu2</td>
<td></td>
</tr>
</tbody>
</table>
```

(3 rows)

```
<table>
<thead>
<tr>
<th>umid</th>
<th>srvid</th>
<th>srvname</th>
<th>umuser</th>
<th>usename</th>
<th>umoptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>16414</td>
<td>16411</td>
<td>oradb</td>
<td>16412</td>
<td>user1</td>
<td>{user=oracleuser,password=mypwd}</td>
</tr>
<tr>
<td>16423</td>
<td>16411</td>
<td>oradb</td>
<td>16421</td>
<td>rdssu1</td>
<td></td>
</tr>
<tr>
<td>16424</td>
<td>16411</td>
<td>oradb</td>
<td>16422</td>
<td>rdssu2</td>
<td></td>
</tr>
</tbody>
</table>
```

(3 rows)

Because of differences in implementation of `information_schema.pg_user_mappings` and `pg_catalog.pg_user_mappings`, a manually created `rds_superuser` requires additional permissions to view passwords in `pg_catalog.pg_user_mappings`.

No additional permissions are required for a user with the `rds_superuser` role to view passwords in `information_schema.pg_user_mappings`.

Users who don't have the `rds_superuser` role can view passwords in `pg_user_mappings` only under the following conditions:

- The current user is the user being mapped and owns the server or holds the `USAGE` privilege on it.
- The current user is the server owner and the mapping is for `PUBLIC`.

Managing PostgreSQL partitions with the `pg_partman` extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.
By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an `INSERT` or `UPDATE` SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the `WHERE` clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.

- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints
  - References
  - Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

**Topics**

- Overview of the PostgreSQL pg_partman extension (p. 1470)
- Enabling the pg_partman extension (p. 1471)
- Configuring partitions using the `create_parent` function (p. 1472)
- Configuring partition maintenance using the `run_maintenance_proc` function (p. 1473)

### Overview of the PostgreSQL pg_partman extension

You can use the PostgreSQL pg_partman extension to automate the creation and maintenance of table partitions. For more general information, see PG Partition Manager in the pg_partman documentation.

**Note**

The pg_partman extension is supported on Aurora PostgreSQL versions 12.6 and higher.

Instead of having to manually create each partition, you configure `pg_partman` with the following settings:

- Table to be partitioned
After you create a PostgreSQL partitioned table, you register it with `pg_partman` by calling the `create_parent` function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The `pg_partman` extension also provides the `run_maintenance_proc` function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

## Enabling the `pg_partman` extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the `pg_partman` extension separately for each database. To enable the `pg_partman` extension for a specific database, create the partition maintenance schema and then create the `pg_partman` extension as follows.

```sql
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

**Note**

To create the `pg_partman` extension, make sure that you have `rds_superuser` privileges.

If you receive an error such as the following, grant the `rds_superuser` privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant `rds_superuser` privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the `pg_partman` extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema `data_mart` contains a table named `events` with a column named `created_at`. The following settings are included in the `events` table:

- Primary keys `event_id` and `created_at`, which must have the column used to guide the partition.
- A check constraint `ck_valid_operation` to enforce values for an `operation` table column.
- Two foreign keys, where one (`fk_orga_membership`) points to the external table `organization` and the other (`fk_parent_event_id`) is a self-referenced foreign key.
- Two indexes, where one (`idx_org_id`) is for the foreign key and the other (`idx_event_type`) is for the event type.

The follow DDL statements create these objects, which are automatically included on each partition.
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization ( org_id BIGSERIAL, org_name TEXT,
    CONSTRAINT pk_organization PRIMARY KEY (org_id) );

CREATE TABLE data_mart.events(
    event_id BIGSERIAL, operation CHAR(1), value FLOAT(24),
    parent_event_id BIGINT, event_type VARCHAR(25), org_id BIGSERIAL,
    created_at timestamp,
    CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
    CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
    CONSTRAINT fk_orga_membership
        FOREIGN KEY(org_id)
        REFERENCES data_mart.organization (org_id),
    CONSTRAINT fk_parent_event_id
        FOREIGN KEY(parent_event_id, created_at)
        REFERENCES data_mart.events (event_id,created_at)
) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id ON  data_mart.events(org_id);
CREATE INDEX idx_event_type ON  data_mart.events(event_type);

Configuring partitions using the create_parent function

After you enable the pg_partman extension, use the create_parent function to configure partitions inside the partition maintenance schema. The following example uses the events table example created in Enabling the pg_partman extension (p. 1471). Call the create_parent function as follows.

SELECT partman.create_parent( p_parent_table => 'data_mart.events', p_control => 'created_at', p_type => 'native', p_interval => 'daily', p_premake => 30 );

The parameters are as follows:

- p_parent_table – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
- p_control – The column on which the partitioning is to be based. The data type must be an integer or time-based.
- p_type – The type is either 'native' or 'partman'. You typically use the native type for its performance improvements and flexibility. The partman type relies on inheritance.
- p_interval – The time interval or integer range for each partition. Example values include daily, hourly, and so on.
- p_premake – The number of partitions to create in advance to support new insert.

For a complete description of the create_parent function, see Creation Functions in the pg_partman documentation.
Configuring partition maintenance using the run_maintenance_proc function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the run_maintenance_proc function of the pg_partman extension and the pg_cron extension, which initiates an internal scheduler. The pg_cron scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the events table example created in Enabling the pg_partman extension (p. 1471) to set partition maintenance operations to run automatically. As a prerequisite, add pg_cron to the shared_preload_libraries parameter in the DB instance's parameter group.

```sql
CREATE EXTENSION pg_cron;
UPDATE partman.part_config
SET infinite_time_partitions = true,
   retention = '3 months',
   retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add pg_cron to the shared_preload_libraries parameter value. This change requires a DB instance restart for it to take effect. For more information, see Modifying parameters in a DB parameter group (p. 343).
2. Run the command CREATE EXTENSION pg_cron; using an account that has the rds_superuser permissions. Doing this enables the pg_cron extension. For more information, see Scheduling maintenance with the PostgreSQL pg_cron extension (p. 1311).
3. Run the command UPDATE partman.part_config to adjust the pg_partman settings for the data_mart.events table.
4. Run the command SET... to configure the data_mart.events table, with these clauses:
   a. infinite_time_partitions = true, - Configures the table to be able to automatically create new partitions without any limit.
   b. retention = '3 months', - Configures the table to have a maximum retention of three months.
   c. retention_keep_table=true - Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.
5. Run the command SELECT cron.schedule... to make a pg_cron function call. This call defines how often the scheduler runs the pg_partman maintenance procedure, partman.run_maintenance_proc. For this example, the procedure runs every hour.

For a complete description of the run_maintenance_proc function, see Maintenance Functions in the pg_partman documentation.

Using Kerberos authentication with Aurora PostgreSQL

You can use Kerberos authentication to authenticate users when they connect to your DB cluster running PostgreSQL. In this case, your DB instance works with AWS Directory Service for Microsoft Active
Directory to enable Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD.

You create an AWS Managed Microsoft AD directory to store user credentials. You then provide to your PostgreSQL DB cluster the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB cluster, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple DB clusters. Using a directory can also improve your overall security profile.

You can also access credentials from your own on-premises Microsoft Active Directory. To do so you create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL clusters with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use Kerberos, AWS Identity and Access Management (IAM), or both Kerberos and IAM authentication. However, since Kerberos and IAM authentication provide different authentication methods, a specific user can log in to a database using only one or the other authentication method but not both. For more information about IAM authentication, see IAM database authentication (p. 1661).

**Topics**

- Availability of Kerberos authentication (p. 1474)
- Overview of Kerberos authentication for PostgreSQL DB clusters (p. 1475)
- Setting up Kerberos authentication for PostgreSQL DB clusters (p. 1476)
- Managing a DB cluster in a Domain (p. 1484)
- Connecting to PostgreSQL with Kerberos authentication (p. 1485)

## Availability of Kerberos authentication

Kerberos authentication is supported on the following engine versions:

- All PostgreSQL 13 versions
- PostgreSQL 12.4 and higher 12 versions
- PostgreSQL 11.6 and higher 11 versions
- PostgreSQL 10.11 and higher 10 versions

For more information, see Amazon Aurora PostgreSQL releases and engine versions (p. 1524).

Amazon Aurora supports Kerberos authentication for PostgreSQL DB clusters in the following AWS Regions:

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
</tr>
<tr>
<td>Asia Pacific (Mumbai)</td>
<td>ap-south-1</td>
</tr>
</tbody>
</table>
Overview of Kerberos authentication for PostgreSQL DB clusters

To set up Kerberos authentication for a PostgreSQL DB cluster, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the cluster.

2. Create a role that provides Amazon Aurora access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

   For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see What is VPC peering? in the Amazon VPC Peering Guide.

5. Create or modify a PostgreSQL DB cluster either from the console, CLI, or RDS API using one of the following methods:
   - Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster (p. 95)
   - Modifying an Amazon Aurora DB cluster (p. 368)
You can locate the cluster in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB cluster, do the following:
- Provide the domain identifier (domain-identifier) that was generated when you created your directory.
- Provide the name of the IAM role that you created.
- Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB cluster. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB cluster using Kerberos authentication.

## Setting up Kerberos authentication for PostgreSQL DB clusters

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB cluster. To set up Kerberos authentication, take the following steps.

### Topics
- Step 1: Create a directory using AWS Managed Microsoft AD (p. 1476)
- Step 2: (Optional) create a trust for an on-premises Active Directory (p. 1479)
- Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service (p. 1480)
- Step 4: Create and configure users (p. 1481)
- Step 5: Enable cross-VPC traffic between the directory and the DB instance (p. 1481)
- Step 6: Create or modify a PostgreSQL DB cluster (p. 1482)
- Step 7: Create Kerberos authentication PostgreSQL logins (p. 1483)
- Step 8: Configure a PostgreSQL client (p. 1483)

### Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:
- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

**Important**

Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB cluster.
When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create a directory with AWS Managed Microsoft AD

1. In the AWS Directory Service console navigation pane, choose Directories, and then choose Set up directory.
2. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option currently supported for use with Amazon Aurora.
3. Choose Next.
4. On the Enter directory information page, provide the following information:

   **Edition**
   
   Choose the edition that meets your requirements.

   **Directory DNS name**
   
   The fully qualified name for the directory, such as corp.example.com.

   **Directory NetBIOS name**
   
   An optional short name for the directory, such as CORP.

   **Directory description**
   
   An optional description for the directory.

   **Admin password**
   
   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

   The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   - Lowercase letters (a–z)
• Uppercase letters (A–Z)
• Numbers (0–9)
• Nonalphanumeric characters (~!#$%^&*_-+=`|(){}[]:;"'<>,.?/)

Confirm password

Retype the administrator password.

**Important**

Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose **Next**.
6. On the **Choose VPC and subnets** page, provide the following information:

   **VPC**

   Choose the VPC for the directory. You can create the PostgreSQL DB cluster in this same VPC or in a different VPC.

   **Subnets**

   Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.
8. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.
It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.

### Directory details

![Directory details screenshot]

**Directory ID**

d-90670a8d36

**VPC**
\[vpc-6594f31c\]

**Subnets**
- subnet-7d36a227
- subnet-a2ab49c6

**Availability zones**
- us-east-1c
- us-east-1d

**DNS address**

---

**Step 2: (Optional) create a trust for an on-premises Active Directory**

If you don't plan to use your own on-premises Microsoft Active Directory, skip to **Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service** (p. 1480).

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in **Step 1: Create a directory using AWS Managed Microsoft AD** (p. 1476)). The trust can be one-way, where the AWS Managed Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see **When to create a trust relationship** in the **AWS Directory Service Administration Guide**.
Note
If you use an on-premises Microsoft Active Directory:

- Windows clients must connect using specialized endpoints as described in Connecting to PostgreSQL with Kerberos authentication (p. 1485).
- Windows clients can't connect with custom endpoints (p. 35).
- For global databases (p. 223):
  - Windows clients can connect using instance endpoints or cluster endpoints in the primary AWS Region of the global database.
  - Windows clients can't connect using cluster endpoints in secondary AWS Regions.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

![Diagram showing DNS suffix routing](image)

Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service

For Amazon Aurora to call AWS Directory Service for you, an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess is required. This role allows Amazon Aurora to make calls to AWS Directory Service. (Note that this IAM role to access the AWS Directory Service is different than the IAM role used for IAM database authentication (p. 1661).)

When a DB instance is created using the AWS Management Console and the console user has the iam:CreateRole permission, the console creates this role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, create the IAM role manually. Choose RDS and then RDS - Directory Service. Attach the AWS managed policy AmazonRDSDirectoryServiceAccess to this role.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.
Note
The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon Aurora.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy AmazonRDSDirectoryServiceAccess. In this case, the IAM role must have the following IAM trust policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "directoryservice.rds.amazonaws.com",
                    "rds.amazonaws.com"
                ],
                "Action": "sts:AssumeRole"
            }
        }
    ]
}
```

The role must also have the following IAM role policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ds:DescribeDirectories",
                "ds:AuthorizeApplication",
                "ds:UnauthorizeApplication",
                "ds:GetAuthorizedApplicationDetails"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

Step 4: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, users are individual people or entities who have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance. Also, this EC2 instance must be a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see Create a user in the AWS Directory Service Administration Guide.

Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB cluster in the same VPC, skip this step and move on to Step 6: Create or modify a PostgreSQL DB cluster (p. 1482).
If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

**To enable cross-VPC traffic using VPC peering**

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

**To share the directory between AWS accounts**

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

**Step 6: Create or modify a PostgreSQL DB cluster**

Create or modify a PostgreSQL DB cluster for use with your directory. You can use the console, CLI, or RDS API to associate a DB cluster with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB cluster using the console, the create-db-cluster CLI command, or the CreateDBCluster RDS API operation. For instructions, see Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster (p. 95).
- Modify an existing PostgreSQL DB cluster using the console, the modify-db-cluster CLI command, or the ModifyDBCluster RDS API operation. For instructions, see Modifying an Amazon Aurora DB cluster (p. 368).
- Restore a PostgreSQL DB cluster from a DB snapshot using the console, the restore-db-cluster-from-db-snapshot CLI command, or the RestoreDBClusterFromDBSnapshot RDS API operation. For instructions, see Restoring from a DB cluster snapshot (p. 493).
- Restore a PostgreSQL DB cluster to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBClusterToPointInTime RDS API operation. For instructions, see Restoring a DB cluster to a specified time (p. 533).

Kerberos authentication is only supported for PostgreSQL DB clusters in a VPC. The DB cluster can be in the same VPC as the directory, or in a different VPC. The DB cluster must use a security group that allows ingress and egress within the directory's VPC so the DB cluster can communicate with the directory.

**Console**

When you use the console to create, modify, or restore a DB cluster, choose Kerberos authentication in the Database authentication section. Then choose Browse Directory. Select the directory or choose Create a new directory to use the Directory Service.
AWS CLI

When you use the AWS CLI, the following parameters are required for the DB cluster to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB cluster to use a directory.

```
aws rds modify-db-cluster --db-cluster-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```

**Important**

If you modify a DB cluster to enable Kerberos authentication, reboot the DB cluster after making the change.

**Step 7: Create Kerberos authentication PostgreSQL logins**

Use the RDS master user credentials to connect to the PostgreSQL DB cluster as you do with any other DB cluster. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision PostgreSQL logins and users from the Microsoft Active Directory users and groups in your domain. To manage database permissions, you grant and revoke standard PostgreSQL permissions to these logins.

To allow an Active Directory user to authenticate with PostgreSQL, use the RDS master user credentials. You use these credentials to connect to the PostgreSQL DB cluster as you do with any other DB cluster. After you're logged in, create an externally authenticated user in PostgreSQL and grant the rds_ad role to this user.

```
CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
```

Replace `username` with the user name and include the domain name in uppercase. Users (both humans and applications) from your domain can now connect to the RDS PostgreSQL cluster from a domain-joined client machine using Kerberos authentication.

Note that a database user can use either Kerberos or IAM authentication but not both, so this user can't also have the rds_iam role. This also applies to nested memberships. For more information, see IAM database authentication (p. 1661).

**Step 8: Configure a PostgreSQL client**

To configure a PostgreSQL client, take the following steps:

- Create a krb5.conf file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
- Verify that traffic can flow between the client host and the DB instance over the database port. For example, use psql to connect and access the database.
The following is sample krb5.conf content for AWS Managed Microsoft AD.

```
[libdefaults]
default_realm = EXAMPLE.COM

[realms]
EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
}

[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```
[libdefaults]
default_realm = EXAMPLE.COM

[realms]
EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
}
ONPREM.COM = {
    kdc = onprem.com
    admin_server = onprem.com
}

[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
.onprem.com = ONPREM.COM
.onprem.com = ONPREM.COM
.rds.amazonaws.com = EXAMPLE.COM
.amazonaws.com.cn = EXAMPLE.COM
.amazonaws.com = EXAMPLE.COM
```

Managing a DB cluster in a Domain

You can use the console, the CLI, or the RDS API to manage your DB cluster and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB cluster to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-cluster` CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the `modify-db-cluster` CLI command. Specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the `modify-db-cluster` CLI command. Specify the domain identifier of the new domain for the `--domain` option.

Understanding Domain membership

After you create or modify your DB cluster, the DB instances become members of the domain. You can view the status of the domain membership in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:
**Connecting with Kerberos authentication**

- **kerberos-enabled** – The DB instance has Kerberos authentication enabled.
- **enabling-kerberos** – AWS is in the process of enabling Kerberos authentication on this DB instance.
- **pending-enable-kerberos** – Enabling Kerberos authentication is pending on this DB instance.
- **pending-maintenance-enable-kerberos** – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **pending-disable-kerberos** – Disabling Kerberos authentication is pending on this DB instance.
- **pending-maintenance-disable-kerberos** – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **enable-kerberos-failed** – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- **disabling-kerberos** – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB cluster. If so, make sure that you are using the correct IAM role, then modify the DB cluster to join the domain.

### Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command line interface such as psql. For more information about connecting, see Connecting to an Amazon Aurora PostgreSQL DB cluster (p. 283).

**pgAdmin**

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, enter a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, enter the following information from your Aurora PostgreSQL database:
   - **For Host**, enter the endpoint. Use a format such as `PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com`.
     
     If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.
     
     For example, suppose that the domain name for the AWS Managed Active Directory is `corp.example.com`. Then for **Host**, use the format `PostgreSQL-endpoint.AWS-Region.corp.example.com`.
   - **For Port**, enter the assigned port.
   - **For Maintenance database**, enter the name of the initial database to which the client will connect.
   - **For Username**, enter the user name that you entered for Kerberos authentication in Step 7: Create Kerberos authentication PostgreSQL logins (p. 1483).
5. Choose **Save**.
Psq1

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

   ```
kinit username
   ```

   Replace *username* with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB cluster is using a publicly accessible VPC, put a private IP address for your DB cluster endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the private IP address and then put it in the `/etc/hosts` file.

   ```
   % dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
   ;; Truncated, retrying in TCP mode.
   ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
   34.210.197.118
   % echo "34.210.197.118 PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/hosts
   ```

   If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.

   For example, suppose that the domain name for your AWS Managed Active Directory is `corp.example.com`. Then use the format `PostgreSQL-endpoint.AWS-Region.corp.example.com` for the endpoint and put it in the `/etc/hosts` file.

   ```
   % echo "34.210.197.118 PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/hosts
   ```

3. Use the following psql command to log in to a PostgreSQL DB cluster that is integrated with Active Directory. Use a cluster or instance endpoint.

   ```
   psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com postgres
   ```

   To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following psql command with the domain name from the previous step (corp.example.com):

   ```
   psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.corp.example.com postgres
   ```

Amazon Aurora PostgreSQL reference

Topics

- Amazon Aurora PostgreSQL parameters (p. 1487)
- Amazon Aurora PostgreSQL wait events (p. 1495)
- Aurora PostgreSQL functions reference (p. 1513)
Amazon Aurora PostgreSQL parameters

You manage your Amazon Aurora DB cluster in the same way that you manage other Amazon RDS DB instances, by using parameters in a DB parameter group. Amazon Aurora differs from other DB engines in that you have a DB cluster that contains multiple DB instances. As a result, some of the parameters that you use to manage your Amazon Aurora DB cluster apply to the entire cluster, while other parameters apply only to a particular DB instance in the DB cluster.

You manage cluster-level parameters in DB cluster parameter groups. You manage instance-level parameters in DB parameter groups. Each DB instance in an Aurora PostgreSQL DB cluster is compatible with the PostgreSQL database engine. However, you apply some of the PostgreSQL database engine parameters at the cluster level and manage them using DB cluster parameter groups. Cluster-level parameters aren't found in the DB parameter group for a DB instance in an Aurora PostgreSQL DB cluster and are listed later in this topic.

You can view both cluster-level and instance-level parameters in the Amazon RDS console, or by using the AWS CLI or Amazon RDS API. For example, to view cluster-level parameters in a DB cluster parameter group, use the describe-db-cluster-parameters AWS CLI command. To view instance-level parameters in a DB parameter group for a DB instance in a DB cluster, use the describe-db-parameters AWS CLI command.

You can manage both cluster-level and instance-level parameters using the Amazon RDS console, the AWS CLI, or the Amazon RDS API. There are separate commands for managing cluster-level parameters and instance-level parameters. For example:

- To manage cluster-level parameters in a DB cluster parameter group, use the modify-db-cluster-parameter-group AWS CLI command.
- To manage instance-level parameters in a DB parameter group for a DB instance in a DB cluster, use the modify-db-parameter-group AWS CLI command.

For more information about parameter groups, see Working with DB parameter groups and DB cluster parameter groups (p. 335).

Aurora PostgreSQL cluster-level parameters

The following table shows all of the parameters that apply to the entire Aurora PostgreSQL DB cluster.

<table>
<thead>

</table>

**Amazon Aurora PostgreSQL wait events**

The following are common wait events for Aurora PostgreSQL.

**Activity:** ArchiverMain

The archiver process is waiting for activity.
Activity:AutoVacuumMain
   The autovacuum launcher process is waiting for activity.
Activity:BgWriterHibernate
   The background writer process is hibernating while waiting for activity.
Activity:BgWriterMain
   The background writer process is waiting for activity.
Activity:CheckpointerMain
   The checkpointer process is waiting for activity.
Activity:LogicalApplyMain
   The logical replication apply process is waiting for activity.
Activity:LogicalLauncherMain
   The logical replication launcher process is waiting for activity.
Activity:PgStatMain
   The statistics collector process is waiting for activity.
Activity:RecoveryWalAll
   A process is waiting for the write-ahead log (WAL) from a stream at recovery.
Activity:RecoveryWalStream
   The startup process is waiting for the write-ahead log (WAL) to arrive during streaming recovery.
Activity:SysLoggerMain
   The syslog process is waiting for activity.
Activity:WalReceiverMain
   The write-ahead log (WAL) receiver process is waiting for activity.
Activity:WalSenderMain
   The write-ahead log (WAL) sender process is waiting for activity.
Activity:WalWriterMain
   The write-ahead log (WAL) writer process is waiting for activity.
BufferPin:BufferPin
   A process is waiting to acquire an exclusive pin on a buffer.
Client:GSSOpenServer
   A process is waiting to read data from the client while establishing a Generic Security Service Application Program Interface (GSSAPI) session.
Client:ClientRead
   A backend process is waiting to receive data from a PostgreSQL client. For more information, see Client:ClientRead (p. 1322).
Client:ClientWrite
   A backend process is waiting to send more data to a PostgreSQL client. For more information, see Client:ClientWrite (p. 1325).
**Client:LibPQWalReceiverConnect**

A process is waiting in the write-ahead log (WAL) receiver to establish connection to remote server.

**Client:LibPQWalReceiverReceive**

A process is waiting in the write-ahead log (WAL) receiver to receive data from remote server.

**Client:SSLOpenServer**

A process is waiting for Secure Sockets Layer (SSL) while attempting connection.

**Client:WalReceiverWaitStart**

A process is waiting for startup process to send initial data for streaming replication.

**Client:WalSenderWaitForWAL**

A process is waiting for the write-ahead log (WAL) to be flushed in the WAL sender process.

**Client:WalSenderWriteData**

A process is waiting for any activity when processing replies from the write-ahead log (WAL) receiver in the WAL sender process.

**CPU**

A backend process is active in or is waiting for CPU. For more information, see CPU (p. 1326).

**Extension:extension**

A backend process is waiting for a condition defined by an extension or module.

**IO:AuroraStorageLogAllocate**

A session is allocating metadata and preparing for a transaction log write.

**IO:BufFileRead**

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations read from the temporary files. For more information, see IO:BufFileRead and IO:BufFileWrite (p. 1330).

**IO:BufFileWrite**

When operations require more memory than the amount defined by working memory parameters, the engine creates temporary files on disk. This wait event occurs when operations write to the temporary files. For more information, see IO:BufFileRead and IO:BufFileWrite (p. 1330).

**IO:ControlFileRead**

A process is waiting for a read from the pg_control file.

**IO:ControlFileSync**

A process is waiting for the pg_control file to reach durable storage.

**IO:ControlFileSyncUpdate**

A process is waiting for an update to the pg_control file to reach durable storage.

**IO:ControlFileWrite**

A process is waiting for a write to the pg_control file.

**IO:ControlFileWriteUpdate**

A process is waiting for a write to update the pg_control file.

**IO:CopyFileRead**

A process is waiting for a read during a file copy operation.
IO:CopyFileWrite
A process is waiting for a write during a file copy operation.

IO:DataFileExtend
A process is waiting for a relation data file to be extended.

IO:DataFileFlush
A process is waiting for a relation data file to reach durable storage.

IO:DataFileImmediateSync
A process is waiting for an immediate synchronization of a relation data file to durable storage.

IO:DataFilePrefetch
A process is waiting for an asynchronous prefetch from a relation data file.

IO:DataFileSync
A process is waiting for changes to a relation data file to reach durable storage.

IO:DataFileRead
A backend process tried to find a page in the shared buffers, didn't find it, and so read it from storage. For more information, see IO:DataFileRead (p. 1336).

IO:DataFileTruncate
A process is waiting for a relation data file to be truncated.

IO:DataFileWrite
A process is waiting for a write to a relation data file.

IO:DSMFillZeroWrite
A process is waiting to write zero bytes to a dynamic shared memory backing file.

IO:LockFileAddToDataDirRead
A process is waiting for a read while adding a line to the data directory lock file.

IO:LockFileAddToDataDirSync
A process is waiting for data to reach durable storage while adding a line to the data directory lock file.

IO:LockFileAddToDataDirWrite
A process is waiting for a write while adding a line to the data directory lock file.

IO:LockFileCreateRead
A process is waiting to read while creating the data directory lock file.

IO:LockFileCreateSync
A process is waiting for data to reach durable storage while creating the data directory lock file.

IO:LockFileCreateWrite
A process is waiting for a write while creating the data directory lock file.

IO:LockFileReCheckDataDirRead
A process is waiting for a read during recheck of the data directory lock file.

IO:LogicalRewriteCheckpointSync
A process is waiting for logical rewrite mappings to reach durable storage during a checkpoint.
IO:LogicalRewriteMappingSync
A process is waiting for mapping data to reach durable storage during a logical rewrite.

IO:LogicalRewriteMappingWrite
A process is waiting for a write of mapping data during a logical rewrite.

IO:LogicalRewriteSync
A process is waiting for logical rewrite mappings to reach durable storage.

IO:LogicalRewriteTruncate
A process is waiting for the truncation of mapping data during a logical rewrite.

IO:LogicalRewriteWrite
A process is waiting for a write of logical rewrite mappings.

IO:RelationMapRead
A process is waiting for a read of the relation map file.

IO:RelationMapSync
A process is waiting for the relation map file to reach durable storage.

IO:RelationMapWrite
A process is waiting for a write to the relation map file.

IO:ReorderBufferRead
A process is waiting for a read during reorder buffer management.

IO:ReorderBufferWrite
A process is waiting for a write during reorder buffer management.

IO:ReorderLogicalMappingRead
A process is waiting for a read of a logical mapping during reorder buffer management.

IO:ReplicationSlotRead
A process is waiting for a read from a replication slot control file.

IO:ReplicationSlotRestoreSync
A process is waiting for a replication slot control file to reach durable storage while restoring it to memory.

IO:ReplicationSlotSync
A process is waiting for a replication slot control file to reach durable storage.

IO:ReplicationSlotWrite
A process is waiting for a write to a replication slot control file.

IO:SLRUFlushSync
A process is waiting for segmented least-recently used (SLRU) data to reach durable storage during a checkpoint or database shutdown.

IO:SLRURed
A process is waiting for a read of a segmented least-recently used (SLRU) page.

IO:SLRUSync
A process is waiting for segmented least-recently used (SLRU) data to reach durable storage following a page write.
IO:SLRUWrite
A process is waiting for a write of a segmented least-recently used (SLRU) page.

IO:SnapbuildRead
A process is waiting for a read of a serialized historical catalog snapshot.

IO:SnapbuildSync
A process is waiting for a serialized historical catalog snapshot to reach durable storage.

IO:SnapbuildWrite
A process is waiting for a write of a serialized historical catalog snapshot.

IO:TimelineHistoryFileSync
A process is waiting for a timeline history file received through streaming replication to reach durable storage.

IO:TimelineHistoryFileWrite
A process is waiting for a write of a timeline history file received through streaming replication.

IO:TimelineHistoryRead
A process is waiting for a read of a timeline history file.

IO:TimelineHistorySync
A process is waiting for a newly created timeline history file to reach durable storage.

IO:TimelineHistoryWrite
A process is waiting for a write of a newly created timeline history file.

IO:TwophaseFileSync
A process is waiting for a two phase state file to reach durable storage.

IO:TwophaseFileWrite
A process is waiting for a write of a two phase state file.

IO:WALBootstrapSync
A process is waiting for the write-ahead log (WAL) to reach durable storage during bootstrapping.

IO:WALBootstrapWrite
A process is waiting for a write of a write-ahead log (WAL) page during bootstrapping.

IO:WALCopyRead
A process is waiting for a read when creating a new write-ahead log (WAL) segment by copying an existing one.

IO:WALCopySync
A process is waiting for a new write-ahead log (WAL) segment created by copying an existing one to reach durable storage.

IO:WALCopyWrite
A process is waiting for a write when creating a new write-ahead log (WAL) segment by copying an existing one.
IO:WALInitSync

A process is waiting for a newly initialized write-ahead log (WAL) file to reach durable storage.

IO:WALInitWrite

A process is waiting for a write while initializing a new write-ahead log (WAL) file.

IO:WALRead

A process is waiting for a read from a write-ahead log (WAL) file.

IO:WALSenderTimelineHistoryRead

A process is waiting for a read from a timeline history file during a WAL sender timeline command.

IO:WALSysync

A process is waiting for a write-ahead log (WAL) file to reach durable storage.

IO:WALSyncMethodAssign

A process is waiting for data to reach durable storage while assigning a new write-ahead log (WAL) sync method.

IO:WALWrite

A process is waiting for a write to a write-ahead log (WAL) file.

IO:XactSync

A backend process is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. For more information, see IO:XactSync (p. 1342).

IPC:BackupWaitWalArchive

A process is waiting for write-ahead log (WAL) files required for a backup to be successfully archived.

IPC:BgWorkerShutdown

A process is waiting for a background worker to shut down.

IPC:BgWorkerStartup

A process is waiting for a background worker to start.

IPC:BtreePage

A process is waiting for the page number needed to continue a parallel B-tree scan to become available.

IPC:CheckpointDone

A process is waiting for a checkpoint to complete.

IPC:CheckpointStart

A process is waiting for a checkpoint to start.

IPC:ClogGroupUpdate

A process is waiting for the group leader to update the transaction status at a transaction's end.

pc:damrecordtxack

A backend process has generated a database activity streams event and is waiting for the event to become durable. For more information, see ipc:damrecordtxack (p. 1344).

IPC:ExecuteGather

A process is waiting for activity from a child process while executing a Gather plan node.
IPC:Hash/Batch/Allocating
A process is waiting for an elected parallel hash participant to allocate a hash table.

IPC:Hash/Batch/Electing
A process is electing a parallel hash participant to allocate a hash table.

IPC:Hash/Batch/Loading
A process is waiting for other parallel hash participants to finish loading a hash table.

IPC:Hash/Build/Allocating
A process is waiting for an elected parallel hash participant to allocate the initial hash table.

IPC:Hash/Build/Electing
A process is electing a parallel hash participant to allocate the initial hash table.

IPC:Hash/Build/HashingInner
A process is waiting for other parallel hash participants to finish hashing the inner relation.

IPC:Hash/Build/HashingOuter
A process is waiting for other parallel hash participants to finish partitioning the outer relation.

IPC:Hash/GrowBatches/Allocating
A process is waiting for an elected parallel hash participant to allocate more batches.

IPC:Hash/GrowBatches/Deciding
A process is electing a parallel hash participant to decide on future batch growth.

IPC:Hash/GrowBatches/Electing
A process is electing a parallel hash participant to allocate more batches.

IPC:Hash/GrowBatches/Finishing
A process is waiting for an elected parallel hash participant to decide on future batch growth.

IPC:Hash/GrowBatches/Repartitioning
A process is waiting for other parallel hash participants to finishing repartitioning.

IPC:Hash/Grow Buckets/Allocating
A process is waiting for an elected parallel hash participant to finish allocating more buckets.

IPC:Hash/Grow Buckets/Electing
A process is electing a parallel hash participant to allocate more buckets.

IPC:Hash/Grow Buckets/Reinserting
A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

IPC:Hash Batch Allocate
A process is waiting for an elected parallel hash participant to allocate a hash table.

IPC:Hash Batch Elect
A process is waiting to elect a parallel hash participant to allocate a hash table.

IPC:Hash Batch Load
A process is waiting for other parallel hash participants to finish loading a hash table.
IPC:HashBuildAllocate
A process is waiting for an elected parallel hash participant to allocate the initial hash table.

IPC:HashBuildElect
A process is waiting to elect a parallel hash participant to allocate the initial hash table.

IPC:HashBuildHashInner
A process is waiting for other parallel hash participants to finish hashing the inner relation.

IPC:HashBuildHashOuter
A process is waiting for other parallel hash participants to finish partitioning the outer relation.

IPC:HashGrowBatchesAllocate
A process is waiting for an elected parallel hash participant to allocate more batches.

IPC:HashGrowBatchesDecide
A process is waiting to elect a parallel hash participant to decide on future batch growth.

IPC:HashGrowBatchesElect
A process is waiting to elect a parallel hash participant to allocate more batches.

IPC:HashGrowBatchesFinish
A process is waiting for an elected parallel hash participant to decide on future batch growth.

IPC:HashGrowBatchesRepartition
A process is waiting for other parallel hash participants to finish repartitioning.

IPC:HashGrowBucketsAllocate
A process is waiting for an elected parallel hash participant to finish allocating more buckets.

IPC:HashGrowBucketsElect
A process is waiting to elect a parallel hash participant to allocate more buckets.

IPC:HashGrowBucketsReinsert
A process is waiting for other parallel hash participants to finish inserting tuples into new buckets.

IPC:LogicalSyncData
A process is waiting for a logical replication remote server to send data for initial table synchronization.

IPC:LogicalSyncStateChange
A process is waiting for a logical replication remote server to change state.

IPC:MessageQueueInternal
A process is waiting for another process to be attached to a shared message queue.

IPC:MessageQueuePutMessage
A process is waiting to write a protocol message to a shared message queue.

IPC:MessageQueueReceive
A process is waiting to receive bytes from a shared message queue.

IPC:MessageQueueSend
A process is waiting to send bytes to a shared message queue.
IPC:ParallelBitmapScan

A process is waiting for a parallel bitmap scan to become initialized.

IPC:ParallelCreateIndexScan

A process is waiting for parallel CREATE INDEX workers to finish a heap scan.

IPC:ParallelFinish

A process is waiting for parallel workers to finish computing.

IPC:ProcArrayGroupUpdate

A process is waiting for the group leader to clear the transaction ID at the end of a parallel operation.

IPC:ProcSignalBarrier

A process is waiting for a barrier event to be processed by all backends.

IPC:Promote

A process is waiting for standby promotion.

IPC:RecoveryConflictSnapshot

A process is waiting for recovery conflict resolution for a vacuum cleanup.

IPC:RecoveryConflictTablespace

A process is waiting for recovery conflict resolution for dropping a tablespace.

IPC:RecoveryPause

A process is waiting for recovery to be resumed.

IPC:ReplicationOriginDrop

A process is waiting for a replication origin to become inactive so it can be dropped.

IPC:ReplicationSlotDrop

A process is waiting for a replication slot to become inactive so it can be dropped.

IPC:SafeSnapshot

A process is waiting to obtain a valid snapshot for a READ ONLY DEFERRABLE transaction.

IPC:SyncRep

A process is waiting for confirmation from a remote server during synchronous replication.

IPC:XactGroupUpdate

A process is waiting for the group leader to update the transaction status at the end of a parallel operation.

Lock:advisory

A backend process requested an advisory lock and is waiting for it. For more information, see Lock:advisory (p. 1344).

Lock:extend

A backend process is waiting for a lock to be released so that it can extend a relation. This lock is needed because only one backend process can extend a relation at a time. For more information, see Lock:extend (p. 1346).

Lock:frozenid

A process is waiting to update pg_database.datfrozenxid and pg_database.datminmxid.
Lock:object

A process is waiting to get a lock on a nonrelation database object.

Lock:page

A process is waiting to get a lock on a page of a relation.

Lock:Relation

A backend process is waiting to acquire a lock on a relation that is locked by another transaction. For more information, see Lock:Relation (p. 1348).

Lock:spectoken

A process is waiting to get a speculative insertion lock.

Lock:speculative token

A process is waiting to acquire a speculative insertion lock.

Lock:transactionid

A transaction is waiting for a row-level lock. For more information, see Lock:transactionid (p. 1351).

Lock:tuple

A backend process is waiting to acquire a lock on a tuple while another backend process holds a conflicting lock on the same tuple. For more information, see Lock:tuple (p. 1354).

Lock:userlock

A process is waiting to get a user lock.

Lock:virtualxid

A process is waiting to get a virtual transaction ID lock.

Lwlock:AddinShmemInit

A process is waiting to manage an extension's space allocation in shared memory.

Lwlock:AddinShmemInitLock

A process is waiting to manage space allocation in shared memory.

Lwlock:async

A process is waiting for I/O on an async (notify) buffer.

Lwlock:AsyncCtlLock

A process is waiting to read or update a shared notification state.

Lwlock:AsyncQueueLock

A process is waiting to read or update notification messages.

Lwlock:AutoFile

A process is waiting to update the postgresql.auto.conf file.

Lwlock:AutoFileLock

A process is waiting to update the postgresql.auto.conf file.

Lwlock:Autovacuum

A process is waiting to read or update the current state of autovacuum workers.

Lwlock:AutovacuumLock

An autovacuum worker or launcher is waiting to update or read the current state of autovacuum workers.
**Lwlock:AutovacuumSchedule**

A process is waiting to ensure that a table selected for autovacuum still needs vacuuming.

**Lwlock:AutovacuumScheduleLock**

A process is waiting to ensure that the table it has selected for a vacuum still needs vacuuming.

**Lwlock:BackendRandomLock**

A process is waiting to generate a random number.

**Lwlock:BackgroundWorker**

A process is waiting to read or update background worker state.

**Lwlock:BackgroundWorkerLock**

A process is waiting to read or update the background worker state.

**Lwlock:BtreeVacuum**

A process is waiting to read or update vacuum-related information for a B-tree index.

**Lwlock:BtreeVacuumLock**

A process is waiting to read or update vacuum-related information for a B-tree index.

**LWLock:buffer_content**

A backend process is waiting to acquire a lightweight lock on the contents of a shared memory buffer. For more information, see `lwlock:buffer_content (BufferContent)` (p. 1356).

**LWLock:buffer_mapping**

A backend process is waiting to associate a data block with a buffer in the shared buffer pool. For more information, see `LWLock:buffer_mapping` (p. 1358).

**LWLock:BufferIO**

A backend process wants to read a page into shared memory. The process is waiting for other processes to finish their I/O for the page. For more information, see `LWLock:BufferIO` (p. 1359).

**Lwlock:Checkpoint**

A process is waiting to begin a checkpoint.

**Lwlock:CheckpointLock**

A process is waiting to perform checkpoint.

**Lwlock:CheckpointerComm**

A process is waiting to manage `fsync` requests.

**Lwlock:CheckpointerCommLock**

A process is waiting to manage `fsync` requests.

**Lwlock:clog**

A process is waiting for I/O on a clog (transaction status) buffer.

**Lwlock:CLogControlLock**

A process is waiting to read or update transaction status.

**Lwlock:CLogTruncationLock**

A process is waiting to run `txid_status` or update the oldest transaction ID available to it.

**Lwlock:commit_timestamp**

A process is waiting for I/O on a commit timestamp buffer.
Lwlock:CommitTs

A process is waiting to read or update the last value set for a transaction commit timestamp.

Lwlock:CommitTsBuffer

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a commit timestamp.

Lwlock:CommitTsControlLock

A process is waiting to read or update transaction commit timestamps.

Lwlock:CommitTsLock

A process is waiting to read or update the last value set for the transaction timestamp.

Lwlock:CommitTsSLRU

A process is waiting to access the segmented least-recently used (SLRU) cache for a commit timestamp.

Lwlock:ControlFile

A process is waiting to read or update the pg_control file or create a new write-ahead log (WAL) file.

Lwlock:ControlFileLock

A process is waiting to read or update the control file or creation of a new write-ahead log (WAL) file.

Lwlock:DynamicSharedMemoryControl

A process is waiting to read or update dynamic shared memory allocation information.

Lwlock:DynamicSharedMemoryControlLock

A process is waiting to read or update the dynamic shared memory state.

LWLock:lock_manager

A backend process is waiting to add or examine locks for backend processes. Or it's waiting to join or exit a locking group that is used by parallel query. For more information, see LWLock:lock_manager (p. 1361).

Lwlock:LockFastPath

A process is waiting to read or update a process's fast-path lock information.

Lwlock:LogicalRepWorker

A process is waiting to read or update the state of logical replication workers.

Lwlock:LogicalRepWorkerLock

A process is waiting for an action on a logical replication worker to finish.

Lwlock:multixact_member

A process is waiting for I/O on a multixact_member buffer.

Lwlock:multixact_offset

A process is waiting for I/O on a multixact offset buffer.

Lwlock:MultiXactGen

A process is waiting to read or update shared multixact state.

Lwlock:MultiXactGenLock

A process is waiting to read or update a shared multixact state.
Lwlock:MultiXactMemberBuffer

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a multixact member.

Lwlock:MultiXactMemberControlLock

A process is waiting to read or update multixact member mappings.

Lwlock:MultiXactMemberSLRU

A process is waiting to access the segmented least-recently used (SLRU) cache for a multixact member.

Lwlock:MultiXactOffsetBuffer

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a multixact offset.

Lwlock:MultiXactOffsetControlLock

A process is waiting to read or update multixact offset mappings.

Lwlock:MultiXactOffsetSLRU

A process is waiting to access the segmented least-recently used (SLRU) cache for a multixact offset.

Lwlock:MultiXactTruncation

A process is waiting to read or truncate multixact information.

Lwlock:MultiXactTruncationLock

A process is waiting to read or truncate multixact information.

Lwlock:NotifyBuffer

A process is waiting for I/O on the segmented least-recently used (SLRU) buffer for a NOTIFY message.

Lwlock:NotifyQueue

A process is waiting to read or update NOTIFY messages.

Lwlock:NotifyQueueTail

A process is waiting to update a limit on NOTIFY message storage.

Lwlock:NotifyQueueTailLock

A process is waiting to update limit on notification message storage.

Lwlock:NotifySLRU

A process is waiting to access the segmented least-recently used (SLRU) cache for a NOTIFY message.

Lwlock:OidGen

A process is waiting to allocate a new object ID (OID).

Lwlock:OidGenLock

A process is waiting to allocate or assign an object ID (OID).

Lwlock:oldserxid

A process is waiting for I/O on an oldserxid buffer.

Lwlock:OldSerXidLock

A process is waiting to read or record conflicting serializable transactions.
Lwlock:OldSnapshotTimeMap
A process is waiting to read or update old snapshot control information.

Lwlock:OldSnapshotTimeMapLock
A process is waiting to read or update old snapshot control information.

Lwlock:parallel_append
A process is waiting to choose the next subplan during parallel append plan execution.

Lwlock:parallel_hash_join
A process is waiting to allocate or exchange a chunk of memory or update counters during a parallel hash plan execution.

Lwlock:parallel_query_dsa
A process is waiting for a lock on dynamic shared memory allocation for a parallel query.

Lwlock:ParallelAppend
A process is waiting to choose the next subplan during parallel append plan execution.

Lwlock:ParallelHashJoin
A process is waiting to synchronize workers during plan execution for a parallel hash join.

Lwlock:ParallelQueryDSA
A process is waiting for dynamic shared memory allocation for a parallel query.

Lwlock:PerSessionDSA
A process is waiting for dynamic shared memory allocation for a parallel query.

Lwlock:PerSessionRecordType
A process is waiting to access a parallel query's information about composite types.

Lwlock:PerSessionRecordTypmod
A process is waiting to access a parallel query's information about type modifiers that identify anonymous record types.

Lwlock:PerXactPredicateList
A process is waiting to access the list of predicate locks held by the current serializable transaction during a parallel query.

Lwlock:predicate_lock_manager
A process is waiting to add or examine predicate lock information.

Lwlock:PredicateLockManager
A process is waiting to access predicate lock information used by serializable transactions.

Lwlock:proc
A process is waiting to read or update the fast-path lock information.

Lwlock:ProcArray
A process is waiting to access the shared per-process data structures (typically, to get a snapshot or report a session's transaction ID).

Lwlock:ProcArrayLock
A process is waiting to get a snapshot or clearing a transaction Id at a transaction's end.
**Lwlock:RelationMapping**

A process is waiting to read or update a `pg_filenode.map` file (used to track the file-node assignments of certain system catalogs).

**Lwlock:RelationMappingLock**

A process is waiting to update the relation map file used to store catalog-to-file-node mapping.

**Lwlock:RelCachelInit**

A process is waiting to read or update a `pg_internal.init` file (a relation cache initialization file).

**Lwlock:RelCachelInitLock**

A process is waiting to read or write a relation cache initialization file.

**Lwlock:replication_origin**

A process is waiting to read or update the replication progress.

**Lwlock:replication_slot_io**

A process is waiting for I/O on a replication slot.

**Lwlock:ReplicationOrigin**

A process is waiting to create, drop, or use a replication origin.

**Lwlock:ReplicationOriginLock**

A process is waiting to set up, drop, or use a replication origin.

**Lwlock:ReplicationOriginState**

A process is waiting to read or update the progress of one replication origin.

**Lwlock:ReplicationSlotAllocation**

A process is waiting to allocate or free a replication slot.

**Lwlock:ReplicationSlotAllocationLock**

A process is waiting to allocate or free a replication slot.

**Lwlock:ReplicationSlotControl**

A process is waiting to read or update a replication slot state.

**Lwlock:ReplicationSlotControlLock**

A process is waiting to read or update the replication slot state.

**Lwlock:ReplicationSlotIO**

A process is waiting for I/O on a replication slot.

**Lwlock:SerialBuffer**

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a serializable transaction conflict.

**Lwlock:SerializableFinishedList**

A process is waiting to access the list of finished serializable transactions.

**Lwlock:SerializableFinishedListLock**

A process is waiting to access the list of finished serializable transactions.

**Lwlock:SerializablePredicateList**

A process is waiting to access the list of predicate locks held by serializable transactions.
**Lwlock:SerializablePredicateLockListLock**

A process is waiting to perform an operation on a list of locks held by serializable transactions.

**Lwlock:SerializableXactHash**

A process is waiting to read or update information about serializable transactions.

**Lwlock:SerializableXactHashLock**

A process is waiting to retrieve or store information about serializable transactions.

**Lwlock:SerialSLRU**

A process is waiting to access the segmented least-recently used (SLRU) cache for a serializable transaction conflict.

**Lwlock:SharedTidBitmap**

A process is waiting to access a shared tuple identifier (TID) bitmap during a parallel bitmap index scan.

**Lwlock:SharedTupleStore**

A process is waiting to access a shared tuple store during a parallel query.

**Lwlock:ShmemIndex**

A process is waiting to find or allocate space in shared memory.

**Lwlock:ShmemIndexLock**

A process is waiting to find or allocate space in shared memory.

**Lwlock:SInvalRead**

A process is waiting to retrieve messages from the shared catalog invalidation queue.

**Lwlock:SInvalReadLock**

A process is waiting to retrieve or remove messages from a shared invalidation queue.

**Lwlock:SInvalWrite**

A process is waiting to add a message to the shared catalog invalidation queue.

**Lwlock:SInvalWriteLock**

A process is waiting to add a message in a shared invalidation queue.

**Lwlock:subtrans**

A process is waiting for I/O on a subtransaction buffer.

**Lwlock:SubtransBuffer**

A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a subtransaction.

**Lwlock:SubtransControlLock**

A process is waiting to read or update subtransaction information.

**Lwlock:SubtransSLRU**

A process is waiting to access the segmented least-recently used (SLRU) cache for a subtransaction.

**Lwlock:SyncRep**

A process is waiting to read or update information about the state of synchronous replication.

**Lwlock:SyncRepLock**

A process is waiting to read or update information about synchronous replicas.
Lwlock:SyncScan
A process is waiting to select the starting location of a synchronized table scan.

Lwlock:SyncScanLock
A process is waiting to get the start location of a scan on a table for synchronized scans.

Lwlock:TablespaceCreate
A process is waiting to create or drop a tablespace.

Lwlock:TablespaceCreateLock
A process is waiting to create or drop the tablespace.

Lwlock:tbm
A process is waiting for a shared iterator lock on a tree bitmap (TBM).

Lwlock:TwoPhaseState
A process is waiting to read or update the state of prepared transactions.

Lwlock:TwoPhaseStateLock
A process is waiting to read or update the state of prepared transactions.

Lwlock:wal_insert
A process is waiting to insert the write-ahead log (WAL) into a memory buffer.

Lwlock:WALBufMapping
A process is waiting to replace a page in write-ahead log (WAL) buffers.

Lwlock:WALBufMappingLock
A process is waiting to replace a page in write-ahead log (WAL) buffers.

Lwlock:WALInsert
A process is waiting to insert write-ahead log (WAL) data into a memory buffer.

Lwlock:WALWrite
A process is waiting for write-ahead log (WAL) buffers to be written to disk.

Lwlock:WALWriteLock
A process is waiting for write-ahead log (WAL) buffers to be written to disk.

Lwlock:WrapLimitsVacuum
A process is waiting to update limits on transaction ID and multixact consumption.

Lwlock:WrapLimitsVacuumLock
A process is waiting to update limits on transaction ID and multixact consumption.

Lwlock:XactBuffer
A process is waiting for I/O on a segmented least-recently used (SLRU) buffer for a transaction status.

Lwlock:XactSLRU
A process is waiting to access the segmented least-recently used (SLRU) cache for a transaction status.

Lwlock:XactTruncation
A process is waiting to run pg_xact_status or update the oldest transaction ID available to it.
Lwlock:XidGen
A process is waiting to allocate a new transaction ID.

Lwlock:XidGenLock
A process is waiting to allocate or assign a transaction ID.

Timeout:BaseBackupThrottle
A process is waiting during base backup when throttling activity.

Timeout:PgSleep
A backend process has called the pg_sleep function and is waiting for the sleep timeout to expire. For more information, see Timeout:PgSleep (p. 1364).

Timeout:RecoveryApplyDelay
A process is waiting to apply write-ahead log (WAL) during recovery because of a delay setting.

Timeout:RecoveryRetrieveRetryInterval
A process is waiting during recovery when write-ahead log (WAL) data is not available from any source (pg_wal, archive, or stream).

Timeout:VacuumDelay
A process is waiting in a cost-based vacuum delay point.

For a complete list of PostgreSQL wait events, see PostgreSQL wait-event table in the PostgreSQL documentation.

Aurora PostgreSQL functions reference

Following, you can find a reference for functions that are available for Amazon RDS instances that run the Amazon Aurora PostgreSQL-Compatible Edition DB engine.

Overview

You can use the following functions for Amazon RDS DB instances running Aurora PostgreSQL:

- aurora_list_builtins (p. 1513)
- aurora_stat_dml_activity (p. 1514)
- aurora_stat_get_db_commit_latency (p. 1517)
- aurora_stat_system_waits (p. 1519)
- aurora_stat_wait_event (p. 1520)
- aurora_stat_wait_type (p. 1522)

aurora_list_builtins

Lists all available Aurora PostgreSQL built-in functions, along with brief descriptions and function details.

Syntax

aurora_list_builtins()
### Return type

SETOF record

### Arguments

None

### Examples

The following example shows results from calling the `aurora_list_builtins` function.

```sql
=> SELECT * FROM aurora_list_builtins();
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Result data type</th>
<th>Argument data</th>
</tr>
</thead>
</table>
| aurora_version         | text             | func | stable | safe | invoker | Amazon Aurora
|                        |                  |     |        |      |          | PostgreSQL-Compatible Edition version string
| aurora_stat_wait_type  | SETOF record     | OUT type_id smallint, OUT type_name text | func | volatile | restricted | invoker | Lists all supported wait types
|                        |                  |     |        |      |          |          |          |
| aurora_stat_wait_event | SETOF record     | OUT type_id smallint, OUT event_id integer, OUT event_name | func | volatile | restricted | invoker | Lists all supported wait events
|                        |                  |     |        |      |          |          |          |
| aurora_list_builtins   | SETOF record     | OUT "Name" text, OUT "Result data type" text, OUT "Argument data types" text, OUT "Type" text, OUT "Volatility" text, OUT "Parallel" text, OUT "Security" text, OUT "Description" text | func | stable | safe | invoker | Lists all Aurora built-in functions
|                        |                  |     |        |      |          |          |          |
| aurora_stat_file       | SETOF record     | OUT filename text, OUT allocated_bytes bigint, OUT used_bytes bigint | func | stable | safe | invoker | Lists all files present in Aurora storage
|                        |                  |     |        |      |          |          |          |

### aurora_stat_dml_activity

Reports cumulative activity for each type of data manipulation language (DML) operation on a database in an Aurora PostgreSQL cluster.

### Syntax
aurora_stat_dml_activity(database_oid)

Return type
SETOF record

Arguments

database_oid
The object ID (OID) of the database in the Aurora PostgreSQL cluster.

Usage notes

The `aurora_stat_dml_activity` function is only available with Aurora PostgreSQL release 3.1 compatible with PostgreSQL engine 11.6 and later.

Use this function on Aurora PostgreSQL clusters with a large number of databases to identify which databases have more or slower DML activity, or both.

The `aurora_stat_dml_activity` function returns the number of times the operations ran and the cumulative latency in microseconds for SELECT, INSERT, UPDATE, and DELETE operations. The report includes only successful DML operations.

You can reset this statistic by using the PostgreSQL statistics access function `pg_stat_reset`. You can check the last time this statistic was reset by using the `pg_stat_get_db_stat_reset_time` function. For more information about PostgreSQL statistics access functions, see The Statistics Collector in the PostgreSQL documentation.

Examples

The following example shows how to report DML activity statistics for the connected database.

```sql
-- Define the oid variable from connected database by using \gset
=> SELECT oid,
       datname
FROM pg_database
WHERE datname=(select current_database()) \gset

=> SELECT *
FROM aurora_stat_dml_activity(:oid);

<table>
<thead>
<tr>
<th>select_count</th>
<th>select_latency_microsecs</th>
<th>insert_count</th>
<th>insert_latency_microsecs</th>
<th>update_count</th>
<th>update_latency_microsecs</th>
<th>delete_count</th>
<th>delete_latency_microsecs</th>
</tr>
</thead>
<tbody>
<tr>
<td>178957</td>
<td>66684115</td>
<td>171065</td>
<td>28876649</td>
<td>519538</td>
<td>1454579206167</td>
<td>1</td>
<td>53027</td>
</tr>
</tbody>
</table>

-- Showing the same results with expanded display on
=> SELECT *
FROM aurora_stat_dml_activity(:oid);
- [ RECORD 1 ]----------------------------------------
<table>
<thead>
<tr>
<th>select_count</th>
<th>select_latency_microsecs</th>
<th>insert_count</th>
<th>insert_latency_microsecs</th>
<th>update_count</th>
<th>update_latency_microsecs</th>
<th>delete_count</th>
<th>delete_latency_microsecs</th>
</tr>
</thead>
<tbody>
<tr>
<td>178957</td>
<td>66684115</td>
<td>171065</td>
<td>28876649</td>
<td>519538</td>
<td>1454579206167</td>
<td>1</td>
<td>53027</td>
</tr>
</tbody>
</table>
The following example shows DML activity statistics for all databases in the Aurora PostgreSQL cluster. This cluster has two databases, postgres and mydb. The comma-separated list corresponds with the select_count, select_latency_microsecs, insert_count, insert_latency_microsecs, update_count, update_latency_microsecs, delete_count, and delete_latency_microsecs fields.

Aurora PostgreSQL creates and uses a system database named rdsadmin to support administrative operations such as backups, restores, health checks, replication, and so on. These DML operations have no impact on your Aurora PostgreSQL cluster.

```sql
=> SELECT oid, datname, aurora_stat_dml_activity(oid) FROM pg_database;

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
<th>aurora_stat_dml_activity</th>
</tr>
</thead>
<tbody>
<tr>
<td>14006</td>
<td>template0</td>
<td>(,,,,,,,)</td>
</tr>
<tr>
<td>16384</td>
<td>rdsadmin</td>
<td>(2346623,1211703821,4297518,817184554,0,0,0,0)</td>
</tr>
<tr>
<td>1</td>
<td>template1</td>
<td>(,,,,,,,)</td>
</tr>
<tr>
<td>14007</td>
<td>postgres</td>
<td>(178961,66716329,171065,28876649,519538,1454579206167,1,53027)</td>
</tr>
<tr>
<td>16401</td>
<td>mydb</td>
<td>(200246,64302436,200036,107101855,600000,83659417514,0,0)</td>
</tr>
</tbody>
</table>
```

The following example shows DML activity statistics for all databases, organized in columns for better readability.

```sql
SELECT db.datname,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 1), '()') AS select_count,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 2), '()') AS select_latency_microsecs,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 3), '()') AS insert_count,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 4), '()') AS insert_latency_microsecs,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 5), '()') AS update_count,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 6), '()') AS update_latency_microsecs,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 7), '()') AS delete_count,
       BTRIM(SPLIT_PART(db.asdmla::TEXT, ',', 8), '()') AS delete_latency_microsecs
FROM  (SELECT datname, aurora_stat_dml_activity(oid) AS asdmla
       FROM pg_database)
       AS db;

<table>
<thead>
<tr>
<th>datname</th>
<th>select_count</th>
<th>select_latency_microsecs</th>
<th>insert_count</th>
<th>insert_latency_microsecs</th>
<th>update_count</th>
<th>update_latency_microsecs</th>
<th>delete_count</th>
<th>delete_latency_microsecs</th>
</tr>
</thead>
<tbody>

1516
The following example shows the average cumulative latency (cumulative latency divided by count) for each DML operation for the database with the OID 16401.

```sql
=> SELECT select_count,
    select_latency_microsecs,
    select_latency_microsecs/NULLIF(select_count,0) select_latency_per_exec,
    insert_count,
    insert_latency_microsecs,
    insert_latency_microsecs/NULLIF(insert_count,0) insert_latency_per_exec,
    update_count,
    update_latency_microsecs,
    update_latency_microsecs/NULLIF(update_count,0) update_latency_per_exec,
    delete_count,
    delete_latency_microsecs,
    delete_latency_microsecs/NULLIF(delete_count,0) delete_latency_per_exec
FROM aurora_stat_dml_activity(16401);
```

| RECORD 1 | -------------- | ------------- |
| select_count | 451312        |
| select_latency_microsecs | 80205857  |
| select_latency_per_exec  | 177         |
| insert_count | 451001        |
| insert_latency_microsecs | 123667646 |
| insert_latency_per_exec  | 274         |
| update_count | 1353067       |
| update_latency_microsecs | 200900695615 |
| update_latency_perExec   | 148478      |
| delete_count | 12            |
| delete_latency_microsecs | 448         |
| delete_latency_perExec   | 37          |

**aurora_stat_get_db_commit_latency**

Gets the cumulative commit latency in microseconds for Aurora PostgreSQL databases. *Commit latency* is measured as the time between when a client submits a commit request and when it receives the commit acknowledgement.

**Syntax**

```sql
aurora_stat_get_db_commit_latency(database_oid)
```

**Return type**

SETOF record

**Arguments**

*database_oid*

The object ID (OID) of the Aurora PostgreSQL database.

**Usage notes**

Amazon CloudWatch uses this function to calculate the average commit latency. For more information about Amazon CloudWatch metrics and how to troubleshoot high commit latency, see Monitoring Amazon Aurora metrics with Amazon CloudWatch (p. 628) and Making better decisions about Amazon RDS with Amazon CloudWatch metrics.
You can reset this statistic by using the PostgreSQL statistics access function `pg_stat_reset`. You can check the last time this statistic was reset by using the `pg_stat_get_db_stat_reset_time` function. For more information about PostgreSQL statistics access functions, see The Statistics Collector in the PostgreSQL documentation.

**Examples**

The following example gets the cumulative commit latency for each database in the `pg_database` cluster.

```sql
=> SELECT oid, datname, aurora_stat_get_db_commit_latency(oid)
   FROM pg_database;
```

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
<th>aurora_stat_get_db_commit_latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>14006</td>
<td>template0</td>
<td>0</td>
</tr>
<tr>
<td>16384</td>
<td>rdsadmin</td>
<td>654387789</td>
</tr>
<tr>
<td>1</td>
<td>template1</td>
<td>0</td>
</tr>
<tr>
<td>16401</td>
<td>mydb</td>
<td>229556</td>
</tr>
<tr>
<td>69768</td>
<td>postgres</td>
<td>22011</td>
</tr>
</tbody>
</table>

The following example gets the cumulative commit latency for the currently connected database. Before calling the `aurora_stat_get_db_commit_latency` function, the example first uses `\gset` to define a variable for the `oid` argument and sets its value from the connected database.

```sql
--Get the oid value from the connected database before calling aurora_stat_get_db_commit_latency
=> SELECT oid
   FROM pg_database
   WHERE datname=(SELECT current_database()) \gset

=> SELECT *
   FROM aurora_stat_get_db_commit_latency(:oid);
```

<table>
<thead>
<tr>
<th>aurora_stat_get_db_commit_latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>1424279160</td>
</tr>
</tbody>
</table>

The following example gets the cumulative commit latency for the `mydb` database in the `pg_database` cluster. Then, it resets this statistic by using the `pg_stat_reset` function and shows the results. Finally, it uses the `pg_stat_get_db_stat_reset_time` function to check the last time this statistic was reset.

```sql
=> SELECT oid, datname, aurora_stat_get_db_commit_latency(oid)
   FROM pg_database
   WHERE datname = 'mydb';
```

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
<th>aurora_stat_get_db_commit_latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>16427</td>
<td>mydb</td>
<td>3320370</td>
</tr>
</tbody>
</table>

=> SELECT pg_stat_reset();

<table>
<thead>
<tr>
<th>pg_stat_reset</th>
</tr>
</thead>
</table>
=> SELECT oid, datname, aurora_stat_get_db_commit_latency(oid) 
    FROM pg_database 
    WHERE datname = 'mydb';

<table>
<thead>
<tr>
<th>oid</th>
<th>datname</th>
<th>aurora_stat_get_db_commit_latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>16427</td>
<td>mydb</td>
<td>6</td>
</tr>
</tbody>
</table>

=> SELECT * 
    FROM pg_stat_get_db_stat_reset_time(16427);

pg_stat_get_db_stat_reset_time
-------------------------------
2021-04-29 21:36:15.707399+00

aurora_stat_system_waits

Reports wait event information for the Aurora PostgreSQL DB instance.

Syntax

aurora_stat_system_waits()

Return type

SETOF record

Arguments

None

Usage notes

This function returns the cumulative number of waits and cumulative wait time for each wait event generated by the DB instance that you’re currently connected to.

The returned recordset includes the following fields:

- type_id – The ID of the type of wait event.
- event_id – The ID of the wait event.
- waits – The number of times the wait event occurred.
- wait_time – The total amount of time in microseconds spent waiting for this event.

Statistics returned by this function are reset when a DB instance restarts.

Examples

The following example shows results from calling the aurora_stat_system_waits function.

=> SELECT * 
    FROM aurora_stat_system_waits();

type_id | event_id | waits | wait_time
---------|---------|------|--------------
1 | 16777219 | 11 | 12864
The following example shows how you can use this function together with `aurora_stat_wait_event` and `aurora_stat_wait_type` to produce more readable results.

```sql
=> SELECT type_name,
    event_name,
    waits,
    wait_time
FROM aurora_stat_system_waits()
NATURAL JOIN aurora_stat_wait_event()
NATURAL JOIN aurora_stat_wait_type();
```

<table>

</tbody>
</table>

`aurora_stat_wait_event`

Lists all supported wait events for Aurora PostgreSQL. For information about Aurora PostgreSQL wait events, see Amazon Aurora PostgreSQL wait events (p. 1495).

**Syntax**

```
aurora_stat_wait_event()
```

**Return type**

SETOF record

**Arguments**

None
Usage notes

To see event names with event types instead of IDs, use this function together with other functions such as `aurora_stat_wait_type` and `aurora_stat_system_waits`. Wait event names returned by this function are the same as those returned by the `aurora_wait_report` function.

Examples

The following example shows results from calling the `aurora_stat_wait_event` function.

```
=> SELECT * FROM aurora_stat_wait_event();
```

<table>
<thead>
<tr>
<th>type_id</th>
<th>event_id</th>
<th>event_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>16777216</td>
<td><a href="">unassigned:0</a></td>
</tr>
<tr>
<td>1</td>
<td>16777217</td>
<td>ShmemIndexLock</td>
</tr>
<tr>
<td>1</td>
<td>16777218</td>
<td>OidGenLock</td>
</tr>
<tr>
<td>1</td>
<td>16777219</td>
<td>XidGenLock</td>
</tr>
<tr>
<td>9</td>
<td>150994945</td>
<td>PgSleep</td>
</tr>
<tr>
<td>9</td>
<td>150994946</td>
<td>RecoveryApplyDelay</td>
</tr>
<tr>
<td>10</td>
<td>167772160</td>
<td>BufFileRead</td>
</tr>
<tr>
<td>10</td>
<td>167772161</td>
<td>BufFileWrite</td>
</tr>
<tr>
<td>10</td>
<td>167772162</td>
<td>ControlFileRead</td>
</tr>
<tr>
<td>10</td>
<td>167772226</td>
<td>WALInitWrite</td>
</tr>
<tr>
<td>10</td>
<td>167772227</td>
<td>WALRead</td>
</tr>
<tr>
<td>10</td>
<td>167772228</td>
<td>WALSync</td>
</tr>
<tr>
<td>10</td>
<td>167772229</td>
<td>WALSyncMethodAssign</td>
</tr>
<tr>
<td>10</td>
<td>167772230</td>
<td>WALSWrite</td>
</tr>
<tr>
<td>10</td>
<td>167772231</td>
<td>XactSync</td>
</tr>
<tr>
<td>11</td>
<td>184549377</td>
<td>LsnAllocate</td>
</tr>
</tbody>
</table>
```

The following example joins `aurora_stat_wait_type` and `aurora_stat_wait_event` to return type names and event names for improved readability.

```
=> SELECT * FROM aurora_stat_wait_type() t
JOIN aurora_stat_wait_event() e
ON t.type_id = e.type_id;
```

<table>
<thead>
<tr>
<th>type_id</th>
<th>type_name</th>
<th>type_id</th>
<th>event_id</th>
<th>event_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>LWLock</td>
<td>1</td>
<td>16777216</td>
<td><a href="">unassigned:0</a></td>
</tr>
<tr>
<td>1</td>

</tr>
</tbody>
</table>
aurora_stat_wait_type

Lists all supported wait types for Aurora PostgreSQL.

Syntax

aurora_stat_wait_type()

Return type

SETOF record

Arguments

None

Usage notes

To see wait event names with wait event types instead of IDs, use this function together with other functions such as aurora_stat_wait_event and aurora_stat_system_waits. Wait type names returned by this function are the same as those returned by the aurora_wait_report function.

Examples

The following example shows results from calling the aurora_stat_wait_type function.

```
=> SELECT *
FROM aurora_stat_wait_type;

<table>
<thead>
<tr>
<th>type_id</th>
<th>type_name</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
```

Amazon Aurora PostgreSQL updates
In this topic, you can find version and update information specific to Amazon Aurora PostgreSQL-Compatible Edition. You can also find out how to upgrade your Amazon Aurora PostgreSQL engine version. For more information about updates that apply generally to Aurora, see Amazon Aurora updates (p. 485).

Topics
- Identifying your versions of Amazon Aurora PostgreSQL (p. 1523)
- Amazon Aurora PostgreSQL releases and engine versions (p. 1524)
- Extension versions for Amazon Aurora PostgreSQL (p. 1589)
- Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605)
- Aurora PostgreSQL long-term support (LTS) releases (p. 1613)

Identifying your versions of Amazon Aurora PostgreSQL

Amazon Aurora includes certain features that are general to Aurora and available to all Aurora DB clusters. Aurora includes other features that are specific to a particular database engine that Aurora supports. These features are available only to those Aurora DB clusters that use that database engine, such as Aurora PostgreSQL.

An Aurora database has two version numbers, the Aurora version number and the database engine version number. See also Amazon Aurora PostgreSQL releases and engine versions (p. 1524) for the association between a specific Aurora version number and a specific PostgreSQL engine version number.

Aurora version number

To get the Aurora version number of an Aurora PostgreSQL DB instance, use the following query.

```
SELECT AURORA_VERSION();
```

Aurora version numbers use the following format: `major-version.minor-version.patch-version`

PostgreSQL engine version number

To get the database engine version number for an Aurora PostgreSQL DB instance, query for the `SERVER_VERSION` runtime parameter as shown following.

```
SHOW SERVER_VERSION;
```

The version numbering sequence for the PostgreSQL database engine is as follows:

`major.minor`

For PostgreSQL versions 10 and later, the engine version number is in the form `major.minor`. The major version number is the integer part of the version number. The minor version number is the fractional part of the version number.

A major version upgrade increases the integer part of the version number, such as upgrading from `10.minor` to `11.minor`.

`major.major.minor`

For PostgreSQL versions earlier than 10, the engine version number is in the form `major.major.minor`. The major engine version number is both the integer and the first fractional part of the version number.
number. For example, 9.6 is a major version. The minor version number is the third part of the version number. For example, for version 9.6.12, the 12 is the minor version number.

A major version upgrade increases the major part of the version number. For example, an upgrade from 9.6.12 to 10.7 is a major version upgrade, where 9.6 and 10 are the major version numbers.

Amazon Aurora PostgreSQL releases and engine versions

Following, you can find information about supported released versions of the Aurora PostgreSQL-Compatible Edition database engine. Starting with the release of PostgreSQL versions 13.3, 12.8, 11.13, 10.18, and for all other later versions, Aurora version numbers aren’t used. To determine the version numbers of your Aurora PostgreSQL database, see Identifying your versions of Amazon Aurora PostgreSQL (p. 1523).

To determine which PostgreSQL engine versions are available in an AWS Region, use the describe-db-engine-versions AWS CLI command. For example:

```bash
aws rds describe-db-engine-versions --engine aurora-postgresql --query '[].[EngineVersion]' --output text --region your-AWS-Region
```

For a list of AWS Regions, see Aurora PostgreSQL Region availability (p. 14).

Topics

- PostgreSQL 11.4, Aurora PostgreSQL release 3.0 (unsupported) (p. 1549)
- PostgreSQL 10.18 (p. 1550)
- PostgreSQL 10.17, Aurora PostgreSQL release 2.9 (p. 1551)
- PostgreSQL 10.16, Aurora PostgreSQL release 2.8 (p. 1552)
- PostgreSQL 10.14, Aurora PostgreSQL release 2.7 (p. 1553)
- PostgreSQL 10.13, Aurora PostgreSQL release 2.6 (p. 1556)
- PostgreSQL 10.12, Aurora PostgreSQL release 2.5 (p. 1558)
- PostgreSQL 10.11, Aurora PostgreSQL release 2.4 (p. 1562)
- PostgreSQL 10.7, Aurora PostgreSQL release 2.3 (unsupported) (p. 1566)
- PostgreSQL 10.6, Aurora PostgreSQL release 2.2 (unsupported) (p. 1568)
- PostgreSQL 10.5, Aurora PostgreSQL release 2.1 (unsupported) (p. 1569)
• PostgreSQL 10.4, Aurora PostgreSQL release 2.0 (unsupported) (p. 1570)
• PostgreSQL 9.6.22, Aurora PostgreSQL release 1.11 (p. 1571)
• PostgreSQL 9.6.21, Aurora PostgreSQL release 1.10 (p. 1572)
• PostgreSQL 9.6.19, Aurora PostgreSQL release 1.9 (p. 1573)
• PostgreSQL 9.6.18, Aurora PostgreSQL release 1.8 (p. 1574)
• PostgreSQL 9.6.17, Aurora PostgreSQL release 1.7 (p. 1575)
• PostgreSQL 9.6.16, Aurora PostgreSQL release 1.6 (p. 1578)
• PostgreSQL 9.6.12, Aurora PostgreSQL release 1.5 (unsupported) (p. 1581)
• PostgreSQL 9.6.11, Aurora PostgreSQL release 1.4 (unsupported) (p. 1583)
• PostgreSQL 9.6.9, Aurora PostgreSQL release 1.3 (unsupported) (p. 1583)
• PostgreSQL 9.6.8, Aurora PostgreSQL release 1.2 (unsupported) (p. 1585)
• PostgreSQL 9.6.6 Aurora PostgreSQL release 1.1 (unsupported) (p. 1587)
• PostgreSQL 9.6.3, Aurora PostgreSQL release 1.0 (unsupported) (p. 1588)

For information about extensions and modules, see Extension versions for Amazon Aurora PostgreSQL (p. 1589).

The following Aurora PostgreSQL versions are supported.

**PostgreSQL 13.4**

This release of Aurora PostgreSQL is compatible with PostgreSQL 13.4. For more information about the improvements in PostgreSQL 13.4, see PostgreSQL release 13.4.

**Aurora PostgreSQL release 13.4**

**New features**

• This version supports Babelfish which extends your Amazon Aurora PostgreSQL database with the ability to accept database connections from Microsoft SQL Server clients. For more information, see Working with Babelfish for Aurora PostgreSQL.

**Critical stability enhancements**

• Fixed an issue where, in rare circumstances, a data cache of a read node may be inconsistent following a restart of that node.

**High priority stability enhancements**

• Fixed an issue where queries may become unresponsive due to I/O resource exhaustion triggered by prefetch.
• Fixed an issue where Aurora may panic following a major version update with the message: "PANIC: could not access status of next transaction id xxxxxxxx".

**Additional improvements and enhancements**

• Fixed an issue where read nodes restart due to a replication origin cache lookup failure.
• Fixed an issue where read queries may time out on read nodes during the replay of lazy truncation triggered by vacuum on the write node.
• Fixed an issue that causes Performance Insights to incorrectly set the backend type of a database connection.
• Fixed an issue where the aurora_postgres_replica_status() function returned stale or lagging CPU stats.
• Fixed an issue where the role rds_superuser did not have permission to execute the pg_stat_statements_reset() function.
• Fixed an issue with the apg_plan_mgmt extension where the planning and execution times were reported as 0.
• Removed support for DES, 3DES and RC4 cipher suites.
• Updated PostGIS extension to version 3.1.4.
• Added support for the following SPI module extensions:
  • autoinc version 1.0
  • insert_username version 1.0
  • moddatetime version 1.0
  • refint version 1.0
• Fixed multiple issues in the Aurora storage daemon that could lead to brief periods of unavailability when specific network configurations are used.
• Fixed an out of memory crash issue with Aurora storage daemon that leads to writer node restart. This also reduces the overall system memory consumption.

**PostgreSQL 13.3**

This release of Aurora PostgreSQL is compatible with PostgreSQL 13.3. For more information about the improvements in PostgreSQL 13.3, see PostgreSQL release 13.3.

**Patch releases**

• Aurora PostgreSQL 13.3.1 (p. 1526)
• Aurora PostgreSQL release 13.3.0 (p. 1527)

**Aurora PostgreSQL 13.3.1**

**Critical stability enhancements**

• Fixed an issue where, in rare circumstances, a data cache of a read node may be inconsistent following a restart of that node.

**High priority stability enhancements**

• Fixed an issue where queries may become unresponsive due to I/O resource exhaustion triggered by prefetch.
• Fixed an issue where Aurora may panic following a major version update with the message: "PANIC: could not access status of next transaction id xxxxxxxx".

**Additional improvements and enhancements**

• Fixed an issue where read nodes restart due to a replication origin cache lookup failure.
• Fixed an issue with the apg_plan_mgmt extension where the planning and execution times were reported as 0.
• Fixed an issue that causes Performance Insights to incorrectly set the backend type of a database connection.
• Fixed an issue with the apg_plan_mgmt extension where plan outline on a partitioned table did not enforce an index-based plan.
• Fixed an issue where orphaned files caused failed translations in read codepaths during or after a major version upgrade.
• Fixed multiple issues in the Aurora storage daemon that could lead to brief periods of unavailability when specific network configurations are used.
• Fixed an out of memory crash issue with Aurora storage daemon that leads to writer node restart. This also reduces the overall system memory consumption.

Aurora PostgreSQL release 13.3.0

New features
• Supports a major version upgrade from PostgreSQL 12.4, Aurora PostgreSQL release 4.0 (p. 1531) and later versions
• Supports bool_plperl version 1.0
• Supports rds_tools version 1.0

Critical stability enhancements
• Fixed an issue where, in rare circumstances, a data cache of a read node may be inconsistent following a restart of that node.

Additional improvements and enhancements
• Contains all of the fixes, features, and improvements present in PostgreSQL 12.7, Aurora PostgreSQL release 4.2 (p. 1528)
• Contains several improvements that were announced for PostgreSQL releases 13.0, 13.1, 13.2 and 13.3
• Instance type R4 was deprecated.
• Updated the following extensions:
  • hll to version 2.15.
  • hstore to version 1.7.
  • intarray to version 1.3.
  • log_fdw to version 1.2.
  • ltree to version 1.2.
  • pg_hint_plan to version 1.3.7.
  • pg_repack to version 1.4.6.
  • pg_stat_statements to version 1.8.
  • pg_trgm to version 1.5.
  • pg_audit to version 1.5.
  • pglogical to version 2.3.3.
  • pgrouting to version 3.1.0
  • plcoffee to version 2.3.15.
  • plls to version 2.3.15.
  • plv8 to version 2.3.15.

PostgreSQL 12.8

This release of Aurora PostgreSQL is compatible with PostgreSQL 12.8. For more information about the improvements in PostgreSQL 12.8, see PostgreSQL release 12.8.
Critical stability enhancements

- Fixed an issue where, in rare circumstances, a data cache of a read node may be inconsistent following a restart of that node.

High priority stability enhancements

- Fixed an issue where queries may become unresponsive due to I/O resource exhaustion triggered by prefetch.
- Fixed an issue where Aurora may panic following a major version update with the message: "PANIC: could not access status of next transaction id xxxxxxxxx".

Additional improvements and enhancements

- Fixed an issue where read nodes restart due to a replication origin cache lookup failure.
- Fixed an issue where read queries may time out on read nodes during the replay of lazy truncation triggered by vacuum on the write node.
- Fixed an issue that causes Performance Insights to incorrectly set the backend type of a database connection.
- Fixed an issue where the aurora_postgres_replica_status() function returned stale or lagging CPU stats.
- Fixed an issue where the role rds_superuser did not have permission to execute the pg_stat_statements_reset() function.
- Fixed an issue with the apg_plan_mgmt extension where the planning and execution times were reported as 0.
- Removed support for DES, 3DES and RC4 cipher suites.
- Updated PostGIS extension to version 3.1.4.

PostgreSQL 12.7, Aurora PostgreSQL release 4.2

This release of Aurora PostgreSQL is compatible with PostgreSQL 12.7. For more information about the improvements in PostgreSQL 12.7, see PostgreSQL release 12.7.

Patch releases

- Aurora PostgreSQL 4.2.1 (p. 1528)
- Aurora PostgreSQL release 4.2.0 (p. 1529)

Aurora PostgreSQL 4.2.1

Critical stability enhancements

- Fixed an issue where, in rare circumstances, a data cache of a read node may be inconsistent following a restart of that node.

High priority stability enhancements

- Fixed an issue where queries may become unresponsive due to I/O resource exhaustion triggered by prefetch.
- Fixed an issue where Aurora may panic following a major version update with the message: "PANIC: could not access status of next transaction id xxxxxxxxx".
Additional improvements and enhancements

- Fixed an issue where read nodes restart due to a replication origin cache lookup failure.
- Fixed an issue with the apg_plan_mgmt extension where planning and execution time were reported as 0.
- Fixed an issue that causes Performance Insights to incorrectly set the backend type of a database connection.
- Fixed an issue with the apg_plan_mgmt extension where plan outline on a partitioned table did not enforce an index-based plan.
- Fixed an issue where orphaned files caused failed translations in read codepaths during or after major version upgrade.
- Fixed multiple issues in the Aurora storage daemon that could lead to brief periods of unavailability when specific network configurations are used.
- Fixed an issue where orphaned files caused failed translations in read codepaths during or after major version upgrade.
- Fixed an issue where orphaned files caused failed translations in read codepaths during or after major version upgrade.
- Fixed an issue where a duplicate file entry can prevent the Aurora PostgreSQL engine from starting up.
- Fixed an issue that could cause temporary unavailability under heavy workloads.
- Added back ability to use a leading forward slash in the S3 path during S3 import.
- Added Graviton support for oracle_fdw extension version 1.2.
- Changed the following extensions:
  - Updated the Orafce extension to version 3.16.
  - Updated the pg_partman extension to version 4.5.1.
  - Updated the pg_cron extension to version 1.3.1.
  - Updated the postgis extension to version 3.0.3.

Aurora PostgreSQL release 4.2.0

New features

- Added support for the oracle_fdw extension version 1.2.

High priority stability enhancements

- Fixed an issue where creating a database from an existing template database with tablespace resulted in an error with the message ERROR: could not open file pg_tblspc/...: No such file or directory.
- Fixed an issue where, in rare cases, an Aurora replica may be unable to start when a large number of PostgreSQL subtransactions (i.e. SQL savepoints) have been used.
- Fixed an issue where, in rare circumstances, read results may be inconsistent for repeated read requests on replica nodes.
### PostgreSQL 12.6, Aurora PostgreSQL release 4.1

This release of Aurora PostgreSQL is compatible with PostgreSQL 12.6. For more information about the improvements in PostgreSQL 12.6, see PostgreSQL release 12.6.

### Aurora PostgreSQL release 4.1.0

#### New features

- Added support for the following extensions:
  - The `pg_proctab` extension version 0.0.9
  - The `pg_partman` extension version 4.4.0. For more information, see Managing PostgreSQL partitions with the `pg_partman` extension (p. 1469).
  - The `pg_cron` extension version 1.3.0. For more information, see Scheduling maintenance with the PostgreSQL `pg_cron` extension (p. 1311).
  - The `pg_bigm` extension version 1.2

#### High priority stability enhancements

- Fixed a bug in the `pglogical` extension that could lead to data inconsistency for inbound replication.
- Fixed a bug where in rare cases a reader had inconsistent results when it restarted while a transaction with more than 64 subtransactions was being processed.
- Backported fixes for the following PostgreSQL community security issues:
  - CVE-2021-32027
  - CVE-2021-32028
  - CVE-2021-32029

#### Additional improvements and enhancements

- Fixed a bug where the database could not be started when there were many relations in memory-constrained environments.
- Fixed a bug in the `apg_plan_mgmt` extension that could cause brief periods of unavailability due to an internal buffer overflow.
- Fixed a bug on reader nodes that could cause brief periods of unavailability during WAL replay.
- Fixed a bug in the `rds_activity_stream` extension that caused an error during startup when attempting to log audit events.
- Fixed bugs in the `aurora_replica_status` function where rows were sometimes partially populated and some values such as Replay Latency, and CPU usage were always 0.
- Fixed a bug where the database engine would attempt to create shared memory segments larger than the instance total memory and fail repeatedly. For example, attempts to create 128 GiB shared buffers on a `db.r5.large` instance would fail. With this change, requests for total shared memory allocations larger than the instance memory allow setting the instance to incompatible parameters.
- Added logic to clean up unnecessary `pg_wal` temporary files on a database startup.
- Fixed a bug that could lead to outbound replication synchronization errors after a major version upgrade.
- Fixed a bug that reported ERROR: `rds_activity_stream` stack item 2 not found on top - cannot pop when attempting to create the `rds_activity_stream` extension.
- Fixed a bug that could cause the error failed to build any 3-way joins in a correlated `IN` subquery under an `EXISTS` subquery.
- Backported the following performance improvement from the PostgreSQL community: `pg_stat_statements: add missing check for pgss_enabled()`.

1530
• Fixed a bug that could cause upgrades to Aurora PostgreSQL 12.x to fail due to the inability to open the pg_control file.
• Fixed a bug that could cause brief periods of unavailability due to running out of memory when creating the postgis extension with pgAudit enabled.
• Backported the following bug fix from the PostgreSQL community: Fix use-after-free bug with AfterTriggersTableData.storeslot.
• Fixed a bug when using outbound logical replication to synchronize changes to another database that could fail with an error message like ERROR: could not map filenode "base/16395/228486645" to relation OID.
• Fixed a bug that could cause a brief period of unavailability when aborting a transaction.
• Fixed a bug that caused no ICU collations to be shown in the pg_collation catalog table after creating a new Aurora PostgreSQL 12.x instance. This issue does not affect upgrading from an older version.
• Fixed a bug where the rds_ad role wasn't created after upgrading from a version of Aurora PostgreSQL that doesn't support Microsoft Active Directory authentication.
• Added btree page checks to detect tuple metadata inconsistency.
• Fixed a bug in asynchronous buffer reads that could cause brief periods of unavailability on reader nodes during WAL replay.
• Fixed a bug where reading a TOAST value from disk could cause a brief period of unavailability.
• Fixed a bug that caused brief periods of unavailability when attempting to fetch a tuple from and index scan.

PostgreSQL 12.4, Aurora PostgreSQL release 4.0

This release of Aurora PostgreSQL is compatible with PostgreSQL 12.4. For more information about the improvements in PostgreSQL 12.4, see PostgreSQL release 12.4.

Patch releases
• Aurora PostgreSQL release 4.0.2 (p. 1531)
• Aurora PostgreSQL release 4.0.1 (p. 1532)
• Aurora PostgreSQL release 4.0.0 (p. 1532)

Aurora PostgreSQL release 4.0.2

High priority stability enhancements
• Fixed a bug where a reader node might render an extra or missing row if the reader restarted while the writer node is processing a long transaction with more than 64 subtransactions.
• Fixed a bug that can cause vacuum to block on GiST indexes.
• Fixed a bug where after upgrade to PostgreSQL 12, vacuum can fail on the system table pg_catalog.pg_shdescription with the following error. ERROR: found xmin 484 from before relfrozenxid

Additional improvements and enhancements
• Fixed a bug that could lead to intermittent unavailability due to a race condition when handling responses from storage nodes.
• Fixed a bug that could lead to intermittent unavailability due to the rotation of network encryption keys.
• Fixed a bug that could lead to intermittent unavailability due to heat management of the underlying storage segments.
• Fixed a bug where a large S3 import with thousands of clients can cause one or more of the import clients to stop responding.
• Removed a restriction that prevented setting configuration variable strings that contained `brazil`.
• Fixed a bug that could lead to intermittent unavailability if a reader node runs a query that accesses many tables while the writer node is acquiring exclusive locks on all of the same tables.

Aurora PostgreSQL release 4.0.1

New features

• This release adds support for the Graviton2 db.r6g instance classes (p. 53) to the PostgreSQL engine version 12.4.

Critical stability enhancements

• Fixed a bug that caused a read replica to unsuccessfullly restart repeatedly in rare cases.
• Fixed a bug where a cluster became unavailable when attempting to create more than 16 read replicas or Aurora global database secondary AWS Regions. The cluster became available again when the new read replica or secondary AWS Region was removed.

Additional improvements and enhancements

• Fixed a bug that when under heavy load, snapshot import, COPY import, or Amazon S3 import stopped responding in rare cases.
• Fixed a bug where a read replica might not join the cluster when the writer was very busy with a write-intensive workload.
• Fixed a bug where a cluster could be unavailable briefly when a high-volume S3 import was running.
• Fixed a bug that caused a cluster to take several minutes to restart if a logical replication stream was terminated while handling many complex transactions.
• Fixed the Just-in-Time (JIT) compilation, which was incorrectly enabled by default in Aurora PostgreSQL release 4.0.0.
• Disallowed the use of both AWS Identity and Access Management (IAM) and Kerberos authentication for the same user.

Aurora PostgreSQL release 4.0.0

New features

• This version supports a major version upgrade from PostgreSQL 11.7, Aurora PostgreSQL release 3.2 (p. 1542) and later versions.

Additional improvements and enhancements

• Contains several improvements that were announced for PostgreSQL releases 12.0, 12.1, 12.2, 12.3, and 12.4.
• Contains all fixes, features, and improvements present in PostgreSQL 11.9, Aurora PostgreSQL release 3.4 (p. 1536).
• Backported fixes for the following PostgreSQL community security issues:
  • CVE-2020-25694
  • CVE-2020-25695
  • CVE-2020-25696
• Updated the following extensions:
  • address_standardizer to version 3.0.2
  • address_standardizer_data_us to version 3.0.2
  • amcheck to version 1.2
  • citext to version 1.6
  • hll to version 2.14
  • hstore to version 1.6
  • ip4r to version 2.4
  • pg_repack to version 1.4.5
  • pg_stat_statements to version 1.7
  • pgaudit to version 1.4
  • plogical to version 2.3.2
  • pgrouting to version 3.0.3
  • plv8 to version 2.3.14
  • postGIS to version 3.0.2
  • postgis_tiger_geocoder to version 3.0.2
  • postgis_topology to version 3.0.2

PostgreSQL 11.13

This release of Aurora PostgreSQL is compatible with PostgreSQL 11.13. For more information about the improvements in PostgreSQL 11.13, see PostgreSQL release 11.13.

Critical stability enhancements

• Fixed an issue where, in rare circumstances, a data cache of a read node may be inconsistent following a restart of that node.

High priority stability enhancements

• Fixed an issue where queries may become unresponsive due to I/O resource exhaustion triggered by prefetch.
• Fixed an issue where Aurora may panic following a major version update with the message: "PANIC: could not access status of next transaction id xyyyyyyyy".

Additional improvements and enhancements

• Fixed an issue where read nodes restart due to a replication origin cache lookup failure.
• Fixed an issue where read queries may time out on read nodes during the replay of lazy truncation triggered by vacuum on the write node.
• Fixed an issue that causes Performance Insights to incorrectly set the backend type of a database connection.
• Fixed an issue where the aurora_postgres_replica_status() function returned stale or lagging CPU stats.
• Fixed an issue where, in rare cases, an Aurora Global Database secondary mirror cluster may restart due to a stall in the log apply process.
• Fixed an issue with the apg_plan_mgnt extension where the planning and execution times were reported as 0.
• Removed support for DES, 3DES and RC4 cipher suites.
• Updated PostGIS extension to version 3.1.4.
• Added support for postgis_raster extension version 3.1.4.

**PostgreSQL 11.12, Aurora PostgreSQL release 3.6**

This release of Aurora PostgreSQL is compatible with PostgreSQL 11.12. For more information about the improvements in PostgreSQL 11.12, see [PostgreSQL release 11.12](#).

**Patch releases**

• Aurora PostgreSQL 3.6.1 (p. 1534)
• Aurora PostgreSQL release 3.6.0 (p. 1535)

**Aurora PostgreSQL 3.6.1**

**Critical stability enhancements**

• Fixed an issue where, in rare circumstances, a data cache of a read node may be inconsistent following a restart of that node.

**High priority stability enhancements**

• Fixed an issue where queries may become unresponsive due to I/O resource exhaustion triggered by prefetch.
• Fixed an issue where Aurora may panic following a major version update with the message: "PANIC: could not access status of next transaction id xxxxxxxx".
• Fixed multiple issues in the Aurora storage daemon that could lead to brief periods of unavailability when specific network configurations are used.
• Fixed an out of memory crash issue with Aurora storage daemon that leads to writer node restart. This also reduces the overall system memory consumption.

**Additional improvements and enhancements**

• Fixed an issue where read nodes restart due to a replication origin cache lookup failure.
• Fixed an issue with the apg_plan_mgmt extension where planning and execution time were reported as 0.
• Fixed an issue that causes Performance Insights to incorrectly set the backend type of a database connection.
• Fixed an issue where in rare cases, an Aurora Global Database secondary mirror cluster may restart due to a stall in the log apply process.
• Fixed an issue where orphaned files caused failed translations in read codepaths during or after major version upgrade.
• Fixed multiple issues in the Aurora storage daemon that could lead to brief periods of unavailability when specific network configurations are used.
• Fixed an out of memory crash issue with Aurora storage daemon that leads to writer node restart. This also reduces the overall system memory consumption.
Aurora PostgreSQL release 3.6.0

High priority stability enhancements

- Fixed an issue where creating a database from an existing template database with tablespace resulted in an error with the message ERROR: could not open file pg_tblspc/...: No such file or directory.
- Fixed an issue where, in rare cases, an Aurora replica may be unable to start when a large number of PostgreSQL subtransactions (i.e. SQL savepoints) have been used.
- Fixed an issue where, in rare circumstances, read results may be inconsistent for repeated read requests on replica nodes.

Additional improvements and enhancements

- Upgraded OpenSSL to 1.1.1k.
- Reduced CPU usage and memory consumption of the WAL apply process on Aurora replicas for some workloads.
- Improved metadata protection from accidental erasure.
- Improved safety checks in the write path to detect incorrect writes to metadata.
- Improved security by removing 3DES and other older ciphers for SSL/TLS connections.
- Fixed an issue where a duplicate file entry can prevent the Aurora PostgreSQL engine from starting up.
- Fixed an issue that could cause temporary unavailability under heavy workloads.
- Added back ability to use a leading forward slash in the S3 path during S3 import.
- Updated the orafce extension to version 3.16.

PostgreSQL 11.11, Aurora PostgreSQL release 3.5

This release of Aurora PostgreSQL is compatible with PostgreSQL 11.11. For more information about the improvements in PostgreSQL 11.11, see PostgreSQL release 11.11.

Aurora PostgreSQL release 3.5.0

New features

- Added support for the following extensions:
  - The pg_proctab extension version 0.0.9
  - The pg_bigm extension version 1.2

High priority stability enhancements

- Fixed a bug where in rare cases a reader had inconsistent results when it restarted while a transaction with more than 64 subtransactions was being processed.
- Backported fixes for the following PostgreSQL community security issues:
  - CVE-2021-32027
  - CVE-2021-32028
  - CVE-2021-32029

Additional improvements and enhancements

- Fixed a bug where the database could not be started when there were many relations in memory-constrained environments.
• Fixed a bug in the `apg_plan_mgmt` extension that could cause brief periods of unavailability due to an internal buffer overflow.

• Fixed a bug on reader nodes that could cause brief periods of unavailability during WAL replay.

• Fixed a bug in the `rds_activity_stream` extension that caused an error during startup when attempting to log audit events.

• Fixed bugs in the `aurora_replica_status` function where rows were sometimes partially populated and some values such as Replay Latency, and CPU usage were always 0.

• Fixed a bug where the database engine would attempt to create shared memory segments larger than the instance total memory and fail repeatedly. For example, attempts to create 128 GiB shared buffers on a `db.r5.large` instance would fail. With this change, requests for total shared memory allocations larger than the instance memory allow setting the instance to incompatible parameters.

• Added logic to clean up unnecessary `pg_wal` temporary files on a database startup.

• Fixed a bug that reported `ERROR: rds_activity_stream stack item 2 not found on top - cannot pop` when attempting to create the `rds_activity_stream` extension.

• Fixed a bug that could cause the error failed to build any 3-way joins in a correlated `IN` subquery under an `EXISTS` subquery.

• Backported the following performance improvement from the PostgreSQL community:
  `pg_stat_statements: add missing check for pgss_enabled()`.

• Fixed a bug that could cause brief periods of unavailability due to running out of memory when creating the `postgis` extension with `pgAudit` enabled.

• Fixed a bug when using outbound logical replication to synchronize changes to another database that could fail with an error message like `ERROR: could not map filenode "base/16395/228486645" to relation OID.`

• Fixed a bug that could cause a brief period of unavailability when aborting a transaction.

• Fixed a bug where the `rds_ad` role wasn't created after upgrading from a version of Aurora PostgreSQL that doesn't support Microsoft Active Directory authentication.

• Added btree page checks to detect tuple metadata inconsistency.

• Fixed a bug in asynchronous buffer reads that could cause brief periods of unavailability on reader nodes during WAL replay.

PostgreSQL 11.9, Aurora PostgreSQL release 3.4

This release of Aurora PostgreSQL is compatible with PostgreSQL 11.9. For more information about the improvements in PostgreSQL 11.9, see PostgreSQL release 11.9.

Patch releases

• Aurora PostgreSQL release 3.4.3 (p. 1536)

• Aurora PostgreSQL release 3.4.2 (p. 1537)

• Aurora PostgreSQL release 3.4.1 (p. 1537)

• Aurora PostgreSQL release 3.4.0 (p. 1538)

Aurora PostgreSQL release 3.4.3

High priority stability enhancements

• Provided a patch for PostgreSQL community security issues CVE-2021-32027, CVE-2021-32028 and CVE-2021-32029.
Additional improvements and enhancements

- Fixed a bug in the `aws_s3` extension to allow import of objects with leading forward slashes in the object identifier.
- Fixed a bug in the `rds_activity_stream` extension that caused an error during startup when attempting to log audit events.
- Fixed a bug that returned an `ERROR` when attempting to create the `rds_activity_stream` extension.
- Fixed a bug that could cause brief periods of unavailability due to running out of memory when creating the `postgis` extension with `pgAudit` enabled.
- Fixed multiple issues in the Aurora storage daemon that could lead to brief periods of unavailability when specific network configurations are used.

**Aurora PostgreSQL release 3.4.2**

High priority stability enhancements

- Fixed a bug where in rare cases a reader had inconsistent results when it restarted while a transaction with more than 64 subtransactions was being processed.

Additional improvements and enhancements

- Fixed a bug that could lead to intermittent unavailability due to a race condition when handling responses from storage nodes.
- Fixed a bug that could lead to intermittent unavailability due to the rotation of network encryption keys.
- Fixed a bug that could lead to intermittent unavailability due to heat management of the underlying storage segments.
- Fixed a bug where a large S3 import with thousands of clients can cause one or more of the import clients to stop responding.
- Removed a restriction that prevented setting configuration variable strings that contained `brazil`.
- Fixed a bug that could lead to intermittent unavailability if a reader node runs a query that access many tables while the writer node is acquiring exclusive locks on all of the same tables.

**Aurora PostgreSQL release 3.4.1**

Critical stability enhancements

- Fixed a bug that caused a read replica to unsuccessfully restart repeatedly in rare cases.
- Fixed a bug where a cluster became unavailable when attempting to create more than 16 read replicas or Aurora global database secondary AWS Regions. The cluster became available again when the new read replica or secondary AWS Region was removed.

Additional improvements and enhancements

- Fixed a bug that when under heavy load, snapshot import, `COPY` import, or S3 import stopped responding in rare cases.
- Fixed a bug where a read replica might not join the cluster when the writer was very busy with a write-intensive workload.
- Fixed a bug where a cluster could be unavailable briefly when a high-volume S3 import was running.
• Fixed a bug that caused a cluster to take several minutes to restart if a logical replication stream was terminated while handling many complex transactions.
• Disallowed the use of both IAM and Kerberos authentication for the same user.

Aurora PostgreSQL release 3.4.0

New features
• Aurora PostgreSQL now supports invocation of AWS Lambda functions. This includes the new aws_lambda extension. For more information, see Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster (p. 1458).
• The db.r6g instance classes are now available in preview for Aurora. For more information, see Aurora DB instance classes (p. 53).

Critical stability enhancements
• None

High priority stability enhancements
• Fixed a bug in Aurora PostgreSQL replication that could result in the error message ERROR: MultiXactId nnnn has not been created yet -- apparent wraparound.
• Fixed a bug where in some cases, DB clusters that have logical replication enabled did not remove truncated WAL segment files from storage. This resulted in volume size growth.
• Backported fixes for the following PostgreSQL community security issues:
  • CVE-2020-25694
  • CVE-2020-25695
  • CVE-2020-25696
• Fixed a bug in the pg_stat_statements extension that caused excessive CPU consumption.

Additional improvements and enhancements
• You can now use pg_replication_slot_advance to advance a logical replication slot for the roles rds_replication and rds_superuser.
• Improved the asynchronous mode performance of database activity streams.
• Reduced the delay when publishing to CloudWatch the rpo_lag_in_msec metric for Aurora global database clusters.
• Aurora PostgreSQL no longer falls behind on a read node when the backend is blocked writing to the database client.
• Fixed a bug that in rare cases caused a brief period of unavailability on a read replica when the storage volume grew.
• Fixed a bug when creating a database that could return the following: ERROR: could not create directory on local disk
• Updated data grid files to fix errors or incorrect transformation results from the ST_Transform method of the PostGIS extension.
• Fixed a bug where in some cases replaying XLOG_BTREE_REUSE_PAGE records on Aurora reader instances caused unnecessary replay lag.
• Fixed a small memory leak in a b-tree index that could lead to an out of memory condition.
• Fixed a bug in the GiST index that could result in an out of memory condition after promoting an Aurora read replica.
• Fixed an S3 import bug that reported ERROR: HTTP 403. Permission denied when importing data from a file inside an S3 subfolder.
• Fixed a bug in the aws_s3 extension for pre-signed URL handling that could result in the error message S3 bucket names with a period (.) are not supported.
• Fixed a bug in the aws_s3 extension where an import might be blocked indefinitely if an exclusive lock was taken on the relation prior to beginning the operation.
• Fixed a bug related to replication when Aurora PostgreSQL is acting as a physical replica of an RDS PostgreSQL instance that uses GiST indexes. In rare cases, this bug caused a brief period of unavailability after promoting the Aurora cluster.
• Fixed a bug in database activity streams where customers were not notified of the end of an outage.
• Updated the pg_audit extension to version 1.3.1.

PostgreSQL 11.8, Aurora PostgreSQL release 3.3

This release of Aurora PostgreSQL is compatible with PostgreSQL 11.8. For more information about the improvements in PostgreSQL 11.8, see PostgreSQL release 11.8.

Patch releases
• Aurora PostgreSQL release 3.3.2 (p. 1539)
• Aurora PostgreSQL release 3.3.1 (p. 1540)
• Aurora PostgreSQL release 3.3.0 (p. 1540)

Aurora PostgreSQL release 3.3.2

Critical stability enhancements
• None

High priority stability enhancements
• Fixed a bug in Aurora PostgreSQL replication that could result in the error message ERROR: MultiXactId nnnn has not been created yet -- apparent wraparound.
• Fixed a bug where in some cases, DB clusters that have logical replication enabled did not remove truncated WAL segment files from storage. This resulted in volume size growth.
• Fixed an issue with creating a global database cluster in a secondary region.
• Backported fixes for the following PostgreSQL community security issues:
  • CVE-2020-25694
  • CVE-2020-25695
  • CVE-2020-25696
• Fixed a bug in the pg_stat_statements extension that caused excessive CPU consumption.

Additional improvements and enhancements
• Aurora PostgreSQL no longer falls behind on a read node when the backend is blocked writing to the database client.
• Reduced the delay when publishing to CloudWatch the rpo_lag_in_msec metric for Aurora global database clusters.
• Fixed a bug where a DROP DATABASE statement didn't remove any relation files.
• Fixed a bug where in some cases replaying XLOG_BTREE_REUSE_PAGE records on Aurora reader instances caused unnecessary replay lag.
• Fixed a small memory leak in a b-tree index that could lead to an out of memory condition.
• Fixed a bug in the `aurora_replica_status()` function where the `server_id` field was sometimes truncated.
• Fixed a bug where a log record was incorrectly processed causing the Aurora replica to crash.
• Fixed an S3 import bug that reported ERROR: HTTP 403. Permission denied when importing data from a file inside an S3 subfolder.
• You can now use `pg_replication_slot_advance` to advance a logical replication slot for the roles `rds_replication` and `rds_superuser`.
• Improved performance of the asynchronous mode for database activity streams.
• Fixed a bug where a log record was incorrectly processed causing the Aurora replica to crash.
• Fixed an S3 import bug that reported ERROR: HTTP 403. Permission denied when importing data from a file inside an S3 subfolder.

Aurora PostgreSQL release 3.3.1

You can find the following improvements in this release.

Critical stability enhancements

1. Fixed a bug that appears when the `NOT EXISTS` operator incorrectly returns TRUE, which can only happen when the following unusual set of circumstances occurs:
   • A query is using the `NOT EXISTS` operator.
   • The column or columns being evaluated against the outer query in the `NOT EXISTS` subquery contain a NULL value.
   • There isn't a another predicate in the subquery that removes the need for the evaluation of the NULL values.
   • The filter used in the subquery does not use an index seek for its execution.
   • The operator isn't converted to a join by the query optimizer.

Aurora PostgreSQL release 3.3.0

New features

• Added support for the RDKit extension version 3.8.

  The RDKit extension provides modeling functions for cheminformatics. Cheminformatics is storing, indexing, searching, retrieving, and applying information about chemical compounds. For example, with the RDKit extension you can construct models of molecules, search for molecular structures, and read or create molecules in various notations. You can also perform research on data loaded from the ChEMBL website or a SMILES file. The Simplified Molecular Input Line Entry System (SMILES) is a typographical notation for representing molecules and reactions. For more information, see The RDKit database cartridge in the RDKit documentation.
• Added support for a minimum TLS version

Support for a minimum Transport Layer Security (TLS) version is back ported from PostgreSQL 12. It allows the Aurora PostgreSQL server to constrain the TLS protocols with which a client is allowed to connect via two new PostgreSQL parameters. These parameters include `ssl_min_protocol_version` and
ssl_max_protocol_version. For example, to limit client connections to the Aurora PostgreSQL server to at least TLS 1.2 protocol version, set the ssl_min_protocol_version to TLSv1.2.

- Added support for the pglogical extension version 2.2.2.

The pglogical extension is a logical streaming replication system that provides additional features beyond what's available in PostgreSQL native logical replication. Features include conflict handling, row filtering, DDL/sequence replication and delayed apply. You can use the pglogical extension to set up replication between Aurora PostgreSQL clusters, between RDS PostgreSQL and Aurora PostgreSQL, and with PostgreSQL databases running outside of RDS.

- Aurora dynamically resizes your cluster storage space. With dynamic resizing, the storage space for your Aurora DB cluster automatically decreases when you remove data from the DB cluster. For more information, see Storage scaling (p. 392).

Note
The dynamic resizing feature is being deployed in phases to the AWS Regions where Aurora is available. Depending on the Region where your cluster is, this feature might not be available yet. For more information, see the What's New announcement.

Critical stability enhancements
- Fixed a bug related to heap page extend that in rare cases resulted in longer recovery time and impacted availability.

High priority stability enhancements
- Fixed a bug in Aurora Global Database that could cause delays in upgrading the database engine in a secondary AWS Region. For more information, see Using Amazon Aurora global databases (p. 223).
- Fixed a bug that in rare cases caused delays in upgrading a database to engine version 11.8.

Additional improvements and enhancements
- Fixed a bug where the Aurora replica crashed when workloads with heavy subtransactions are made on the writer instance.
- Fixed a bug where the writer instance crashed due to a memory leak and the depletion of memory used to track active transactions.
- Fixed a bug that lead to a crash due to improper initialization when there is no free memory available during PostgreSQL backend startup.
- Fixed a bug where an Aurora PostgreSQL Serverless DB cluster might return the following error after a scaling event: ERROR: prepared statement "S_6" already exists.
- Fixed an out-of-memory problem when issuing the CREATE EXTENSION command with PostGIS when Database Activity Streams enabled.
- Fixed a bug where a SELECT query might incorrectly return the error Attempting to read past EOF of relation rrr. blockno=bbb nblocks=nnn.
- Fixed a bug where the database might be unavailable briefly due to error handling in database storage growth.
- Fixed a bug in Aurora PostgreSQL Serverless where queries that executed on previously idle connections got delayed until the scale operation completed.
- Fixed a bug where an Aurora PostgreSQL DB cluster with Database Activity Streams enabled might report the beginning of a potential loss window for activity records, but does not report the restoration of connectivity.
- Fixed a bug with the aws_s3.table_import_from_s3 (p. 1387) function where a COPY from S3 failed with the error HTTP error code: 248.
**PostgreSQL 11.7, Aurora PostgreSQL release 3.2**

This release of Aurora PostgreSQL is compatible with PostgreSQL 11.7. For more information about the improvements in PostgreSQL 11.7, see PostgresSQL release 11.7.

**Patch releases**
- Aurora PostgreSQL release 3.2.7 (p. 1542)
- Aurora PostgreSQL release 3.2.6 (p. 1542)
- Aurora PostgreSQL release 3.2.4 (p. 1543)
- Aurora PostgreSQL release 3.2.3 (p. 1543)
- Aurora PostgreSQL release 3.2.2 (p. 1544)
- Aurora PostgreSQL release 3.2.1 (p. 1544)

**Aurora PostgreSQL release 3.2.7**

You can find the following improvements in this release.

**Critical stability enhancements**
- None

**High priority stability enhancements**
- Backported fixes for the following PostgreSQL community security issues:
  - CVE-2020-25694
  - CVE-2020-25695
  - CVE-2020-25696

**Additional improvements and enhancements**
- None

**Aurora PostgreSQL release 3.2.6**

You can find the following improvements in this release.

**Critical stability enhancements**
- None

**High priority stability enhancements**
- Fixed a bug in Aurora PostgreSQL replication that might result in the error message, ERROR: MultiXactId nnnn has not been created yet -- apparent wraparound.

**Additional improvements and enhancements**
- Fixed a bug that in rare cases caused brief read replica unavailability when storage volume grew.
- Aurora PostgreSQL Serverless now supports execution of queries on all connections during a scale event.
Amazon Aurora User Guide for Aurora

Aurora PostgreSQL releases

- Fixed a bug in Aurora PostgreSQL Serverless where a leaked lock resulted in a prolonged scale event.
- Fixed a bug where the `aurora_replica_status` function showed truncated server identifiers.
- Fixed a bug in Aurora PostgreSQL Serverless where connections being migrated during a scale event disconnected with the message: “ERROR: could not open relation with OID ....
- Fixed a small memory leak in a b-tree index that could lead to an out of memory condition.
- Fixed a bug in a GiST index that might result in an out of memory condition after promoting an Aurora Read Replica.
- Improved performance for Database Activity Streams.
- Fixed a bug in Database Activity Streams where customers were not notified when an outage ended.
- Fixed a bug in the `aws_s3` extension for pre-signed URL handling that could have resulted in the error message S3 bucket names with a period (.) are not supported.
- Fixed a bug in the `aws_s3` extension where incorrect error handling could lead to failures during the import process.
- Fixed a bug in the `aws_s3` extension where an import may be blocked indefinitely if an exclusive lock was taken on the relation prior to beginning the operation.

Aurora PostgreSQL release 3.2.4

You can find the following improvements in this release.

**Critical stability enhancements**

1. Fixed a bug that appears when the `NOT EXISTS` operator incorrectly returns TRUE, which can only happen when the following unusual set of circumstances occurs:
   - A query is using the `NOT EXISTS` operator.
   - The column or columns being evaluated against the outer query in the `NOT EXISTS` subquery contain a NULL value.
   - There isn't another predicate in the subquery that removes the need for the evaluation of the NULL values.
   - The filter used in the subquery does not use an index seek for its execution.
   - The operator isn't converted to a join by the query optimizer.

Aurora PostgreSQL release 3.2.3

You can find the following improvements in this release.

**Critical stability enhancements**

- None

**High priority stability enhancements**

- None

**Additional improvements and enhancements**

- Fixed a bug in Aurora PostgreSQL Serverless where queries that ran on previously idle connections got delayed until the scale operation completed.
- Fixed a bug that might cause brief unavailability for heavy subtransaction workloads when multiple reader instances restart or rejoin the cluster.
Aurora PostgreSQL release 3.2.2

You can find the following improvements in this release.

Critical stability enhancements

- Fixed a bug related to heap page extend that in rare cases resulted in longer recovery time and impacted availability.

High priority stability enhancements

- Fixed a bug in Aurora Global Database that could cause delays in upgrading the database engine in a secondary region. For more information, see Using Amazon Aurora global databases (p. 223).
- Fixed a bug that in rare cases caused delays in upgrading a database to engine version 11.7.

Additional improvements and enhancements

- Fixed a bug where the database might be unavailable briefly due to error handling in database storage growth.
- Fixed a bug where a SELECT query might incorrectly return the error, Attempting to read past EOF of relation rrr. blockno=bbb nbblocks=nnn.
- Fixed a bug where an Aurora PostgreSQL Serverless DB cluster might return the following error after a scaling event: ERROR: prepared statement "S_6" already exists.

Aurora PostgreSQL release 3.2.1

New features

- Added support for Amazon Aurora PostgreSQL Global Database. For more information, see Using Amazon Aurora global databases (p. 223).
- Added the ability to configure the recovery point objective (RPO) of a global database for Aurora PostgreSQL. For more information, see Managing RPOs for Aurora PostgreSQL–based global databases (p. 269).

You can find the following improvements in this release.

Critical stability enhancements

None.

High priority stability enhancements

- Improved performance and availability of read instances when applying DROP TABLE and TRUNCATE TABLE operations.
- Fixed a small but continuous memory leak in a diagnostic module that could lead to an out-of-memory condition on smaller DB instance types.
- Fixed a bug in the PostGIS extension which could lead to a database restart. This has been reported to the PostGIS community as https://trac.osgeo.org/postgis/ticket/4646.
- Fixed a bug where read requests might stop responding due to incorrect error handling in the storage engine.
- Fixed a bug that fails for some queries and results in the message ERROR: found xmin xxxxxx from before refrozenxid yyyyyyy. This could occur following the promotion of a read instance to a write instance.
• Fixed a bug where an Aurora serverless DB cluster might crash while rolling back a scale attempt.

**Additional improvements and enhancements**

• Improved performance for queries that read many rows from storage.
• Improved performance and availability of reader DB instances during heavy read workload.
• Enabled correlated IN and NOT IN subqueries to be transformed to joins when possible.
• Improved the filtering estimation for enhanced semi-join filter pushdown by using multi-column statistics or indexes when available.
• Improved read performance of the `pg_prewarm` extension.
• Fixed a bug where an Aurora serverless DB cluster might report the message ERROR: incorrect binary data format in bind parameter ... following a scale event.
• Fixed a bug where a serverless DB cluster might report the message ERROR: insufficient data left in message following a scale event.
• Fixed a bug where an Aurora serverless DB cluster can experience prolonged or failed scale attempts.
• Fixed a bug that resulted in the message ERROR: could not create file "base/xxxxxx/yyyyyyy" as a previous version still exists on disk: Success. Please contact AWS customer support. This can occur during object creation after PostgreSQL's 32-bit object identifier has wrapped around.
• Fixed a bug where the write-ahead-log (WAL) segment files for PostgreSQL logical replication were not deleted when changing the `wal_level` value from `logical` to `replica`.
• Fixed a bug in the `pg_hint_plan` extension where a multi-statement query could lead to a crash when `enable_hint_table` is enabled. This is tracked in the PostgreSQL community as [https://github.com/ossc-db/pg_hint_plan/issues/25](https://github.com/ossc-db/pg_hint_plan/issues/25).
• Fixed a bug where JDBC clients might report the message java.io.IOException: Unexpected packet type: 75 following a scale event in an Aurora serverless DB cluster.
• Fixed a bug in PostgreSQL logical replication that resulted in the message ERROR: snapshot reference is not owned by resource owner TopTransaction.
• Changed the following extensions:
  • Updated orafce to version 3.8
  • Updated pgTAP to version 1.1
• Provided support for fault injection queries.

**PostgreSQL 11.6, Aurora PostgreSQL release 3.1**

This release of Aurora PostgreSQL is compatible with PostgreSQL 11.6. For more information about the improvements in PostgreSQL 11.6, see PostgreSQL release 11.6.

This release contains multiple critical stability enhancements. Amazon highly recommends upgrading your Aurora PostgreSQL clusters that use older PostgreSQL 11 engines to this release.

**Patch releases**

• Aurora PostgreSQL release 3.1.4 (p. 1545)
• Aurora PostgreSQL release 3.1.3 (p. 1546)
• Aurora PostgreSQL release 3.1.2 (p. 1546)
• Aurora PostgreSQL release 3.1.1 (p. 1547)
• Aurora PostgreSQL release 3.1.0 (p. 1547)

**Aurora PostgreSQL release 3.1.4**

You can find the following improvements in this release.
Critical stability enhancements

• None

High priority stability enhancements

• Backported fixes for the following PostgreSQL community security issues:
  • CVE-2020-25694
  • CVE-2020-25695
  • CVE-2020-25696

Additional improvements and enhancements

• None

Aurora PostgreSQL release 3.1.3

New features

• Aurora PostgreSQL now supports the PostgreSQL vacuum_truncate storage parameter to manage vacuum truncation for specific tables. Set this storage parameter to false for a table to prevent the VACUUM SQL command from truncating the table's trailing empty pages.

Critical stability enhancements

• None

High priority stability enhancements

• Fixed a bug where reads from storage might stop responding due to incorrect error handling.

Additional improvements and enhancements

• None

Aurora PostgreSQL release 3.1.2

This release contains a critical stability enhancement. Amazon highly recommends updating your older Aurora PostgreSQL 11-compatible clusters to this release.

Critical stability enhancements

• Fixed a bug in which a reader DB instance might temporarily use stale data. This could lead to wrong results such as too few or too many rows. This error is not persisted on storage, and will clear when the database page containing the row has been evicted from cache. This can happen when the primary DB instance enters a transaction snapshot overflow due to having more than 64 subtransactions in a single transaction. Applications susceptible to this bug include those that use SQL savepoints or PostgreSQL exception handlers with more than 64 subtransactions in the top transaction.
High priority stability enhancements

- Fixed a bug that might cause a reader DB instance to crash causing unavailability while attempting to join the DB cluster. This can happen in some cases when the primary DB instance has a transaction snapshot overflow due to a high number of subtransactions. In this situation the reader DB instance will be unable to join until the snapshot overflow has cleared.

Additional improvements and enhancements

- Fixed a bug that prevented Performance Insights from determining the query ID of a running statement.

Aurora PostgreSQL release 3.1.1

You can find the following improvements in this release.

Critical stability enhancements

- Fixed a bug in which the DB instance might be briefly unavailable due to the self-healing function of the underlying storage.

High priority stability enhancements

- Fixed a bug in which the database engine might crash causing unavailability. This occurred while scanning an included, non-key column of a B-Tree index. This only applies to PostgreSQL 11 “included column” indexes.
- Fixed a bug that might cause the database engine to crash causing unavailability. This occurred if a newly established database connection encountered a resource exhaustion-related error during initialization after successful authentication.

Additional improvements and enhancements

- Provided a fix for the `pg_hint_plan` extension that could lead the database engine to crash causing unavailability. The open source issue can be tracked at https://github.com/ossc-db/pg_hint_plan/pull/45.
- Fixed a bug where SQL of the form `ALTER FUNCTION ... OWNER TO ...` incorrectly reported `ERROR: improper qualified name (too many dotted names)`.
- Improved the performance of GIN index vacuum via prefetching.
- Fixed a bug in open source PostgreSQL that could lead to a database engine crash causing unavailability. This occurred during parallel B-Tree index scans. This issue has been reported to the PostgreSQL community.
- Improved the performance of in-memory B-Tree index scans.

For information about extensions and modules, see Extensions supported for Aurora PostgreSQL 11.x (p. 1595).

Aurora PostgreSQL release 3.1.0

You can find the following new features and improvements in this engine version.

New features

1. Support for exporting data to Amazon S3. For more information, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 (p. 1391).
2. Support for Amazon Aurora Machine Learning. For more information, see Using machine learning (ML) with Aurora PostgreSQL (p. 1435).

3. SQL processing enhancements include:
   - Optimizations for NOT IN with the `apg_enable_not_in_transform` parameter.
   - Semi-join filter pushdown enhancements for hash joins with the `apg_enable_semijoin_push_down` parameter.
   - Optimizations for redundant inner join removal with the `apg_enable_remove_redundant_inner_joins` parameter.
   - Improved ANSI compatibility options with the `ansi_constraint_trigger_ordering`, `ansi_force_foreign_key_checks` and `ansi_qualified_update_set_target` parameters.

   For more information, see Amazon Aurora PostgreSQL parameters (p. 1487).

4. New and updated PostgreSQL extensions include:
   - The new `aws_ml` extension. For more information, see Using machine learning (ML) with Aurora PostgreSQL (p. 1435).
   - The new `aws_s3` extension. For more information, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 (p. 1391).
   - Updates to the `apg_plan_mgmt` extension. For more information, see Managing query execution plans for Aurora PostgreSQL (p. 1401)

Critical stability enhancements

1. Fixed a bug related to creating B-tree indexes on temporary tables that in rare cases might result in longer recovery time, and impact availability.

2. Fixed a bug related to replication when Aurora PostgreSQL is acting as a physical replica of an RDS PostgreSQL instance. In rare cases, this bug causes a log write failure that might result in longer recovery time, and impact availability.

3. Fixed a bug related to handling of reads with high I/O latency that in rare cases might result in longer recovery time, and impact availability.

High priority stability enhancements

1. Fixed a bug related to logical replication in which `wal` segments are not properly removed from storage. This can result in storage bloat. To monitor this, view the `TransactionLogDiskUsage` parameter.

2. Fixed multiple bugs, which cause Aurora to crash during prefetch operations on Btree indexes.

3. Fixed a bug in which an Aurora restart might time out when logical replication is used.

4. Enhanced the validation checks performed on data blocks in the buffer cache. This improves Aurora's detection of inconsistency.

Additional improvements and enhancements

1. The query plan management extension `apg_plan_mgmt` has an improved algorithm for managing plan generation for highly partitioned tables.

2. Reduced startup time on instances with large caches via improvements in the buffer cache recovery algorithm.

3. Improved the performance of the read-node-apply process under high transaction rate workloads by using changes to PostgreSQL LWLock prioritization. These changes prevent starvation of the read-node-apply process while the PostgreSQL ProcArray is under heavy contention.

4. Improved handling of batch reads during vacuum, table scans, and index scans. This results in greater throughput and lower CPU consumption.
5. Fixed a bug in which a read node might crash during the replay of a PostgreSQL SLRU-truncate operation.

6. Fixed a bug where in rare cases, database writes might stall following an error returned by one of the six copies of an Aurora log record.

7. Fixed a bug related to logical replication where an individual transaction larger than 1 GB in size might result in an engine crash.

8. Fixed a memory leak on read nodes when cluster cache management is enabled.

9. Fixed a bug in which importing an RDS PostgreSQL snapshot might stop responding if the source snapshot contains a large number of unlogged relations.

10. Fixed a bug in which the Aurora storage daemon might crash under heavy I/O load.

11. Fixed a bug related to SELECT standby_feedback for read nodes in which the read node might report the wrong transaction id epoch to the write node. This can cause the write node to ignore the SELECT standby_feedback and invalidate snapshots on the read node.

12. Fixed a bug in which storage errors that occur during CREATE DATABASE statements are not properly handled. The bug left the resulting database inaccessible. The correct behavior is to fail the database creation and return the appropriate error to the user.

13. Improved handling of PostgreSQL snapshot overflow when a read node attempts to connect to a write node. Prior to this change, if the write node was in a snapshot overflow state, the read node was unable to join. A message appeared in the PostgreSQL log file in the form DEBUG: recovery snapshot waiting for non-overflowed snapshot or until oldest active xid on standby is at least $xxxxxxx$ (now $yyyyyy$). A snapshot overflow occurs when an individual transaction has created over 64 subtransactions.

14. Fixed a bug related to common table expressions in which an error is incorrectly raised when a NOT IN class exists in a CTE. The error is CTE with NOT IN fails with ERROR: could not find CTE CTE-Name.

15. Fixed a bug related to an incorrect last_error_timestamp value in the aurora_replica_status table.

16. Fixed a bug to avoid populating shared buffers with blocks belonging to temporary objects. These blocks correctly reside in PostgreSQL backend local buffers.

17. Changed the following extensions:
   - Updated pg_hint_plan to version 1.3.4.
   - Added plprofiler version 4.1.
   - Added pgTAP version 1.0.0.

**PostgreSQL 11.4, Aurora PostgreSQL release 3.0 (unsupported)**

**Note**
The PostgreSQL engine version 11.4 with the Aurora PostgreSQL release 3.0 is no longer supported. To upgrade, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605).

This release of Aurora PostgreSQL is compatible with PostgreSQL 11.4. For more information about the improvements in PostgreSQL 11.4, see PostgreSQL release 11.4.

You can find the following improvements in this release.

**Improvements**

1. This release contains all fixes, features, and improvements present in Aurora PostgreSQL release 2.3.5 (p. 1566).

2. Partitioning – Partitioning improvements include support for hash partitioning, enabling creation of a default partition, and dynamic row movement to another partition based on the key column update.
3. Performance – Performance improvements include parallelism while creating indexes, materialized views, hash joins, and sequential scans to make the operations perform better.

4. Stored procedures – SQL stored procedures now added support for embedded transactions.

5. Autovacuum improvements – To provide valuable logging, the parameter `rds.force_autovacuum_logging` is ON by default in conjunction with the `log.autovacuum_min_duration` parameter set to 10 seconds. To increase autovacuum effectiveness, the values for the `autovacuum.max_workers` and `autovacuum.vacuum_cost_limit` parameters are computed based on host memory capacity to provide larger default values.

6. Improved transaction timeout – The parameter `idle_in_transaction_session_timeout` is set to 24 hours. Any session that has been idle more than 24 hours is terminated.

7. The `tsearch2` module is no longer supported – If your application uses `tsearch2` functions, update it to use the equivalent functions provided by the core PostgreSQL engine. For more information about the `tsearch2` module, see PostgreSQL `tsearch2`.

8. The `chkpass` module is no longer supported – For more information about the `chkpass` module, see PostgreSQL `chkpass`.

9. Updated the following extensions:
   - `address_standardizer` to version 2.5.1
   - `address_standardizer_data_us` to version 2.5.1
   - `btree_gin` to version 1.3
   - `citext` to version 1.5
   - `cube` to version 1.4
   - `hstore` to version 1.5
   - `ip4r` to version 2.2
   - `isn` to version 1.2
   - `orafce` to version 3.7
   - `pg_hint_plan` to version 1.3.4
   - `pg_prewarm` to version 1.2
   - `pg_repack` to version 1.4.4
   - `pg_trgm` to version 1.4
   - `pgaudit` to version 1.3
   - `pgrouting` to version 2.6.1
   - `pgtap` to version 1.0.0
   - `plcoffee` to version 2.3.8
   - `plls` to version 2.3.8
   - `plv8` to version 2.3.8
   - `postgis` to version 2.5.1
   - `postgis_tiger_geocoder` to version 2.5.1
   - `postgis_topology` to version 2.5.1
   - `rds_activity_stream` to version 1.3

**PostgreSQL 10.18**

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.18. For more information about the improvements in PostgreSQL 10.18, see PostgreSQL release 10.18.
Critical stability enhancements

- Fixed an issue where, in rare circumstances, a data cache of a read node may be inconsistent following a restart of that node.

High priority stability enhancements

- Fixed an issue where queries may become unresponsive due to I/O resource exhaustion triggered by prefetch.
- Fixed an issue where Aurora may panic following a major version update with the message: "PANIC: could not access status of next transaction id xxxxxxxx".

Additional improvements and enhancements

- Fixed an issue where read nodes restart due to a replication origin cache lookup failure.
- Fixed an issue where read queries may time out on read nodes during the replay of lazy truncation triggered by vacuum on the write node.
- Fixed an issue that causes Performance Insights to incorrectly set the backend type of a database connection.
- Fixed an issue where the aurora_postgres_replica_status() function returned stale or lagging CPU stats.
- Fixed an issue where, in rare cases, an Aurora Global Database secondary mirror cluster may restart due to a stall in the log apply process.
- Removed support for DES, 3DES and RC4 cipher suites.
- Updated PostGIS extension to version 3.1.4.
- Added support for postgis_raster extension version 3.1.4.

PostgreSQL 10.17, Aurora PostgreSQL release 2.9

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.17. For more information about the improvements in PostgreSQL 10.17, see PostgreSQL release 10.17.

Patch releases

- Aurora PostgreSQL 2.9.1 (p. 1551)
- Aurora PostgreSQL release 2.9 (p. 1552)

Aurora PostgreSQL 2.9.1

Critical stability enhancements

- Fixed an issue where, in rare circumstances, a data cache of a read node may be inconsistent following a restart of that node.

High priority stability enhancements

- Fixed an issue where queries may become unresponsive due to I/O resource exhaustion triggered by prefetch.
- Fixed an issue where Aurora may panic following a major version update with the message: "PANIC: could not access status of next transaction id xxxxxxxx".
Additional improvements and enhancements

- Fixed an issue where read nodes restart due to a replication origin cache lookup failure.
- Fixed an issue where in rare cases, an Aurora Global Database secondary mirror cluster may restart due to a stall in the log apply process.
- Fixed an issue that causes Performance Insights to incorrectly set the backend type of a database connection.
- Fixed an issue where orphaned files caused failed translations in read codepaths during or after major version upgrade.
- Fixed multiple issues in the Aurora storage daemon that could lead to brief periods of unavailability when specific network configurations are used.
- Fixed an out of memory crash issue with Aurora storage daemon that leads to writer node restart. This also reduces the overall system memory consumption.

Aurora PostgreSQL release 2.9

High priority stability enhancements

1. Fixed an issue where creating a database from an existing template database with tablespace resulted in an error with the message ERROR: could not open file pg_tblspc/...: No such file or directory.
2. Fixed an issue where, in rare cases, an Aurora replica may be unable to start when a large number of PostgreSQL subtransactions (i.e. SQL savepoints) have been used.
3. Fixed an issue where, in rare circumstances, read results may be inconsistent for repeated read requests on replica nodes.

Additional improvements and enhancements

1. Upgraded OpenSSL to 1.1.1k.
2. Reduced CPU usage and memory consumption of the WAL apply process on Aurora replicas for some workloads.
3. Improved safety checks in the write path to detect incorrect writes to metadata.
4. Improved security by removing 3DES and other older ciphers for SSL/TLS connections.
5. Fixed an issue where a duplicate file entry can prevent the Aurora PostgreSQL engine from starting up.
6. Fixed an issue that could cause temporary unavailability under heavy workloads.
7. Added back ability to use a leading forward slash in the S3 path during S3 import.
8. Updated the orafce extension to version 3.16.
9. Updated the PostGIS extension to version 2.4.7.

PostgreSQL 10.16, Aurora PostgreSQL release 2.8

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.16. For more information about the improvements in PostgreSQL 10.16, see PostgreSQL release 10.16.

Aurora PostgreSQL release 2.8.0

High priority stability enhancements

1. Fixed a bug where in rare cases a reader had inconsistent results when it restarted while a transaction with more than 64 subtransactions was being processed.
2. Backported fixes for the following PostgreSQL community security issues:
   - CVE-2021-32027
   - CVE-2021-32028
   - CVE-2021-32029

Additional improvements and enhancements

1. Fixed a bug where the database could not be started when there were many relations in memory-constrained environments.
2. Fixed a bug in the `apg_plan_mgmt` extension that could cause brief periods of unavailability due to an internal buffer overflow.
3. Fixed a bug on reader nodes that could cause brief periods of unavailability during WAL replay.
4. Fixed a bug in the `rds_activity_stream` extension that caused an error during startup when attempting to log audit events.
5. Fixed a bug that prevented minor version updates of an Aurora global database cluster.
6. Fixed bugs in the `aurora_replica_status` function where rows were sometimes partially populated and some values such as Replay Latency, and CPU usage were always 0.
7. Fixed a bug where the database engine would attempt to create shared memory segments larger than the instance total memory and fail repeatedly. For example, attempts to create 128 GiB shared buffers on a db.r5.large instance would fail. With this change, requests for total shared memory allocations larger than the instance memory allow setting the instance to incompatible parameters.
8. Added logic to clean up unnecessary `pg_wal` temporary files on a database startup.
9. Fixed a bug that reported ERROR: rds_activity_stream stack item 2 not found on top - cannot pop when attempting to create the `rds_activity_stream` extension.
10. Fixed a bug that could cause the error failed to build any 3-way joins in a correlated `IN` subquery under an `EXISTS` subquery.
11. Fixed a bug that could cause brief periods of unavailability due to running out of memory when creating the `postgis` extension with `pgAudit` enabled.
12. Fixed a bug when using outbound logical replication to synchronize changes to another database that could fail with an error message like ERROR: could not map filenode "base/16395/228486645" to relation OID.
13. Fixed a bug where the `rds_ad` role wasn't created after upgrading from a version of Aurora PostgreSQL that doesn't support Microsoft Active Directory authentication.
15. Fixed a bug in asynchronous buffer reads that could cause brief periods of unavailability on reader nodes during WAL replay.

PostgreSQL 10.14, Aurora PostgreSQL release 2.7

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.14. For more information about the improvements in PostgreSQL 10.14, see PostgreSQL release 10.14.

Patch releases
   - Aurora PostgreSQL release 2.7.3 (p. 1554)
   - Aurora PostgreSQL release 2.7.2 (p. 1554)
   - Aurora PostgreSQL release 2.7.1 (p. 1554)
   - Aurora PostgreSQL release 2.7.0 (p. 1555)
**Aurora PostgreSQL release 2.7.3**

**High priority stability enhancements**

1. Provided a patch for PostgreSQL community security issues CVE-2021-32027, CVE-2021-32028 and CVE-2021-32029.

**Additional improvements and enhancements**

1. Fixed a bug in the aws_s3 extension to allow import of objects with leading forward slashes in the object identifier.
2. Fixed a bug in the rds_activity_stream extension that caused an error during startup when attempting to log audit events.
3. Fixed a bug that returned an ERROR when attempting to create the rds_activity_stream extension.
4. Fixed a bug that could cause brief periods of unavailability due to running out of memory when creating the postgis extension with pgAudit enabled.
5. Fixed multiple issues in the Aurora storage daemon that could lead to brief periods of unavailability when specific network configurations are used.

**Aurora PostgreSQL release 2.7.2**

**High priority stability enhancements**

1. Fixed a bug where a reader node might render an extra or missing row if the reader restarted while the writer node is processing a long transaction with more than 64 subtransactions.

**Additional improvements and enhancements**

1. Fixed a bug that could lead to intermittent unavailability due to the rotation of network encryption keys.
2. Fixed a bug where a large S3 import with thousands of clients can cause one or more of the import clients to stop responding.

**Aurora PostgreSQL release 2.7.1**

**Critical stability enhancements**

1. Fixed a bug that caused a read replica to unsuccessfully restart repeatedly in rare cases.
2. Fixed a bug where a cluster became unavailable when attempting to create more than 16 read replicas or Aurora global database secondary AWS Regions. The cluster became available again when the new read replica or secondary AWS Region was removed.

**Additional improvements and enhancements**

1. Fixed a bug that when under heavy load, snapshot import, COPY import, or S3 import stopped responding in rare cases.
2. Fixed a bug where a read replica might not join the cluster when the writer was very busy with a write-intensive workload.
3. Fixed a bug that caused a cluster to take several minutes to restart if a logical replication stream was terminated while handling many complex transactions.
4. Disallowed the use of both IAM and Kerberos authentication for the same user.

**Aurora PostgreSQL release 2.7.0**

**Critical stability enhancements**

- None

**High priority stability enhancements**

1. Backported fixes for the following PostgreSQL community security issues:
   - CVE-2020-25694
   - CVE-2020-25695
   - CVE-2020-25696

2. Fixed a bug in Aurora PostgreSQL replication that could result in the error message ERROR: MultiXactId nnnn has not been created yet -- apparent wraparound.

3. Fixed a bug where in some cases, DB clusters that have logical replication enabled did not remove truncated WAL segment files from storage. This resulted in volume size growth.

4. Fixed a bug in the `pg_stat_statements` extension that caused excessive CPU consumption.

**Additional improvements and enhancements**

1. Improved the asynchronous mode performance of database activity streams.

2. Aurora Serverless v1 for PostgreSQL now supports query execution on all connections during a scale event.

3. Reduced the delay when publishing to CloudWatch the `rpo_lag_in_msec` metric for Aurora global database clusters.

4. Fixed a bug in Serverless clusters where transaction processing was unnecessarily suspended for long periods when creating a scale point.

5. Fixed a bug in Aurora Serverless v1 for PostgreSQL where a leaked lock resulted in a prolonged scale event.

6. Fixed a bug in Aurora Serverless v1 for PostgreSQL where connections being migrated during a scale event was disconnected with the following message: ERROR: could not open relation with OID ...

7. Aurora PostgreSQL no longer falls behind on a read node when the backend is blocked writing to the database client.

8. Fixed a bug that in rare cases caused a brief period of unavailability on a read replica when the storage volume grew.

9. Fixed a bug when creating a database that could return the following error: ERROR: could not create directory on local disk

10. Fixed a bug where in some cases replaying `XLOG_BTREE_REUSE_PAGE` records on Aurora reader instances caused unnecessary replay lag.

11. Fixed a bug in the GiST index that could result in an out of memory condition after promoting an Aurora read replica.

12. Fixed a bug where the `aurora_replica_status` function showed truncated server identifiers.

13. Fixed an S3 import bug that reported ERROR: HTTP 403. Permission denied when importing data from a file inside an S3 subfolder.

14. Fixed a bug in the `aws_s3` extension for pre-signed URL handling that could result in the error message S3 bucket names with a period (.) are not supported.
Fixed a bug in the `aws_s3` extension where an import might be blocked indefinitely if an exclusive lock was taken on the relation prior to beginning the operation.

Fixed a bug related to replication when Aurora PostgreSQL is acting as a physical replica of an RDS PostgreSQL instance that uses GiST indexes. In rare cases, this bug caused a brief period of unavailability after promoting the Aurora cluster.

Fixed a bug in database activity streams where customers were not notified of the end of an outage.

**PostgreSQL 10.13, Aurora PostgreSQL release 2.6**

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.13. For more information about the improvements in PostgreSQL 10.13, see PostgreSQL release 10.13.

**Patch releases**
- Aurora PostgreSQL release 2.6.2 (p. 1556)
- Aurora PostgreSQL release 2.6.1 (p. 1557)
- Aurora PostgreSQL release 2.6.0 (p. 1557)

**Aurora PostgreSQL release 2.6.2**

**Critical stability enhancements**

1. None

**High priority stability enhancements**

1. Fixed a bug in Aurora PostgreSQL replication that could result in the error message ERROR: MultiXactId nnnn has not been created yet -- apparent wraparound.
2. Fixed a bug where in some cases, DB clusters that have logical replication enabled did not remove truncated WAL segment files from storage. This resulted in volume size growth.
3. Fixed an issue with creating a global database cluster in a secondary region.
4. Backported fixes for the following PostgreSQL community security issues:
   - CVE-2020-25694
   - CVE-2020-25695
   - CVE-2020-25696
5. Fixed a bug in the `pg_stat_statements` extension that caused excessive CPU consumption.

**Additional improvements and enhancements**

1. Aurora PostgreSQL no longer falls behind on a read node when the backend is blocked writing to the database client.
2. Reduced the delay when publishing to CloudWatch the `rpo_lag_in_msec` metric for Aurora global database clusters.
3. Fixed a bug where a `DROP DATABASE` statement didn't remove any relation files.
4. Fixed a bug where in some cases replaying `XLOG_BTREE_REUSE_PAGE` records on Aurora reader instances caused unnecessary replay lag.
5. Fixed a small memory leak in a b-tree index that could lead to an out of memory condition.
6. Fixed a bug in the `aurora_replica_status()` function where the `server_id` field was sometimes truncated.
7. Fixed a bug where a log record was incorrectly processed causing the Aurora replica to crash.
8. Fixed an S3 import bug that reported ERROR: HTTP 403. Permission denied when importing data from a file inside an S3 subfolder.

10. Fixed a bug in the `aws_s3` extension that could result in the error message S3 bucket names with a period (.) are not supported.

11. Fixed a race condition that caused valid imports to intermittently fail.

12. Fixed a bug related to replication when Aurora PostgreSQL is acting as a physical replica of an RDS PostgreSQL instance that uses GiST indexes. In rare cases, this bug caused a brief period of unavailability after promoting the Aurora DB cluster.

13. Fixed a bug in the `aws_s3` extension where an import may be blocked indefinitely if an exclusive lock was taken on the relation prior to beginning the operation.

**Aurora PostgreSQL release 2.6.1**

You can find the following improvements in this release.

**Critical stability enhancements**

1. Fixed a bug that appears when the `NOT EXISTS` operator incorrectly returns TRUE, which can only happen when the following unusual set of circumstances occurs:
   - A query is using the `NOT EXISTS` operator.
   - The column or columns being evaluated against the outer query in the `NOT EXISTS` subquery contain a NULL value.
   - There isn’t another predicate in the subquery that removes the need for the evaluation of the NULL values.
   - The filter used in the subquery does not use an index seek for its execution.
   - The operator isn’t converted to a join by the query optimizer.

**Aurora PostgreSQL release 2.6.0**

You can find the following improvements in this release.

**New features**

1. Added support for the RDKit extension version 3.8.

   The RDKit extension provides modeling functions for cheminformatics. Cheminformatics is storing, indexing, searching, retrieving, and applying information about chemical compounds. For example, with the RDKit extension you can construct models of molecules, search for molecular structures, and read or create molecules in various notations. You can also perform research on data loaded from the ChEMBL website or a SMILES file. The Simplified Molecular Input Line Entry System (SMILES) is a typographical notation for representing molecules and reactions. For more information, see The RDKit database cartridge in the RDKit documentation.

2. Added support for the `pglogical` extension version 2.2.2.

   The `pglogical` extension is a logical streaming replication system that provides additional features beyond what’s available in PostgreSQL native logical replication. Features include conflict handling, row filtering, DDL/sequence replication and delayed apply. You can use the `pglogical` extension to set up replication between Aurora PostgreSQL clusters, between RDS PostgreSQL and Aurora PostgreSQL, and with PostgreSQL databases running outside of RDS.

3. Aurora dynamically resizes your cluster storage space. With dynamic resizing, the storage space for your Aurora DB cluster automatically decreases when you remove data from the DB cluster. For more information, see Storage scaling (p. 392).
Note
The dynamic resizing feature is being deployed in phases to the AWS Regions where Aurora is available. Depending on the Region where your cluster is, this feature might not be available yet. For more information, see the What’s New announcement.

Critical stability enhancements

1. Fixed a bug related to heap page extend that in rare cases resulted in longer recovery time and impacted availability.

High priority stability enhancements

1. Fixed a bug when upgrading Aurora Global Database clusters from 10.11.
2. Fixed a bug in Aurora Global Database that could cause delays in upgrading the database engine in a secondary AWS Region. For more information, see Using Amazon Aurora global databases (p. 223).
3. Fixed a bug that in rare cases caused delays in upgrading a database to engine version 10.13.

Additional improvements and enhancements

1. Fixed a bug where the Aurora replica crashed when workloads with heavy subtransactions are made on the writer instance.
2. Fixed a bug where the writer instance crashed due to a memory leak and the depletion of memory used to track active transactions.
3. Fixed a bug that lead to a crash due to improper initialization when there is no free memory available during PostgreSQL backend startup.
4. Fixed a bug where an Aurora PostgreSQL Serverless DB cluster might return the following error after a scaling event: ERROR: prepared statement "$_6" already exists.
5. Fixed an out-of-memory problem when issuing the CREATE EXTENSION command with PostGIS when Database Activity Streams enabled.
6. Fixed a bug where a SELECT query might incorrectly return the error Attempting to read past EOF of relation rrrr. blockno=bbb nblocks=nnn.
7. Fixed a bug where the database might be unavailable briefly due to error handling in database storage growth.
8. Fixed a bug in Aurora PostgreSQL Serverless where queries that executed on previously idle connections got delayed until the scale operation completed.
9. Fixed a bug where an Aurora PostgreSQL DB cluster with Database Activity Streams enabled might report the beginning of a potential loss window for activity records, but does not report the restoration of connectivity.

PostgreSQL 10.12, Aurora PostgreSQL release 2.5

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.12. For more information about the improvements in PostgreSQL 10.12, see PostgreSQL release 10.12.

Patch releases

- Aurora PostgreSQL release 2.5.7 (p. 1559)
- Aurora PostgreSQL release 2.5.6 (p. 1559)
- Aurora PostgreSQL release 2.5.4 (p. 1560)
- Aurora PostgreSQL release 2.5.3 (p. 1560)
• Aurora PostgreSQL release 2.5.2 (p. 1560)
• Aurora PostgreSQL release 2.5.1 (p. 1561)

### Aurora PostgreSQL release 2.5.7

You can find the following improvements in this release.

**Critical stability enhancements**

- None

**High priority stability enhancements**

1. Backported fixes for the following PostgreSQL community security issues:
   - CVE-2020-25694
   - CVE-2020-25695
   - CVE-2020-25696

**Additional improvements and enhancements**

- None

### Aurora PostgreSQL release 2.5.6

You can find the following improvements in this release.

**Critical stability enhancements**

- None

**High priority stability enhancements**

1. Fixed a bug in Aurora PostgreSQL replication that might result in the error message, ERROR: MultiXactId nnnn has not been created yet -- apparent wraparound.

**Additional improvements and enhancements**

1. Fixed a bug in Aurora PostgreSQL Serverless where a leaked lock resulted in a prolonged scale event.
2. Fixed a bug where the `aurora_replica_status` function showed truncated server identifiers.
3. Fixed a bug in Aurora PostgreSQL Serverless where connections being migrated during a scale event disconnected with the message: "ERROR: could not open relation with OID ....
4. Fixed a bug in a GiST index that might result in an out of memory condition after promoting an Aurora Read Replica.
5. Improved performance for Database Activity Streams.
6. Fixed a bug in Database Activity Streams where customers were not notified when an outage ended.
7. Fixed a bug in the `aws_s3` extension for pre-signed URL handling that could have resulted in the error message S3 bucket names with a period (.) are not supported.
Fixed a bug in the `aws_s3` extension where incorrect error handling could lead to failures during the import process.

Fixed a bug in the `aws_s3` extension where an import may be blocked indefinitely if an exclusive lock was taken on the relation prior to beginning the operation.

**Aurora PostgreSQL release 2.5.4**

You can find the following improvements in this release.

**Critical stability enhancements**

1. Fixed a bug that appears when the `NOT EXISTS` operator incorrectly returns TRUE, which can only happen when the following unusual set of circumstances occurs:
   - A query is using the `NOT EXISTS` operator.
   - The column or columns being evaluated against the outer query in the `NOT EXISTS` subquery contain a NULL value.
   - There isn’t a another predicate in the subquery that removes the need for the evaluation of the NULL values.
   - The filter used in the subquery does not use an index seek for its execution.
   - The operator isn’t converted to a join by the query optimizer.

**Aurora PostgreSQL release 2.5.3**

You can find the following improvements in this release.

**Critical stability enhancements**

- None

**High priority stability enhancements**

- None

**Additional improvements and enhancements**

1. Fixed a bug in Aurora PostgreSQL Serverless where queries that ran on previously idle connections got delayed until the scale operation completed.
2. Fixed a bug that might cause brief unavailability for heavy subtransaction workloads when multiple reader instances restart or rejoin the cluster.
3. Fixed a bug in Aurora PostgreSQL Global Database where upgrading a secondary cluster might result in failure due to incorrect checksum versioning. This might have required re-creating the secondary clusters.

**Aurora PostgreSQL release 2.5.2**

You can find the following improvements in this release.

**Critical stability enhancements**

1. Fixed a bug related to heap page extend that in rare cases resulted in longer recovery time and impacted availability.
High priority stability enhancements

1. Fixed a bug in Aurora Global Database that could cause delays in upgrading the database engine in a secondary region. For more information, see Using Amazon Aurora global databases (p. 223).
2. Fixed a bug that in rare cases caused delays in upgrading a database to engine version 10.12.

Additional improvements and enhancements

1. Fixed a bug where the database might be unavailable briefly due to error handling in database storage growth.
2. Fixed a bug where a SELECT query might incorrectly return the error, Attempting to read past EOF of relation rrrr. blockno=bbb nblocks=nnn.
3. Fixed a bug where an Aurora PostgreSQL Serverless DB cluster might return the following error after a scaling event: ERROR: prepared statement "S_6" already exists.

Aurora PostgreSQL release 2.5.1

New features

1. Added support for Amazon Aurora PostgreSQL Global Database. For more information, see Using Amazon Aurora global databases (p. 223).
2. Added the ability to configure the recovery point objective (RPO) of a global database for Aurora PostgreSQL. For more information, see Managing RPOs for Aurora PostgreSQL–based global databases (p. 269).

You can find the following improvements in this release.

Critical stability enhancements

None.

High priority stability enhancements

1. Improved performance and availability of read instances when applying DROP TABLE and TRUNCATE TABLE operations.
2. Fixed a small but continuous memory leak in a diagnostic module that could lead to an out-of-memory condition on smaller DB instance types.
3. Fixed a bug in the PostGIS extension which could lead to a database restart. This has been reported to the PostGIS community as https://trac.osgeo.org/postgis/ticket/4646.
4. Fixed a bug where read requests might stop responding due to incorrect error handling in the storage engine.
5. Fixed a bug that fails for some queries and results in the message ERROR: found xmin xxxxxxx from before relfrozenxid yyyyyyy. This could occur following the promotion of a read instance to a write instance.
6. Fixed a bug where an Aurora serverless DB cluster might crash while rolling back a scale attempt.

Additional improvements and enhancements

1. Improved performance for queries that read many rows from storage.
2. Improved performance and availability of reader DB instances during heavy read workload.
3. Enabled correlated IN and NOT IN subqueries to be transformed to joins when possible.
4. Improved read performance of the `pg_prewarm` extension.

5. Fixed a bug where an Aurora serverless DB cluster might report the message `ERROR: incorrect binary data format in bind parameter ... following a scale event`.

6. Fixed a bug where a serverless DB cluster might report the message `ERROR: insufficient data left in message following a scale event`.

7. Fixed a bug where an Aurora serverless DB cluster may experience prolonged or failed scale attempts.

8. Fixed a bug that resulted in the message `ERROR: could not create file "base/xxxxx/yyyyyyy" as a previous version still exists on disk: Success. Please contact AWS customer support. This can occur during object creation after PostgreSQL's 32-bit object identifier has wrapped around`.

9. Fixed a bug where the write-ahead-log (WAL) segment files for PostgreSQL logical replication were not deleted when changing the `wal_level` value from `logical` to `replica`.

10. Fixed a bug in the `pg_hint_plan` extension where a multi-statement query could lead to a crash when `enable_hint_table` is enabled. This is tracked in the PostgreSQL community as [https://github.com/ossc-db/pg_hint_plan/issues/25](https://github.com/ossc-db/pg_hint_plan/issues/25).

11. Fixed a bug where JDBC clients might report the message `java.io.IOException: Unexpected packet type: 75 following a scale event in an Aurora serverless DB cluster`.

12. Fixed a bug in PostgreSQL logical replication that resulted in the message `ERROR: snapshot reference is not owned by resource owner TopTransaction`.

13. Changed the following extensions:
   - Updated `orafce` to version 3.8

### PostgreSQL 10.11, Aurora PostgreSQL release 2.4

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.11. For more information about the improvements in PostgreSQL 10.11, see [PostgreSQL release 10.11](#).

This release contains multiple critical stability enhancements. Amazon highly recommends upgrading your Aurora PostgreSQL clusters that use older PostgreSQL 10 engines to this release.

#### Patch releases

- [Aurora PostgreSQL release 2.4.4](#) (p. 1562)
- [Aurora PostgreSQL release 2.4.3](#) (p. 1563)
- [Aurora PostgreSQL release 2.4.2](#) (p. 1563)
- [Aurora PostgreSQL release 2.4.1](#) (p. 1563)
- [Aurora PostgreSQL release 2.4.0](#) (p. 1564)

### Aurora PostgreSQL release 2.4.4

You can find the following improvements in this release.

#### Critical stability enhancements

- None

#### High priority stability enhancements

1. Backported fixes for the following PostgreSQL community security issues:
   - [CVE-2020-25694](#)
   - [CVE-2020-25695](#)
   - [CVE-2020-25696](#)
Additional improvements and enhancements

• None

Aurora PostgreSQL release 2.4.3

New features

1. Aurora PostgreSQL now supports the PostgreSQL vacuum_truncate storage parameter to manage vacuum truncation for specific tables. Set this storage parameter to false for a table to prevent the VACUUM SQL command from truncating the table's trailing empty pages.

Critical stability enhancements

• None

High priority stability enhancements

1. Fixed a bug where reads from storage might stop responding due to incorrect error handling.

Additional improvements and enhancements

• None

Aurora PostgreSQL release 2.4.2

You can find the following improvements in this release.

Critical stability enhancements

1. Fixed a bug in which a reader DB instance might temporarily use stale data. This could lead to wrong results such as too few or too many rows. This error is not persisted on storage, and will clear when the database page containing the row has been evicted from cache. This can happen when the primary DB instance enters a transaction snapshot overflow due to having more than 64 subtransactions in a single transaction. Applications susceptible to this bug include those that use SQL savepoints or PostgreSQL exception handlers with more than 64 subtransactions in the top transaction.

High priority stability enhancements

1. Fixed a bug that may cause a reader DB instance to crash causing unavailability while attempting to join the DB cluster. This can happen in some cases when the primary DB instance has a transaction snapshot overflow due to a high number of subtransactions. In this situation the reader DB instance will be unable to join until the snapshot overflow has cleared.

Additional improvements and enhancements

1. Fixed a bug that prevented Performance Insights from determining the query ID of a running statement.

Aurora PostgreSQL release 2.4.1

You can find the following improvements in this release.
Critical stability enhancements

1. Fixed a bug in which the DB instance might be briefly unavailable due to the self-healing function of the underlying storage.

High priority stability enhancements

1. Fixed a bug that might cause the database engine to crash causing unavailability. This occurred if a newly established database connection encountered a resource exhaustion-related error during initialization after successful authentication.

Additional improvements and enhancements

1. Provided a fix for the `pg_hint_plan` extension that could lead the database engine to crash causing unavailability. The open source issue can be tracked at https://github.com/ossc-db/pg_hint_plan/pull/45.
2. Fixed a bug where SQL of the form `ALTER FUNCTION ... OWNER TO ...` incorrectly reported `ERROR: improper qualified name (too many dotted names)`.
3. Improved the performance of GIN index vacuum via prefetching.
4. Fixed a bug in open source PostgreSQL that could lead to a database engine crash causing unavailability. This occurred during parallel B-Tree index scans. This issue has been reported to the PostgreSQL community.
5. Improved the performance of in-memory B-Tree index scans.
6. Additional general improvements to the stability and availability of Aurora PostgreSQL.

Aurora PostgreSQL release 2.4.0

You can find the following new features and improvements in this engine version.

New features

1. Support for exporting data to Amazon S3. For more information, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 (p. 1391).
2. Support for Amazon Aurora Machine Learning. For more information, see Using machine learning (ML) with Aurora PostgreSQL (p. 1435).
3. SQL processing enhancements include:
   - Optimizations for `NOT IN` with the `apg_enable_not_in_transform` parameter.
   - Semi-join filter pushdown enhancements for hash joins with the `apg_enable_semi_join_push_down` parameter.
   - Optimizations for redundant inner join removal with the `apg_enable_remove_redundant_inner_joins` parameter.
   - Improved ANSI compatibility options with the `ansi_constraint_trigger_ordering`, `ansi_force_foreign_key_checks` and `ansi_qualified_update_set_target` parameters.
   For more information, see Amazon Aurora PostgreSQL parameters (p. 1487).
4. New and updated PostgreSQL extensions include:
   - The new `aws_ml` extension. For more information, see Using machine learning (ML) with Aurora PostgreSQL (p. 1435).
   - The new `aws_s3` extension. For more information, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3 (p. 1391).
   - Updates to the `apg_plan_mgmt` extension. For more information, see Managing query execution plans for Aurora PostgreSQL (p. 1401)
Critical stability enhancements

1. Fixed a bug related to creating B-tree indexes on temporary tables that in rare cases may result in longer recovery time, and impact availability.
2. Fixed a bug related to replication when Aurora PostgreSQL is acting as a physical replica of an RDS PostgreSQL instance. In rare cases, this bug causes a log write failure that may result in longer recovery time, and impact availability.
3. Fixed a bug related to handling of reads with high I/O latency that in rare cases may result in longer recovery time, and impact availability.

High priority stability enhancements

1. Fixed a bug related to logical replication in which wal segments are not properly removed from storage. This can result in storage bloat. To monitor this, view the TransactionLogDiskUsage parameter.
2. Fixed multiple bugs, which cause Aurora to crash during prefetch operations on Btree indexes.
3. Fixed a bug in which an Aurora restart may timeout when logical replication is used.
4. Enhanced the validation checks performed on data blocks in the buffer cache. This improves Aurora's detection of inconsistency.

Additional improvements and enhancements

1. The query plan management extension apg_plan_mgmt has an improved algorithm for managing plan generation for highly partitioned tables.
2. Reduced startup time on instances with large caches via improvements in the buffer cache recovery algorithm.
3. Improved the performance of the read-node-apply process under high transaction rate workloads by using changes to PostgreSQL LWLock prioritization. These changes prevent starvation of the read-node-apply process while the PostgreSQL ProcArray is under heavy contention.
4. Improved handling of batch reads during vacuum, table scans, and index scans. This results in greater throughput and lower CPU consumption.
5. Fixed a bug in which a read node may crash during the replay of a PostgreSQL SLRU-truncate operation.
6. Fixed a bug where in rare cases, database writes may stall following an error returned by one of the six copies of an Aurora log record.
7. Fixed a bug related to logical replication where an individual transaction larger than 1 GB in size may result in an engine crash.
8. Fixed a memory leak on read nodes when cluster cache management is enabled.
9. Fixed a bug in which importing an RDS PostgreSQL snapshot might stop responding if the source snapshot contains a large number of unlogged relations.
10. Fixed a bug in which the Aurora storage daemon may crash under heavy I/O load.
11. Fixed a bug related to hot_standby_feedback for read nodes in which the read node may report the wrong transaction id epoch to the write node. This can cause the write node to ignore the hot_standby_feedback and invalidate snapshots on the read node.
12. Fixed a bug in which storage errors that occur during CREATE DATABASE statements are not properly handled. The bug left the resulting database inaccessible. The correct behavior is to fail the database creation and return the appropriate error to the user.
13. Improved handling of PostgreSQL snapshot overflow when a read node attempts to connect to a write node. Prior to this change, if the write node was in a snapshot overflow state, the read node was unable to join. A message appeared in the PostgreSQL log file in the form DEBUG: recovery
snapshot waiting for non-overflowed snapshot or until oldest active xid on standby is at least \texttt{xxxxxxx} (now \texttt{yyyyyy}). A snapshot overflow occurs when an individual transaction has created over 64 subtransactions.

14 Fixed a bug related to common table expressions in which an error is incorrectly raised when a NOT IN class exists in a CTE. The error is \texttt{CTE with NOT IN fails with ERROR: could not find CTE CTE-Name}.

15 Fixed a bug related to an incorrect last_error_timestamp value in the \texttt{aurora_replica_status} table.

16 Fixed a bug to avoid populating shared buffers with blocks belonging to temporary objects. These blocks correctly reside in PostgreSQL backend local buffers.

17 Improved the performance of vacuum cleanup on GIN indexes.

18 Fixed a bug where in rare cases Aurora may exhibit 100% CPU utilization while acting as a replica of an RDS PostgreSQL instance even when the replication stream is idle.

19 Backported a change from PostgreSQL 11 which improves the cleanup of orphaned temporary tables. Without this change, it is possible that in rare cases orphaned temporary tables can lead to transaction ID wraparound. For more information, see this PostgreSQL community commit.

20 Fixed a bug where a Writer instance may accept replication registration requests from Reader instances while having an uninitialized startup process.

21 Changed the following extensions:
   - Updated \texttt{pg_hint_plan} to version 1.3.3.
   - Added \texttt{plprofiler} version 4.1.

For information about extensions and modules, see Extensions supported for Aurora PostgreSQL 10.x (p. 1598).

**PostgreSQL 10.7, Aurora PostgreSQL release 2.3 (unsupported)**

**Note**

The PostgreSQL engine version 10.7 with the Aurora PostgreSQL release 2.3 is no longer supported. To upgrade, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605).

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.7. For more information about the improvements in PostgreSQL 10.7, see PostgreSQL release 10.7.

**Patch releases**

- Aurora PostgreSQL release 2.3.5 (p. 1566)
- Aurora PostgreSQL release 2.3.3 (p. 1567)
- Aurora PostgreSQL release 2.3.1 (p. 1567)
- Aurora PostgreSQL release 2.3.0 (p. 1567)

**Aurora PostgreSQL release 2.3.5**

You can find the following improvements in this release.

**Improvements**

1. Fixed a bug that could cause DB instance restarts.
2. Fixed a bug that could cause a crash when the PostgreSQL backend exits while using logical replication.
3. Fixed a bug that could cause a restart when reads occurred during failovers.
4. Fixed a bug with the wal2json module for logical replication.
5. Fixed a bug that could result in inconsistent metadata.

**Aurora PostgreSQL release 2.3.3**

You can find the following improvements in this release.

**Improvements**

3. Fixed a bug in which data activity streaming could consume excessive CPU time.
4. Fixed a bug in which parallel threads scanning a B-tree index might stop responding following a disk read.
5. Fixed a bug where use of the `not in` predicate against a common table expression (CTE) could return the following error: "ERROR: bad levelsup for CTE".
6. Fixed a bug in which the read node replay process might stop responding while applying a modification to a generalized search tree (GiST) index.
7. Fixed a bug in which visibility map pages could contain incorrect freeze bits following a failover to a read node.
8. Optimized log traffic between the write node and read nodes during index maintenance.
9. Fixed a bug in which queries on read nodes may crash while performing a B-tree index scan.
10. Fixed a bug in which a query that has been optimized for redundant inner join removal could crash.
11. The function `aurora_stat_memctx_usage` now reports the number of instances of a given context name.
12. Fixed a bug in which the function `aurora_stat_memctx_usage` reported incorrect results.
13. Fixed a bug in which the read node replay process could wait to stop conflicting queries beyond the configured `max_standby_streaming_delay` value.
14. Additional information is now logged on read nodes when active connections conflict with the relay process.
15. Provided a backport fix for the PostgreSQL community bug #15677, where a crash could occur while deleting from a partitioned table.

**Aurora PostgreSQL release 2.3.1**

You can find the following improvements in this release.

**Improvements**

1. Fixed multiple bugs related to I/O prefetching that caused engine crashes.

**Aurora PostgreSQL release 2.3.0**

You can find the following improvements in this release.

**New features**

1. Aurora PostgreSQL now performs I/O prefetching while scanning B-tree indexes. This results in significantly improved performance for B-tree scans over uncached data.
Improvements

1. Fixed a bug in which read nodes may fail with the error "too many LWLocks taken".
2. Addressed numerous issues that caused read nodes to fail to startup while the cluster is under heavy write workload.
3. Fixed a bug in which usage of the aurora_stat_memctx_usage() function could lead to a crash.
4. Improved the cache replacement strategy used by table scans to minimize thrashing of the buffer cache.

PostgreSQL 10.6, Aurora PostgreSQL release 2.2 (unsupported)

Note
The PostgreSQL engine version 10.6 with the Aurora PostgreSQL release 2.2 is no longer supported. To upgrade, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605).

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.6. For more information about the improvements in PostgreSQL 10.6, see PostgreSQL release 10.6.

Patch releases
- Aurora PostgreSQL release 2.2.1 (p. 1568)
- Aurora PostgreSQL release 2.2.0 (p. 1568)

Aurora PostgreSQL release 2.2.1

You can find the following improvements in this release.

Improvements

1. Improved stability of logical replication.
2. Fixed a bug which could cause an error running queries. The message reported was of the form "CLOG segment 123 does not exist: No such file or directory".
3. Increased the supported size of IAM passwords to 8KB.
4. Improved consistency of performance under high throughput write workloads.
5. Fixed a bug which could cause a read replica to crash during a restart.
6. Fixed a bug which could cause an error running queries. The message reported was of the form "SQL ERROR: Attempting to read past EOF of relation".
7. Fixed a bug which could cause an increase in memory usage after a restart.
8. Fixed a bug which could cause a transaction with a large number of subtransactions to fail.
9. Merged a patch from community PostgreSQL which addresses potential failures when using GIN indexes. For more information see https://git.postgresql.org/gitweb/?p=postgresql.git;a=commit;h=f9e66f2fbbb49a493045c8d8086a9b15d95b8f18.
10. Fixed a bug which could cause a snapshot import from RDS for PostgreSQL to fail.

Aurora PostgreSQL release 2.2.0

You can find the following improvements in this release.

New features

1. Added the restricted password management feature. Restricted password management enables you to restrict who can manage user passwords and password expiration changes by using the parameter
rds.restrict_password_commands and the role rds_password. For more information, see Restricting password management (p. 1229).

PostgreSQL 10.5, Aurora PostgreSQL release 2.1 (unsupported)

Note
The PostgreSQL engine version 10.5 with the Aurora PostgreSQL release 2.1 is no longer supported. To upgrade, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605).

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.5. For more information about the improvements in PostgreSQL 10.5, see PostgreSQL release 10.5.

Patch releases
• Aurora PostgreSQL release 2.1.1 (p. 1569)
• Aurora PostgreSQL release 2.1.0 (p. 1569)

Aurora PostgreSQL release 2.1.1

You can find the following improvements in this release.

Improvements
1. Fixed a bug which could cause an error running queries. The message reported was of the form "CLOG segment 123 does not exist: No such file or directory".
2. Increased the supported size of IAM passwords to 8KB.
3. Improved consistency of performance under high throughput write workloads.
4. Fixed a bug which could cause a read replica to crash during a restart.
5. Fixed a bug which could cause an error running queries. The message reported was of the form "SQL ERROR: Attempting to read past EOF of relation".
6. Fixed a bug which could cause an increase in memory usage after a restart.
7. Fixed a bug which could cause a transaction with a large number of subtransactions to fail.
8. Merged a patch from community PostgreSQL which addresses potential failures when using GIN indexes. For more information see https://git.postgresql.org/gitweb/?p=postgresql.git;a=commit;h=f9e66f2fbbb49a493045c8d8086a9b15d95b8f18.
9. Fixed a bug which could cause a snapshot import from RDS for PostgreSQL to fail.

For information about extensions and modules, see Extensions supported for Aurora PostgreSQL 10.x (p. 1598).

Aurora PostgreSQL release 2.1.0

You can find the following improvements in this release.

New features
1. General availability of Aurora Query Plan Management, which enables customers to track and manage any or all query plans used by their applications, to control query optimizer plan selection, and to ensure high and stable application performance. For more information, see Managing query execution plans for Aurora PostgreSQL (p. 1401).
2. Updated the libprotobuf extension to version 1.3.0. This is used by the PostGIS extension.
3. Updated the pg_similarity extension to version 1.0.
4. Updated the log_fdw extension to version 1.1.
5. Updated the `pg_hint_plan` extension to version 1.3.1.

**Improvements**

1. Network traffic between the writer and reader nodes is now compressed to reduce network utilization. This reduces the chance of read node unavailability due to network saturation.
2. Implemented a high performance, scalable subsystem for PostgreSQL subtransactions. This improves the performance of applications which make extensive use of savepoints and PL/pgSQL exception handlers.
3. The `rds_superuser` role can now set the following parameters on a per-session, database, or role level:
   - `log_duration`
   - `log_error_verbosity`
   - `log_executor_stats`
   - `log_lock_waits`
   - `log_min_duration_statement`
   - `log_min_error_statement`
   - `log_min_messages`
   - `log_parser_stats`
   - `log_planner_stats`
   - `log_replication_commands`
   - `log_statement_stats`
   - `log_temp_files`
4. Fixed a bug in which the SQL command "ALTER FUNCTION ... OWNER TO ..." might fail with error "improper qualified name (too many dotted names).
5. Fixed a bug in which a crash could occur while committing a transaction with more than two million subtransactions.
6. Fixed a bug in community PostgreSQL code related to GIN indexes which can cause the Aurora Storage volume to become unavailable.
7. Fixed a bug in which an Aurora PostgreSQL replica of an RDS for PostgreSQL instance might fail to start, reporting error: "PANIC: could not locate a valid checkpoint record".
8. Fixed a bug in which passing an invalid parameter to the `aurora_stat_backend_waits` function could cause a crash.

**Known issues**

1. The `pageinspect` extension is not supported in Aurora PostgreSQL.

**PostgreSQL 10.4, Aurora PostgreSQL release 2.0 (unsupported)**

**Note**

The PostgreSQL engine version 10.4 with the Aurora PostgreSQL release 2.0 is no longer supported. To upgrade, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL](p. 1605).

This release of Aurora PostgreSQL is compatible with PostgreSQL 10.4. For more information about the improvements in PostgreSQL 10.4, see [PostgreSQL release 10.4](p. 1605).

**Patch releases**

- [Aurora PostgreSQL release 2.0.1](p. 1571)
Aurora PostgreSQL release 2.0.1

You can find the following improvements in this release.

**Improvements**

1. Fixed a bug which could cause an error running queries. The message reported was of the form "CLOG segment 123 does not exist: No such file or directory".
2. Increased the supported size of IAM passwords to 8KB.
3. Improved consistency of performance under high throughput write workloads.
4. Fixed a bug which could cause a read replica to crash during a restart.
5. Fixed a bug which could cause an error running queries. The message reported was of the form "SQL ERROR: Attempting to read past EOF of relation".
6. Fixed a bug which could cause an increase in memory usage after a restart.
7. Fixed a bug which could cause a transaction with a large number of subtransactions to fail.
8. Merged a patch from community PostgreSQL which addresses potential failures when using GIN indexes. For more information see [https://git.postgresql.org/gitweb/?p=postgresql.git;a=commit;h=f9e66f2fbb49a493045c8d8086a9b15d95b8f18](https://git.postgresql.org/gitweb/?p=postgresql.git;a=commit;h=f9e66f2fbb49a493045c8d8086a9b15d95b8f18).
9. Fixed a bug which could cause a snapshot import from RDS for PostgreSQL to fail.

For information about extensions and modules, see [Extensions supported for Aurora PostgreSQL 10.x](p. 1598).

Aurora PostgreSQL release 2.0.0

You can find the following improvements in this release.

**Improvements**

1. This release contains all fixes, features, and improvements present in PostgreSQL 9.6.9, [Aurora PostgreSQL release 1.3 (unsupported)](p. 1583).
2. The temporary file size limitation is user-configurable. You require the `rds_superuser` role to modify the `temp_file_limit` parameter.
3. Updated the GDAL library, which is used by the PostGIS extension.
4. Updated the ip4r extension to version 2.1.1.
5. Updated the `pg_repack` extension to version 1.4.3.
6. Updated the `plv8` extension to version 2.1.2.
7. Parallel queries – When you create a new Aurora PostgreSQL version 2.0 instance, parallel queries are enabled for the `default.postgres10` parameter group. The parameter `max_parallel_workers_per_gather` is set to 2 by default, but you can modify it to support your specific workload requirements.
8. Fixed a bug in which read nodes may crash following a specific type of free space change from the write node.

PostgreSQL 9.6.22, Aurora PostgreSQL release 1.11

This release of Aurora PostgreSQL is compatible with PostgreSQL 9.6.22. For more information about the improvements in PostgreSQL 9.6.22, see [PostgreSQL release 9.6.22](p. 1598).

**Patch releases**
• Aurora PostgreSQL 1.11.1 (p. 1572)
• Aurora PostgreSQL release 1.11 (p. 1571)

Aurora PostgreSQL 1.11.1

High priority stability enhancements
• Fixed an issue where queries may become unresponsive due to I/O resource exhaustion triggered by prefetch.

Additional improvements and stability enhancements
• Fixed multiple issues in the Aurora storage daemon that could lead to brief periods of unavailability when specific network configurations are used.

Aurora PostgreSQL release 1.11

High priority stability enhancements
1. Fixed an issue where creating a database from an existing template database with tablespace resulted in an error with the message ERROR: could not open file pg_tblspc/...: No such file or directory.
2. Fixed an issue where, in rare cases, an Aurora replica may be unable to start when a large number of PostgreSQL subtransactions (i.e. SQL savepoints) have been used.
3. Fixed an issue where, in rare circumstances, read results may be inconsistent for repeated read requests on replica nodes.

Additional improvements and enhancements
1. Upgraded OpenSSL to 1.1.1k.
2. Reduced CPU usage and memory consumption of the WAL apply process on Aurora replicas for some workloads.
3. Improve safety checks in the write path to detect incorrect writes to metadata.
4. Fixed an issue where a duplicate file entry can prevent the Aurora PostgreSQL engine from starting up.
5. Fixed an issue that could cause temporary unavailability under heavy workloads.
6. Added back ability to use a leading forward slash in the S3 path during S3 import.
7. Updated the PostGIS extension to version 2.4.7.
8. Updated the Oracle extension to version 3.16.

PostgreSQL 9.6.21, Aurora PostgreSQL release 1.10

This release of Aurora PostgreSQL is compatible with PostgreSQL 9.6.21. For more information about the improvements in PostgreSQL 9.6.21, see PostgreSQL release 9.6.21.

Aurora PostgreSQL release 1.10.0

High priority stability enhancements
1. Fixed a bug where in rare cases a reader had inconsistent results when it restarted while a transaction with more than 64 subtransactions was being processed.
2. Backported fixes for the following PostgreSQL community security issues:
   - CVE-2021-32027
   - CVE-2021-32028
   - CVE-2021-32029

Additional improvements and enhancements

1. Fixed a bug where the database could not be started when there were many relations in memory-constrained environments.
2. Fixed a bug in the `apg_plan_mgmt` extension that could cause brief periods of unavailability due to an internal buffer overflow.
3. Fixed a bug where the database engine would attempt to create shared memory segments larger than the instance total memory and fail repeatedly. For example, attempts to create 128 GiB shared buffers on a db.r5.large instance would fail. With this change, requests for total shared memory allocations larger than the instance memory allow setting the instance to incompatible parameters.
4. Added logic to clean up unnecessary `pg_wal` temporary files on a database startup.
5. Fixed a bug in Aurora PostgreSQL 9.6 that sometimes prevented read/write nodes from starting up when inbound replication is used.
6. Fixed a bug that could cause brief periods of unavailability due to running out of memory when creating the `postgis` extension with `pgAudit` enabled.
7. Added btree page checks to detect tuple metadata inconsistency.

PostgreSQL 9.6.19, Aurora PostgreSQL release 1.9

This release of Aurora PostgreSQL is compatible with PostgreSQL 9.6.19. For more information about the improvements in PostgreSQL 9.6.19, see PostgreSQL release 9.6.19.

Patch releases

- Aurora PostgreSQL release 1.9.2 (p. 1573)
- Aurora PostgreSQL release 1.9.1 (p. 1573)
- Aurora PostgreSQL release 1.9.0 (p. 1574)

Aurora PostgreSQL release 1.9.2

High priority stability enhancements

1. Fixed a bug where a reader node might render an extra or missing row if the reader restarted while the writer node is processing a long transaction with more than 64 subtransactions.

Additional improvements and enhancements

1. Fixed a bug where a large S3 import with thousands of clients can cause one or more of the import clients to stop responding.

Aurora PostgreSQL release 1.9.1

Critical stability enhancements

1. Fixed a bug that caused a read replica to unsuccessfully restart repeatedly in rare cases.
Additional improvements and enhancements

1. Fixed a bug that when under heavy load, snapshot import, COPY import, or S3 import stopped responding in rare cases.
2. Fixed a bug where a read replica might not join the cluster when the writer was very busy with a write-intensive workload.

Aurora PostgreSQL release 1.9.0

Critical stability enhancements

• None

High priority stability enhancements

2. Fixed a bug in Aurora PostgreSQL replication that might result in the following error message: ERROR: MultiXactId nnnn has not been created yet -- apparent wraparound

Additional improvements and enhancements

1. Aurora PostgreSQL no longer falls behind on a read node when the backend is blocked writing to the database client.
2. Fixed a bug that in rare cases caused a brief period of unavailability on a read replica when the storage volume grew.
3. Fixed a bug when creating a database that could return the following error: ERROR: could not create directory on local disk.
4. Fixed a bug in the GiST index that could result in an out of memory condition after promoting an Aurora read replica.
5. Fixed a bug related to replication when Aurora PostgreSQL is acting as a physical replica of an RDS PostgreSQL instance that uses GiST indexes. In rare cases, this bug caused a brief period of unavailability after promoting the Aurora cluster.

PostgreSQL 9.6.18, Aurora PostgreSQL release 1.8

This release of Aurora PostgreSQL is compatible with PostgreSQL 9.6.18. For more information about the improvements in PostgreSQL 9.6.18, see PostgreSQL release 9.6.18.

Patch releases

• Aurora PostgreSQL release 1.8.2 (p. 1574)
• Aurora PostgreSQL release 1.8.0 (p. 1575)

There is no version 1.8.1.

Aurora PostgreSQL release 1.8.2

Critical stability enhancements

1. None
High priority stability enhancements

1. Fixed a bug in Aurora PostgreSQL replication that could result in the error message ERROR: MultiXactId nnnn has not been created yet -- apparent wraparound.
2. Backported fixes for the following PostgreSQL community security issues:
   - CVE-2020-25694
   - CVE-2020-25695
   - CVE-2020-25696

Additional improvements and enhancements

1. Aurora PostgreSQL no longer falls behind on a read node when the backend is blocked writing to the database client.
2. Fixed a bug where a DROP DATABASE statement didn't remove any relation files.
3. Fixed a small memory leak in a b-tree index that could lead to an out of memory condition.
4. Fixed a bug in the aurora_replica_status() function where the server_id field was sometimes truncated.
5. Fixed a bug related to replication when Aurora PostgreSQL is acting as a physical replica of an RDS PostgreSQL instance that uses GiST indexes. In rare cases, this bug caused a brief period of unavailability after promoting the Aurora DB cluster.

**Aurora PostgreSQL release 1.8.0**

You can find the following improvements in this release.

Critical stability enhancements

1. Fixed a bug related to heap page extend that in rare cases resulted in longer recovery time and impacted availability.

Additional improvements and enhancements

1. Fixed a bug where the Aurora replica crashed when workloads with heavy subtransactions are made on the writer instance.
2. Fixed a bug where the writer instance crashed due to a memory leak and the depletion of memory used to track active transactions.
3. Fixed a bug that lead to a crash due to improper initialization when there is no free memory available during PostgreSQL backend startup.
4. Fixed a crash during a BTree prefetch that occurred under certain conditions that depended on the shape and data contained in the index.
5. Fixed a bug where a SELECT query might incorrectly return the error Attempting to read past EOF of relation rrr. blockno=bbb nblocks=nnn.
6. Fixed a bug where the database might be unavailable briefly due to error handling in database storage growth.

**PostgreSQL 9.6.17, Aurora PostgreSQL release 1.7**

This release of Aurora PostgreSQL is compatible with PostgreSQL 9.6.17. For more information about the improvements in PostgreSQL 9.6.17, see [PostgreSQL release 9.6.17](https://www.postgresql.org/download/9.6/).

Patch releases
You can find the following improvements in this release.

**Critical stability enhancements**
- None

**High priority stability enhancements**
1. Backported fixes for the following PostgreSQL community security issues:
   - CVE-2020-25694
   - CVE-2020-25695
   - CVE-2020-25696

**Additional improvements and enhancements**
- None

---

**Aurora PostgreSQL release 1.7.6**

You can find the following improvements in this release.

**Critical stability enhancements**
- None

**High priority stability enhancements**
1. Fixed a bug in Aurora PostgreSQL replication that might result in the error message, ERROR: MultiXactId nnnn has not been created yet -- apparent wraparound.

**Additional improvements and enhancements**
1. Fixed a bug that in rare cases caused brief read replica unavailability when storage volume grew.
2. Fixed a bug in a b-tree index read optimization that might have caused a brief period of unavailability.
3. Fixed a bug in a GiST index that might result in an out of memory condition after promoting an Aurora Read Replica.
Critical stability enhancements

• None

High priority stability enhancements

• None

Additional improvements and enhancements

1. Fixed a bug that might cause brief unavailability for heavy subtransaction workloads when multiple reader instances restart or rejoin the cluster.

Aurora PostgreSQL release 1.7.2

You can find the following improvements in this release.

Critical stability enhancements

1. Fixed a bug related to heap page extend that in rare cases resulted in longer recovery time and impacted availability.

High Priority Stability Enhancements

None

Additional improvements and enhancements

1. Fixed a bug where the database might be unavailable briefly due to error handling in database storage growth.
2. Fixed a bug where a SELECT query might incorrectly return the error, Attempting to read past EOF of relation rrr. blockno=bbb nblocks=nnn.
3. Fixed an issue with the internal metrics collector that could result in erratic CPU spikes on database instances.

Aurora PostgreSQL release 1.7.1

You can find the following improvements in this release.

Critical stability enhancements

None.

High priority stability enhancements

1. Improved performance and availability of read instances when applying DROP TABLE and TRUNCATE TABLE operations.
2. Fixed a small but continuous memory leak in a diagnostic module that could lead to an out-of-memory condition on smaller DB instance types.
3. Fixed a bug in the PostGIS extension which could lead to a database restart. This has been reported to the PostGIS community as https://trac.osgeo.org/postgis/ticket/4646.
4. Fixed a bug where read requests might stop responding due to incorrect error handling in the storage engine.
5. Fixed a bug that fails for some queries and results in the message ERROR: found xmin xxxxxx from before relfrozenxid yyyyyyy. This could occur following the promotion of a read instance to a write instance.

**Additional improvements and enhancements**

1. Improved performance for queries that read many rows from storage.
2. Improved performance and availability of reader DB instances during heavy read workload.
3. Fixed a bug that resulted in the message ERROR: could not create file "base/xxxxxx/yyyyyy" as a previous version still exists on disk: Success. Please contact AWS customer support. This can occur during object creation after PostgreSQL's 32-bit object identifier has wrapped around.
4. Fixed a bug in the `pg_hint_plan` extension where a multi-statement query could lead to a crash when `enable_hint_table` is enabled. This is tracked in the PostgreSQL community as [https://github.com/ossc-db/pg_hint_plan/issues/25](https://github.com/ossc-db/pg_hint_plan/issues/25).
5. Changed the following extensions:
   - Updated `orafce` to version 3.8

For information about extensions and modules, see Extensions supported for Aurora PostgreSQL 9.6.x (p. 1600).

**PostgreSQL 9.6.16, Aurora PostgreSQL release 1.6**

This version of Aurora PostgreSQL is compatible with PostgreSQL 9.6.16. For more information about the improvements in release 9.6.16, see PostgreSQL release 9.6.16.

This release contains multiple critical stability enhancements. Amazon highly recommends upgrading your Aurora PostgreSQL clusters that use older PostgreSQL 9.6 engines to this release.

**Patch versions**

- Aurora PostgreSQL release 1.6.4 (p. 1578)
- Aurora PostgreSQL release 1.6.3 (p. 1579)
- Aurora PostgreSQL release 1.6.2 (p. 1579)
- Aurora PostgreSQL release 1.6.1 (p. 1579)
- Aurora PostgreSQL release 1.6.0 (p. 1580)

**Aurora PostgreSQL release 1.6.4**

You can find the following improvements in this release.

**Critical stability enhancements**

- None

**High priority stability enhancements**

1. Backported fixes for the following PostgreSQL community security issues:
   - CVE-2020-25694
   - CVE-2020-25695
   - CVE-2020-25696
Additional improvements and enhancements

- None

**Aurora PostgreSQL release 1.6.3**

**New features**

1. Aurora PostgreSQL now supports the PostgreSQL `vacuum_truncate` storage parameter to manage vacuum truncation for specific tables. Set this storage parameter to false when creating or altering a table to prevent the VACUUM SQL command from truncating the table's trailing empty pages.

**Critical stability enhancements**

- None

**High priority stability enhancements**

1. Fixed a bug where reads from storage might stop responding due to incorrect error handling.

**Additional improvements and enhancements**

- None

**Aurora PostgreSQL release 1.6.2**

You can find the following improvements in this engine update.

**Critical stability enhancements**

1. Fixed a bug in which a reader DB instance might temporarily use stale data. This could lead to wrong results such as too few or too many rows. This error is not persisted on storage, and will clear when the database page containing the row has been evicted from cache. This can happen when the primary DB instance enters a transaction snapshot overflow due to having more than 64 subtransactions in a single transaction. Applications susceptible to this bug include those that use SQL savepoints or PostgreSQL exception handlers with more than 64 subtransactions in the top transaction.

**High priority stability enhancements**

1. Fixed a bug that may cause a reader DB instance to crash causing unavailability while attempting to join the DB cluster. This can happen in some cases when the primary DB instance has a transaction snapshot overflow due to a high number of subtransactions. In this situation the reader DB instance will be unable to join until the snapshot overflow has cleared.

**Additional improvements and enhancements**

1. Fixed a bug that prevented Performance Insights from determining the query ID of a running statement.

**Aurora PostgreSQL release 1.6.1**

You can find the following improvements in this engine update.
Critical stability enhancements
1. None

High priority stability enhancements
1. Fixed a bug that might cause the database engine to crash causing unavailability. This occurred if a newly established database connection encountered a resource exhaustion-related error during initialization after successful authentication.

Additional improvements and enhancements
1. Provided general improvements to the stability and availability of Aurora PostgreSQL.

Aurora PostgreSQL release 1.6.0
You can find the following new features and improvements in this engine version.

New features
1. Updates to the `apg_plan_mgmt` extension. For more information, see Managing query execution plans for Aurora PostgreSQL (p. 1401)

Critical stability enhancements
1. Fixed a bug related to creating B-tree indexes on temporary tables that in rare cases may result in longer recovery time, and impact availability.
2. Fixed a bug related to replication when Aurora PostgreSQL is acting as a physical replica of an RDS PostgreSQL instance. In rare cases, this bug causes a log write failure that may result in longer recovery time, and impact availability.
3. Fixed a bug related to handling of reads with high I/O latency that in rare cases may result in longer recovery time, and impact availability.

High priority stability enhancements
1. Fixed multiple bugs, which cause Aurora to crash during prefetch operations on Btree indexes.
2. Enhanced the validation checks performed on data blocks in the buffer cache. This improves Aurora's detection of inconsistency.

Additional improvements and enhancements
1. The query plan management extension `apg_plan_mgmt` has an improved algorithm for managing plan generation for highly partitioned tables.
2. Reduced startup time on instances with large caches via improvements in the buffer cache recovery algorithm.
3. Improved the performance of the read-node-apply process under high transaction rate workloads by using changes to PostgreSQL LWLock prioritization. These changes prevent starvation of the read-node-apply process while the PostgreSQL ProcArray is under heavy contention.
4. Fixed a bug in which a read node may crash during the replay of a PostgreSQL SLRU-truncate operation.
5. Fixed a bug where in rare cases, database writes might stall following an error returned by one of the six copies of an Aurora log record.
6. Fixed a memory leak on read nodes when cluster cache management is enabled.

7. Fixed a bug in which importing an RDS PostgreSQL snapshot might stop responding if the source snapshot contains a large number of unlogged relations.

8. Fixed a bug related to `hot_standby_feedback` for read nodes in which the read node may report the wrong transaction id epoch to the write node. This can cause the write node to ignore the `hot_standby_feedback` and invalidate snapshots on the read node.

9. Fixed a bug in which storage errors that occur during `CREATE DATABASE` statements are not properly handled. The bug left the resulting database inaccessible. The correct behavior is to fail the database creation and return the appropriate error to the user.

10. Improved handling of PostgreSQL snapshot overflow when a read node attempts to connect to a write node. Prior to this change, if the write node was in a snapshot overflow state, the read node was unable to join. A message appear in the PostgreSQL log file in the form `DEBUG: recovery snapshot waiting for non-overflowed snapshot or until oldest active xid on standby is at least xxxxxxx (now yyyyyyy)`. A snapshot overflow occurs when an individual transaction has created over 64 subtransactions.

11. Fixed a bug related to common table expressions in which an error is incorrectly raised when a NOT IN class exists in a CTE. The error is `CTE with NOT IN fails with ERROR: could not find CTE CTE-Name`.

12. Fixed a bug related to an incorrect `last_error_timestamp` value in the `aurora_replica_status` table.

13. Fixed a bug to avoid populating shared buffers with blocks belonging to temporary objects. These blocks correctly reside in PostgreSQL backend local buffers.

14. Fixed a bug where in rare cases Aurora may exhibit 100% CPU utilization while acting as a replica of an RDS PostgreSQL instance even when the replication stream is idle.

15. Backported a change from PostgreSQL 11 which improves the cleanup of orphaned temporary tables. Without this change, it is possible that in rare cases orphaned temporary tables can lead to transaction ID wraparound. For more information, see this PostgreSQL community commit.

16. Fixed a bug where a Writer instance may accept replication registration requests from Reader instances while having an uninitialized startup process.

17. Changed the following extensions:
   - Updated `pg_hint_plan` to version 1.2.5.

**PostgreSQL 9.6.12, Aurora PostgreSQL release 1.5 (unsupported)**

**Note**
The PostgreSQL engine version 9.6.12 with the Aurora PostgreSQL release 1.5 is no longer supported. To upgrade, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605).

This release of Aurora PostgreSQL is compatible with PostgreSQL 9.6.12. For more information about the improvements in PostgreSQL 9.6.12, see PostgreSQL release 9.6.12.

**Patch releases**
- Aurora PostgreSQL release 1.5.3 (p. 1582)
- Aurora PostgreSQL release 1.5.2 (p. 1582)
- Aurora PostgreSQL release 1.5.1 (p. 1582)
- Aurora PostgreSQL release 1.5.0 (p. 1582)
Aurora PostgreSQL release 1.5.3
You can find the following improvements in this release.

Improvements
1. Fixed a bug that could cause DB instance restarts.
2. Fixed a bug that could cause a restart when reads occurred during failovers.
3. Fixed a bug that could result in inconsistent metadata.

Aurora PostgreSQL release 1.5.2
You can find the following improvements in this release.

Improvements
2. Fixed a bug in which the read node replay process might stop responding while applying a modification to a generalized search tree (GiST) index.
3. Fixed a bug in which visibility map pages may contain incorrect freeze bits following a failover to a read node.
4. Fixed a bug in which the error "relation relation-name does not exist" is incorrectly reported.
5. Optimized log traffic between the write node and read nodes during index maintenance.
6. Fixed a bug in which queries on read nodes may crash while performing a B-tree index scan.
7. The function aurora_stat_memctx_usage now reports the number of instances of a given context name.
8. Fixed a bug in which the function aurora_stat_memctx_usage reported incorrect results.
9. Fixed a bug in which the read node replay process may wait to stop conflicting queries beyond the configured max_standby_streaming_delay.
10. Additional information is now logged on read nodes when active connections conflict with the relay process.

Aurora PostgreSQL release 1.5.1
You can find the following improvements in this release.

Improvements
1. Fixed multiple bugs related to I/O prefetching, which caused engine crashes.

Aurora PostgreSQL release 1.5.0
You can find the following improvements in this release.

New features
1. Aurora PostgreSQL now performs I/O prefetching while scanning B-tree indexes. This results in significantly improved performance for B-tree scans over uncached data.

Improvements
1. Addressed numerous issues that caused read nodes to fail to startup while the cluster is under heavy write workload.
2. Fixed a bug in which usage of the `aurora_stat_memctx_usage()` function could lead to a crash.
3. Improved the cache replacement strategy used by table scans to minimize thrashing of the buffer cache.

**PostgreSQL 9.6.11, Aurora PostgreSQL release 1.4 (unsupported)**

**Note**
The PostgreSQL engine version 9.6.11 with the Aurora PostgreSQL release 1.4 is no longer supported. To upgrade, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL](p. 1605).

This release of Aurora PostgreSQL is compatible with PostgreSQL 9.6.11. For more information about the improvements in PostgreSQL 9.6.11, see [PostgreSQL release 9.6.11](p. 1583).

You can find the following improvements in this release.

**New features**
1. Support is added for the `pg_similarity` extension version 1.0.
2. Aurora PostgreSQL now supports the PostgreSQL `vacuum_truncate` storage parameter to manage vacuum truncation for specific tables. Set this storage parameter to false when creating or altering a table to prevent the VACUUM SQL command from truncating the table's trailing empty pages.

**Improvements**
1. This release contains all fixes, features, and improvements present in PostgreSQL 9.6.9, Aurora PostgreSQL release 1.3 (unsupported) (p. 1583).
2. Network traffic between the writer and reader nodes is now compressed to reduce network utilization. This reduces the chance of read node unavailability due to network saturation.
3. Performance of subtransactions has improved under high concurrency workloads.
4. An update for the `pg_hint_plan` extension to version 1.2.3.
5. Fixed an issue where on a busy system, a commit with millions of subtransactions (and sometimes with commit timestamps enabled) can cause Aurora to crash.
6. Fixed an issue where an `INSERT` statement with `VALUES` could fail with the message "Attempting to read past EOF of relation".
7. An upgrade of the `apg_plan_mgmt` extension to version 1.0.1. For details, see [Version 1.0.1 of the Aurora PostgreSQL apg_plan_mgmt extension](p. 1603).

The `apg_plan_mgmt` extension is used with query plan management. For more about how to install, upgrade, and use the `apg_plan_mgmt` extension, see [Managing query execution plans for Aurora PostgreSQL](p. 1401).

For information about extensions and modules, see [Extensions supported for Aurora PostgreSQL 9.6.x](p. 1600).

**PostgreSQL 9.6.9, Aurora PostgreSQL release 1.3 (unsupported)**

**Note**
The PostgreSQL engine version 9.6.9 with the Aurora PostgreSQL release 1.3 is no longer supported. To upgrade, see [Upgrading the PostgreSQL DB engine for Aurora PostgreSQL](p. 1605).
This release of Aurora PostgreSQL is compatible with PostgreSQL 9.6.9. For more information about the improvements in PostgreSQL 9.6.9, see PostgreSQL release 9.6.9.

Patch releases

- Aurora PostgreSQL release 1.3.2 (p. 1584)
- Aurora PostgreSQL release 1.3.0 (p. 1584)

Aurora PostgreSQL release 1.3.2

You can find the following improvements in this release.

New features

1. Added the ProcArrayGroupUpdate wait event.

Improvements

1. Fixed a bug which could cause an error running queries. The message reported was of the form "CLOG segment 123 does not exist: No such file or directory".
2. Increased the supported size of IAM passwords to 8KB.
3. Improved consistency of performance under high throughput write workloads.
4. Fixed a bug which could cause a read replica to crash during a restart.
5. Fixed a bug which could cause an error running queries. The message reported was of the form "SQL ERROR: Attempting to read past EOF of relation".
6. Fixed a bug which could cause an increase in memory usage after a restart.
7. Fixed a bug which could cause a transaction with a large number of subtransactions to fail.
8. Merged a patch from community PostgreSQL which addresses potential failures when using GIN indexes. For more information see https://git.postgresql.org/gitweb/?p=postgresql.git;a=commit;h=f9e66f2fbbb49a493045c8d8086a9b15d95b8f18.
9. Fixed a bug which could cause a snapshot import from RDS for PostgreSQL to fail.

Aurora PostgreSQL release 1.3.0

You can find the following improvements in this release.

Improvements

1. This release contains all fixes, features, and improvements present in PostgreSQL 9.6.8, Aurora PostgreSQL release 1.2 (unsupported) (p. 1585).
2. Updated the GDAL library, which is used by the PostGIS extension.
3. Updated the following PostgreSQL extensions:
   - ip4r updated to version 2.1.1.
   - pgaudit updated to version 1.1.1.
   - pg_repack updated to version 1.4.3.
   - plv8 updated to version 2.1.2.
4. Fixed an issue in the monitoring system that could incorrectly cause a failover when local disk usage is high.
5. Fixed a bug in which Aurora PostgreSQL can repeatedly crash, reporting:

   PANIC: new_record_total_len (8201) must be less than BLCKSZ (8192), rmid (6), info (32)
6. Fixed a bug in which an Aurora PostgreSQL read node might be unable to rejoin a cluster due to recovery of a large buffer cache. This issue is unlikely to occur on instances other than r4.16xlarge.

7. Fixed a bug in which inserting into an empty GIN index leaf page imported from pre-9.4 engine versions can cause the Aurora storage volume to become unavailable.

8. Fixed a bug in which, in rare circumstances, a crash during transaction commit could result in the loss of CommitTs data for the committing transaction. The actual durability of the transaction was not impacted by this bug.

9. Fixed a bug in the PostGIS extension in which PostGIS can crash in the function gserialized_gist_picksplit_2d().

10. Improved the stability of read-only nodes during heavy write traffic on instances smaller than r4.8xl. This specifically addresses a situation where the network bandwidth between the writer and the reader is constrained.

11. Fixed a bug in which an Aurora PostgreSQL instance acting as a replication target of an RDS for PostgreSQL instance crashed with the following error:

    FATAL: could not open file "base/16411/680897_vm": No such file or directory
    during "xlog redo at 782/3122D540 for Storage/TRUNCATE"

12. Fixed a memory leak on read-only nodes in which the heap size for the "aurora wal replay process" will continue to grow. This is observable via Enhanced Monitoring.

13. Fixed a bug in which Aurora PostgreSQL can fail to start, with the following message reported in the PostgreSQL log:

    FATAL: Storage initialization failed.

14. Fixed a performance limitation on heavy write workloads that caused waits on the LWLock:buffer_content and IO:ControlFileSyncUpdate events.

15. Fixed a bug in which read nodes could crash following a specific type of free space change from the write node.

**PostgreSQL 9.6.8, Aurora PostgreSQL release 1.2 (unsupported)**

**Note**

The PostgreSQL engine version 9.6.8 with the Aurora PostgreSQL release 1.2 is no longer supported. To upgrade, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605).

For more information about PostgreSQL 9.6.8, see PostgreSQL release 9.6.8.

**Patch releases**

- Aurora PostgreSQL release 1.2.2 (p. 1585)
- Aurora PostgreSQL release 1.2.0 (p. 1586)

**Aurora PostgreSQL release 1.2.2**

You can find the following improvements in this release.

**New features**

1. Added the ProcArrayGroupUpdate wait event.

**Improvements**

1. Fixed a bug which could cause an error running queries. The message reported was of the form "CLOG segment 123 does not exist: No such file or directory".
2. Increased the supported size of IAM passwords to 8KB.
3. Improved consistency of performance under high throughput write workloads.
4. Fixed a bug which could cause a read replica to crash during a restart.
5. Fixed a bug which could cause an error running queries. The message reported was of the form "SQL ERROR: Attempting to read past EOF of relation".
6. Fixed a bug which could cause an increase in memory usage after a restart.
7. Fixed a bug which could cause a transaction with a large number of subtransactions to fail.
8. Merged a patch from community PostgreSQL which addresses potential failures when using GIN indexes. For more information see https://git.postgresql.org/gitweb/?p=postgresql.git;a=commit;h=f9e66f2fbbb49a493045c8d8086a9b15d95b8f18.
9. Fixed a bug which could cause a snapshot import from RDS for PostgreSQL to fail.

Aurora PostgreSQL release 1.2.0

You can find the following improvements in this release.

New features

1. Introduced the `aurora_stat_memctx_usage()` function. This function reports internal memory context usage for each PostgreSQL backend. You can use this function to help determine why certain backends are consuming large amounts of memory.

Improvements

1. This release contains all fixes, features, and improvements present in PostgreSQL 9.6.6 Aurora PostgreSQL release 1.1 (unsupported) (p. 1587).
2. Updates the following PostgreSQL extensions:
   - `pg_hint_plan` updated to version 1.2.2
   - `plv8` updated to version 2.1.0
3. Improves efficiency of traffic between writer and reader nodes.
4. Improves connection establishment performance.
5. Improve the diagnostic data provided in the PostgreSQL error log when an out-of-memory error is encountered.
6. Multiple fixes to improve the reliability and performance of snapshot import from Amazon RDS for PostgreSQL to Aurora PostgreSQL-Compatible Edition.
7. Multiple fixes to improve the reliability and performance of Aurora PostgreSQL read nodes.
8. Fixes a bug in which an otherwise idle instance can generate unnecessary read traffic on an Aurora storage volume.
9. Fixes a bug in which duplicate sequence values can be encountered during insert. The problem only occurs when migrating a snapshot from RDS for PostgreSQL to Aurora PostgreSQL. The fix prevents the problem from being introduced when performing the migration. Instances migrated before this release can still encounter duplicate key errors.
10. Fixes a bug in which an RDS for PostgreSQL instance migrated to Aurora PostgreSQL using replication can run out of memory doing insert/update of GIST indexes, or cause other issues with GIST indexes.
11. Fixes a bug in which vacuum can fail to update the corresponding `pg_database.datfrozenxid` value for a database.
12. Fixes a bug in which a crash while creating a new MultiXact (contended row level lock) can cause Aurora PostgreSQL to stop responding indefinitely on the first access to the same relation after the engine restarts.
13. Fixes a bug in which a PostgreSQL backend can't be terminated or canceled while invoking an `fdisable` call.
14Fixes a bug in which one vCPU is fully utilized at all times by the Aurora storage daemon. This issue is especially noticeable on smaller instance classes, such as r4.large, where it can lead to 25–50 percent CPU usage when idle.
15Fixes a bug in which an Aurora PostgreSQL writer node can fail over spuriously.
16Fixes a bug in which, in a rare scenario, an Aurora PostgreSQL read node can report:

"FATAL: lock buffer_io is not held"
17Fixes a bug in which stale relcache entries can halt vacuuming of relations and push the system close to transaction ID wraparound. The fix is a port of a PostgreSQL community patch scheduled to be released in a future minor version.
18Fixes a bug in which a failure while extending a relation can cause Aurora to crash while scanning the partially extended relation.

**PostgreSQL 9.6.6 Aurora PostgreSQL release 1.1 (unsupported)**

**Note**
The PostgreSQL engine version 9.6.6 with the Aurora PostgreSQL release 1.1 is no longer supported. To upgrade, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605).

For more information about PostgreSQL 9.6.6 see, PostgreSQL release 9.6.6.

You can find the following improvements in this engine update:

**New features**
1. Introduced the *aurora_stat_utils* extension. This extension includes two functions:
   • *aurora_wait_report()* function for wait event monitoring
   • *aurora_log_report()* for log record write monitoring
2. Added support for the following extensions:
   • orafce 3.6.1
   • pgrouting 2.4.2
   • postgresql-hll 2.10.2
   • prefix 1.2.6

**Improvements**
1. This release contains all fixes, features, and improvements present in Aurora PostgreSQL release 1.0.11 (p. 1588)
2. Updates for the following PostgreSQL extensions:
   • postgis extension updated to version 2.3.4
   • geos library updated to version 3.6.2
   • pg_repack updated to version 1.4.2
3. Access to the pg_statistic relation enabled.
4. Disabled the 'effective_io_concurrency' guc parameter, as it does not apply to Aurora storage.
5. Changed the 'hot_standby_feedback' guc parameter to not-modifiable and set the value to ‘1’.
6. Improved heap page read performance during a vacuum operation.
7. Improved performance of snapshot conflict resolution on read nodes.
8. Improved performance of transaction snapshot acquisition on read nodes.
9. Improved write performance for GIN meta page updates.
10. Improved buffer cache recovery performance during startup.
11. Fixes a bug that caused a database engine crash at startup while recovering prepared transactions.
12. Fixes a bug that could result in the inability to start a read node when there are a large number of prepared transactions.
13. Fixes a bug that could cause a read node to report:

   ERROR: could not access status of transaction 6080077

   DETAIL: * *Could not open file "pg_subtrans/005C": No such file or directory.

14. Fixes a bug that could cause the error below when replicating from RDS PostgreSQL to Aurora PostgreSQL:

   FATAL: lock buffer_content is not held

   CONTEXT: xlog redo at 46E/F1330870 for Storage/TRUNCATE: base/13322/8058750 to 0 blocks flags 7

15. Fixes a bug that could cause Aurora PostgreSQL to stop responding while replaying a multixact WAL record when replicating from RDS PostgreSQL to Aurora PostgreSQL.

16. Multiple improvements to the reliability of importing snapshots from RDS PostgreSQL to Aurora PostgreSQL.

For information about extensions and modules, see Extensions supported for Aurora PostgreSQL 9.6.x (p. 1600).

PostgreSQL 9.6.3, Aurora PostgreSQL release 1.0 (unsupported)

   Note

The PostgreSQL engine version 9.6.3 with the Aurora PostgreSQL release 1.0 is no longer supported. To upgrade, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL (p. 1605).

For more information about PostgreSQL 9.6.3 see, PostgreSQL release 9.6.3.

This version includes the following patch releases:

**Patch releases**

- Aurora PostgreSQL release 1.0.11 (p. 1588)
- Aurora PostgreSQL release 1.0.10 (p. 1589)
- Aurora PostgreSQL release 1.0.9 (p. 1589)
- Aurora PostgreSQL release 1.0.8 (p. 1589)
- Aurora PostgreSQL release 1.0.7 (p. 1589)

**Aurora PostgreSQL release 1.0.11**

You can find the following improvements in this engine update:

1. Fixes an issue with parallel query processing that can lead to incorrect results.
2. Fixes an issue with visibility map handling during replication from Amazon RDS for PostgreSQL that can cause the Aurora storage volume to become unavailable.
3. Corrects the pg-repack extension.
4. Implements improvements to maintain fresh nodes.
5. Fixes issues that can lead to an engine crash.
For information about extensions and modules, see Extensions supported for Aurora PostgreSQL 9.6.x (p. 1600).

### Aurora PostgreSQL release 1.0.10

This update includes a new feature. You can now replicate an Amazon RDS PostgreSQL DB instance to Aurora PostgreSQL. For more information, see Replication with Amazon Aurora PostgreSQL (p. 1372).

You can find the following improvements in this engine update:

1. Adds error logging when a cache exists and a parameter change results in a mismatched buffer cache, storage format, or size.
2. Fixes an issue that causes an engine reboot if there is an incompatible parameter value for huge pages.
3. Improves handling of multiple truncate table statements during a replay of a write ahead log (WAL) on a read node.
4. Reduces static memory overhead to reduce out-of-memory errors.
5. Fixes an issue that can lead to out-of-memory errors while performing an insert with a GiST index.
6. Improves snapshot import from RDS PostgreSQL, removing the requirement that a vacuum be performed on uninitialized pages.
7. Fixes an issue that causes prepared transactions to return to the previous state following an engine crash.
8. Implements improvements to prevent read nodes from becoming stale.
9. Implements improvements to reduce downtime with an engine restart.
10. Fixes issues that can cause an engine crash.

### Aurora PostgreSQL release 1.0.9

In this engine update, we fix an issue that can cause the Aurora storage volume to become unavailable when importing a snapshot from RDS PostgreSQL that contained uninitialized pages.

### Aurora PostgreSQL release 1.0.8

You can find the following improvements in this engine update:

1. Fixes an issue that prevented the engine from starting if the shared_preload_libraries instance parameter contained pg_hint_plan.
2. Fixes the error "Attempt to fetch heap block XXX is beyond end of heap (YYY blocks)," which can occur during parallel scans.
3. Improves the effectiveness of prefetching on reads for a vacuum.
4. Fixes issues with snapshot import from RDS PostgreSQL, which can fail if there are incompatible pg_internal.init files in the source snapshot.
5. Fixes an issue that can cause a read node to crash with the message “aurora wal replay process (PID XXX) was terminated by signal 11: Segmentation fault”. This issue occurs when the reader applied a visibility map change for an uncached visibility map page.

### Aurora PostgreSQL release 1.0.7

This is the first generally available release of Amazon Aurora PostgreSQL-Compatible Edition.

### Extension versions for Amazon Aurora PostgreSQL

Topics
• Extensions supported for Aurora PostgreSQL 13.x (p. 1590)
• Extensions supported for Aurora PostgreSQL 12.x (p. 1592)
• Extensions supported for Aurora PostgreSQL 11.x (p. 1595)
• Extensions supported for Aurora PostgreSQL 10.x (p. 1598)
• Extensions supported for Aurora PostgreSQL 9.6.x (p. 1600)
• Aurora PostgreSQL apg_plan_mgmt extension versions (p. 1602)

To upgrade a PostgreSQL extension, see Upgrading PostgreSQL extensions (p. 1612).

Extensions supported for Aurora PostgreSQL 13.x

The following table shows the PostgreSQL extension versions that are currently supported on Aurora PostgreSQL versions 13.x. "NA" indicates that the extension isn't available for that PostgreSQL version. For more information about PostgreSQL extensions, see Packaging Related Objects into an Extension in the PostgreSQL documentation.

## Extensions supported for Aurora PostgreSQL 10.x

The following table shows PostgreSQL extension versions currently supported on Aurora PostgreSQL versions 10.x. "NA" indicates that the extension isn't available for that PostgreSQL version. For more information about PostgreSQL extensions, see Packaging Related Objects into an Extension.

**Note**

- The adminpack extension is no longer supported because it accesses the file system.
- The plperlu extension is no longer supported because it is an untrusted language extension.
- The pltclu extension is no longer supported because it is an untrusted language extension.

Version 2.0 of the Aurora PostgreSQL apg_plan_mgmt extension

You use the apg_plan_mgmt extension with query plan management. For more about how to install, upgrade, and use the apg_plan_mgmt extension, see Managing query execution plans for Aurora PostgreSQL (p. 1401).

The apg_plan_mgmt extension changes for version 2.0 include the following:

**New extension features**

1. You can now manage all queries inside SQL functions, whether they have parameters or not.
2. You can now manage all queries inside PL/pgSQL functions, whether they have parameters or not.
3. You can now manage queries in generic plans, whether they have parameters or not. To learn more about generic plans versus custom plans, see the PREPARE statement in the PostgreSQL documentation.
4. You can now use query plan management to enforce the use of specific types of aggregate methods in query plans.

**Extension improvements**

1. You can now save plans with a size up to 8KB times the setting of the max_worker_processes parameter. Previously the maximum plan size was 8KB.
2. Fixed bugs for unnamed prepared statements such as those from JDBC.
3. Previously, when you tried to do CREATE EXTENSION apg_plan_mgmt when it is not loaded in the shared_preload_libraries, the PostgreSQL backend connection was dropped. Now, an error message prints and the connection is not dropped.
4. The default value of the cardinality_error in the apg_plan_mgmt.plans table is NULL, but it can be set to -1 during the apg_plan_mgmt.evolve_plan_baselines function. NULL is now used consistently.
5. Plans are now saved for queries that refer to temporary tables.
6. The default maximum number of plans is increased from 1000 to 10000.
7. The following pgss parameters are deprecated because the automatic plan capture mode should be used instead of those parameters.
   - apg_plan_mgmt.pgss_min_calls
   - apg_plan_mgmt.pgss_min_mean_time_ms
   - apg_plan_mgmt.pgss_min_stddev_time_ms
   - apg_plan_mgmt.pgss_min_total_time_ms

Version 1.0.1 of the Aurora PostgreSQL apg_plan_mgmt extension

The apg_plan_mgmt extension changes for version 1.0.1 include the following:

**New extension features**

1. The validate_plans function has a new action value called update_plan_hash. This action updates the plan_hash ID for plans that can't be reproduced exactly. The update_plan_hash value also allows you to fix a plan by rewriting the SQL. You can then register the good plan as an Approved plan for the original SQL. Following is an example of using the update_plan_hash action.

   ```sql
   UPDATE apg_plan_mgmt.plans SET plan_hash = new__plan_hash, plan_outline = good_plan_outline
   ```
WHERE sql_hash = bad_plan_sql_hash AND plan_hash = bad_plan_plan_hash;
SELECT apg_plan_mgmt.validate_plans(bad_plan_sql_hash, bad_plan_plan_hash,
'update_plan_hash');
SELECT apg_plan_mgmt.reload();

2. A new get_explain_stmt function is available that generates the text of an EXPLAIN
statement for the specified SQL statement. It includes the parameters sql_hash, plan_hash and
explain_options.

The parameter explain_options can be any comma-separated list of valid EXPLAIN options, as
shown following.

analyzerverbosebuffershashesformat json

If the parameter explain_options is NULL or an empty string, the get_explain_stmt function
generates a simple EXPLAIN statement.

To create an EXPLAIN script for your workload or a portion of it, use the \a, \t, and \o options to
redirect the output to a file. For example, you can create an EXPLAIN script for the top-ranked (top-
K) statements by using the PostgreSQL pg_stat_statements view sorted by total_time in DESC
order.

3. The precise location of the Gather parallel query operator is determined by costing, and may
change slightly over time. To prevent these differences from invalidating the entire plan, query plan
management now computes the same plan_hash even if the Gather operators move to different
places in the plan tree.

4. Support is added for nonparameterized statements inside pl/pgsql functions.

5. Overhead is reduced when the apg_plan_mgmt extension is installed on multiple databases in the
same cluster while two or more databases are being accessed concurrently. Also, this release fixed a
bug in this area that caused plans to not be stored in shared memory.

Extension improvements

1. Improvements to the evolve_plan_baselines function.
   a. The evolve_plan_baselines function now computes a cardinality_error metric
      over all nodes in the plan. Using this metric, you can identify any plan where the cardinality
      estimation error is large, and the plan quality is more doubtful. Long-running statements with high
      cardinality_error values are high-priority candidates for query tuning.
   b. Reports generated by evolve_plan_baselines now include sql_hash, plan_hash, and the
      plan status.
   c. You can now allow evolve_plan_baselines to approve previously Rejected plans.
   d. The meaning of speedup_factor for evolve_plan_baselines is now always relative to the
      baseline plan. For example, a value of 1.1 now means 10 percent faster than the baseline plan.
      A value of 0.9 means 10 percent slower than the baseline plan. The comparison is made using
      running time alone instead of total time.
   e. The evolve_plan_baselines function now warms the cache in a new way. It does this by
      running the baseline plan, then running the baseline plan one more time, and then running the
      candidate plan once. Previously, evolve_plan_baselines ran the candidate plan twice. This
      approach added significantly to running time, especially for slow candidate plans. However, running
      the candidate plan twice is more reliable when the candidate plan uses an index that isn't used in
      the baseline plan.

2. Query plan management no longer saves plans that refer to system tables or views, temporary tables,
or the query plan management's own tables.

3. Bug fixes include caching a plan immediately when saved and fixing a bug that caused the back end to
terminate.
Upgrading the PostgreSQL DB engine for Aurora PostgreSQL

When Aurora PostgreSQL supports a new version of a database engine, you can upgrade your DB clusters to the new version. There are two kinds of upgrades for PostgreSQL DB clusters: major version upgrades and minor version upgrades.

**Major version upgrades** can contain database changes that are not backward-compatible with previous versions of the database. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB cluster. However, before you perform a major version upgrade, we recommend that you follow the steps described in *How to perform a major version upgrade* (p. 1606).

In contrast, **minor version upgrades** include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB cluster. Or you can enable the **Auto minor version upgrade** option when creating or modifying a DB cluster. Doing so means that your DB cluster is automatically upgraded after Aurora PostgreSQL tests and approves the new version. For more details, see *Automatic minor version upgrades for PostgreSQL* (p. 1610). For information about manually performing a minor version upgrade, see *Manually upgrading the Aurora PostgreSQL engine* (p. 1609).

Aurora DB clusters that are configured as logical replication publishers or subscribers can't undergo a major version upgrade. For more information, see *Using PostgreSQL logical replication with Aurora* (p. 1373).

For how to determine valid upgrade targets, see *Determining which engine version to upgrade to* (p. 1606).

**Topics**
- Overview of upgrading Aurora PostgreSQL (p. 1605)
- Determining which engine version to upgrade to (p. 1606)
- How to perform a major version upgrade (p. 1606)
- Manually upgrading the Aurora PostgreSQL engine (p. 1609)
- Automatic minor version upgrades for PostgreSQL (p. 1610)
- Upgrading PostgreSQL extensions (p. 1612)

Overview of upgrading Aurora PostgreSQL

Major version upgrades can contain database changes that are not backward-compatible with previous versions of the database. This functionality can cause your existing applications to stop working correctly. As a result, Amazon Aurora doesn't apply major version upgrades automatically. To perform a major version upgrade, you modify your DB cluster manually.

To safely upgrade your DB instances, Aurora PostgreSQL uses the `pg_upgrade` utility described in the PostgreSQL documentation. After the writer upgrade completes, each reader instance experiences a brief outage while it's upgraded to the new major version automatically.

Aurora PostgreSQL takes a DB cluster snapshot before a major version upgrade begins. It doesn't take a DB cluster snapshot before a minor version upgrade.

If you want to return to a previous version after a major version upgrade is complete, you can restore the DB cluster from this snapshot. You can also restore the DB cluster to a specific point in time before either a major or minor version upgrade started. For more information, see *Restoring from a DB cluster snapshot* (p. 493) or *Restoring a DB cluster to a specified time* (p. 533).
During the major version upgrade process, a cloned volume is allocated. If the upgrade fails for some reason, such as due to a schema incompatibility, Aurora PostgreSQL uses this clone to roll back the upgrade. Note, when more than 15 clones of a source volume are allocated, subsequent clones become full copies and will take longer. This can cause the upgrade process to take longer as well. If Aurora PostgreSQL rolls back the upgrade, be aware of the following:

- You may see billing entries and metrics for both the original volume and the cloned volume allocated during the upgrade. Aurora PostgreSQL will clean up the extra volume after the cluster backup retention window is beyond the time of the upgrade.
- The next cross region snapshot copy from this cluster will be a full copy instead of an incremental copy.

Determining which engine version to upgrade to

To determine which major engine version that you can upgrade your database to, use the `describe-db-engine-versions` CLI command. If you can't do a major version upgrade. You first upgrade to a minor version that has a major version upgrade path.

For example, the following command displays the major engine versions available for upgrading a DB cluster currently running the Aurora PostgreSQL engine version 10.11.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions \
  --engine aurora-postgresql \
  --engine-version 10.11 \
  --query 'DBEngineVersions[].ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].
  {EngineVersion:EngineVersion}' \
  --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
  --engine aurora-postgresql ^
  --engine-version 10.11 ^
  --query "DBEngineVersions[].ValidUpgradeTarget[?IsMajorVersionUpgrade == `true`].
  {EngineVersion:EngineVersion}" ^
  --output text
```

How to perform a major version upgrade

Major version upgrades can contain database changes that are not backward-compatible with previous versions of the database. This functionality can cause your existing applications to stop working correctly. As a result, Amazon Aurora doesn't apply major version upgrades automatically. To perform a major version upgrade, you modify your DB cluster manually.

The following Aurora PostgreSQL major version upgrades are available for Graviton2-based instances.

<table>
<thead>
<tr>
<th>Current source version</th>
<th>Major upgrade targets</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.6.9 and higher minor versions</td>
<td>10.11 or higher minor versions</td>
</tr>
<tr>
<td>10.7 and higher minor versions</td>
<td>11.7 or higher minor versions</td>
</tr>
<tr>
<td>Current source version</td>
<td>Major upgrade targets</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------</td>
</tr>
<tr>
<td>11.7 and higher minor versions</td>
<td>12.4 or higher minor versions</td>
</tr>
<tr>
<td>12.4 and higher minor versions</td>
<td>13.3 or higher minor versions</td>
</tr>
</tbody>
</table>

The following Aurora PostgreSQL major version upgrades are available for Intel-based instances.

<table>
<thead>
<tr>
<th>Current source version</th>
<th>Major upgrade targets</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.6.9 and higher minor versions</td>
<td>10.11 or higher minor versions</td>
</tr>
<tr>
<td>10.7 and higher minor versions</td>
<td>11.7 or higher minor versions</td>
</tr>
<tr>
<td>11.7 and higher minor versions</td>
<td>12.4 or higher minor versions</td>
</tr>
<tr>
<td>12.7 and higher minor versions</td>
<td>13.3 or higher minor versions</td>
</tr>
</tbody>
</table>

Before applying an upgrade to your production DB clusters, make sure that you thoroughly test any upgrade to verify that your applications work correctly.

We recommend the following process when upgrading an Aurora PostgreSQL DB cluster:

1. Have a version-compatible parameter group ready.
   
   If you are using a custom DB instance or DB cluster parameter group, you have two options:
   
   - Specify the default DB instance, DB cluster parameter group, or both for the new DB engine version.
   - Create your own custom parameter group for the new DB engine version.
   
   If you associate a new DB instance or DB cluster parameter group as a part of the upgrade request, make sure to reboot the database after the upgrade completes to apply the parameters. If a DB instance needs to be rebooted to apply the parameter group changes, the instance's parameter group status shows pending-reboot. You can view an instance's parameter group status in the console or by using a CLI command such as `describe-db-instances` or `describe-db-clusters`.

2. Check for unsupported usage:
   
   - Commit or roll back all open prepared transactions before attempting an upgrade. You can use the following query to verify that there are no open prepared transactions on your instance.

   ```sql
   SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
   ```

   - Remove all uses of the `reg*` data types before attempting an upgrade. Except for `regtype` and `regclass`, you can't upgrade the `reg*` data types. The `pg_upgrade` utility can't persist this data type, which is used by Amazon Aurora to do the upgrade. For more information about the `pg_upgrade` utility, see the PostgreSQL documentation.

   To verify that there are no uses of unsupported `reg*` data types, use the following query for each database.

   ```sql
   SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n, pg_catalog.pg_attribute a
   WHERE c.oid = a.attrelid
       AND NOT a.attisdropped
       AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
                           'pg_catalog.regprocedure'::pg_catalog.regtype,
                           'pg_catalog.regoper'::pg_catalog.regtype,
                           'pg_catalog.regclass'::pg_catalog.regtype,
                           'pg_catalog.regtype'::pg_catalog.regtype,
                           'pg_catalog.regnamespace'::pg_catalog.regtype);
   ```
3. Perform a backup.

The upgrade process creates a DB cluster snapshot of your DB cluster during upgrading. If you also want to do a manual backup before the upgrade process, see Creating a DB cluster snapshot (p. 491) for more information.

4. Upgrade certain extensions to the latest available version before performing the major version upgrade. The extensions to update include the following:
   - pgRouting
   - postgis_raster
   - postgis_tiger_geocoder
   - postgis_topology
   - address_standardizer
   - address_standardizer_data_us

   Run the following command for each extension that you are using.

   ```sql
   ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version'
   ```

   For more information, see Upgrading PostgreSQL extensions (p. 1612).

5. If you're upgrading to version 11.x, drop the extensions that it doesn't support before performing the major version upgrade. The extensions to drop include:
   - chkpass
   - tsearch2

6. Drop unknown data types, depending on your target version.

   PostgreSQL version 10 stopped supporting the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to a version 10 shows an error message such as the following.

   ```sql
   Database instance is in a state that cannot be upgraded: PreUpgrade checks failed: The instance could not be upgraded because the 'unknown' data type is used in user tables. Please remove all usages of the 'unknown' data type and try again.
   ```

   To find the unknown data type in your database so you can remove the offending column or change it to a supported data type, use the following SQL code.

   ```sql
   SELECT DISTINCT data_type FROM information_schema.columns WHERE data_type ILIKE 'unknown';
   ```

7. Perform a dry run upgrade.

   We highly recommend testing a major version upgrade on a duplicate of your production database before trying the upgrade on your production database. To create a duplicate test instance, you can either restore your database from a recent snapshot or clone your database. For more information, see Restoring from a snapshot (p. 494) or Cloning a volume for an Aurora DB cluster (p. 398).

   For more information, see Manually upgrading the Aurora PostgreSQL engine (p. 1609).

8. Upgrade your production instance.
When your dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see Manually upgrading the Aurora PostgreSQL engine (p. 1609).

**Note**
During the upgrade process, you can't do a point-in-time restore of your cluster. Aurora PostgreSQL takes a DB cluster snapshot during the upgrade process if your backup retention period is greater than 0. You can perform a point-in-time restore to times before the upgrade began and after the automatic snapshot of your instance has completed.

For information about an upgrade in progress, you can use Amazon RDS to view two logs that the `pg_upgrade` utility produces. These are `pg_upgrade_internal.log` and `pg_upgrade_server.log`. Amazon Aurora appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see Working with Amazon Aurora database log files (p. 665).

9. Upgrade PostgreSQL extensions. The PostgreSQL upgrade process doesn't upgrade any PostgreSQL extensions. For more information, see Upgrading PostgreSQL extensions (p. 1612).

After you complete a major version upgrade, we recommend the following:

- Run the `ANALYZE` operation to refresh the `pg_statistic` table.
- If you upgraded to PostgreSQL version 10, run `REINDEX` on any hash indexes you have. Hash indexes were changed in version 10 and must be rebuilt. To locate invalid hash indexes, run the following SQL for each database that contains hash indexes.

```sql
SELECT idx.indrelid::regclass AS table_name,
       idx.indexrelid::regclass AS index_name
FROM pg_catalog.pg_index idx
     JOIN pg_catalog.pg_class cls ON cls.oid = idx.indexrelid
     JOIN pg_catalog.pg_am am ON am.oid = cls.relam
WHERE am.amname = 'hash'
   AND NOT idx.indisvalid;
```

- Consider testing your application on the upgraded database with a similar workload to verify that everything works as expected. After the upgrade is verified, you can delete this test instance.

**Manually upgrading the Aurora PostgreSQL engine**

To perform an upgrade of an Aurora PostgreSQL DB cluster, use the following instructions for the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

**To upgrade the engine version of a DB cluster by using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the DB cluster that you want to upgrade.
4. For Engine version, choose the new version.
5. Choose Continue and check the summary of modifications.
6. To apply the changes immediately, choose Apply immediately. Choosing this option can cause an outage in some cases. For more information, see Modifying an Amazon Aurora DB cluster (p. 368).
7. On the confirmation page, review your changes. If they are correct, choose Modify Cluster to save your changes.

Or choose Back to edit your changes or Cancel to cancel your changes.

AWS CLI

To upgrade the engine version of a DB cluster, use the CLI modify-db-cluster command. Specify the following parameters:

- `--db-cluster-identifier` – the name of the DB cluster.
- `--engine-version` – the version number of the database engine to upgrade to. For information about valid engine versions, use the AWS CLI describe-db-engine-versions command.
- `--allow-major-version-upgrade` – a required flag when the `--engine-version` parameter is a different major version than the DB cluster's current major version.
- `--no-apply-immediately` – apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier mydbcluster \
  --engine-version new_version \
  --allow-major-version-upgrade \
  --no-apply-immediately
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier mydbcluster ^
  --engine-version new_version ^
  --allow-major-version-upgrade ^
  --no-apply-immediately
```

RDS API

To upgrade the engine version of a DB cluster, use the ModifyDBCluster operation. Specify the following parameters:

- `DBClusterIdentifier` – the name of the DB cluster, for example `mydbcluster`.
- `EngineVersion` – the version number of the database engine to upgrade to. For information about valid engine versions, use the DescribeDBEngineVersions operation.
- `AllowMajorVersionUpgrade` – a required flag when the `EngineVersion` parameter is a different major version than the DB cluster's current major version.
- `ApplyImmediately` – whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

Automatic minor version upgrades for PostgreSQL

For each PostgreSQL major version, one minor version is designated by Amazon Aurora as the automatic upgrade version. After a minor version has been tested and approved by Amazon Aurora, the minor
Version upgrade occurs automatically during your maintenance window. Aurora doesn't automatically set newer released minor versions as the automatic upgrade version. Before Aurora designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the PostgreSQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command and script to determine the current automatic upgrade minor versions.

```
aws rds describe-db-engine-versions --engine aurora-postgresql | grep -A 1 AutoUpgrade| grep -A 2 true |grep PostgreSQL | sort --unique | sed -e 's/"Description": //g'
```

If no results are returned, there is no automatic minor version upgrade available and scheduled.

A PostgreSQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The DB cluster has the **Auto minor version upgrade** option turned on.
- The DB cluster is running a minor DB engine version that is less than the current automatic upgrade minor version.

If any of the DB instances in a cluster don’t have the auto minor version upgrade setting turned on, Aurora doesn’t automatically upgrade any of the instances in that cluster. Make sure to keep that setting consistent for all the DB instances in the cluster.

**Turning on automatic minor version upgrades**

To turn on automatic minor version upgrades for an Aurora PostgreSQL DB cluster, use the following instructions for the AWS Management Console, the AWS CLI, or the RDS API.

**Console**

Follow the general procedure to modify the DB instances in your cluster, as described in Modify a DB instance in a DB cluster (p. 369). Repeat this procedure for each DB instance in your cluster.

1. Sign in to the Amazon RDS console, choose **Databases**, and find the DB cluster where you want to turn automatic minor version upgrade on or off.
2. Choose each DB instance in the DB cluster that you want to modify. Apply the following change for each DB instance in sequence:
   a. Choose **Modify**.
   b. In the **Maintenance** section, select the **Enable auto minor version upgrade** box.
   c. Choose **Continue** and check the summary of modifications.
   d. (Optional) Choose **Apply immediately** to apply the changes immediately.
   e. On the confirmation page, choose **Modify DB instance**.

**AWS CLI**

To use the CLI to implement minor version upgrades, use the `modify-db-instance` command.
When you call the modify-db-instance AWS CLI command, specify the name of your DB instance for the --db-instance-identifier option and true for the --auto-minor-version-upgrade option. Optionally, specify the --apply-immediately option to immediately turn this setting on for your DB instance. Run a separate modify-db-instance command for each DB instance in the cluster.

You can use a CLI command such as the following to check the status of Enable auto minor version upgrade for all of the DB instances in your Aurora PostgreSQL clusters.

```
aws rds describe-db-instances
  --query '.*[].{DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVersionUpgrade:AutoMinorVersionUpgrade}'
```

That command produces output similar to the following.

```
[
  {
    "DBInstanceIdentifier": "db-t2-medium-instance",
    "DBClusterIdentifier": "cluster-57-2020-06-03-6411",
    "AutoMinorVersionUpgrade": true
  },
  {
    "DBInstanceIdentifier": "db-t2-small-original-size",
    "DBClusterIdentifier": "cluster-57-2020-06-03-6411",
    "AutoMinorVersionUpgrade": false
  },
  {
    "DBInstanceIdentifier": "instance-2020-05-01-2332",
    "DBClusterIdentifier": "cluster-57-2020-05-01-4615",
    "AutoMinorVersionUpgrade": true
  },
  ... output omitted ...
```

RDS API

To use the API to implement minor version upgrades, use the ModifyDBInstance operation.

Call the ModifyDBInstance API operation, and specify the name of your DB cluster for the DBInstanceIdentifier parameter and true for the AutoMinorVersionUpgrade parameter. Optionally, set the ApplyImmediately parameter to true to immediately turn this setting on for your DB instance. Call a separate ModifyDBInstance operation for each DB instance in the cluster.

Upgrading PostgreSQL extensions

A PostgreSQL engine upgrade doesn't automatically upgrade any PostgreSQL extensions. To update an extension after an engine upgrade, use the ALTER EXTENSION UPDATE command.

**Note**

If you are running the PostGIS extension in your Amazon RDS PostgreSQL DB instance, make sure that you follow the PostGIS upgrade instructions in the PostGIS documentation before you upgrade the extension.

To upgrade an extension, use the following command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

To list your currently installed extensions, use the PostgreSQL pg_extension catalog in the following command.
Aurora PostgreSQL long-term support (LTS) releases

Each new Aurora PostgreSQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora PostgreSQL version is no longer supported.

Aurora designates certain Aurora PostgreSQL versions as long-term support (LTS) releases. Database clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. LTS minor versions include only bug fixes (through patch versions); an LTS version doesn't include new features released after its introduction.

Once a year, DB clusters running on an LTS minor version are patched to the latest patch version of the LTS release. We do this patching to help ensure that you benefit from cumulative security and stability fixes. We might patch an LTS minor version more frequently if there are critical fixes, such as for security, that need to be applied.

**Note**
To remain on an LTS minor version for the duration of its lifecycle, make sure to turn off Auto minor version upgrade for your DB instances. To avoid automatically upgrading your DB cluster from the LTS minor version, set Auto minor version upgrade to No on all DB instances in your Aurora cluster.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora PostgreSQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. LTS releases are intended for clusters with the following characteristics:

- You can’t afford downtime on your Aurora PostgreSQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora PostgreSQL database engine.
- The database version for your Aurora PostgreSQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS release for Aurora PostgreSQL is release 3.4 (PostgreSQL 11.9). It was released on December 11, 2020. For more information about this version, see PostgreSQL 11.9, Aurora PostgreSQL release 3.4 (p. 1536).
Best practices with Amazon Aurora

Following, you can find information on general best practices and options for using or migrating data to an Amazon Aurora DB cluster.

Some of the best practices for Amazon Aurora are specific to a particular database engine. For more information about Aurora best practices specific to a database engine, see the following.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Best practices</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>See Best practices with Amazon Aurora MySQL (p. 998)</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL</td>
<td>See Best practices with Amazon Aurora PostgreSQL (p. 1364)</td>
</tr>
</tbody>
</table>

**Note**

For common recommendations for Aurora, see Viewing Amazon Aurora recommendations (p. 554).

**Topics**

- Basic operational guidelines for Amazon Aurora (p. 1614)
- DB instance RAM recommendations (p. 1614)
- Monitoring Amazon Aurora (p. 1615)
- Working with DB parameter groups and DB cluster parameter groups (p. 1615)
- Amazon Aurora best practices presentation video (p. 1615)

Basic operational guidelines for Amazon Aurora

The following are basic operational guidelines that everyone should follow when working with Amazon Aurora. The Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Monitor your memory, CPU, and storage usage. You can set up Amazon CloudWatch to notify you when usage patterns change or when you approach the capacity of your deployment. This way, you can maintain system performance and availability.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Thus, caching the DNS data for an extended time can lead to connection failures if your application tries to connect to an IP address that no longer is in service. Aurora DB clusters with multiple read replicas can experience connection failures also when connections use the reader endpoint and one of the read replica instances is in maintenance or is deleted.
- Test failover for your DB cluster to understand how long the process takes for your use case. Testing failover can help you ensure that the application that accesses your DB cluster can automatically connect to the new DB cluster after failover.

DB instance RAM recommendations

To optimize performance, allocate enough RAM so that your working set resides almost completely in memory. To determine whether your working set is almost all in memory, examine the following metrics in Amazon CloudWatch:
• **VolumeReadIOPS** – This metric measures the average number of read I/O operations from a cluster volume, reported at 5-minute intervals. The value of **VolumeReadIOPS** should be small and stable. In some cases, you might find your read I/O is spiking or is higher than usual. If so, investigate the DB instances in your DB cluster to see which DB instances are causing the increased I/O.

  **Tip**
  If your Aurora MySQL cluster uses parallel query, you might see an increase in **VolumeReadIOPS** values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

• **BufferCacheHitRatio** – This metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. This metric gives you an insight into the amount of data that is being served from memory. If the hit ratio is low, it's a good indication that your queries on this DB instance are going to disk more often than not. In this case, investigate your workload to see which queries are causing this behavior.

If, after investigating your workload, you find that you need more memory, consider scaling up the DB instance class to a class with more RAM. After doing so, you can investigate the metrics discussed preceding and continue to scale up as necessary. If your Aurora cluster is larger than 40 TB, don't use **db.t2** or **db.t3** instance classes. For more information about monitoring a DB cluster, see Monitoring Amazon Aurora metrics with Amazon CloudWatch (p. 628).

---

**Monitoring Amazon Aurora**

Amazon Aurora provides a variety of Amazon CloudWatch metrics that you can monitor to determine the health and performance of your Aurora DB cluster. You can use various tools, such as the AWS Management Console, AWS CLI, and CloudWatch API, to view Aurora metrics. For more information, see Monitoring an Amazon Aurora DB cluster (p. 537).

**Working with DB parameter groups and DB cluster parameter groups**

We recommend that you try out DB parameter group and DB cluster parameter group changes on a test DB cluster before applying parameter group changes to your production DB cluster. Improperly setting DB engine parameters can have unintended adverse effects, including degraded performance and system instability.

Always use caution when modifying DB engine parameters, and back up your DB cluster before modifying a DB parameter group. For information about backing up your DB cluster, see Backing up and restoring an Amazon Aurora DB cluster (p. 486).

**Amazon Aurora best practices presentation video**

The 2016 AWS Summit conference in Chicago included a presentation on best practices for creating and configuring an Amazon Aurora DB cluster to be more secure and highly available. For a video of the presentation, see Amazon Aurora best practices on the AWS YouTube channel.
Performing a proof of concept with Amazon Aurora

Following, you can find an explanation of how to set up and run a proof of concept for Aurora. A proof of concept is an investigation that you do to see if Aurora is a good fit with your application. The proof of concept can help you understand Aurora features in the context of your own database applications and how Aurora compares with your current database environment. It can also show what level of effort you need to move data, port SQL code, tune performance, and adapt your current management procedures.

In this topic, you can find an overview and a step-by-step outline of the high-level procedures and decisions involved in running a proof of concept, listed following. For detailed instructions, you can follow links to the full documentation for specific subjects.

Overview of an Aurora proof of concept

When you conduct a proof of concept for Amazon Aurora, you learn what it takes to port your existing data and SQL applications to Aurora. You exercise the important aspects of Aurora at scale, using a volume of data and activity that's representative of your production environment. The objective is to feel confident that the strengths of Aurora match up well with the challenges that cause you to outgrow your previous database infrastructure. At the end of a proof of concept, you have a solid plan to do larger-scale performance benchmarking and application testing. At this point, you understand the biggest work items on your way to a production deployment.

The following advice about best practices can help you avoid common mistakes that cause problems during benchmarking. However, this topic doesn't cover the step-by-step process of performing benchmarks and doing performance tuning. Those procedures vary depending on your workload and the Aurora features that you use. For detailed information, consult performance-related documentation such as Managing performance and scaling for Aurora DB clusters (p. 392), Amazon Aurora MySQL performance enhancements (p. 714), Managing Amazon Aurora PostgreSQL (p. 1302), and Monitoring DB load with Performance Insights on Amazon Aurora (p. 561).

The information in this topic applies mainly to applications where your organization writes the code and designs the schema and that support the MySQL and PostgreSQL open-source database engines. If you're testing a commercial application or code generated by an application framework, you might not have the flexibility to apply all of the guidelines. In such cases, check with your AWS representative to see if there are Aurora best practices or case studies for your type of application.

1. Identify your objectives

When you evaluate Aurora as part of a proof of concept, you choose what measurements to make and how to evaluate the success of the exercise.

You must ensure that all of the functionality of your application is compatible with Aurora. Because Aurora major versions are wire-compatible with corresponding major versions of MySQL and PostgreSQL, most applications developed for those engines are also compatible with Aurora. However, you must still validate compatibility on a per-application basis.
For example, some of the configuration choices that you make when you set up an Aurora cluster influence whether you can or should use particular database features. You might start with the most general-purpose kind of Aurora cluster, known as provisioned. You might then decide if a specialized configuration such as serverless or parallel query offers benefits for your workload.

Use the following questions to help identify and quantify your objectives:

- Does Aurora support all functional use cases of your workload?
- What dataset size or load level do you want? Can you scale to that level?
- What are your specific query throughput or latency requirements? Can you reach them?
- What is the minimum acceptable amount of planned or unplanned downtime for your workload? Can you achieve it?
- What are the necessary metrics for operational efficiency? Can you accurately monitor them?
- Does Aurora support your specific business goals, such as cost reduction, increase in deployment, or provisioning speed? Do you have a way to quantify these goals?
- Can you meet all security and compliance requirements for your workload?

Take some time to build knowledge about Aurora database engines and platform capabilities, and review the service documentation. Take note of all the features that can help you achieve your desired outcomes. One of these might be workload consolidation, described in the AWS Database Blog post How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads. Another might be demand-based scaling, described in Using Amazon Aurora Auto Scaling with Aurora replicas (p. 423) in the Amazon Aurora User Guide. Others might be performance gains or simplified database operations.

2. Understand your workload characteristics

Evaluate Aurora in the context of your intended use case. Aurora is a good choice for online transaction processing (OLTP) workloads. You can also run reports on the cluster that holds the real-time OLTP data without provisioning a separate data warehouse cluster. You can recognize if your use case falls into these categories by checking for the following characteristics:

- High concurrency, with dozens, hundreds, or thousands of simultaneous clients.
- Large volume of low-latency queries (milliseconds to seconds).
- Short, real-time transactions.
- Highly selective query patterns, with index-based lookups.
- For HTAP, analytical queries that can take advantage of Aurora parallel query.

One of the key factors affecting your database choices is the velocity of the data. High velocity involves data being inserted and updated very frequently. Such a system might have thousands of connections and hundreds of thousands of simultaneous queries reading from and writing to a database. Queries in high-velocity systems usually affect a relatively small number of rows, and typically access multiple columns in the same row.

Aurora is designed to handle high-velocity data. Depending on the workload, an Aurora cluster with a single r4.16xlarge DB instance can process more than 600,000 SELECT statements per second. Again depending on workload, such a cluster can process 200,000 INSERT, UPDATE, and DELETE statements per second. Aurora is a row store database and is ideally suited for high-volume, high-throughput, and highly parallelized OLTP workloads.

Aurora can also run reporting queries on the same cluster that handles the OLTP workload. Aurora supports up to 15 replicas (p. 69), each of which is on average within 10–20 milliseconds of the primary
3. Practice with the AWS Management Console or AWS CLI

As a next step, practice with the AWS Management Console or the AWS CLI, to become familiar with these tools and with Aurora.

Practice with the AWS Management Console

The following initial activities with Aurora database clusters are mainly so you can familiarize yourself with the AWS Management Console environment and practice setting up and modifying Aurora clusters. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

By taking advantage of the Aurora shared storage model and features such as replication and snapshots, you can treat entire database clusters as another kind of object that you freely manipulate. You can set up, tear down, and change the capacity of Aurora clusters frequently during the proof of concept. You aren't locked into early choices about capacity, database settings, and physical data layout.

To get started, set up an empty Aurora cluster. Choose the **provisioned** capacity type and **regional** location for your initial experiments.

Connect to that cluster using a client program such as a SQL command-line application. Initially, you connect using the cluster endpoint. You connect to that endpoint to perform any write operations, such as data definition language (DDL) statements and extract, transform, load (ETL) processes. Later in the proof of concept, you connect query-intensive sessions using the reader endpoint, which distributes the query workload among multiple DB instances in the cluster.

Scale the cluster out by adding more Aurora Replicas. For those procedures, see Replication with Amazon Aurora (p. 69). Scale the DB instances up or down by changing the AWS instance class. Understand how Aurora simplifies these kinds of operations, so that if your initial estimates for system capacity are inaccurate, you can adjust later without starting over.

Create a snapshot and restore it to a different cluster.

Examine cluster metrics to see activity over time, and how the metrics apply to the DB instances in the cluster.

It's useful to become familiar with how to do these things through the AWS Management Console in the beginning. After you understand what you can do with Aurora, you can progress to automating those operations using the AWS CLI. In the following sections, you can find more details about the procedures and best practices for these activities during the proof-of-concept period.

Practice with the AWS CLI

We recommend automating deployment and management procedures, even in a proof-of-concept setting. To do so, become familiar with the AWS CLI if you're not already. If you use the MySQL-
compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

Aurora typically involves groups of DB instances arranged in clusters. Thus, many operations involve determining which DB instances are associated with a cluster and then performing administrative operations in a loop for all the instances.

For example, you might automate steps such as creating Aurora clusters, then scaling them up with larger instance classes or scaling them out with additional DB instances. Doing so helps you to repeat any stages in your proof of concept and explore what-if scenarios with different kinds or configurations of Aurora clusters.

Learn the capabilities and limitations of infrastructure deployment tools such as AWS CloudFormation. You might find activities that you do in a proof-of-concept context aren't suitable for production use. For example, the AWS CloudFormation behavior for modification is to create a new instance and delete the current one, including its data. For more details on this behavior, see Update behaviors of stack resources in the AWS CloudFormation User Guide.

4. Create your Aurora cluster

With Aurora, you can explore what-if scenarios by adding DB instances to the cluster and scaling up the DB instances to more powerful instance classes. You can also create clusters with different configuration settings to run the same workload side by side. With Aurora, you have a lot of flexibility to set up, tear down, and reconfigure DB clusters. Given this, it's helpful to practice these techniques in the early stages of the proof-of-concept process. For the general procedures to create Aurora clusters, see Creating an Amazon Aurora DB cluster (p. 124).

Where practical, start with a cluster using the following settings. Skip this step only if you have certain specific use cases in mind. For example, you might skip this step if your use case requires a specialized kind of Aurora cluster. Or you might skip it if you need a particular combination of database engine and version.

- Amazon Aurora.
- MySQL 5.7 compatibility. This combination of database engine and version has wide compatibility with other Aurora features and substantial customer usage for production applications.
- Turn off Easy create. For the proof of concept, we recommend that you be aware of all the settings you choose so that you can create identical or slightly different clusters later.
- Regional. The Global setting is for specific high availability scenarios. You can try it out later after your initial functional and performance experiments.
- One writer, multiple readers. This is the most widely used, general purpose kind of cluster. This setting persists for the life of the cluster. Thus, if you later do experiments with other kinds of clusters such as serverless or parallel query, you create other clusters and compare and contrast the results on each.
- Choose the Dev/Test template. This choice isn't significant for your proof-of-concept activities.
- For DB instance class, choose Memory optimized classes and one of the xlarge instance classes. You can adjust the instance class up or down later.
- Under Multi-AZ Deployment, choose Create an Aurora Replica or Reader node in a different AZ. Many of the most useful aspects of Aurora involve clusters of multiple DB instances. It makes sense to always start with at least two DB instances in any new cluster. Using a different Availability Zone for the second DB instance helps to test different high availability scenarios.
- When you pick names for the DB instances, use a generic naming convention. Don't refer to any cluster DB instance as the "master" or "writer," because different DB instances assume those roles as needed. We recommend using something like clustername-az-serialnumber, for example myprodappdb-a-01. These pieces uniquely identify the DB instance and its placement.
5. Set up your schema

On the Aurora cluster, set up databases, tables, indexes, foreign keys, and other schema objects for your application. If you're moving from another MySQL-compatible or PostgreSQL-compatible database system, expect this stage to be simple and straightforward. You use the same SQL syntax and command line or other client applications that you're familiar with for your database engine.

To issue SQL statements on your cluster, find its cluster endpoint and supply that value as the connection parameter to your client application. You can find the cluster endpoint on the Connectivity tab of the detail page of your cluster. The cluster endpoint is the one labeled Writer. The other endpoint, labeled Reader, represents a read-only connection that you can supply to end users who run reports or other read-only queries. For help with any issues around connecting to your cluster, see Connecting to an Amazon Aurora DB cluster (p. 279).

If you're porting your schema and data from a different database system, expect to make some schema changes at this point. These schema changes are to match the SQL syntax and capabilities available in Aurora. You might leave out certain columns, constraints, triggers, or other schema objects at this point. Doing so can be useful particularly if these objects require rework for Aurora compatibility and aren't significant for your objectives with the proof of concept.

If you're migrating from a database system with a different underlying engine than Aurora's, consider using the AWS Schema Conversion Tool (AWS SCT) to simplify the process. For details, see the AWS Schema Conversion Tool User Guide. For general details about migration and porting activities, see the AWS whitepaper Aurora migration handbook.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Such inefficiencies can be amplified when you deploy your application on a cluster with multiple DB instances and a heavy workload. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

6. Import your data

During the proof of concept, you bring across the data, or a representative sample, from your former database system. If practical, set up at least some data in each of your tables. Doing so helps to test compatibility of all data types and schema features. After you have exercised the basic Aurora features, scale up the amount of data. By the time you finish the proof of concept, you should test your ETL tools, queries, and overall workload with a dataset that's big enough to draw accurate conclusions.

You can use several techniques to import either physical or logical backup data to Aurora. For details, see Migrating data to an Amazon Aurora MySQL DB cluster (p. 747) or Migrating data to Amazon Aurora with PostgreSQL compatibility (p. 1235) depending on the database engine you're using in the proof of concept.
Experiment with the ETL tools and technologies that you're considering. See which one best meets your needs. Consider both throughput and flexibility. For example, some ETL tools perform a one-time transfer, and others involve ongoing replication from the old system to Aurora.

If you're migrating from a MySQL-compatible system to Aurora MySQL, you can use the native data transfer tools. The same applies if you're migrating from a PostgreSQL-compatible system to Aurora PostgreSQL. If you're migrating from a database system that uses a different underlying engine than Aurora does, you can experiment with the AWS Database Migration Service (AWS DMS). For details about AWS DMS, see the AWS Database Migration Service User Guide.

For details about migration and porting activities, see the AWS whitepaper Aurora migration handbook.

### 7. Port your SQL code

Trying out SQL and associated applications requires different levels of effort depending on different cases. In particular, the level of effort depends on whether you move from a MySQL-compatible or PostgreSQL-compatible system or another kind.

- If you're moving from RDS for MySQL or RDS for PostgreSQL, the SQL changes are small enough that you can try the original SQL code with Aurora and manually incorporate needed changes.
- Similarly, if you move from an on-premises database compatible with MySQL or PostgreSQL, you can try the original SQL code and manually incorporate changes.
- If you're coming from a different commercial database, the required SQL changes are more extensive. In this case, consider using the AWS SCT.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

You can verify the database connection logic in your application. To take advantage of Aurora distributed processing, you might need to use separate connections for read and write operations, and use relatively short sessions for query operations. For information about connections, see 9. Connect to Aurora (p. 1622).

Consider if you had to make compromises and tradeoffs to work around issues in your production database. Build time into the proof-of-concept schedule to make improvements to your schema design and queries. To judge if you can achieve easy wins in performance, operating cost, and scalability, try the original and modified applications side by side on different Aurora clusters.

For details about migration and porting activities, see the AWS whitepaper Aurora migration handbook.

### 8. Specify configuration settings

You can also review your database configuration parameters as part of the Aurora proof-of-concept exercise. You might already have MySQL or PostgreSQL configuration settings tuned for performance and scalability in your current environment. The Aurora storage subsystem is adapted and tuned for a distributed cloud-based environment with a high-speed storage subsystem. As a result, many former database engine settings don't apply. We recommend conducting your initial experiments with the default Aurora configuration settings. Reapply settings from your current environment only if you encounter performance and scalability bottlenecks. If you're interested, you can look more deeply into this subject in Introducing the Aurora storage engine on the AWS Database Blog.

Aurora makes it easy to reuse the optimal configuration settings for a particular application or use case. Instead of editing a separate configuration file for each DB instance, you manage sets of parameters that
you assign to entire clusters or specific DB instances. For example, the time zone setting applies to all DB instances in the cluster, and you can adjust the page cache size setting for each DB instance.

You start with one of the default parameter sets, and apply changes to only the parameters that you need to fine-tune. For details about working with parameter groups, see Amazon Aurora DB cluster and DB instance parameters (p. 337). For the configuration settings that are or aren't applicable to Aurora clusters, see Aurora MySQL configuration parameters (p. 1007) or Amazon Aurora PostgreSQL parameters (p. 1487) depending on your database engine.

9. Connect to Aurora

As you find when doing your initial schema and data setup and running sample queries, you can connect to different endpoints in an Aurora cluster. The endpoint to use depends on whether the operation is a read such as SELECT statement, or a write such as a CREATE or INSERT statement. As you increase the workload on an Aurora cluster and experiment with Aurora features, it's important for your application to assign each operation to the appropriate endpoint.

By using the cluster endpoint for write operations, you always connect to a DB instance in the cluster that has read/write capability. By default, only one DB instance in an Aurora cluster has read/write capability. This DB instance is called the primary instance. If the original primary instance becomes unavailable, Aurora activates a failover mechanism and a different DB instance takes over as the primary.

Similarly, by directing SELECT statements to the reader endpoint, you spread the work of processing queries among the DB instances in the cluster. Each reader connection is assigned to a different DB instance using round-robin DNS resolution. Doing most of the query work on the read-only DB Aurora Replicas reduces the load on the primary instance, freeing it to handle DDL and DML statements.

Using these endpoints reduces the dependency on hard-coded hostnames, and helps your application to recover more quickly from DB instance failures.

Note
Aurora also has custom endpoints that you create. Those endpoints usually aren't needed during a proof of concept.

The Aurora Replicas are subject to a replica lag, even though that lag is usually 10 to 20 milliseconds. You can monitor the replication lag and decide whether it is within the range of your data consistency requirements. In some cases, your read queries might require strong read consistency (read-after-write consistency). In these cases, you can continue using the cluster endpoint for them and not the reader endpoint.

To take full advantage of Aurora capabilities for distributed parallel execution, you might need to change the connection logic. Your objective is to avoid sending all read requests to the primary instance. The read-only Aurora Replicas are standing by, with all the same data, ready to handle SELECT statements. Code your application logic to use the appropriate endpoint for each kind of operation. Follow these general guidelines:

• Avoid using a single hard-coded connection string for all database sessions.
• If practical, enclose write operations such as DDL and DML statements in functions in your client application code. That way, you can make different kinds of operations use specific connections.
• Make separate functions for query operations. Aurora assigns each new connection to the reader endpoint to a different Aurora Replica to balance the load for read-intensive applications.
• For operations involving sets of queries, close and reopen the connection to the reader endpoint when each set of related queries is finished. Use connection pooling if that feature is available in your software stack. Directing queries to different connections helps Aurora to distribute the read workload among the DB instances in the cluster.
For general information about connection management and endpoints for Aurora, see Connecting to an Amazon Aurora DB cluster (p. 279). For a deep dive on this subject, see Aurora MySQL database administrator's handbook – Connection management.

10. Run your workload

After the schema, data, and configuration settings are in place, you can begin exercising the cluster by running your workload. Use a workload in the proof of concept that mirrors the main aspects of your production workload. We recommend always making decisions about performance using real-world tests and workloads rather than synthetic benchmarks such as sysbench or TPC-C. Wherever practical, gather measurements based on your own schema, query patterns, and usage volume.

As much as practical, replicate the actual conditions under which the application will run. For example, you typically run your application code on Amazon EC2 instances in the same AWS Region and the same virtual private cloud (VPC) as the Aurora cluster. If your production application runs on multiple EC2 instances spanning multiple Availability Zones, set up your proof-of-concept environment in the same way. For more information on AWS Regions, see Regions and Availability Zones in the Amazon RDS User Guide. To learn more about the Amazon VPC service, see What is Amazon VPC? in the Amazon VPC User Guide.

After you've verified that the basic features of your application work and you can access the data through Aurora, you can exercise aspects of the Aurora cluster. Some features you might want to try are concurrent connections with load balancing, concurrent transactions, and automatic replication.

By this point, the data transfer mechanisms should be familiar, and so you can run tests with a larger proportion of sample data.

This stage is when you can see the effects of changing configuration settings such as memory limits and connection limits. Revisit the procedures that you explored in 8. Specify configuration settings (p. 1621).

You can also experiment with mechanisms such as creating and restoring snapshots. For example, you can create clusters with different AWS instance classes, numbers of AWS Replicas, and so on. Then on each cluster, you can restore the same snapshot containing your schema and all your data. For the details of that cycle, see Creating a DB cluster snapshot (p. 491) and Restoring from a DB cluster snapshot (p. 493).

11. Measure performance

Best practices in this area are designed to ensure that all the right tools and processes are set up to quickly isolate abnormal behaviors during workload operations. They're also set up to see that you can reliably identify any applicable causes.

You can always see the current state of your cluster, or examine trends over time, by examining the Monitoring tab. This tab is available from the console detail page for each Aurora cluster or DB instance. It displays metrics from the Amazon CloudWatch monitoring service in the form of charts. You can filter the metrics by name, by DB instance, and by time period.

To have more choices on the Monitoring tab, enable Enhanced Monitoring and Performance Insights in the cluster settings. You can also enable those choices later if you didn't choose them when setting up the cluster.

To measure performance, you rely mostly on the charts showing activity for the whole Aurora cluster. You can verify whether the Aurora Replicas have similar load and response times. You can also see how the work is split up between the read/write primary instance and the read-only Aurora Replicas. If there is some imbalance between the DB instances or an issue affecting only one DB instance, you can examine the Monitoring tab for that specific instance.
After the environment and the actual workload are set up to emulate your production application, you can measure how well Aurora performs. The most important questions to answer are as follows:

- How many queries per second is Aurora processing? You can examine the **Throughput** metrics to see the figures for various kinds of operations.
- How long does it take, on average for Aurora to process a given query? You can examine the **Latency** metrics to see the figures for various kinds of operations.

To do so, look at the **Monitoring** tab for a given Aurora cluster in the Amazon RDS console as illustrated following.

If you can, establish baseline values for these metrics in your current environment. If that's not practical, construct a baseline on the Aurora cluster by executing a workload equivalent to your production application. For example, run your Aurora workload with a similar number of simultaneous users and queries. Then observe how the values change as you experiment with different instance classes, cluster size, configuration settings, and so on.

If the throughput numbers are lower than you expect, investigate further the factors affecting database performance for your workload. Similarly, if the latency numbers are higher than you expect, further investigate. To do so, monitor the secondary metrics for the DB server (CPU, memory, and so on). You can see whether the DB instances are close to their limits. You can also see how much extra capacity your DB instances have to handle more concurrent queries, queries against larger tables, and so on.

**Tip**

To detect metric values that fall outside the expected ranges, set up CloudWatch alarms.

When evaluating the ideal Aurora cluster size and capacity, you can find the configuration that achieves peak application performance without over-provisioning resources. One important factor is finding
Exercise Aurora high availability

12. Exercise Aurora high availability

Many of the main Aurora features involve high availability. These features include automatic replication, automatic failover, automatic backups with point-in-time restore, and ability to add DB instances to the cluster. The safety and reliability from features like these are important for mission-critical applications.

To evaluate these features requires a certain mindset. In earlier activities, such as performance measurement, you observe how the system performs when everything works correctly. Testing high availability requires you to think through worst-case behavior. You must consider various kinds of failures, even if such conditions are rare. You might intentionally introduce problems to make sure that the system recovers correctly and quickly.

Tip
For a proof of concept, set up all the DB instances in an Aurora cluster with the same AWS instance class. Doing so makes it possible to try out Aurora availability features without major changes to performance and scalability as you take DB instances offline to simulate failures.

We recommend using at least two instances in each Aurora cluster. The DB instances in an Aurora cluster can span up to three Availability Zones (AZs). Locate each of the first two or three DB instances in a different AZ. When you begin using larger clusters, spread your DB instances across all of the AZs in your AWS Region. Doing so increases fault tolerance capability. Even if a problem affects an entire AZ, Aurora can fail over to a DB instance in a different AZ. If you run a cluster with more than three instances, distribute the DB instances as evenly as you can over all three AZs.

Tip
The storage for an Aurora cluster is independent from the DB instances. The storage for each Aurora cluster always spans three AZs.

When you test high availability features, always use DB instances with identical capacity in your test cluster. Doing so avoids unpredictable changes in performance, latency, and so on whenever one DB instance takes over for another.

To learn how to simulate failure conditions to test high availability features, see Testing Amazon Aurora using fault injection queries (p. 795).
As part of your proof-of-concept exercise, one objective is to find the ideal number of DB instances and the optimal instance class for those DB instances. Doing so requires balancing the requirements of high availability and performance.

For Aurora, the more DB instances that you have in a cluster, the greater the benefits for high availability. Having more DB instances also improves scalability of read-intensive applications. Aurora can distribute multiple connections for `SELECT` queries among the read-only Aurora Replicas.

On the other hand, limiting the number of DB instances reduces the replication traffic from the primary node. The replication traffic consumes network bandwidth, which is another aspect of overall performance and scalability. Thus, for write-intensive OLTP applications, prefer to have a smaller number of large DB instances rather than many small DB instances.

In a typical Aurora cluster, one DB instance (the primary instance) handles all the DDL and DML statements. The other DB instances (the Aurora Replicas) handle only `SELECT` statements. Although the DB instances don't do exactly the same amount of work, we recommend using the same instance class for all the DB instances in the cluster. That way, if a failure happens and Aurora promotes one of the read-only DB instances to be the new primary instance, the primary instance has the same capacity as before.

If you need to use DB instances of different capacities in the same cluster, set up failover tiers for the DB instances. These tiers determine the order in which Aurora Replicas are promoted by the failover mechanism. Put DB instances that are a lot larger or smaller than the others into a lower failover tier. Doing so ensures that they are chosen last for promotion.

Exercise the data recovery features of Aurora, such as automatic point-in-time restore, manual snapshots and restore, and cluster backtracking. If appropriate, copy snapshots to other AWS Regions and restore into other AWS Regions to mimic DR scenarios.

Investigate your organization's requirements for restore time objective (RTO), restore point objective (RPO), and geographic redundancy. Most organizations group these items under the broad category of disaster recovery. Evaluate the Aurora high availability features described in this section in the context of your disaster recovery process to ensure that your RTO and RPO requirements are met.

13. What to do next

At the end of a successful proof-of-concept process, you confirm that Aurora is a suitable solution for you based on the anticipated workload. Throughout the preceding process, you've checked how Aurora works in a realistic operational environment and measured it against your success criteria.

After you get your database environment up and running with Aurora, you can move on to more detailed evaluation steps, leading to your final migration and production deployment. Depending on your situation, these other steps might or might not be included in the proof-of-concept process. For details about migration and porting activities, see the AWS whitepaper Aurora migration handbook.

In another next step, consider the security configurations relevant for your workload and designed to meet your security requirements in a production environment. Plan what controls to put in place to protect access to the Aurora cluster master user credentials. Define the roles and responsibilities of database users to control access to data stored in the Aurora cluster. Take into account database access requirements for applications, scripts, and third-party tools or services. Explore AWS services and features such as AWS Secrets Manager and AWS Identity and Access Management (IAM) authentication.

At this point, you should understand the procedures and best practices for running benchmark tests with Aurora. You might find you need to do additional performance tuning. For details, see Managing performance and scaling for Aurora DB clusters (p. 392), Amazon Aurora MySQL performance enhancements (p. 714), Managing Amazon Aurora PostgreSQL (p. 1302), and Monitoring DB load with Performance Insights on Amazon Aurora (p. 561). If you do additional tuning, make sure that you're...
familiar with the metrics that you gathered during the proof of concept. For a next step, you might create new clusters with different choices for configuration settings, database engine, and database version. Or you might create specialized kinds of Aurora clusters to match the needs of specific use cases.

For example, you can explore Aurora parallel query clusters for hybrid transaction/analytical processing (HTAP) applications. If wide geographic distribution is crucial for disaster recovery or to minimize latency, you can explore Aurora global databases. If your workload is intermittent or you're using Aurora in a development/test scenario, you can explore Aurora Serverless clusters.

Your production clusters might also need to handle high volumes of incoming connections. To learn those techniques, see the AWS whitepaper Aurora MySQL database administrator's handbook – Connection management.

If, after the proof of concept, you decide that your use case is not suited for Aurora, consider these other AWS services:

- For purely analytic use cases, workloads benefit from a columnar storage format and other features more suitable to OLAP workloads. AWS services that address such use cases include the following:
  - Amazon Redshift
  - Amazon EMR
  - Amazon Athena
- Many workloads benefit from a combination of Aurora with one or more of these services. You can move data between these services by using these:
  - AWS Glue
  - AWS DMS
  - Importing from Amazon S3, as described in the Amazon Aurora User Guide
  - Exporting to Amazon S3, as described in the Amazon Aurora User Guide
  - Many other popular ETL tools
Security in Amazon Aurora

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon Aurora (Aurora), see AWS services in scope by compliance program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Aurora. The following topics show you how to configure Amazon Aurora to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon Aurora resources.

You can manage access to your Amazon Aurora resources and your databases on a DB cluster. The method you use to manage access depends on what type of task the user needs to perform with Amazon Aurora:

- Run your DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB cluster in a VPC, see Amazon Virtual Private Cloud VPCs and Amazon Aurora (p. 1708).

- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon Aurora resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB clusters, tag resources, or modify security groups. For information on setting up an IAM user, see Create an IAM user (p. 83).

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB cluster. When you first create a DB cluster, its firewall prevents any database access except through rules specified by an associated security group.

- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB clusters running the Aurora MySQL or Aurora PostgreSQL. For more information on using SSL/TLS with a DB cluster, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634).

- Use Amazon Aurora encryption to secure your DB clusters and snapshots at rest. Amazon Aurora encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB cluster. For more information, see Encrypting Amazon Aurora resources (p. 1631).

- Use the security features of your DB engine to control who can log in to the databases on a DB cluster. These features work just as if the database was on your local network.

For information about security with Aurora MySQL, see Security with Amazon Aurora MySQL (p. 739). For information about security with Aurora PostgreSQL, see Security with Amazon Aurora PostgreSQL (p. 1228).
Aurora is part of the managed database service Amazon Relational Database Service (Amazon RDS). Amazon RDS is a web service that makes it easier to set up, operate, and scale a relational database in the cloud. If you are not already familiar with Amazon RDS, see the Amazon RDS user guide.

Aurora includes a high-performance storage subsystem. Its MySQL- and PostgreSQL-compatible database engines are customized to take advantage of that fast distributed storage. Aurora also automates and standardizes database clustering and replication, which are typically among the most challenging aspects of database configuration and administration.

For both Amazon RDS and Aurora, you can access the RDS API programmatically, and you can use the AWS CLI to access the RDS API interactively. Some RDS API operations and AWS CLI commands apply to both Amazon RDS and Aurora, while others apply to either Amazon RDS or Aurora. For information about RDS API operations, see Amazon RDS API reference. For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

Note
You only have to configure security for your use cases. You don't have to configure security access for processes that Amazon Aurora manages. These include creating backups, replicating data between a primary DB instance and a read replica, and other processes.

For more information on managing access to Amazon Aurora resources and your databases on a DB cluster, see the following topics.

Database authentication with Amazon Aurora

Amazon Aurora supports several ways to authenticate database users.

Password authentication is available by default for all DB clusters. For Aurora MySQL, you can also add IAM database authentication. For Aurora PostgreSQL, you can also add either or both IAM database authentication and Kerberos authentication for the same DB cluster.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the rds_iam role to the user.
- To use Kerberos authentication, assign the rds_ad role to the user.
- To use password authentication, don't assign either the rds_iam or rds_ad roles to the user.
Don't assign both the rds_iam and rds_ad roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the rds_iam role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

Topics
- Password authentication (p. 1630)
- IAM database authentication (p. 1630)
- Kerberos authentication (p. 1630)

Password authentication

With password authentication, your DB instance performs all administration of user accounts. You create users with SQL statements such as CREATE USER, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is CREATE USER name IDENTIFIED BY password, while in PostgreSQL, the statement is CREATE USER name WITH PASSWORD password.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon Aurora, see Creating a basic secret and Rotating secrets for supported Amazon RDS databases in the AWS Secrets Manager User Guide. For information about programmatically retrieving your secrets in your custom applications, see Retrieving the secret value in the AWS Secrets Manager User Guide.

IAM database authentication

You can authenticate to your DB cluster using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL and Aurora PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see IAM database authentication (p. 1661).

Kerberos authentication

Amazon Aurora supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon Aurora support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB instances.

You can enable your database users to authenticate against DB instances in two ways. They can use credentials stored either in AWS Directory Service for Microsoft Active Directory or in your on-premises Active Directory.

Currently, Aurora supports Kerberos authentication for Aurora PostgreSQL DB clusters. With Kerberos authentication, Aurora PostgreSQL DB clusters support one- and two-way forest trust relationships. For more information, see Using Kerberos authentication with Aurora PostgreSQL (p. 1473).
Data protection in Amazon RDS

The AWS shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing personal data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form fields such as a Name field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs.

If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Topics
- Protecting data using encryption (p. 1631)
- Internetwork traffic privacy (p. 1644)

Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB clusters.

Topics
- Encrypting Amazon Aurora resources (p. 1631)
- AWS KMS key management (p. 1633)
- Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634)
- Rotating your SSL/TLS certificate (p. 1636)

Encrypting Amazon Aurora resources

Amazon Aurora can encrypt your Amazon Aurora DB clusters. Data that is encrypted at rest includes the underlying storage for DB clusters, its automated backups, read replicas, and snapshots.
Amazon Aurora encrypted DB clusters use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon Aurora DB clusters. After your data is encrypted, Amazon Aurora handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

Note
For encrypted and unencrypted DB clusters, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

Topics
- Overview of encrypting Amazon Aurora resources (p. 1632)
- Enabling encryption for an Amazon Aurora DB cluster (p. 1632)
- Availability of Amazon Aurora encryption (p. 1633)
- Limitations of Amazon Aurora encrypted DB clusters (p. 1633)

Overview of encrypting Amazon Aurora resources
Amazon Aurora encrypted DB clusters provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon Aurora encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

For an Amazon Aurora encrypted DB cluster, all DB instances, logs, backups, and snapshots are encrypted. You can also encrypt a read replica of an Amazon Aurora encrypted cluster. Amazon Aurora uses an AWS KMS key to encrypt these resources. For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide. Each DB instance in the DB cluster is encrypted using the same KMS key as the DB cluster. If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon Aurora resources, you use the AWS Key Management Service (AWS KMS). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see AWS Service Integration.

Enabling encryption for an Amazon Aurora DB cluster
To enable encryption for a new DB cluster, choose Enable encryption on the console. For information on creating a DB cluster, see Creating an Amazon Aurora DB cluster (p. 124).

If you use the create-db-cluster AWS CLI command to create an encrypted DB cluster, set the --storage-encrypted parameter. If you use the CreateDBCluster API operation, set the StorageEncrypted parameter to true.

When you create an encrypted DB cluster, you can choose a customer managed key or the AWS managed key for Amazon Aurora to encrypt your DB cluster. If you don't specify the key identifier for a customer managed key, Amazon Aurora uses the AWS managed key for your new DB cluster. Amazon Aurora creates an AWS managed key for Amazon Aurora for your AWS account. Your AWS account has a different AWS managed key for Amazon Aurora for each AWS Region.

Once you have created an encrypted DB cluster, you can't change the KMS key used by that DB cluster. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB cluster.
If you use the AWS CLI `create-db-cluster` command to create an encrypted DB cluster with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

**Important**
In some cases, Amazon Aurora can lose access to the KMS key for a DB cluster. For example, Aurora loses access when RDS access to a KMS key is revoked. In these cases, the encrypted DB cluster goes into a terminal state, and you can only restore the DB cluster from a backup. We strongly recommend that you always enable backups for encrypted DB clusters to guard against the loss of encrypted data in your databases.

### Availability of Amazon Aurora encryption

Amazon Aurora encryption is currently available for all database engines and storage types.

**Note**
Amazon Aurora encryption is not available for the db.t2.micro DB instance class.

### Limitations of Amazon Aurora encrypted DB clusters

The following limitations exist for Amazon Aurora encrypted DB clusters:

- You can't disable encryption on an encrypted DB cluster.
- You can't create an encrypted snapshot of an unencrypted DB cluster.
- A snapshot of an encrypted DB cluster must be encrypted using the same KMS key as the DB cluster.
- You can't convert an unencrypted DB cluster to an encrypted one. However, you can restore an unencrypted snapshot to an encrypted Aurora DB cluster. To do this, specify a KMS key when you restore from the unencrypted snapshot.
- You can't create an encrypted Aurora Replica from an unencrypted Aurora DB cluster. You can't create an unencrypted Aurora Replica from an encrypted Aurora DB cluster.
- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

The source snapshot remains encrypted throughout the copy process. Amazon Aurora uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.

- You can't unencrypt an encrypted DB cluster. However, you can export data from an encrypted DB cluster and import the data into an unencrypted DB cluster.

### AWS KMS key management

Amazon Aurora automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon Aurora uses envelope encryption. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.

An **AWS KMS key** is a logical representation of a key. The KMS key includes metadata, such as the key ID, creation date, description, and key state. The KMS key also contains the key material used to encrypt and decrypt data. For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide.

You can manage KMS keys used for Amazon Aurora encrypted DB clusters using the AWS Key Management Service (AWS KMS) in the AWS KMS console, the AWS CLI, or the AWS KMS API. If you want full control over a KMS key, then you must create a customer managed key. For more information about
customer managed keys, see Customer managed keys in the AWS Key Management Service Developer Guide.

AWS managed keys are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. You can't delete, edit, or rotate AWS managed keys. For more information about AWS managed keys, see AWS managed keys in the AWS Key Management Service Developer Guide.

You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.

You can view audit logs of every action taken with an AWS managed or customer managed key by using AWS CloudTrail.

Important
If you disable or revoke permissions to a KMS key used by an RDS database, RDS puts your database into a terminal state when access to the KMS key is required. This change could be immediate, or deferred, depending on the use case that required access to the KMS key. In this state, the DB cluster is no longer available, and the current state of the database can't be recovered. To restore the DB cluster, you must re-enable access to the KMS key for RDS, and then restore the DB cluster from the latest available backup.

Authorizing use of a customer managed key

When Aurora uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the Aurora resource.

To use the customer managed key for an Aurora resource on your behalf, a user must have permissions to call the following operations on the customer managed key:

- kms:GenerateDataKey
- kms:Decrypt

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

You can make the IAM policy stricter in various ways. For example, to allow the customer managed key to be used only for requests that originate in Aurora, you can use the kms:ViaService condition key with the rds.<region>.amazonaws.com value.

You can also use the keys or values in the encryption context as a condition for using the customer managed key for cryptographic operations.

For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.

Using SSL/TLS to encrypt a connection to a DB cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB cluster running Aurora MySQL or Aurora PostgreSQL.

SSL/TLS connections provide one layer of security by encrypting data that moves between your client and a DB cluster. Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon Aurora DB cluster. It does so by checking the server certificate that is automatically installed on all DB clusters that you provision.

Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your DB cluster, use the link following that corresponds to your DB engine:

- Security with Amazon Aurora MySQL (p. 739)
- Security with Amazon Aurora PostgreSQL (p. 1228)
**Note**
All certificates are only available for download using SSL/TLS connections.

To get a certificate bundle that contains both the intermediate and root certificates for all AWS Regions, download from https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem.

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b.

**Note**
Amazon RDS Proxy and Aurora Serverless use certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, you don’t need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see Using TLS/SSL with RDS Proxy (p. 290). If you are Aurora Serverless, downloading Amazon RDS certificates isn’t required. For more information about using TLS/SSL with Aurora Serverless, see Using TLS/SSL with Aurora Serverless v1 (p. 149).

**Certificate bundles for AWS Regions**
To get a certificate bundle that contains both the intermediate and root certificates for an AWS Region, download from the link for the AWS Region in the following table.

<table>
<thead>
<tr>
<th>AWS Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-bundle.pem</td>
<td>us-east-1-bundle.p7b</td>
</tr>
<tr>

**AWS GovCloud (US) certificates**

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at [https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b](https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b).

To get a certificate bundle that contains both the intermediate and root certificates for an AWS GovCloud (US) Region, download from the link for the AWS GovCloud (US) Region in the following table.

<table>
<thead>
<tr>
<th>AWS GovCloud (US) Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
</table>

**Rotating your SSL/TLS certificate**

As of March 5, 2020, Amazon RDS CA-2015 certificates have expired. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances, you require Amazon RDS CA-2019 certificates, which are enabled by default for new DB instances. If you currently do not use SSL/TLS with certificate verification, you might still have expired CA-2015 certificates and must update them to CA-2019 certificates if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Follow these instructions to complete your updates. Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see [Using SSL/TLS to encrypt a connection to a DB cluster](p. 1634).

**Note**

Amazon RDS Proxy and Aurora Serverless use certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see [Using TLS/SSL with RDS Proxy](p. 290).

If you are Aurora Serverless, rotating your SSL/TLS certificate isn't required. For more information about using TLS/SSL with Aurora Serverless, see [Using TLS/SSL with Aurora Serverless v1](p. 149).

**Note**

If you are using a Go version 1.15 application with a DB instance that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Run the `modify-db-instance` command shown in the AWS CLI section using `rds-ca-2019` as
the CA certificate identifier. In this case, it isn't possible to update the certificate using the AWS Management Console. If you created your DB instance or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

Topics

- Updating your CA certificate by modifying your DB instance (p. 1637)
- Updating your CA certificate by applying DB instance maintenance (p. 1639)
- Sample script for importing certificates into your trust store (p. 1643)

Updating your CA certificate by modifying your DB instance

Complete the following steps to update your CA certificate.

To update your CA certificate by modifying your DB instance

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634).
2. Update your applications to use the new SSL/TLS certificate.

   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

   For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

   - Updating applications to connect to Aurora MySQL DB clusters using new SSL/TLS certificates (p. 743)
   - Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates (p. 1232)

   For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store (p. 1643).

   **Note**

   The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from `rds-ca-2015` to `rds-ca-2019`.

   **Important**

   By default, this operation restarts your DB instance. If you don't want to restart your DB instance during this operation, you can use the `modify-db-instance` CLI command and specify the `--no-certificate-rotation-restart` option. This option will not rotate the certificate until the next time the database restarts, either for planned or unplanned maintenance. This option is only recommended if you don't use SSL/TLS.

   If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.

You can use the AWS Management Console or the AWS CLI to change the CA certificate from `rds-ca-2015` to `rds-ca-2019` for a DB instance.
Console

To change the CA from rds-ca-2015 to rds-ca-2019 for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.

3. Choose Modify.

The Modify DB Instance page appears.

5. Choose Continue and check the summary of modifications.

6. To apply the changes immediately, choose Apply immediately.

Important
Choosing this option restarts your database immediately.
7. On the confirmation page, review your changes. If they are correct, choose Modify DB Instance to save your changes.

   **Important**
   When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

   Or choose Back to edit your changes or Cancel to cancel your changes.

**AWS CLI**

To use the AWS CLI to change the CA from rds-ca-2015 to rds-ca-2019 for a DB instance, call the modify-db-instance command. Specify the DB instance identifier and the --ca-certificate-identifier option.

   **Important**
   When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

**Example**

The following code modifies mydbinstance by setting the CA certificate to rds-ca-2019. The changes are applied during the next maintenance window by using --no-apply-immediately. Use --apply-immediately to apply the changes immediately.

   **Important**
   By default, this operation reboots your DB instance. If you don't want to reboot your DB instance during this operation, you can use the modify-db-instance CLI command and specify the --no-certificate-rotation-restart option.
   This option will not rotate the certificate until the next time the database restarts, either for planned or unplanned maintenance. This option is only recommended if you do not use SSL/TLS.
   Use --apply-immediately to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

For Linux, macOS, or Unix:

    aws rds modify-db-instance  
    --db-instance-identifier mydbinstance  
    --ca-certificate-identifier rds-ca-2019  
    --no-apply-immediately

For Windows:

    aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --ca-certificate-identifier rds-ca-2019 ^
    --no-apply-immediately

**Updating your CA certificate by applying DB instance maintenance**

Complete the following steps to update your CA certificate by applying DB instance maintenance.

**To update your CA certificate by applying DB instance maintenance**

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634).
2. 
Update your database applications to use the new SSL/TLS certificate.

The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

• Updating applications to connect to Aurora MySQL DB clusters using new SSL/TLS certificates (p. 743)
• Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates (p. 1232)

For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store (p. 1643).

Note
The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period.

3. Apply DB instance maintenance to change the CA from rds-ca-2015 to rds-ca-2019.

Important
You can choose to apply the change immediately. By default, this operation is scheduled to run during your next maintenance window.

You can use the AWS Management Console to apply DB instance maintenance to change the CA certificate from rds-ca-2015 to rds-ca-2019 for multiple DB instances.

Updating your CA certificate by applying maintenance to multiple DB instances

Use the AWS Management Console to change the CA certificate for multiple DB instances.

To change the CA from rds-ca-2015 to rds-ca-2019 for multiple DB instances

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.

   In the navigation pane, there is a Certificate update option that shows the total number of affected DB instances.
Choose **Certificate update** in the navigation pane.

The **Update your Amazon RDS SSL/TLS certificates** page appears.
Note
This page only shows the DB instances for the current AWS Region. If you have DB instances in more than one AWS Region, check this page in each AWS Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing Update at the next maintenance window. Apply the rotation immediately by choosing Update now.

Important
When your CA certificate is rotated, the operation restarts your DB instance.
If you experience connectivity issues after certificate expiry, use the Update now option.

4. If you choose Update at the next maintenance window or Update now, you are prompted to confirm the CA certificate rotation.

Important
Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. To determine whether your applications use SSL/TLS and the server certificate to connect, see Step 2: Update Your Database Applications to Use the New SSL/TLS Certificate (p. 1639). After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose Confirm.

5. Repeat steps 3 and 4 for each DB instance that you want to update.
Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Topics

• Sample script for importing certificates on Linux (p. 1643)
• Sample script for importing certificates on macOS (p. 1643)

Sample script for importing certificates on Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```bash
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
  mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

curl -sS "https://s3.amazonaws.com/rds-downloads/rds-combined-ca-bundle.pem" > ${mydir}/
rds-combined-ca-bundle.pem
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/ {split_after=1}{print > "rds-ca-" n ".pem"}' < ${mydir}/rds-combined-ca-bundle.pem

for CERT in rds-ca-*; do
  alias="$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')"
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "$alias" -storepass $storepassword -keystore
  ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/rds-combined-ca-bundle.pem

echo "Trust store content is:"

keytool -list -v -keystore "${truststore}" -storepass $storepassword | grep Alias | cut -d " " -f3- | while read alias
do
  expiry=`keytool -list -v -keystore "$truststore" -storepass $storepassword -alias
  "$alias" | grep Valid | perl -ne 'if(/until: (.*?)/) { print "$1\n"; }'`
  echo " Certificate $alias expires in '$expiry'"
done
```

Sample script for importing certificates on macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```bash
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
  mkdir -p "${mydir}"
fi
```
Internetwork traffic privacy

Connections are protected both between Amazon Aurora and on-premises applications and between Amazon Aurora and other AWS resources within the same AWS Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS Site-to-Site VPN?](#)
- An AWS Direct Connect connection. For more information, see [What is AWS Direct Connect?](#)

You get access to Amazon Aurora through the network by using AWS-published API operations. Clients must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2. Clients must also support cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key identifier and a secret access key that are associated with an IAM principal. Or you can use the AWS security token service (STS) to generate temporary security credentials to sign requests.

```bash
truststore=${mydir}/rds-truststore.jks
storepassword=changeit
curl -S "https://s3.amazonaws.com/rds-downloads/rds-combined-ca-bundle.pem" > ${mydir}/
   rds-combined-ca-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/rds-combined-ca-bundle.pem rds-ca-
for CERT in rds-ca-*; do
  alias=${(openssl x509 -noout -text -in CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')}
  echo "Importing $alias"
  keytool -import -file CERT -alias "$alias" -storepass $storepassword -keystore
   ${truststore} -noprompt
  rm CERT
done
rm ${mydir}/rds-combined-ca-bundle.pem
keytool -list -v -keystore "$truststore" -storepass $storepassword | grep Alias | cut -d
   " " -f3- | while read alias
  expiry=`keytool -list -v -keystore "$truststore" -storepass $storepassword -alias
   "$alias" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
  echo " Certificate $alias expires in $expiry"
done
```
Identity and access management in Amazon Aurora

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Aurora resources. IAM is an AWS service that you can use with no additional charge.

Topics
- Audience (p. 1645)
- Authenticating with identities (p. 1645)
- Managing access using policies (p. 1647)
- How Amazon Aurora works with IAM (p. 1648)
- Amazon Aurora identity-based policy examples (p. 1651)
- IAM database authentication (p. 1661)
- Troubleshooting Amazon Aurora identity and access (p. 1690)

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Aurora.

Service user – If you use the Aurora service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Aurora features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Aurora, see Troubleshooting Amazon Aurora identity and access (p. 1690).

Service administrator – If you’re in charge of Aurora resources at your company, you probably have full access to Aurora. It’s your job to determine which Aurora features and resources your employees should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Aurora, see How Amazon Aurora works with IAM (p. 1648).

IAM administrator – If you’re an IAM administrator, you might want to learn details about how you can write policies to manage access to Aurora. To view example Aurora identity-based policies that you can use in IAM, see Amazon Aurora identity-based policy examples (p. 1651).

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see The IAM console and sign-in page in the IAM User Guide.

You must be authenticated (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company's single sign-on authentication, or even sign in using Google or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.

To sign in directly to the AWS Management Console, use your password with your root user email or your IAM user name. You can access AWS programmatically using your root user or IAM user access keys. AWS
provides SDK and command line tools to cryptographically sign your request using your credentials. If you don’t use AWS tools, you must sign the request yourself. Do this using Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. An IAM user can have long-term credentials such as a user name and password or a set of access keys. To learn how to generate access keys, see Managing access keys for IAM users in the IAM User Guide. When you generate access keys for an IAM user, make sure you view and securely save the key pair. You cannot recover the secret access key in the future. Instead, you must generate a new access key pair.

An IAM group is an identity that specifies a collection of IAM users. You can’t sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

You can authenticate to your DB cluster using IAM database authentication.

IAM database authentication works with Aurora. For more information about authenticating to your DB cluster using IAM, see IAM database authentication (p. 1661).

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

• Temporary IAM user permissions – An IAM user can assume an IAM role to temporarily take on different permissions for a specific task.
• **Federated user access** – Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated users and roles in the IAM User Guide.

• **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

• **AWS service access** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

To learn whether to use IAM roles, see When to create an IAM role (instead of a user) in the IAM User Guide.

### Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when an entity (root user, IAM user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

An IAM administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (user or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

### Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, role, or group. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.
The following AWS managed policies, which you can attach to users in your account, are specific to Amazon Aurora:

- **AmazonRDSReadOnlyAccess** – Grants read-only access to all Amazon Aurora resources for the AWS account specified.
- **AmazonRDSFullAccess** – Grants full access to all Amazon Aurora resources for the AWS account specified.

### Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the **Principal** field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.

### Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

For more information about identity and access management for Aurora, continue to the following pages:

- How Amazon Aurora works with IAM (p. 1648)
- Troubleshooting Amazon Aurora identity and access (p. 1690)

### How Amazon Aurora works with IAM

Before you use IAM to manage access to Aurora, you should understand what IAM features are available to use with Aurora. To get a high-level view of how Aurora and other AWS services work with IAM, see AWS services that work with IAM in the IAM User Guide.

### Topics

- Aurora identity-based policies (p. 1649)
Aurora identity-based policies

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. Aurora supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON policy elements reference in the IAM User Guide.

Actions

The Action element of an IAM identity-based policy describes the specific action or actions that will be allowed or denied by the policy. Policy actions usually have the same name as the associated AWS API operation. The action is used in a policy to grant permissions to perform the associated operation.

Policy actions in Aurora use the following prefix before the action: rds:. For example, to grant someone permission to describe DB instances with the Amazon RDS DescribeDBInstances API operation, you include the rds:DescribeDBInstances action in their policy. Policy statements must include either an Action or NotAction element. Aurora defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": [  
    "rds:action1",  
    "rds:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```
"Action": "rds:Describe*"
```

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

Resources

The Resource element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. You specify a resource using an ARN or using the wildcard (*) to indicate that the statement applies to all resources.

The DB instance resource has the following ARN:

```
arn:${Partition}:rds:${Region}:${Account}:${ResourceType}/${Resource}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and AWS service namespaces.

For example, to specify the dbtest DB instance in your statement, use the following ARN:

```
```
To specify all DB instances that belong to a specific account, use the wildcard (*):

```
"Resource": "arn:aws:rds:us-east-1:123456789012:db:*"
```

Some RDS API operations, such as those for creating resources, cannot be performed on a specific resource. In those cases, you must use the wildcard (*):

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, CreateDBInstance creates a DB instance. You can specify that an IAM user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
    "resource1",
    "resource2"
]
```

To see a list of Aurora resource types and their ARNs, see Resources Defined by Amazon RDS in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

**Condition keys**

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can build conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: Variables and tags in the IAM User Guide.

Aurora defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

All RDS API operations support the aws:RequestedRegion condition key.

To see a list of Aurora condition keys, see Condition Keys for Amazon RDS in the Service Authorization Reference. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon RDS.

**Examples**

To view examples of Aurora identity-based policies, see Amazon Aurora identity-based policy examples (p. 1651).

**Aurora resource-based policies**

Aurora does not support resource-based policies.
Authorization based on Aurora tags

You can attach tags to Aurora resources or pass tags in a request to Aurora. To control access based on tags, you provide tag information in the condition element of a policy using the \( \text{rds:ResourceTag/key-name} \), \( \text{aws:RequestTag/key-name} \), or \( \text{aws:TagKeys} \) condition keys. For more information about tagging Aurora resources, see Specifying conditions: Using custom tags (p. 1658).

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Grant permission for actions on a resource with a specific tag with two different values (p. 1655).

Aurora IAM roles

An IAM role is an entity within your AWS account that has specific permissions.

Using temporary credentials with Aurora

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

Aurora supports using temporary credentials.

Service-linked roles

Service-linked roles allow AWS services to access resources in other services to complete an action on your behalf. Service-linked roles appear in the Roles list in the IAM Management Console and are owned by the service. An IAM administrator can view but not edit the permissions for service-linked roles.

Aurora supports service-linked roles. For details about creating or managing Aurora service-linked roles, see Using service-linked roles for Amazon Aurora (p. 1704).

Service roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in the Roles list in the IAM Management Console and are owned by your account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

Aurora supports service roles.

Amazon Aurora identity-based policy examples

By default, IAM users and roles don't have permission to create or modify Aurora resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the IAM User Guide.
Identity-based policy examples

• Using the Aurora console (p. 1652)
• Allow users to view their own permissions (p. 1653)
• Allow a user to create DB instances in an AWS account (p. 1653)
• Permissions required to use the console (p. 1654)
• Allow a user to perform any describe action on any RDS resource (p. 1655)
• Allow a user to create a DB instance that uses the specified DB parameter group and subnet group (p. 1655)
• Grant permission for actions on a resource with a specific tag with two different values (p. 1655)
• Prevent a user from deleting a DB instance (p. 1656)
• Deny all access to a resource (p. 1656)
• Example policies: Using condition keys (p. 1656)
• Specifying conditions: Using custom tags (p. 1658)

Policy best practices

Identity-based policies are very powerful. They determine whether someone can create, access, or delete Aurora resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

• Get Started Using AWS Managed Policies – To start using Aurora quickly, use AWS managed policies to give your employees the permissions they need. These policies are already available in your account and are maintained and updated by AWS. For more information, see Get started using permissions with AWS managed policies in the IAM User Guide.
• Grant Least Privilege – When you create custom policies, grant only the permissions required to perform a task. Start with a minimum set of permissions and grant additional permissions as necessary. Doing so is more secure than starting with permissions that are too lenient and then trying to tighten them later. For more information, see Grant least privilege in the IAM User Guide.
• Enable MFA for Sensitive Operations – For extra security, require IAM users to use multi-factor authentication (MFA) to access sensitive resources or API operations. For more information, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.
• Use Policy Conditions for Extra Security – To the extent that it’s practical, define the conditions under which your identity-based policies allow access to a resource. For example, you can write conditions to specify a range of allowable IP addresses that a request must come from. You can also write conditions to allow requests only within a specified date or time range, or to require the use of SSL or MFA. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

Using the Aurora console

To access the Amazon Aurora console, you must have a minimum set of permissions. These permissions must enable you to list and view details about the Aurora resources in your AWS account. You can create an identity-based policy that is more restrictive than the minimum required permissions. However, if you do, the console doesn’t function as intended for entities (IAM users or roles) with that policy.

To ensure that those entities can still use the Aurora console, also attach the following AWS managed policy to the entities. For more information, see Adding permissions to a user in the IAM User Guide.

AmazonRDSReadOnlyAccess

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.
Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": [
                "arn:aws:iam::*:user/${aws:username}"
            ]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

Allow a user to create DB instances in an AWS account

The following is an example policy that allows the user with the ID 123456789012 to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with test. The new DB instance must also use the MySQL database engine and the db.t2.micro DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with default, and it must use the default subnet group.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCreateDBInstanceOnly",
            "Effect": "Allow",
            "Action": [
                "rds:CreateDBInstance"
            ],
            "Resource": [
                "arn:aws:rds:*:123456789012:db:test*",
                "arn:aws:rds:*:123456789012:og:default*"
            ]
        }
    ]
}
```
The policy includes a single statement that specifies the following permissions for the IAM user:

- The policy allows the IAM user to create a DB instance using the CreateDBInstance API operation (this also applies to the create-db-instance AWS CLI command and the AWS Management Console).

- The Resource element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resource Name (ARN). This ARN includes the name of the service that the resource belongs to (rds), the AWS Region (* indicates any region in this example), the user account number (123456789012 is the user ID in this example), and the type of resource. For more information about creating ARNs, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 478).

  The Resource element in the example specifies the following policy constraints on resources for the user:
  - The DB instance identifier for the new DB instance must begin with test (for example, testCustomerData1, test-region2-data).
  - The option group for the new DB instance must begin with default.
  - The DB parameter group for the new DB instance must begin with default.
  - The subnet group for the new DB instance must be the default subnet group.

- The Condition element specifies that the DB engine must be MySQL and the DB instance class must be db.t2.micro. The Condition element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the Condition element. For more information about specifying conditions, see Condition keys (p. 1650). This example specifies the rds:DatabaseEngine and rds:DatabaseClass conditions. For information about the valid condition values for rds:DatabaseEngine, see the list under the Engine parameter in CreateDBInstance. For information about the valid condition values for rds:DatabaseClass, see Supported DB engines for DB instance classes (p. 53).

The policy doesn't specify the Principal element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon Aurora resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the AmazonRDSReadOnlyAccess managed policy to the user, as described in Managing access using policies (p. 1647).
You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon Aurora resources for the root AWS account:

```
AmazonRDSFullAccess
```

### Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with `Describe`. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the `Resource` element indicates that the actions are allowed for all Amazon Aurora resources owned by the account.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowRDSDescribe",
      "Effect": "Allow",
      "Action": "rds:Describe*",
      "Resource": "*"
    }
  ]
}
```

### Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the `mydbpg` DB parameter group and the `mydbsubnetgroup` DB subnet group.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": [
        "arn:aws:rds:*:*:pg:mydbpg",
        "arn:aws:rds:*:*:subgrp:mydbsubnetgroup"
      ]
    }
  ]
}
```

### Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Aurora resources based on tags. The following policy allows permission to perform the `ModifyDBInstance` and `CreateDBSnapshot` APIs on DB instances with either the `stage` tag set to `development` or `test`.
Identity-based policy examples

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "DenyDelete1",
         "Effect": "Deny",
         "Action": "rds:DeleteDBInstance",
      }
   ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": "rds:*",
      }
   ]
}
```

Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon Aurora IAM permissions policies.
Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The Condition element indicates the requirement that the database engine is MySQL.

```json
{
   "Version":"2012-10-17",
   "Statement":[
     {
       "Sid":"AllowMySQLCreate",
       "Effect":"Allow",
       "Action":"rds:CreateDBInstance",
       "Resource":"*",
       "Condition":{
         "StringEquals":{
           "rds:DatabaseEngine":"mysql"
         },
         "Bool":{
           "rds:MultiAz": false
         }
       }
     }
   ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes r3.8xlarge and m4.10xlarge, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```json
{
   "Version":"2012-10-17",
   "Statement":[
     {
       "Sid":"DenyLargeCreate",
       "Effect":"Deny",
       "Action":"rds:CreateDBInstance",
       "Resource":"*",
       "Condition":{
         "StringEquals":{
           "rds:DatabaseClass":[
             "db.r3.8xlarge",
             "db.m4.10xlarge"
           ]
         }
       }
     },
     {
       "Sid":"DenyPIOPSCreate",
       "Effect":"Deny",
       "Action":"rds:CreateDBInstance",
       "Resource":"*",
   ```
Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key `stage` to be added to a resource with the values `test`, `qa`, and `production`.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [ "rds:AddTagsToResource", "rds:RemoveTagsFromResource" ],
      "Resource": "*",
      "Condition": { "streq": { "rds:req-tag/stage": [ "test", "qa", "production" ] } } }
  ]
}
```

Specifying conditions: Using custom tags

Amazon Aurora supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

**Note**

Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a `Condition` element.

<table>
<thead>
<tr>
<th>RDS tag identifier</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>db-tag</td>
<td>DB instances, including read replicas</td>
</tr>
<tr>
<td>snapshot-tag</td>
<td>DB snapshots</td>
</tr>
<tr>
<td>ri-tag</td>
<td>Reserved DB instances</td>
</tr>
<tr>
<td>secgrp-tag</td>
<td>DB security groups</td>
</tr>
<tr>
<td>og-tag</td>
<td>DB option groups</td>
</tr>
<tr>
<td>pg-tag</td>
<td>DB parameter groups</td>
</tr>
<tr>
<td>subgrp-tag</td>
<td>DB subnet groups</td>
</tr>
<tr>
<td>RDS tag identifier</td>
<td>Applies to</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>es-tag</td>
<td>Event subscriptions</td>
</tr>
<tr>
<td>cluster-tag</td>
<td>DB clusters</td>
</tr>
<tr>
<td>cluster-pg-tag</td>
<td>DB cluster parameter groups</td>
</tr>
<tr>
<td>cluster-snapshot-tag</td>
<td>DB cluster snapshots</td>
</tr>
</tbody>
</table>

The syntax for a custom tag condition is as follows:

"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name": ["value"]} } 

For example, the following Condition element applies to DB instances with a tag named environment and a tag value of production.

"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]} } 

For information about creating tags, see Tagging Amazon RDS resources (p. 470).

**Important**

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the AddTagsToResource and RemoveTagsFromResource actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```json
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"DenyTagUpdates",
      "Effect":"Deny",
      "Action":[
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource":"*"
    }
  ]
}
```

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

**Example policies: Using custom tags**

Following are examples of how you can use custom tags in Amazon Aurora IAM permissions policies. For more information about adding tags to an Amazon Aurora resource, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 478).

**Note**

All examples use the us-west-2 region and contain fictitious account IDs.

**Example 1: Grant permission for actions on a resource with a specific tag with two different values**

The following policy allows permission to perform the ModifyDBInstance and CreateDBSnapshot APIs on DB instances with either the stage tag set to development or test.
Identity-based policy examples

Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to AddTagsToResource or RemoveTagsFromResource) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called stage equal to devo or that has no tag called stage.

The Resource line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon Aurora resources, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 478).
IAM database authentication

You can authenticate to your DB cluster using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL and Aurora PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

An **authentication token** is a unique string of characters that Amazon Aurora generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon Aurora, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634).
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB cluster.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

**Topics**

- Availability for IAM database authentication (p. 1661)
- Limitations for IAM database authentication (p. 1662)
- Aurora MySQL recommendations for IAM database authentication (p. 1662)
- Enabling and disabling IAM database authentication (p. 1663)
- Creating and using an IAM policy for IAM database access (p. 1664)
- Creating a database account using IAM authentication (p. 1667)
- Connecting to your DB cluster using IAM authentication (p. 1668)

**Availability for IAM database authentication**

IAM database authentication is available for the following database engines:
IAM database authentication

- **Aurora MySQL**
  - Aurora MySQL version 3, all minor versions
  - Aurora MySQL version 2, all minor versions
  - Aurora MySQL version 1.10 and higher 1.1 minor versions

- **Aurora PostgreSQL**
  - All Aurora PostgreSQL 13 versions
  - All Aurora PostgreSQL 12 versions
  - Aurora PostgreSQL 11.6 and higher 11 versions
  - Aurora PostgreSQL 10.11 and higher 10 versions
  - Aurora PostgreSQL 9.6.16 and higher 9.6 versions

For more information, see Amazon Aurora PostgreSQL releases and engine versions (p. 1524).

For Aurora MySQL, all supported DB instance classes support IAM database authentication, except for db.t2.small and db.t3.small. For information about the supported DB instance classes, see Supported DB engines for DB instance classes (p. 53).

**Limitations for IAM database authentication**

When using IAM database authentication, the following limitations apply:

- The maximum number of connections per second for your DB cluster might be limited depending on its DB instance class and your workload.
- Currently, IAM database authentication doesn't support all global condition context keys.

  For more information about global condition context keys, see AWS global condition context keys in the IAM User Guide.
- Currently, IAM database authentication isn't supported for CNAMEs.
- For PostgreSQL, if the IAM role (`rds_iam`) is added to the master user, IAM authentication takes precedence over Password authentication so the master user has to log in as an IAM user.

**Aurora MySQL recommendations for IAM database authentication**

We recommend the following when using the Aurora MySQL DB engine:

- Use IAM database authentication as a mechanism for temporary, personal access to databases.
- Use IAM database authentication only for workloads that can be easily retried.
- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon Aurora don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB cluster. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling. The extra overhead can cause even existing connections to drop. For information about the maximum total connections for Aurora MySQL, see Maximum connections to an Aurora MySQL DB instance (p. 779).

**Note**

These recommendations don't apply to Aurora PostgreSQL DB clusters.
Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB clusters. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB cluster with IAM database authentication enabled, see Creating an Amazon Aurora DB cluster (p. 124).
- To modify a DB cluster to enable IAM database authentication, see Modifying an Amazon Aurora DB cluster (p. 368).
- To restore a DB cluster from a snapshot with IAM database authentication enabled, see Restoring from a DB cluster snapshot (p. 493).
- To restore a DB cluster to a point in time with IAM database authentication enabled, see Restoring a DB cluster to a specified time (p. 533).

Console

Each creation or modification workflow has a Database authentication section, where you can enable or disable IAM database authentication. In that section, choose Password and IAM database authentication to enable IAM database authentication.

To enable or disable IAM database authentication for an existing DB cluster

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the DB cluster that you want to modify.
   
   Note
   You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Availability for IAM database authentication (p. 1661).
4. Choose Modify.
5. In the Database authentication section, choose Password and IAM database authentication to enable IAM database authentication.
6. Choose Continue.
7. To apply the changes immediately, choose Immediately in the Scheduling of modifications section.
8. Choose Modify cluster.

AWS CLI

To create a new DB cluster with IAM authentication by using the AWS CLI, use the create-db-cluster command. Specify the --enable-iam-database-authentication option.

To update an existing DB cluster to have or not have IAM authentication, use the AWS CLI command modify-db-cluster. Specify either the --enable-iam-database-authentication or --no-enable-iam-database-authentication option, as appropriate.

   Note
   You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Availability for IAM database authentication (p. 1661).

By default, Aurora performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the --apply-immediately parameter.
If you are restoring a DB cluster, use one of the following AWS CLI commands:

- `restore-db-cluster-to-point-in-time`
- `restore-db-cluster-from-db-snapshot`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

**RDS API**

To create a new DB instance with IAM authentication by using the API, use the API operation `CreateDBCluster`. Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB cluster to have IAM authentication, use the API operation `ModifyDBCluster`. Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

**Note**

You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Availability for IAM database authentication (p. 1661).

If you are restoring a DB cluster, use one of the following API operations:

- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

**Creating and using an IAM policy for IAM database access**

To allow an IAM user or role to connect to your DB cluster, you must create an IAM policy. After that, you attach the policy to an IAM user or role.

**Note**

To learn more about IAM policies, see Identity and access management in Amazon Aurora (p. 1645).

The following example policy allows an IAM user to connect to a DB cluster using IAM database authentication.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["rds-db:connect"],
            "Resource": [
            ]
        }
    ]
}
```
Important
An IAM administrator user can access DB clusters without explicit permissions in an IAM policy. The example in Create an IAM user (p. 83) creates an IAM administrator user. If you want to restrict administrator access to DB clusters, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

Note
Don’t confuse the rds-db: prefix with other RDS API operation prefixes that begin with rds:. You use the rds-db: prefix and the rds-db:connect action only for IAM database authentication. They aren’t valid in any other context. Currently, the IAM console displays an error for policies with the rds-db:connect action. You can ignore this error.

The example policy includes a single statement with the following elements:

- **Effect** – Specify Allow to grant access to the DB cluster. If you don’t explicitly allow access, then access is denied by default.
- **Action** – Specify rds-db:connect to allow connections to the DB cluster.
- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB cluster. The ARN format is as follows.

```
arn:aws:rds-db:region:account-id:dbuser:DbClusterResourceId/db-user-name
```

In this format, replace the following:

- **region** is the AWS Region for the DB cluster. In the example policy, the AWS Region is us-east-2.
- **account-id** is the AWS account number for the DB cluster. In the example policy, the account number is 1234567890.
- **DbClusterResourceId** is the identifier for the DB cluster. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is cluster-ABCDEFGHIJKL01234.

To find a DB cluster resource ID in the AWS Management Console for Amazon Aurora, choose the DB cluster to see its details. Then choose the Configuration tab. The Resource ID is shown in the Configuration section.

Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB cluster in the current AWS Region, as shown following.

```
aws rds describe-db-clusters --query "DBClusters[*].[DBClusterIdentifier,DbClusterResourceId]"
```

Note
If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as prx-ABCDEFGHIJKL01234. For information about using IAM database authentication with RDS Proxy, see Connecting to a proxy using IAM authentication (p. 302).

- **db-user-name** is the name of the database account to associate with IAM authentication. In the example policy, the database account is db_user.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB cluster.
IAM database authentication

The following policy uses the "*" character to match all DB clusters and database accounts for a particular AWS account and AWS Region.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
            ]
        }
    ]
}
```

The following policy matches all of the DB clusters for a particular AWS account and AWS Region. However, the policy only grants access to DB clusters that have a jane_doe database account.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws:rds-db:us-east-2:1234567890:dbuser:*/jane_doe"
            ]
        }
    ]
}
```

The IAM user or role has access to only those databases that the database user does. For example, suppose that your DB cluster has a database named dev, and another database named test. If the
database user jane_doe has access only to dev, any IAM users or roles that access that DB cluster with the jane_doe user also have access only to dev. This access restriction is also true for other database objects, such as tables, views, and so on.

An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions. For examples of policies, see Amazon Aurora identity-based policy examples (p. 1651).

Attaching an IAM policy to an IAM user or role

After you create an IAM policy to allow database authentication, you need to attach the policy to an IAM user or role. For a tutorial on this topic, see Create and attach your first customer managed policy in the IAM User Guide.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have an IAM user with an attached policy that can make use of the rds-db:connect action.

Note
You can map multiple IAM users or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

arn:aws:rds-db:us-east-2:123456789012:dbuser:cluster-12ABC34DEFG5HIJ6KLMNOP78QR/jane_doe

If you attach the policy to IAM users Jane, Bob, and Diego, then each of those users can connect to the specified DB cluster using the jane_doe database account.

Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove an IAM user that is mapped to a database account, you should also remove the database account with the DROP USER statement.

Note
The user name used for IAM authentication must match the case of the user name in the database.

Topics
- Using IAM authentication with MySQL (p. 1667)
- Using IAM authentication with PostgreSQL (p. 1668)

Using IAM authentication with MySQL

With MySQL, authentication is handled by AWSAuthenticationPlugin—an AWS-provided plugin that works seamlessly with IAM to authenticate your IAM users. Connect to the DB cluster and issue the CREATE USER statement, as shown in the following example.

```
CREATE USER jane_doe IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The IDENTIFIED WITH clause allows MySQL to use the AWSAuthenticationPlugin to authenticate the database account (jane_doe). The AS ‘RDS’ clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 1664).
Note
If you see the following message, it means that the AWS-provided plugin is not available for the current DB cluster.
ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded
To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB cluster. For more information, see Availability for IAM database authentication (p. 1661) and Enabling and disabling IAM database authentication (p. 1663).

After you create an account using AWSAuthenticationPlugin, you manage it in the same way as other database accounts. For example, you can modify account privileges with GRANT and REVOKE statements, or modify various account attributes with the ALTER USER statement.

Using IAM authentication with PostgreSQL

To use IAM authentication with PostgreSQL, connect to the DB cluster, create database users, and then grant them the rds_iam role as shown in the following example.

```sql
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 1664).

Note that a PostgreSQL database user can use either IAM or Kerberos authentication but not both, so this user can't also have the rds_ad role. This also applies to nested memberships. For more information, see Step 7: Create Kerberos authentication PostgreSQL logins (p. 1483).

Connecting to your DB cluster using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB cluster. An authentication token is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see Signature Version 4 signing process in the AWS General Reference.) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon Aurora from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Aurora DB cluster. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL
- Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL

The following are prerequisites for connecting to your DB cluster using IAM authentication:
• Enabling and disabling IAM database authentication (p. 1663)
• Creating and using an IAM policy for IAM database access (p. 1664)
• Creating a database account using IAM authentication (p. 1667)

Topics
• Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and mysql client (p. 1669)
• Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and psql client (p. 1671)
• Connecting to your DB cluster using IAM authentication and the AWS SDK for .NET (p. 1672)
• Connecting to your DB cluster using IAM authentication and the AWS SDK for Go (p. 1674)
• Connecting to your DB cluster using IAM authentication and the AWS SDK for Java (p. 1680)
• Connecting to your DB cluster using IAM authentication and the AWS SDK for Python (Boto3) (p. 1687)

Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Aurora DB cluster with the AWS CLI and mysql command line tool as described following.

The following are prerequisites for connecting to your DB cluster using IAM authentication:

• Enabling and disabling IAM database authentication (p. 1663)
• Creating and using an IAM policy for IAM database access (p. 1664)
• Creating a database account using IAM authentication (p. 1667)

Note
For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics
• Generating an IAM authentication token (p. 1669)
• Connecting to a DB cluster (p. 1670)

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```bash
aws rds generate-db-auth-token \
   --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
   --port 3306 \
   --region us-west-2 \
   --username jane_doe
```

In the example, the parameters are as follows:

• --hostname – The host name of the DB cluster that you want to access
• --port – The port number used for connecting to your DB cluster
• --region – The AWS Region where the DB cluster is running
• --username – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

Connecting to a DB cluster

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=[full path]rds-combined-ca-bundle.pem --enable-cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- --host – The host name of the DB cluster that you want to access
- --port – The port number used for connecting to your DB cluster
- --ssl-ca – The SSL certificate file that contains the public key

For more information, see Using SSL/TLS with Aurora MySQL DB clusters (p. 741).

For more information, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634).

- --enable-cleartext-plugin – A value that specifies that AWSAuthenticationPlugin must be used for this connection

  If you are using a MariaDB client, the --enable-cleartext-plugin option isn't required.

- --user – The database account that you want to access
- --password – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround.

```
RDSHOST="rdsmysql.123456789012.us-west-2.rds.amazonaws.com"
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-west-2 --username jane_doe )"
mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/rds-combined-ca-bundle.pem --enable-cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using AWSAuthenticationPlugin, the connection is secured using SSL. To verify this, type the following at the mysql> command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+---------------+-------------+
| Variable_name | Value       |
+---------------+-------------+
| ...           | ...         |
+---------------+-------------+

Connecting to your DB cluster using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Aurora PostgreSQL DB cluster with the AWS CLI and psql command line tool as described following.

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1663)
- Creating and using an IAM policy for IAM database access (p. 1664)
- Creating a database account using IAM authentication (p. 1667)

**Note**
For information about connecting to your database using pgAdmin with IAM authentication, see the blog post Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL.

**Topics**
- Generating an IAM authentication token (p. 1671)
- Connecting to an Aurora PostgreSQL cluster (p. 1672)

**Generating an IAM authentication token**

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```bash
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB cluster (cluster endpoint) that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--region` – The AWS Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```bash
mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

1671
Connecting to an Aurora PostgreSQL cluster

The general format for using psql to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full sslrootcert=certificateFile
dbname=DBName user=userName password=authToken"
```

The parameters are as follows:

- **host** – The host name of the DB cluster (cluster endpoint) that you want to access
- **port** – The port number used for connecting to your DB cluster
- **sslmode** – The SSL mode to use

  When you use `sslmode=verify-full`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.

- **sslrootcert** – The SSL certificate file that contains the public key

  For more information, see [Securing Aurora PostgreSQL data with SSL/TLS](p. 1229).

  For information about downloading the SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB cluster](p. 1634).

- **dbname** – The database that you want to access
- **user** – The database account that you want to access
- **password** – A signed IAM authentication token

The following example shows using psql to connect. In the example psql uses the environment variable `PGPASSWORD` that was set when the token was generated in the previous section.

```
psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/rds-combined-ca-bundle.pem
dbname=DBName user=jane_doe password=$PGPASSWORD"
```

Connecting to your DB cluster using IAM authentication and the AWS SDK for .NET

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for .NET as described following.

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1663)
- Creating and using an IAM policy for IAM database access (p. 1664)
- Creating a database account using IAM authentication (p. 1667)

The following code example shows how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the AWS SDK for .NET, found on the AWS site. The AWSSDK_CORE and the AWSSDK_RDS packages are required. To connect to a DB instance, use the .NET database connector for the DB engine, such as MySqlConnector for MySQL or Npgsql for PostgreSQL.

Modify the values of the following variables as needed:
• server – The endpoint of the DB cluster that you want to access
• port – The port number used for connecting to your DB cluster
• user – The database account that you want to access.

This code connects to an Aurora MySQL DB cluster.

```csharp
using System;
using System.Data;
using MySql.Data;
using Amazon;
namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd = Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1, 
            "mysqldb.123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
            // for debug only
            Console.Write("{0}\n", pwd);  // this verifies the token is generated

            MySqlConnection conn = new MySqlConnection(
                "server=mysqldb.123456789012.us-east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;SslCa=../rds-ca-2019-root.pem");
            conn.Open();

            // Define a query
            MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

            // Execute a query
            MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

            // Read all rows and output the first column in each row
            while (mysqlDataRdr.Read())
            {
                Console.WriteLine(mysqlDataRdr[0]);
            }
            mysqlDataRdr.Close();
            // Close connection
            conn.Close();
        }
    }
}
```

This code connects to an Aurora PostgreSQL DB cluster.

```csharp
using System;
using Npgsql;
using Amazon.RDS.Util;
namespace ConsoleApp1
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd = RDSAuthTokenGenerator.GenerateAuthToken("postgresqldb.123456789012.us-east-1.rds.amazonaws.com", 5432, "jane_doe");
            // for debug only
            Console.Write("{0}\n", pwd);  // this verifies the token is generated
```
Connecting to your DB cluster using IAM authentication and the AWS SDK for Go

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Go as described following.

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1663)
- Creating and using an IAM policy for IAM database access (p. 1664)
- Creating a database account using IAM authentication (p. 1667)

To run these code examples, you need the AWS SDK for Go, found on the AWS site.

Modify the values of the following variables as needed:

- **dbName** – The database that you want to access
- **dbUser** – The database account that you want to access
- **dbHost** – The endpoint of the DB cluster that you want to access
- **dbPort** – The port number used for connecting to your DB cluster
- **region** – The AWS Region where the DB cluster is running

In addition, make sure the imported libraries in the sample code exist on your system.

**Important**
The examples in this section use the following code to provide credentials that access a database from a local environment:

```go
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```go
sess := session.Must(session.NewSession())
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:

```go
"github.com/aws/aws-sdk-go/aws/session"
```
Connecting using IAM authentication and the AWS SDK for V2

You can connect to a DB cluster using IAM authentication and the AWS SDK for Go V2.

Topics

• Generating an IAM authentication token (p. 1675)
• Connecting to a DB cluster (p. 1676)

Generating an IAM authentication token

The auth package provides utilities for generating authentication tokens for connecting to Amazon RDS MySQL and PostgreSQL database instances. Using the BuildAuthToken method, you generate a database authorization token by providing the database endpoint, AWS Region, username, and an aws.CredentialProvider implementation that returns IAM credentials with permission connect to the database using IAM database authentication.

The following example shows how to use BuildAuthToken to create an authentication token for connecting to an Aurora MySQL DB cluster.

```go
package main

import "context"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/feature/rds/auth"

func main() {
    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(),
        "mydb.123456789012.us-east-1.rds.amazonaws.com:3306", // Database Endpoint (With Port)
        "us-east-1", // AWS Region
        "jane_doe", // Database Account
        cfg.Credentials,
    )
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }
}
```

The following example shows how to use BuildAuthToken to create an authentication token for connecting to an Aurora PostgreSQL DB cluster.

```go
package main

import "context"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/feature/rds/auth"

func main() {
   cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authToken := auth.BuildAuthToken(
        context.TODO(),
        "mydb.123456789012.us-east-1.rds.amazonaws.com:5432", // Database Endpoint (With Port)
        "us-east-1", // AWS Region
        "jane_doe", // Database Account
        cfg.Credentials,
    )
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }
}
```
Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a DB cluster.

This code connects to an Aurora MySQL DB cluster.

```go
package main

import "context"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/feature/rds/auth"

func main() {

cfg, err := config.LoadDefaultConfig(context.TODO())
if err != nil {
    panic("configuration error: " + err.Error())
}

authenticationToken, err := auth.BuildAuthToken(
    context.TODO(),
    "mydb.123456789012.us-east-1.rds.amazonaws.com:3306", // Database Endpoint (With Port)
    "us-east-1", // AWS Region
    "jane_doe", // Database Account
    cfg.Credentials,
)
if err != nil {
    panic("failed to create authentication token: " + err.Error())
}

dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
    dbUser, authToken, dbEndpoint, dbName,
)

db, err := sql.Open("mysql", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}```

This code connects to an Aurora PostgreSQL DB cluster.
package main

import "context"
import "github.com/aws/aws-sdk-go-v2/config"
import "github.com/aws/aws-sdk-go-v2/feature/rds/auth"

func main() {
    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authToken, err := auth.BuildAuthToken(
        context.TODO(),
        "mydb.123456789012.us-east-1.rds.amazonaws.com:5432", // Database Endpoint (With Port)
        "us-east-1", // AWS Region
        "jane_doe", // Database Account
        cfg.Credentials,
    )
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s", dbHost, dbPort, dbUser, authToken, dbName,
    )
    db, err := sql.Open("postgres", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}

Connecting using IAM authentication and the AWS SDK for Go V1.

You can connect to a DB cluster using IAM authentication and the AWS SDK for Go V1

Topics
• Generating an IAM authentication token (p. 1677)
• Connecting to a DB cluster (p. 1678)

Generating an IAM authentication token

You can use the rdsutils package to generate tokens used to connect to a DB cluster. Call the BuildAuthToken function to generate a token. Provide the DB instance endpoint, AWS region, username, and IAM credentials to generate the token for connecting to a DB cluster with IAM credentials.

The following example shows how to use BuildAuthToken to create an authentication token for connecting to an Aurora MySQL DB cluster.

package main

import (
    "database/sql"
    "fmt"
IAM database authentication

The following example shows how to use `BuildAuthToken` to create an authentication token for connecting to an Aurora PostgreSQL DB cluster.

```go
package main

import (  
    "database/sql"  
    "fmt"  
    "log"  
    "github.com/aws/aws-sdk-go/aws/credentials"  
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
)

func main() {  
    dbName := "app"  
    dbUser := "jane_doe"  
    dbHost := "mydb.123456789012.us-east-1.rds.amazonaws.com"  
    dbPort := 3306  
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)  
    region := "us-east-1"
    creds := credentials.NewEnvCredentials()  
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)  
    if err != nil {  
        log.Fatalf("failed to build auth token %v", err)
    }
}
```

Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a DB cluster.

This code connects to an Aurora MySQL DB cluster.

```go
package main

import (  
    "database/sql"  
    "fmt"  
    "log"
)
```
func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "mydb.123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 3306
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"
    creds := credentials.NewEnvCredentials()
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
    if err != nil {
        panic(err)
    }
    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true", dbUser, authToken, dbEndpoint, dbName,
    )
    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }
    err = db.Ping()
    if err != nil {
        panic(err)
    }
}

This code connects to an Aurora PostgreSQL DB cluster.

package main

import {
    "database/sql"
    "fmt"
    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    _ "github.com/lib/pq"
}

func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "mydb.123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 5432
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"
    creds := credentials.NewEnvCredentials()
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
    if err != nil {
        panic(err)
    }
    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s", dbHost, dbPort, dbUser, authToken, dbName,
    )
}
Connecting to your DB cluster using IAM authentication and the AWS SDK for Java

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Java as described following.

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1663)
- Creating and using an IAM policy for IAM database access (p. 1664)
- Creating a database account using IAM authentication (p. 1667)
- Set up the AWS SDK for Java

Topics

- Generating an IAM authentication token (p. 1680)
- Manually constructing an IAM authentication token (p. 1681)
- Connecting to a DB cluster (p. 1684)

Generating an IAM authentication token

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the RdsIamAuthTokenGenerator class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the DefaultAWSCredentialsProviderChain class. DefaultAWSCredentialsProviderChain uses the first AWS access key and secret key that it finds in the default credential provider chain. For more information about AWS access keys, see Managing access keys for IAM users.

After you create an instance of RdsIamAuthTokenGenerator, you can call the getAuthToken method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```java
package com.amazonaws.codesamples;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;
public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        String region = "us-west-2";
        String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        
        String region = "us-west-2";
        String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
```
Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use RdsIamAuthTokenGenerator. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see Signature version 4 signing process in the AWS General Reference.

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```java
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;
import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;
import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
    public static String canonicalURIParameter = "/";
    public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();
    public static String payload = StringUtils.EMPTY;
    public static String signedHeader = "host";
    public static String algorithm = "AWS4-HMAC-SHA256";
    public static String serviceName = "rds-db";
    public static String requestWithoutSignature;
```
public static void main(String[] args) throws Exception {
    String region = "us-west-2";
    String instanceName = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
    String port = "3306";
    String username = "jane_doe";

    Date now = new Date();
    String date = new SimpleDateFormat("yyyyMMdd").format(now);
    String dateTimeStamp = new SimpleDateFormat("yyyyMMdd'T'HHmmss'Z'").format(now);
    DefaultAWSCredentialsProviderChain creds = new DefaultAWSCredentialsProviderChain();
    String awsAccessKey = creds.getCredentials().getAWSAccessKeyId();
    String awsSecretKey = creds.getCredentials().getAWSSecretKey();
    String expiryMinutes = "900";

    System.out.println("Step 1: Create a canonical request:");
    String canonicalString = createCanonicalString(username, awsAccessKey, date, dateTimeStamp, region, expiryMinutes, instanceName, port);
    System.out.println(canonicalString);
    System.out.println();

    System.out.println("Step 2: Create a string to sign:");
    String stringToSign = createStringToSign(dateTimeStamp, canonicalString, awsAccessKey, date, region);
    System.out.println(stringToSign);
    System.out.println();

    System.out.println("Step 3: Calculate the signature:");
    String signature = BinaryUtils.toHex(calculateSignature(stringToSign, newSigningKey(awsSecretKey, date, region, serviceName)));
    System.out.println(signature);
    System.out.println();

    System.out.println("Step 4: Add the signing info to the request");
    System.out.println(appendSignature(signature));
    System.out.println();
}

//Step 1: Create a canonical request date should be in format YYYYMMDD and dateTime should be in format YYYYMMDDTHHMMSSZ
public static String createCanonicalString(String user, String accessKey, String date, String dateTime, String region, String expiryPeriod, String hostName, String port) throws Exception {
    canonicalQueryParameters.put("Action", action);
    canonicalQueryParameters.put("DBUser", user);
    canonicalQueryParameters.put("X-Amz-Algorithm", "AWS4-HMAC-SHA256");
    canonicalQueryParameters.put("X-Amz-Credential", accessKey + "%2F" + date + "%2F" + region + "%2F" + service + "%2F%2F" + request);
    canonicalQueryParameters.put("X-Amz-Expires", expiryPeriod);
    canonicalQueryParameters.put("X-Amz-SignedHeaders", signedHeader);
    String canonicalQueryString = "";
    while(!canonicalQueryParameters.isEmpty()) {
        String currentQueryParameter = canonicalQueryParameters.firstKey();
        String currentQueryParameterValue = canonicalQueryParameters.remove(currentQueryParameter);
        canonicalQueryString = canonicalQueryString + currentQueryParameter + "=" + currentQueryParameterValue;
        if (!currentQueryParameter.equals("X-Amz-SignedHeaders")) {
            canonicalQueryString += ";";
        }
    }
    String canonicalHeaders = "host:" + hostName + ":" + port + "\n";
    //Missing the rest of the canonical request
Amazon Aurora User Guide for Aurora

Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a cluster running MySQL.

To run this code example, you need the AWS SDK for Java, found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with mysql-connector-java-5.1.33-bin.jar.
- An intermediate certificate for Amazon Aurora that is specific to an AWS Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634).) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - RDS_INSTANCE_HOSTNAME – The host name of the DB cluster that you want to access.
  - RDS_INSTANCE_PORT – The port number used for connecting to your PostgreSQL DB cluster.
  - REGION_NAME – The AWS Region where the DB cluster is running.
  - DB_USER – The database account that you want to access.
  - SSL_CERTIFICATE – An SSL certificate for Amazon Aurora that is specific to an AWS Region.

    To download a certificate for your AWS Region, see Using SSL/TLS to encrypt a connection to a DB cluster (p. 1634). Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the default credential provider chain.

```java
package com.amazonaws.samples;

import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import java.io.File;
import java.io.FileOutputStream;
import java.io.InputStream;
import java.security.KeyStore;
import java.security.cert.CertificateFactory;
import java.security.cert.X509Certificate;
```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;
import java.util.Properties;
import java.net.URL;

public class IAMDatabaseAuthenticationTester {
    // AWS Credentials of the IAM user with policy enabling IAM Database Authenticated access to the db by the db user.
    private static final DefaultAWSCredentialsProviderChain creds = new DefaultAWSCredentialsProviderChain();
    private static final String AWS_ACCESS_KEY = creds.getCredentials().getAWSAccessKeyId();
    private static final String AWS_SECRET_KEY = creds.getCredentials().getAWSSecretKey();

    // Configuration parameters for the generation of the IAM Database Authentication token
    private static final String RDS_INSTANCE_HOSTNAME = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";

}
Connecting to your DB cluster using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the AWS SDK for Python (Boto3) as described following.

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1663)
- Creating and using an IAM policy for IAM database access (p. 1664)
- Creating a database account using IAM authentication (p. 1667)

In addition, make sure the imported libraries in the sample code exist on your system.

The code examples use profiles for shared credentials. For information about the specifying credentials, see Credentials in the AWS SDK for Python (Boto3) documentation.

Topics
- Generating an IAM authentication token (p. 1688)
- Connecting to a DB cluster (p. 1688)
Generating an IAM authentication token

You can call the `generate_db_auth_token` method to obtain a signed token. Provide the DB cluster endpoint, port, user name, AWS Region, and DB engine to generate the token for connecting to a DB cluster with IAM credentials.

This code generates an IAM authentication token for an Aurora MySQL DB cluster.

```python
import sys
import boto3
import os

ENDPOINT="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USR="jane_doe"
REGION="us-east-1"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

# gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USR,
Region=REGION)
```

This code generates an IAM authentication token for an Aurora PostgreSQL DB cluster.

```python
import sys
import boto3
import os

ENDPOINT="postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USR="jane_doe"
REGION="us-east-1"

# gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USR,
Region=REGION)
```

Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the AWS SDK for Python (Boto3), found on the AWS site.

Modify the values of the following variables as needed:

- **ENDPOINT** – The endpoint of the DB cluster that you want to access
- **PORT** – The port number used for connecting to your DB cluster
- **USER** – The database account that you want to access.
- **REGION** – The AWS Region where the DB cluster is running
• **DBNAME** – The database that you want to access

This code connects to an Aurora MySQL DB cluster.

```python
import mysql.connector
import sys
import boto3
import os

ENDPOINT="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USR="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

# gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

# gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USR, Region=REGION)

try:
    conn = mysql.connector.connect(host=ENDPOINT, user=USR, passwd=token, port=PORT, database=DBNAME, ssl_ca='[full path]rds-combined-ca-bundle.pem')
    cur = conn.cursor()
    cur.execute("SELECT now()")
    query_results = cur.fetchall()
    print(query_results)

except Exception as e:
    print("Database connection failed due to {}").format(e)
```

This code connects to an Aurora PostgreSQL DB cluster.

```python
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USR="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

# gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USR, Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USR, password=token, sslmode='prefer', sslrootcert='[full path]rds-combined-ca-bundle.pem')
    cur = conn.cursor()
    cur.execute("SELECT now()")
    query_results = cur.fetchall()
    print(query_results)
```

1689
except Exception as e:
    print("Database connection failed due to {}\).format(e))

Troubleshooting Amazon Aurora identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Aurora and IAM.

Topics

• I’m not authorized to perform an action in Aurora (p. 1690)
• I’m not authorized to perform iam:PassRole (p. 1690)
• I want to view my access keys (p. 1690)
• I’m an administrator and want to allow others to access Aurora (p. 1691)
• I want to allow people outside of my AWS account to access my Aurora resources (p. 1691)

I’m not authorized to perform an action in Aurora

If the AWS Management Console tells you that you’re not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a widget but does not have rds:GetWidget permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: rds:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the my-example-widget resource using the rds:GetWidget action.

I’m not authorized to perform iam:PassRole

If you receive an error that you’re not authorized to perform the iam:PassRole action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password. Ask that person to update your policies to allow you to pass a role to Aurora.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in Aurora. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the iam:PassRole action.

I want to view my access keys

After you create your IAM user access keys, you can view your access key ID at any time. However, you can’t view your secret access key again. If you lose your secret key, you must create a new access key pair.
Access keys consist of two parts: an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

Important
Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the IAM User Guide.

I'm an administrator and want to allow others to access Aurora

To enable others to access Aurora, you must create an IAM entity (user or role) for the person or application that needs access. They use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in Aurora.

To get started right away, see Creating your first IAM delegated user and group in the IAM User Guide.

I want to allow people outside of my AWS account to access my Aurora resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Aurora supports these features, see How Amazon Aurora works with IAM (p. 1648).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

Logging and monitoring in Amazon Aurora

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon Aurora resources and responding to potential incidents:

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto
Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

**AWS CloudTrail Logs**

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon Aurora. CloudTrail captures all API calls for Amazon Aurora as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon Aurora, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Working with AWS CloudTrail and Amazon RDS](p. 679).

**Enhanced Monitoring**

Amazon Aurora provides metrics in real time for the operating system (OS) that your DB cluster runs on. You can view the metrics for your DB cluster using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see [Monitoring the OS by using Enhanced Monitoring](p. 617).

**Amazon RDS Performance Insights**

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora](p. 561).

**Database Logs**

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see [Working with Amazon Aurora database log files](p. 665).

**Amazon Aurora Recommendations**

Amazon Aurora provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB cluster configuration, usage, and performance data. For more information, see [Viewing Amazon Aurora recommendations](p. 554).

**Amazon Aurora Event Notification**

Amazon Aurora uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon Aurora event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see [Using Amazon RDS event notification](p. 646).

**AWS Trusted Advisor**

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon Aurora-related checks:

- Amazon Aurora Idle DB Instances
- Amazon Aurora Security Group Access Risk
- Amazon Aurora Backups
- Amazon Aurora Multi-AZ
- Aurora DB Instance Accessibility

For more information on these checks, see [Trusted Advisor best practices (checks)](p. 1692).
Database activity streams

Database activity streams can protect your databases from internal threats by controlling DBA access to the database activity streams. Thus, the collection, transmission, storage, and subsequent processing of the database activity stream is beyond the access of the DBAs that manage the database. Database activity streams can provide safeguards for your database and meet compliance and regulatory requirements. For more information, see Monitoring Amazon Aurora using Database Activity Streams (p. 683).

For more information about monitoring Aurora see Monitoring an Amazon Aurora DB cluster (p. 537).
Compliance validation for Amazon Aurora

Third-party auditors assess the security and compliance of Amazon Aurora as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Amazon Aurora is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and compliance quick start guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA security and compliance whitepaper** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS compliance resources** – This collection of workbooks and guides that might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
Resilience in Amazon Aurora

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

In addition to the AWS global infrastructure, Aurora offers features to help support your data resiliency and backup needs.

Backup and restore

Aurora backs up your cluster volume automatically and retains restore data for the length of the backup retention period. Aurora backups are continuous and incremental so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period, from 1 to 35 days, when you create or modify a DB cluster.

If you want to retain a backup beyond the backup retention period, you can also take a snapshot of the data in your cluster volume. Aurora retains incremental restore data for the entire backup retention period. Thus, you need to create a snapshot only for data that you want to retain beyond the backup retention period. You can create a new DB cluster from the snapshot.

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, or from a DB cluster snapshot that you have saved. You can quickly create a new copy of a DB cluster from backup data to any point in time during your backup retention period. The continuous and incremental nature of Aurora backups during the backup retention period means you don't need to take frequent snapshots of your data to improve restore times.

For more information, see Backing up and restoring an Amazon Aurora DB cluster (p. 486).

Replication

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an AWS Region. The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary DB instance and to Aurora Replicas in the DB cluster. If the primary DB instance fails, an Aurora Replica is promoted to be the primary DB instance.

Aurora also supports replication options that are specific to Aurora MySQL and Aurora PostgreSQL.

For more information, see Replication with Amazon Aurora (p. 69).

Failover

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single AWS Region. This storage occurs regardless of whether the DB instances in the DB cluster span multiple Availability Zones. When you create Aurora Replicas across Availability Zones, Aurora automatically provisions and maintains them synchronously. The primary DB instance is synchronously replicated across Availability Zones to Aurora Replicas to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups. Running a DB cluster with high availability can enhance availability during
planned system maintenance, and help protect your databases against failure and Availability Zone disruption.

For more information, see High availability for Amazon Aurora (p. 67).
Infrastructure security in Amazon Aurora

As a managed service, Amazon RDS is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of security processes whitepaper.

You use AWS published API calls to access Amazon Aurora through the network. Clients must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

In addition, Aurora offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off to a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group.

For more information, see Controlling access with security groups (p. 1701).

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the Public accessibility parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the Public accessibility parameter.

For more information, see Hiding a DB instance in a VPC from the internet (p. 1710).

Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 1644).
Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an interface VPC endpoint. Interface endpoints are powered by AWS PrivateLink.

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don’t need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB clusters. Your instances also don’t need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn’t leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see Elastic network interfaces in the Amazon EC2 User Guide.

For more information about VPC endpoints, see Interface VPC endpoints (AWS PrivateLink) in the Amazon VPC User Guide. For more information about RDS API operations, see Amazon RDS API Reference.

Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review Interface endpoint properties and limitations in the Amazon VPC User Guide.

All RDS API operations relevant to managing Amazon Aurora resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Availability

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the Amazon VPC User Guide.

Create a VPC endpoint for Amazon RDS API using the service name `com.amazonaws.region.rds`.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example `rds.us-east-1.amazonaws.com`. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using `rds-api.cn-north-1.amazonaws.com.cn` and `rds-api.cn-northwest-1.amazonaws.com.cn`, respectively.

For more information, see Accessing a service through an interface endpoint in the Amazon VPC User Guide.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```json
{
    "Statement": [ 
        {
            "Principal": "*",
            "Effect": "Allow",
            "Action": [
                "rds:CreateDBInstance",
            
```
Security best practices for Amazon Aurora

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon Aurora resources. Such resources include DB clusters, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB clusters.

- Create an individual IAM user for each person who manages Amazon Aurora resources, including yourself. Don’t use AWS root credentials to manage Amazon Aurora resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon Aurora. For more information, see Rotating your AWS Secrets Manager secrets in the AWS Secrets Manager User Guide. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see Retrieving the secret value in the AWS Secrets Manager User Guide.

For more information about IAM, see AWS Identity and Access Management. For information on IAM best practices, see IAM best practices.

Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.
Controlling access with security groups

Security groups control the access that traffic has in and out of a DB instance. Aurora supports VPC security groups.

**VPC security groups**

Each VPC security group rule enables a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic, though the outbound traffic rules typically do not apply to DB instances. Outbound traffic rules only apply if the DB instance acts as a client. You must use the Amazon EC2 API or the Security Group option on the VPC Console to create VPC security groups.

When you create rules for your VPC security group that allow access to the instances in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to enable SSH access to instances in the VPC, then you create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for Aurora MySQL DB instances in your VPC.

**Note**

In an Aurora DB cluster, the VPC security group associated with the DB cluster is also associated with all of the DB instances in the DB cluster. If you change the VPC security group for the DB cluster or for a DB instance, the change is applied automatically to all of the DB instances in the DB cluster.

For more information on VPC security groups, see Security groups in the Amazon Virtual Private Cloud User Guide.

**Note**

If your DB cluster is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 1644).

**Security group scenario**

A common use of a DB instance in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, sg-0123ec2example) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.
2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (sg-0123ec2example) that you created in the previous step.
3. Create a second VPC security group (for example, sg-6789rdsexample) and create a new rule by specifying the VPC security group that you created in step 1 (sg-0123ec2example) as the source.
4. Create a new DB instance and add the DB instance to the VPC security group (sg-6789rdsexample) that you created in the previous step. When you create the DB instance, use the same port number as the one specified for the VPC security group (sg-6789rdsexample) rule that you created in step 3.
The following diagram shows this scenario.

For more information about using a VPC, see *Amazon Virtual Private Cloud VPCs and Amazon Aurora* (p. 1708).

## Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see *Provide access to the DB cluster in the VPC by creating a security group* (p. 86) and *Security groups* in the *Amazon Virtual Private Cloud User Guide*.

### Associating a security group with a DB instance

You can associate a security group with a DB instance by using Modify on the RDS console, the ModifyDBInstance Amazon RDS API, or the modify-db-instance AWS CLI command.

For information about modifying a DB instance in a DB cluster, see *Modify a DB instance in a DB cluster* (p. 369). For security group considerations when you restore a DB instance from a DB snapshot, see *Security group considerations* (p. 493).

### Associating a security group with a DB cluster

You can associate a security group with a DB cluster by using Modify cluster on the RDS console, the ModifyDBCluster Amazon RDS API, or the modify-db-cluster AWS CLI command.

For information about modifying a DB cluster, see *Modifying an Amazon Aurora DB cluster* (p. 368).
Master user account privileges

When you create a new DB cluster, the default master user that you use gets certain privileges for that DB cluster. The following table shows the privileges and database roles the master user gets for each of the database engines.

**Important**
We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

**Note**
If you accidentally delete the permissions for the master user, you can restore them by modifying the DB cluster and setting a new master user password. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster (p. 368).

<table>
<thead>
<tr>
<th>Database engine</th>
<th>System privilege</th>
<th>Database role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Aurora MySQL</td>
<td>CREATE, DROP, GRANT OPTION, REFERENCES, EVENT, ALTER, DELETE, INDEX, INSERT, SELECT, UPDATE, CREATE TEMPORARY TABLES, LOCK TABLES, TRIGGER, CREATE VIEW, SHOW VIEW, LOAD FROM S3, SELECT INTO S3, ALTER ROUTINE, CREATE ROUTINE, EXECUTE, CREATE USER, PROCESS, SHOW DATABASES, RELOAD, REPLICATION CLIENT, REPLICATION SLAVE</td>
<td>—</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL</td>
<td>LOGIN, NOSUPERUSER, INHERIT, CREATEDB, CREATEROLE, NOREPLICATION, VALID UNTIL 'infinity'</td>
<td>RDS_SUPERUSER</td>
</tr>
</tbody>
</table>
Using service-linked roles for Amazon Aurora

Amazon Aurora uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon Aurora. Service-linked roles are predefined by Amazon Aurora and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon Aurora easier because you don't have to manually add the necessary permissions. Amazon Aurora defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon Aurora can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon Aurora resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon Aurora

Amazon Aurora uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB clusters.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- rds.amazonaws.com

The role permissions policy allows Amazon Aurora to complete the following actions on the specified resources:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:AuthorizeSecurityGroupIngress",
                "ec2:CreateNetworkInterface",
                "ec2:CreateSecurityGroup",
                "ec2:DeleteNetworkInterface",
                "ec2:DeleteSecurityGroup",
                "ec2:DescribeAvailabilityZones",
                "ec2:DescribeInternetGateways",
                "ec2:DescribeSecurityGroups",
                "ec2:DescribeSubnets",
                "ec2:DescribeVpcAttribute",
                "ec2:DescribeVpcs",
                "ec2:ModifyNetworkInterfaceAttribute",
                "ec2:ModifyVpcEndpoint",
                "ec2:RevokeSecurityGroupIngress",
                "ec2:CreateVpcEndpoint",
                "ec2:DescribeVpcEndpoints",
                "ec2:DeleteVpcEndpoints",
                "ec2:AssignPrivateIpAddresses",
                "ec2:UnassignPrivateIpAddresses"
            ],
            "Resource": "*"
        }
    ]
}
```
Note
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:
Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.
Make sure you have the following permissions enabled:

```json
{
   "Action": "iam:CreateServiceLinkedRole",
   "Effect": "Allow",
   "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/AWSServiceRoleForRDS",
}```
"Condition": {
    "StringLike": {
        "iam:AWSServiceName":"rds.amazonaws.com"
    }
}
}

For more information, see Service-linked role permissions in the IAM User Guide.

Creating a service-linked role for Amazon Aurora

You don't need to manually create a service-linked role. When you create a DB cluster, Amazon Aurora creates the service-linked role for you.

Important
If you were using the Amazon Aurora service before December 1, 2017, when it began supporting service-linked roles, then Amazon Aurora created the AWSServiceRoleForRDS role in your account. To learn more, see A new role appeared in my AWS account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB cluster, Amazon Aurora creates the service-linked role for you again.

Editing a service-linked role for Amazon Aurora

Amazon Aurora does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon Aurora

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB clusters before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the Summary page for the chosen role, choose the Access Advisor tab.
4. On the Access Advisor tab, review recent activity for the service-linked role.

Note
If you are unsure whether Amazon Aurora is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.
If you want to remove the AWSServiceRoleForRDS role, you must first delete all of your DB clusters.

Deleting all of your clusters

Use one of the following procedures to delete a single cluster. Repeat the procedure for each of your clusters.

**To delete a cluster (console)**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the Databases list, choose the cluster that you want to delete.
3. For Cluster Actions, choose Delete.
4. Choose Delete.

**To delete a cluster (CLI)**

See delete-db-cluster in the AWS CLI Command Reference.

**To delete a cluster (API)**

See DeleteDBCluster in the Amazon RDS API Reference.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.
Amazon Virtual Private Cloud VPCs and Amazon Aurora

Amazon Virtual Private Cloud (Amazon VPC) enables you to launch AWS resources, such as Aurora DB clusters, into a virtual private cloud (VPC).

When you use an Amazon VPC, you have control over your virtual networking environment: you can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB instance in an Amazon VPC.

Accounts that support only the EC2-VPC platform have a default VPC. All new DB instances are created in the default VPC unless you specify otherwise. If you are a new Amazon Aurora customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, you are most likely on the EC2-VPC platform and have a default VPC.

Topics
- Working with a DB instance in a VPC (p. 1708)
- How to create a VPC for use with Amazon Aurora (p. 1714)
- Scenarios for accessing a DB instance in a VPC (p. 1721)
- Tutorial: Create an Amazon VPC for use with a DB instance (p. 1726)

This documentation only discusses VPC functionality relevant to Amazon Aurora DB clusters. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide. For information about using a network address translation (NAT) gateway, see NAT gateways in the Amazon Virtual Private Cloud User Guide.

Working with a DB instance in a VPC

Your DB instance is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC lets you launch AWS resources, such as an Amazon Aurora DB instance or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon Aurora DB instances in a VPC, see Scenarios for accessing a DB instance in a VPC (p. 1721).

For a tutorial that shows you how to create a VPC that you can use with a common Amazon Aurora scenario, see Tutorial: Create an Amazon VPC for use with a DB instance (p. 1726).

To learn how to work with DB instances inside a VPC, see the following:

Topics
- Working with a DB instance in a VPC (p. 1709)
- Working with DB subnet groups (p. 1709)
- Hiding a DB instance in a VPC from the internet (p. 1710)
- Creating a DB instance in a VPC (p. 1711)
Working with a DB instance in a VPC

Here are some tips on working with a DB instance in a VPC:

• Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB instance. A subnet is a segment of a VPC's IP address range that you can specify and that lets you group instances based on your security and operational needs.

• If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes DNS hostnames and DNS resolution.

• Your VPC must have a DB subnet group that you create (for more information, see the next section). You create a DB subnet group by specifying the subnets you created. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet.

• Your VPC must have a VPC security group that allows access to the DB instance.

• The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon Aurora to use during maintenance activities, including failover and compute scaling.

• A VPC can have an instance tenancy attribute of either default or dedicated. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB instance in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB instance must be one of the approved Amazon EC2 dedicated instance types. For example, the m3.medium EC2 dedicated instance corresponds to the db.m3.medium DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

For more information about the instance types that can be in a dedicated instance, see Amazon EC2 dedicated instances on the EC2 pricing page.

Note
When you set the instance tenancy attribute to dedicated for an Amazon RDS DB instance, it doesn't guarantee that the DB instance will run on a dedicated host.

Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A DB subnet group is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when creating DB instances using the CLI or API; if you use the console, you can just choose the VPC and subnets you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB instance in a VPC, you must choose a DB subnet group. From the DB subnet group, Amazon Aurora chooses a subnet and an IP address within that subnet to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet. If the primary DB instance of a Multi-AZ deployment fails, Amazon Aurora can promote the corresponding standby and subsequently create a new standby using an IP address of the subnet in one of the other Availability Zones.

The subnets in a DB subnet group are either public or private. They can't be a mix of both public and private subnets. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables.

When Amazon Aurora creates a DB instance in a VPC, it assigns a network interface to your DB instance by using an IP address from your DB subnet group. However, we strongly recommend that you use the DNS name to connect to your DB instance because the underlying IP address changes during failover.
Note
For each DB instance that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon Aurora for recovery actions.

Hiding a DB instance in a VPC from the internet

One common Amazon Aurora scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB instance with a database that is not publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet, and the DB instances are deployed in the private subnet. In such a deployment, only the web servers have access to the DB instances. For an illustration of this scenario, see A DB instance in a VPC accessed by an EC2 Instance in the same VPC (p. 1721).

When you launch a DB instance inside a VPC, the DB instance has a private IP address for traffic inside the VPC. This private IP address isn’t publicly accessible. You can use the Public access option to designate whether the DB instance also has a public IP address in addition to the private IP address. If the DB instance is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the DB instance’s VPC, and to the public IP address from outside of the DB instance’s VPC. Access to the DB instance is ultimately controlled by the security group it uses, and that public access is not permitted if the security group assigned to the DB instance doesn’t permit it.

You can modify a DB instance to turn on or off public accessibility by modifying the Public access option. For more information, see the modifying section for your DB engine.

The following illustration shows the Public access option in the Additional connectivity configuration section. To set the option, open the Additional connectivity configuration section in the Connectivity section.
Creating a DB instance in a VPC

The following procedures help you create a DB instance in a VPC. If your account has a default VPC, you can begin with step 3 because the VPC and DB subnet group have already been created for you. If your AWS account doesn't have a default VPC, or if you want to create an additional VPC, you can create a new VPC.

Note
If you want your DB instance in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes DNS hostnames and DNS resolution. For information about updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

Follow these steps to create a DB instance in a VPC:
Step 1: Create a VPC

If your AWS account does not have a default VPC or if you want to create an additional VPC, follow the instructions for creating a new VPC. See Create a VPC with private and public subnets (p. 1726), or see Step 1: Create a VPC in the Amazon VPC documentation.

Step 2: Add subnets to the VPC

Once you have created a VPC, you need to create subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For instructions on how to create subnets in a VPC, see Create a VPC with private and public subnets (p. 1726).

Step 3: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when you create DB instances using the CLI or API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region.

For a DB instance to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see Internet gateways in the Amazon VPC documentation.

When you create a DB instance in a VPC, make sure to choose a DB subnet group. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with your DB instance. Amazon Aurora creates and associates an Elastic Network Interface to your DB instance with that IP address. The DB instance uses the Availability Zone that contains the subnet. For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon Aurora to create a new standby in another Availability Zone should the need arise. You need to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

To create a DB subnet group

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Subnet groups.
3. Choose Create DB Subnet Group.
4. For Name, type the name of your DB subnet group.
5. For Description, type a description for your DB subnet group.
6. For VPC, choose the VPC that you created.
7. In the Add subnets section, choose the Availability Zones that include the subnets from Availability Zones, and then choose the subnets from Subnets.
8. Choose Create.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

**Step 4: Create a VPC security group**

Before you create your DB instance, you must create a VPC security group to associate with your DB instance. For instructions on how to create a security group for your DB instance, see Create a VPC security group for a private DB instance (p. 1729), or see Security groups for your VPC in the Amazon VPC documentation.

**Step 5: Create a DB instance in the VPC**

In this step, you create a DB instance and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

**Note**

If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes DNS hostnames and DNS resolution. For information on updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

For details on how to create a DB instance, see Creating an Amazon Aurora DB cluster (p. 124).

When prompted in the Network & Security section, enter the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

**Note**

Updating VPCs is not currently supported for Aurora clusters.

**How to create a VPC for use with Amazon Aurora**

The following sections discuss how to create a VPC for use with Amazon Aurora.

**Note**

For a helpful and detailed guide on connecting to an Amazon Aurora DB cluster, you can see Aurora MySQL database administrator's handbook – Connection management.

**Create a VPC and subnets**

You can only create an Amazon Aurora DB cluster in a Virtual Private Cloud (VPC) that spans two Availability Zones, and each zone must contain at least one subnet. You can create an Aurora DB cluster in the default VPC for your AWS account, or you can create a user-defined VPC. For information, see Amazon Virtual Private Cloud VPCs and Amazon Aurora (p. 1708).

Amazon Aurora optionally can create a VPC and subnet group for you to use with your DB cluster. Doing this can be helpful if you have never created a VPC, or if you would like to create a new VPC that is separate from your other VPCs. If you want Amazon Aurora to create a VPC and subnet group for you, then skip this procedure and see Create an Aurora MySQL DB cluster (p. 88) or Create an Aurora PostgreSQL DB cluster (p. 96).

**Note**

All VPC and EC2 resources that you use with your Aurora DB cluster must be in one of the regions listed in Regions and Availability Zones (p. 11).

**To create a VPC for use with an Aurora DB cluster**
1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

2. In the top-right corner of the AWS Management Console, choose the AWS Region to create your VPC in. This example uses the US East (Ohio) Region.

3. In the upper-left corner, choose VPC Dashboard. Choose Start VPC Wizard to begin creating a VPC.

4. In the Create VPC wizard, choose VPC with a Single Public Subnet. Choose Select.

5. Set the following values in the Create VPC panel:
   - **IP CIDR block**: 10.0.0.0/16
   - **VPC name**: gs-cluster-vpc
   - **Public subnet**: 10.0.0.0/24
   - **Availability Zone**: us-east-1a
   - **Subnet name**: gs-subnet1
   - **Enable DNS hostnames**: Yes
   - **Hardware tenancy**: Default
6. Choose **Create VPC**.

7. When your VPC has been created, choose **Close** on the notification page.

---

**To create additional subnets**

1. To add the second subnet to your VPC, in the VPC Dashboard choose **Subnets**, and then choose **Create Subnet**. An Amazon Aurora DB cluster requires at least two VPC subnets.

2. Set the following values in the **Create Subnet** panel:
   - **Name tag**: gs-subnet2
   - **VPC**: Choose the VPC that you created in the previous step, for example: `vpc-a464d1c1 10.0.0.0/16 | gs-cluster-vpc`
   - **Availability Zone**: `us-east-1c`
   - **CIDR block**: `10.0.1.0/24`
3. Choose Yes Create.
4. To ensure that the second subnet that you created uses the same route table as the first subnet, in
the VPC Dashboard, choose Subnets, and then choose the first subnet that was created for the VPC, gs-subnet1. Choose the Route Table tab, and note the Current Route Table, for example: rtb-c16ce5bc.
5. In the list of subnets, clear the first subnet and choose the second subnet, gs-subnet2. Choose the Route Table tab, and then choose Edit. In the Change to list, choose the route table from the previous step, for example: rtb-c16ce5bc. Choose Save to save your choice.

Create a security group and add inbound rules

After you've created your VPC and subnets, the next step is to create a security group and add inbound rules.

To create a security group

The last step in creating a VPC for use with your Amazon Aurora DB cluster is to create a VPC security
group, which identifies which network addresses and protocols are allowed to access DB instances in your VPC.

1. In the VPC Dashboard, choose Security Groups, and then choose Create Security Group.
2. Set the following values in the Create Security Group panel:
• **Name tag:** gs-securitygroup1
• **Group name:** gs-securitygroup1
• **Description:** Getting Started Security Group
• **VPC:** Choose the VPC that you created earlier, for example: vpc-b5754bcd | gs-cluster-vpc.

3. Choose **Yes, Create** to create the security group.

---

### To add inbound rules to the security group

To connect to your Aurora DB cluster, you need to add an inbound rule to your VPC security group that allows inbound traffic to connect.

1. Determine the IP address to use to connect to the Aurora cluster. You can use the service at [https://checkip.amazonaws.com](https://checkip.amazonaws.com) to determine your public IP address. If you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

   **Warning**
   
   If you use 0.0.0.0/0, you enable all IP addresses to access your DB cluster. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you'll authorize only a specific IP address or range of addresses to access your DB cluster.

2. In the VPC Dashboard, choose **Security Groups**, and then choose the gs-securitygroup1 security group that you created in the previous procedure.

3. Choose the **Inbound** tab, and then choose the **Edit** button.

4. Set the following values for your new inbound rule:
   
   • **Type:** All Traffic
   
   • **Source:** The IP address or range from the previous step, for example 203.0.113.25/32.

5. Choose **Save** to save your settings.
Create a DB subnet group

The last thing that you need before you can create an Aurora DB cluster is a DB subnet group. Your DB subnet group identifies the subnets that your DB cluster uses from the VPC that you created in the previous steps. Your DB subnet group must include at least one subnet in at least two of the Availability Zones in the AWS Region where you want to deploy your DB cluster.

To create a DB subnet group for use with your Aurora DB cluster

1. Open the Amazon Aurora console at https://console.aws.amazon.com/rds.
2. Choose Subnet Groups, and then choose Create DB Subnet Group.
3. Set the following values for your new DB subnet group:
   - Name: gs-subnetgroup1
   - Description: Getting Started Subnet Group
   - VPC ID: Choose the VPC that you created in the previous procedure, for example, gs-cluster-vpc (vpc-b5754bcd).
4. In the Add subnets section, choose the Availability Zones that include the subnets from Availability Zones, and then choose the subnets from Subnets.
Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

Subnet group details

Name
You won't be able to modify the name after your subnet group has been created.

gs-subnetgroup1
Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Description

Getting Started Subnet Group

VPC
Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.

gs-cluster-vpc (vpc-068e388385a9014)

Add subnets

Availability Zones
Choose the Availability Zones that include the subnets you want to add.

Choose an availability zone

us-east-1a ✗  us-east-1c ✗

Subnets
Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

Select subnets

subnet-079bd4b8953aae16d (10.0.0.0/24) ✗
subnet-057e85b72c46f9d9a (10.0.1.0/24) ✗

Subnets selected (2)

Scenarios for accessing a DB instance in a VPC

Amazon Aurora supports the following scenarios for accessing a DB instance in a VPC:

- An EC2 instance in the same VPC (p. 1721)
- An EC2 instance in a different VPC (p. 1722)
- A client application through the internet (p. 1723)
- A private network (p. 1724)
- An EC2 instance not in a VPC (p. 1724)

A DB instance in a VPC accessed by an EC2 instance in the same VPC

A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC. This is the user scenario created if you use AWS Elastic Beanstalk to create an EC2 instance and a DB instance in the same VPC.

The following diagram shows this scenario.

The simplest way to manage access between EC2 instances and DB instances in the same VPC is to do the following:

- Create a VPC security group for your DB instances to be in. This security group can be used to restrict access to the DB instances. For example, you can create a custom rule for this security group that
allows TCP access using the port you assigned to the DB instance when you created it and an IP address you use to access the DB instance for development or other purposes.

- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB instances that allow connections from the security group you created for your EC2 instances. This would allow any member of the security group to access the DB instances.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create an Amazon VPC for use with a DB instance (p. 1726).

To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose Security Groups.
3. Choose or create a security group for which you want to allow access to members of another security group. In the scenario preceding, this is the security group that you use for your DB instances. Choose the Inbound rules tab, and then choose Edit inbound rules.
5. From Type, choose the entry that corresponds to the port you used when you created your DB instance, such as MYSQL/Aurora.
6. In the Source box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with All TCP as the Type and your security group in the Source box. If you intend to use the UDP protocol, create a rule with All UDP as the Type and your security group in the Source box.
8. Choose Save rules when you are done.

The following screen shows an inbound rule with a security group for its source.

A DB instance in a VPC accessed by an EC2 instance in a different VPC

When your DB instance is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB instance.

The following diagram shows this scenario.
VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Instances in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see VPC peering in the Amazon Virtual Private Cloud User Guide.

A DB instance in a VPC accessed by a client application through the internet

To access a DB instance in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon Aurora DB instance that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB instance.
- An internet gateway which connects the VPC to the internet and to other AWS products.
• A security group associated with the DB instance. The security group's inbound rules allow your client application to access to your DB instance.

For information about creating a DB instance in a VPC, see Creating a DB instance in a VPC (p. 1711).

**A DB instance in a VPC accessed by a private network**

If your DB instance isn't publicly accessible, you have the following options for accessing it from a private network:

• An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
• An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.

For more information, see Internetwork traffic privacy (p. 1644).

**A DB instance in a VPC accessed by an EC2 instance not in a VPC**

You can communicate between an Amazon Aurora DB instance that is in a VPC and an EC2 instance that is not in an Amazon VPC by using ClassicLink. When you use ClassicLink, an application on the EC2 instance can connect to the DB instance by using the endpoint for the DB instance. ClassicLink is available at no charge.

**Important**

If your EC2 instance was created after 2013, it is probably in a VPC.

The following diagram shows this scenario.
Using ClassicLink, you can connect an EC2 instance to a logically isolated database where you define the IP address range and control the access control lists (ACLs) to manage network traffic. You don’t have to use public IP addresses or tunneling to communicate with the DB instance in the VPC. This arrangement provides you with higher throughput and lower latency connectivity for inter-instance communications.

**To enable ClassicLink between a DB instance in a VPC and an EC2 instance not in a VPC**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose **Your VPCs**.
3. Choose the VPC used by the DB instance.
4. In **Actions**, choose **Enable ClassicLink**. In the confirmation dialog box, choose **Yes, Enable**.
5. On the EC2 console, choose the EC2 instance you want to connect to the DB instance in the VPC.
6. In **Actions**, choose **ClassicLink**, and then choose **Link to VPC**.
7. On the **Link to VPC** page, choose the security group you want to use, and then choose **Link to VPC**.

**Note**

The ClassicLink features are only visible in the consoles for accounts and regions that support EC2-Classic. For more information, see **ClassicLink** in the *Amazon EC2 User Guide for Linux Instances*.
Tutorial: Create an Amazon VPC for use with a DB instance

A common scenario includes a DB instance in an Amazon VPC, that shares data with a web server that is running in the same VPC. In this tutorial you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB instance in a VPC (p. 1721).

Because your DB instance only needs to be available to your web server, and not to the public Internet, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public Internet. The DB instance is hosted in a private subnet. The web server is able to connect to the DB instance because it is hosted within the same VPC, but the DB instance is not available to the public Internet, providing greater security.

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Note

For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon Aurora DB cluster (p. 102).

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.
To create a VPC and subnets

1. If you don't have an Elastic IP address to associate with a network address translation (NAT) gateway, allocate one now. A NAT gateway is required for this tutorial. If you have an available Elastic IP address, move on to the next step.
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the top-right corner of the AWS Management Console, choose the Region to allocate your Elastic IP address in. The Region of your Elastic IP address should be the same as the Region where you want to create your VPC. This example uses the US West (Oregon) Region.
   c. In the navigation pane, choose Elastic IPs.
   d. Choose Allocate Elastic IP address.
   e. If the console shows the Network Border Group field, keep the default value for it.
   f. For Public IPv4 address pool, choose Amazon's pool of IPv4 addresses.
   g. Choose Allocate.
   Note the allocation ID of the new Elastic IP address because you'll need this information when you create your VPC.

For more information about Elastic IP addresses, see Elastic IP addresses in the Amazon EC2 User Guide. For more information about NAT gateways, see NAT gateways in the Amazon VPC User Guide.

2. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
3. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
4. In the upper-left corner, choose VPC Dashboard. To begin creating a VPC, choose Launch VPC Wizard.
5. On the Step 1: Select a VPC Configuration page, choose VPC with Public and Private Subnets, and then choose Select.
6. On the Step 2: VPC with Public and Private Subnets page, set these values:
   - IPv4 CIDR block: 10.0.0.0/16
   - IPv6 CIDR block: No IPv6 CIDR Block
   - VPC name: tutorial-vpc
   - Public subnet’s IPv4 CIDR: 10.0.0.0/24
   - Availability Zone: us-west-2a
   - Public subnet name: Tutorial public
   - Private subnet's IPv4 CIDR: 10.0.1.0/24
   - Availability Zone: us-west-2b
   - Private subnet name: Tutorial private 1
   - Elastic IP Allocation ID: An Elastic IP address to associate with the NAT gateway
   - Service endpoints: Skip this field.
   - Enable DNS hostnames: Yes
   - Hardware tenancy: Default
7. Choose Create VPC.

Create additional subnets

You must have either two private subnets or two public subnets available to create a DB subnet group for a DB instance to use in a VPC. Because the DB instance for this tutorial is private, add a second private subnet to the VPC.
To create an additional subnet

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. To add the second private subnet to your VPC, choose VPC Dashboard, choose Subnets, and then choose Create subnet.
3. On the Create subnet page, set these values:
   - VPC ID: Choose the VPC that you created in the previous step, for example: vpc-identifier (tutorial-vpc)
   - Subnet name: Tutorial private 2
   - Availability Zone: us-west-2c
     \* Note: Choose an Availability Zone that is different from the one that you chose for the first private subnet.
   - IPv4 CIDR block: 10.0.2.0/24
4. Choose Create subnet.
5. To ensure that the second private subnet that you created uses the same route table as the first private subnet, complete the following steps:
   a. Choose VPC Dashboard, choose Subnets, and then choose the first private subnet that you created for the VPC, Tutorial private 1.
   b. Below the list of subnets, choose the Route table tab, and note the value for Route Table—for example: rtb-98b613fd.
   c. In the list of subnets, deselect the first private subnet.
   d. In the list of subnets, choose the second private subnet, choose the Route table tab.
   e. If the current route table is not the same as the route table for the first private subnet, choose Edit route table association. For Route table ID, choose the route table that you noted earlier—for example: rtb-98b613fd. Next, to save your selection, choose Save.

Create a VPC security group for a public web server

Next you create a security group for public access. To connect to public instances in your VPC, you add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - Security group name: tutorial-securitygroup
   - Description: Tutorial Security Group
   - VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to instances in your VPC. To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 203.0.113.25/32.

If you are connecting through an Internet service provider (ISP) or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.
Warning
If you use 0.0.0.0/0, you enable all IP addresses to access your public instances. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you'll authorize only a specific IP address or range of addresses to access your instances.

b. In the Inbound rules section, choose Add rule.
c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your EC2 instance. If you do this, you can connect to your EC2 instance to install the web server and other utilities, and to upload content for your web server.
   - **Type:** SSH
   - **Source:** The IP address or range from Step a, for example: 203.0.113.25/32.
d. Choose Add rule.
e. Set the following values for your new inbound rule to allow HTTP access to your web server.
   - **Type:** HTTP
   - **Source:** 0.0.0.0/0

5. To create the security group, choose Create security group.

Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private instances in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:
   - **Security group name:** tutorial-db-securitygroup
   - **Description:** Tutorial DB Instance Security Group
   - **VPC:** Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)
4. Add inbound rules to the security group.
   a. In the Inbound rules section, choose Add rule.
   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your EC2 instance. If you do this, you can connect from your web server to your DB instance to store and retrieve data from your web application to your database.
      - **Type:** MySQL/Aurora
      - **Source:** The identifier of the tutorial-securitygroup security group that you created previously in this tutorial, for example: sg-9edd5cfd.
5. To create the security group, choose Create security group.

Create a DB subnet group

A DB subnet group is a collection of subnets that you create in a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when creating DB instances.
To create a DB subnet group

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   
   **Note**
   Make sure you connect to the Amazon RDS console, not to the Amazon VPC console.

2. In the navigation pane, choose **Subnet groups**.

3. Choose **Create DB Subnet Group**.

4. On the **Create DB subnet group** page, set these values in **Subnet group details**:
   - **Name**: tutorial-db-subnet-group
   - **Description**: Tutorial DB Subnet Group
   - **VPC**: tutorial-vpc (vpc-identifier)

5. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.
   For this tutorial, choose **us-west-2b** and **us-west-2c** for the **Availability Zones**. Next, for **Subnets**, choose the subnets for IPv4 CIDR block 10.0.1.0/24 and 10.0.2.0/24.

6. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can click the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

   **Note**
   If you created this VPC to complete Tutorial: Create a web server and an Amazon Aurora DB cluster (p. 102), create the DB cluster by following the instructions in Create an Amazon Aurora DB cluster (p. 103).

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

**Note**
If you added resources in the Amazon VPC you created for this tutorial, such as Amazon EC2 instances or Amazon RDS DB instances, you might need to delete these resources before you can delete the VPC. For more information, see Delete your VPC in the Amazon VPC User Guide.

To delete a VPC and related resources

1. Delete the DB subnet group.
   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group you want to delete, such as **tutorial-db-subnet-group**.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.

2. Note the VPC ID.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose **VPC Dashboard**, and then choose **VPCs**.
   c. In the list, identify the VPC you created, such as **tutorial-vpc**.
   d. Note the **VPC ID** of the VPC you created. You will need the VPC ID in subsequent steps.

3. Delete the security groups.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
b. Choose VPC Dashboard, and then choose Security Groups.
c. Select the security group for the Amazon RDS DB instance, such as tutorial-db-securitygroup.
d. From Actions, choose Delete security groups, and then choose Delete on the confirmation page.
e. On the Security Groups page, select the security group for the Amazon EC2 instance, such as tutorial-securitygroup.
f. From Actions, choose Delete security groups, and then choose Delete on the confirmation page.

4. Delete the NAT gateway.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose NAT Gateways.
   c. Select the NAT gateway of the VPC you created. Use the VPC ID to identify the correct NAT gateway.
   d. From Actions, choose Delete NAT gateway.
   e. On the confirmation page, enter delete, and then choose Delete.

5. Delete the VPC.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. Select the VPC you want to delete, such as tutorial-vpc.
   d. From Actions, choose Delete VPC.

       The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.
   e. On the confirmation page, enter delete, and then choose Delete.

   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. Choose EC2 Dashboard, and then choose Elastic IPs.
   c. Select the Elastic IP address you want to release.
   d. From Actions, choose Release Elastic IP addresses.
   e. On the confirmation page, choose Release.
Quotas and constraints for Amazon Aurora

Following, you can find a description of the resource quotas and naming constraints for Amazon Aurora.

Topics

• Quotas in Amazon Aurora (p. 1732)
• Naming constraints in Amazon Aurora (p. 1733)
• Amazon Aurora size limits (p. 1734)

Quotas in Amazon Aurora

Each AWS account has quotas, for each AWS Region, on the number of Amazon Aurora resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorizations per DB security group</td>
<td>All supported Regions: 20</td>

</tbody>
</table>
The following table describes naming constraints in Amazon Aurora.

<table>
<thead>
<tr>
<th>Resource or item</th>
<th>Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB cluster identifier</td>
<td>Identifiers have these naming constraints:</td>
</tr>
<tr>
<td></td>
<td>• Must contain 1–63 alphanumeric characters or hyphens.</td>
</tr>
</tbody>
</table>
## Amazon Aurora size limits

### Storage size limits

An Aurora cluster volume can grow to a maximum size of 128 tebibytes (TiB) for the following engine versions:
- Aurora MySQL versions 2.09 compatible with MySQL 5.7 and 1.23 compatible with MySQL 5.6
- All Aurora PostgreSQL 13 versions, Aurora PostgreSQL versions 12.4 and higher, 11.7 and higher, 10.12 and higher, and 9.6.17 and higher

For lower engine versions, the maximum size of an Aurora cluster volume is 64 TiB. For more information, see How Aurora storage automatically resizes (p. 64).

### SQL table size limits

For Aurora MySQL, the maximum table size is 64 tebibytes (TiB). For an Aurora PostgreSQL DB cluster, the maximum table size is 32 tebibytes (TiB). We recommend that you follow table design best practices, such as partitioning of large tables.

Troubleshooting for Aurora

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Aurora.

Topics
- Can't connect to Amazon RDS DB instance (p. 1735)
- Amazon RDS security issues (p. 1737)
- Resetting the DB instance owner password (p. 1737)
- Amazon RDS DB instance outage or reboot (p. 1737)
- Amazon RDS DB parameter changes not taking effect (p. 1738)
- Amazon Aurora MySQL out of memory issues (p. 1738)
- Amazon Aurora MySQL replication issues (p. 1739)

For information about debugging problems using the Amazon RDS API, see Troubleshooting applications on Aurora (p. 1744).

Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

  By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

  **Note**
  When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

  For more information about setting up security groups, see Provide access to the DB cluster in the VPC by creating a security group (p. 86).

  **Note**
  Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

  To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see Hiding a DB instance in a VPC from the internet (p. 1710).

- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.
Testing the DB instance connection

- **Availability** – For a newly created DB instance, the DB instance has a status of creating until the DB instance is ready to use. When the state changes to available, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.

- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

**To configure an internet gateway for a subnet**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the name of the DB instance.
3. In the Connectivity & security tab, write down the values of the VPC ID under VPC and the subnet ID under Subnets.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose Internet Gateways. Verify that there is an internet gateway attached to your VPC. Otherwise, choose Create Internet Gateway to create an internet gateway. Select the internet gateway, and then choose Attach to VPC and follow the directions to attach it to your VPC.
6. In the navigation pane, choose Subnets, and then select your subnet.
7. On the Route Table tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target.
   a. Choose the ID of the route table (rtb-xxxxxxxx) to navigate to the route table.
   b. On the Routes tab, choose Edit routes. Choose Add route, use 0.0.0.0/0 as the destination and the internet gateway as the target.
   c. Choose Save routes.

For more information, see Working with a DB instance in a VPC (p. 1708).

**Testing a connection to a DB instance**

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following (replace DB-instance-endpoint with the endpoint and port with the port of your DB instance).

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299
```

Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/v4rdata] succeeded!

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819
Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not open connection to the host, on port 819: Connect failed
```
If Telnet actions return success, your security group is properly configured.

**Note**
Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

**Troubleshooting connection authentication**

If you can connect to your DB instance but you get authentication errors, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

**Amazon RDS security issues**

To avoid security issues, never use your master AWS user name and password for a user account. Best practice is to use your master AWS account to create AWS Identity and Access Management (IAM) users and assign those to DB user accounts. You can also use your master account to create other user accounts, if necessary.

For more information on creating IAM users, see Create an IAM user (p. 83).

**Error message "failed to retrieve account attributes, certain console functions may be impaired."**

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your IAM administrator needs to provide the necessary roles to your account. For more information, see the IAM documentation.

**Resetting the DB instance owner password**

If you get locked out of your DB cluster, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see Master user account privileges (p. 1703).

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command `modify-db-instance`, or by using the `ModifyDBInstance` API operation. For more information about modifying a DB instance in a DB cluster, see Modify a DB instance in a DB cluster (p. 369).

**Amazon RDS DB instance outage or reboot**

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you either manually reboot your DB instance or change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately or it can occur during the DB instance's maintenance window.
A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0 and set **Apply Immediately** to true.
- You change the DB instance class, and **Apply Immediately** is set to true.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to false.
- You change the DB instance class, and **Apply Immediately** is set to false.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console or explicitly calling the **RebootDBInstance** API operation (without failover, if the DB instance is in a Multi-AZ deployment). The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this might be calling **ModifyDBInstance** to change the DB instance class. For more information, see **Modifying parameters in a DB parameter group** (p. 343).

Amazon Aurora MySQL out of memory issues

The Aurora MySQL **aurora_oom_response** instance-level parameter can enable the DB instance to monitor the system memory and estimate the memory consumed by various statements and connections. If the system runs low on memory, it can perform a list of actions to release that memory in an attempt to avoid out-of-memory (OOM) and database restart. The instance-level parameter takes a string of comma-separated actions that a DB instance should take when its memory is low. Valid actions include **print**, **tune**, **decline**, **kill_query**, or any combination of these. An empty string means that no action should be taken and effectively disables the feature.

**Note**
This parameter only applies to Aurora MySQL version 1.18 and higher. It isn't used in Aurora MySQL version 2.

The following are usage examples for the **aurora_oom_response** parameter:

- **print** – Only prints the queries taking high amount of memory.
- **tune** – Tunes the internal table caches to release some memory back to the system.
- **decline** – Declines new queries once the instance is low on memory.
• kill_query – Ends the queries in descending order of memory consumption until the instance memory surfaces above the low threshold. Data definition language (DDL) statements aren’t ended.
• print, tune – Performs actions described for both print and tune.
• tune, decline, kill_query – Performs the actions described for tune, decline, and kill_query.

For the db.t2.small DB instance class, the aurora_oom_response parameter is set to print, tune by default. For all other DB instance classes, the parameter value is empty by default (disabled).

Amazon Aurora MySQL replication issues

Some MySQL replication issues also apply to Aurora MySQL. You can diagnose and correct these.

Topics
• Diagnosing and resolving lag between read replicas (p. 1739)
• Diagnosing and resolving a MySQL read replication failure (p. 1740)
• Replication stopped error (p. 1741)

Diagnosing and resolving lag between read replicas

After you create a MySQL read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS AuroraBinlogReplicaLag metric.

The AuroraBinlogReplicaLag metric reports the value of the Seconds_Behind_Master field of the MySQL SHOW SLAVE STATUS command. For more information, see SHOW SLAVE STATUS. When the AuroraBinlogReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the AuroraBinlogReplicaLag metric returns -1, replication might not be active. To troubleshoot a replication error, see Diagnosing and resolving a MySQL read replication failure (p. 1740). A AuroraBinlogReplicaLag value of -1 can also mean that the Seconds_Behind_Master value can’t be determined or is NULL.

Note
Previous versions of Aurora MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using Aurora MySQL version 1 or 2, then use SHOW SLAVE STATUS. Use SHOW REPLICA STATUS for Aurora MySQL version 3 and higher.

The AuroraBinlogReplicaLag metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the AuroraBinlogReplicaLag metric again.

The MySQL read replication technology is asynchronous. Thus, you can expect occasional increases for the BinLogDiskUsage metric on the source DB instance and for the AuroraBinlogReplicaLag metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see Replication implementation details in the MySQL documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:
• Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
• Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
• Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type` parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see Query cache configuration.
• Warm the buffer pool on the read replica for InnoDB for MySQL. For example, suppose that you have a small set of tables that are being updated often and you’re using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```bash
PROMPT> mysqldump \
   -h <endpoint> \
   --port=<port> \
   -u=<username> \
   -p <password> \
   database_name table1 table2 > /dev/null
```

For Windows:

```bash
PROMPT> mysqldump ^
   -h <endpoint> ^
   --port=<port> ^
   -u=<username> ^
   -p <password> ^
   database_name table1 table2 > /dev/null
```

Diagnosing and resolving a MySQL read replication failure

Amazon RDS monitors the replication status of your read replicas and updates the Replication State field of the read replica instance to Error if replication stops for any reason. You can review the details of the associated error thrown by the MySQL engines by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 650), RDS-EVENT-0046 (p. 650), and RDS-EVENT-0047 (p. 649). For more information about events and subscribing to events, see Using Amazon RDS event notification (p. 646). If a MySQL error message is returned, check the error in the MySQL error message documentation.

Common situations that can cause replication errors include the following:

• The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

  The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. If the `max_allowed_packet` value for the source DB instance is larger than the `max_allowed_packet` value for the read replica, the replication process can throw an error and stop replication. The most common error is packet
bigger than 'max_allowed_packet' bytes. You can fix the error by having the source and read replica use DB parameter groups with the same max_allowed_packet parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the read_only parameter set to 0 to create the indexes. If you're writing to tables on the read replica, it can break replication.

- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

You can convert a MyISAM table to InnoDB with the following command:

```sql
alter table <schema>.<table_name> engine=innodb;
```

- Using unsafe nondeterministic queries such as SYSDATE(). For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in Skipping the current replication error. Your Aurora MySQL DB instance must be running a version that includes the mysql_rds_skip_repl_error procedure. For more information, see mysql_rds_skip_repl_error.

- If you encounter a binary log (binlog) position issue, you can change the replica replay position with the mysql.rds_next_master_log (Aurora MySQL version 1 and 2) or mysql.rds_next_source_log (Aurora MySQL version 3 and higher) command. Your Aurora MySQL DB instance must be running a version that supports this command to change the replica replay position. For version information, see mysql_rds_next_master_log.

- If you encounter a temporary performance issue due to high DML load, you can set the innodb_flush_log_at_trx_commit parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).

- You can delete the read replica and create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the Replication State changes to replicating. For more information, see Troubleshooting a MySQL read replica problem.

### Replication stopped error

When you call the mysql.rds_skip_repl_error command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the mysql.rds_skip_repl_error command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the mysql.rds_skip_repl_error command as needed.

To set the binlog retention time, use the mysql_rds_set_configuration procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, up to 2160 (90 days). The default for Aurora MySQL is 24 (1 day). The following example sets the retention period for binlog files to 48 hours.
CALL mysql.rds_set_configuration('binlog retention hours', 48);
Amazon RDS application programming interface (API) reference

In addition to the AWS Management Console, and the AWS Command Line Interface (AWS CLI), Amazon Relational Database Service (Amazon RDS) also provides an application programming interface (API). You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

**Topics**
- Using the Query API (p. 1743)
- Troubleshooting applications on Aurora (p. 1744)

**Using the Query API**

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the Amazon EC2 API Reference.

**Query parameters**

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named Action.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the \texttt{param.n} notation. Values of \texttt{n} are integers starting from 1.

For information about Amazon RDS regions and endpoints, go to Amazon Relational Database Service (RDS) in the Regions and Endpoints section of the Amazon Web Services General Reference.

**Query request authentication**

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.
Troubleshooting applications on Aurora

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

Topics

• Retrieving errors (p. 1744)
• Troubleshooting tips (p. 1744)

For information about troubleshooting for Amazon RDS DB instances, see Troubleshooting for Aurora (p. 1735).

Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an Error node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an Error node, as well as an easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find('//Error') )
{print "There was an error processing your request:\n", " Error code: ",
 $xp->findvalue('//Error[1]/Code'), "\n", " ",
 $xp->findvalue('//Error[1]/Message'), "\n\n"; }
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API.

• Verify that Amazon RDS is operating normally in the AWS Region you are targeting by visiting http://status.aws.amazon.com.
• Check the structure of your request
  Each Amazon RDS operation has a reference page in the Amazon RDS API Reference. Double-check that you are using parameters correctly. In order to give you ideas regarding what might be wrong, look at the sample requests or user scenarios to see if those examples are doing similar operations.
• Check the forum
  Amazon RDS has a development community forum where you can search for solutions to problems others have experienced along the way. To view the forum, go to AWS Discussion Forums.
# Document history

**Current API version:** 2014-10-31

The following table describes important changes to the *Amazon Aurora User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed. For information about Amazon Relational Database Service (Amazon RDS), see the *Amazon Relational Database Service User Guide*.

**Note**

Before August 31, 2018, Amazon Aurora was documented in the *Amazon Relational Database Service User Guide*. For earlier Aurora document history, see Document history in the *Amazon Relational Database Service User Guide*.

You can filter new Amazon Aurora features on the What's New with Database? page. For Products, choose *Amazon Aurora*. Then search using keywords such as global database or Serverless.

### Aurora PostgreSQL releases

**4.1.0, 3.5.0, 2.8.0, and 1.10.0 compatible with PostgreSQL 12.6, 11.11, 10.16, and 9.6.21 (p. 1745)**

New versions of Amazon Aurora PostgreSQL-Compatible Edition include 4.1.0 (compatible with PostgreSQL 12.6), 3.5.0 (compatible with PostgreSQL 11.11), 2.8.0 (compatible with PostgreSQL 10.16), and 1.10.0 (compatible with PostgreSQL 9.6.21). For more information, see Database engine versions for Amazon Aurora PostgreSQL-Compatible Edition.

**June 17, 2021**

### Amazon Aurora PostgreSQL-Compatible Edition supports additional extensions (p. 1745)

Newly supported extensions include `pg_bigm`, `pg_cron`, `pg_partman`, and `pg_proctab`. For more information, see Extension versions for Amazon Aurora PostgreSQL-Compatible Edition.

**June 17, 2021**

### Cloning for Aurora Serverless v1 clusters (p. 1745)

You can now create cloned clusters that are Aurora Serverless v1. For information about cloning, see Cloning a volume for an Aurora DB cluster.

**June 16, 2021**

### Aurora MySQL version 1.22.5 (p. 1156)

Aurora MySQL version 1.22.5 is available.

**June 3, 2021**

### Aurora MySQL version 2.10.0 (p. 1074)

Aurora MySQL version 2.10.0 is available. Some of the highlights include higher availability of reader instances during writer restarts, improvements to zero-downtime patching (ZDP), improvements to zero-downtime restart (ZDR), and the binlog I/O cache optimization.

**May 25, 2021**

### Aurora global databases available in China (Beijing) and China (Ningxia) Regions (p. 1745)

You can now create Aurora global databases in the China (Beijing) and China (Ningxia) Regions. For information about Aurora global databases, see Working with Amazon Aurora global databases.

**May 19, 2021**

### FIPS 140-2 support for Data API (p. 1745)

The Data API supports the Federal Information Processing Standard Publication 140-2 (FIPS 140-2) for SSL/TLS connections. For more information, see Data API availability.

</tbody>
</table>
**Aurora PostgreSQL releases 3.4.0, 2.7.0, and 1.9.0 (p. 1745)**

New releases of Amazon Aurora PostgreSQL-Compatible Edition include release 3.4.0 (compatible with PostgreSQL 11.9), release 2.7.0 (compatible with PostgreSQL 10.14), and release 1.9.0 (compatible with PostgreSQL 9.6.19). For more information, see Database engine versions for Amazon Aurora PostgreSQL.

**December 11, 2020**

---

**Aurora MySQL version 2.09.1 (p. 1084)**

Aurora MySQL version 2.09.1 is available.

**December 11, 2020**

---

**Amazon Aurora supports the Graviton2 DB instance classes in preview (p. 1745)**

You can now use the Graviton2 DB instance classes db.r6g.x in preview to create DB clusters running MySQL or PostgreSQL. For more information, see DB instance class types.

**December 11, 2020**

---

**Amazon Aurora Serverless v2 (preview) is now available in preview. (p. 1745)**

Amazon Aurora Serverless v2 (preview) is available in preview. To work with Amazon Aurora Serverless v2 (preview), you must apply for access. For more information, see the Aurora Serverless v2 (preview) page.

**December 1, 2020**

---

**Aurora PostgreSQL is now available for Aurora Serverless v1 in more AWS Regions. (p. 1745)**

Aurora PostgreSQL is now available for Aurora Serverless v1 in more AWS Regions. You can now choose to run Aurora PostgreSQL Serverless in the same AWS Regions that offer Aurora MySQL Serverless. Additional AWS Regions with Aurora Serverless v1 support include US West (N. California), Asia Pacific (Singapore) Asia Pacific (Sydney) Asia Pacific (Seoul) Asia Pacific (Mumbai) Canada (Central) Europe (London) and Europe (Paris). For a list of all Regions and supported Aurora DB engines for Aurora Serverless v1, see Aurora Serverless. Amazon RDS Data API for Aurora Serverless v1 is also now available in these same AWS Regions. For a list of all Regions with support for the Data API for Aurora Serverless v1, see Data API for Aurora Serverless.

</tbody>
</table>
### Aurora parallel query enhancements (p. 1745)

Starting with Aurora MySQL 2.09 and 1.23, you can take advantage of enhancements to the parallel query feature. Creating a parallel query cluster no longer requires a special engine mode. You can now turn parallel query on and off using the `aurora_parallel_query` configuration option for any provisioned cluster that's running a compatible Aurora MySQL version. You can upgrade an existing cluster to a compatible Aurora MySQL version and use parallel query, instead of creating a new cluster and importing data into it. You can use Performance Insights for parallel query clusters. You can stop and start parallel query clusters. You can create Aurora parallel query clusters that are compatible with MySQL 5.7. Parallel query works for tables that use the `DYNAMIC` row format. Parallel query clusters can use AWS Identity and Access Management (IAM) authentication. Reader DB instances in parallel query clusters can take advantage of the `READ COMMITTED` isolation level. You can also now create parallel query clusters in additional AWS Regions. For more information about the parallel query feature and these enhancements, see [Working with parallel query for Aurora MySQL](#).

</table>
Aurora global database supports PostgreSQL version 11.7 and managed recovery point objective (RPO) (p. 1745)

You can now create Aurora global databases for the PostgreSQL database engine version 11.7. You can also manage how a PostgreSQL global database recovers from a failure using a recovery point objective (RPO). For more information, see Cross-Region Disaster Recovery for Aurora global databases.

June 4, 2020

New releases of Amazon Aurora PostgreSQL-Compatible Edition include Aurora PostgreSQL release 3.2.1 (compatible with PostgreSQL 11.7), Aurora PostgreSQL release 2.5.1 (compatible with PostgreSQL 10.12), and Aurora PostgreSQL release 1.7.1 (compatible with PostgreSQL 9.6.17). For more information, see Database engine versions for Amazon Aurora PostgreSQL.

June 4, 2020

Aurora MySQL version 2.08.0 (p. 1096)

Aurora MySQL version 2.08.0 is available.

June 2, 2020

Aurora MySQL version 1.19.6 for parallel query clusters (p. 1167)

Aurora MySQL version 1.19.6 is available when you create a parallel query cluster.

June 2, 2020

Aurora MySQL supports database monitoring with database activity streams (p. 1745)

Aurora MySQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see Using database activity streams.

June 2, 2020

The query editor available in additional AWS Regions (p. 1745)

The query editor for Aurora Serverless is now available in additional AWS Regions. For more information, see Availability of the query editor.

May 28, 2020

The Data API available in additional AWS Regions (p. 1745)

The Data API is now available in additional AWS Regions. For more information, see Availability of the Data API.

May 28, 2020

RDS Proxy available in Canada (Central) Region (p. 1745)

You can now use the RDS Proxy preview in the Canada (Central) Region. For more information about RDS Proxy, see Managing connections with Amazon RDS proxy (preview).

<td>Performance Insights support for Aurora global database (p. 1745)</td>
<td>You can now use Performance Insights with Aurora Global Database. For information about Performance Insights for Aurora, see Using Amazon RDS performance insights. For information about Aurora global databases, see Working with Aurora global database.</td>
<td>May 13, 2019</td>
</tr>
<tr>
<td>Aurora PostgreSQL release 1.4 (p. 1745)</td>
<td>Release 1.4 of Amazon Aurora PostgreSQL-Compatible Edition is available and compatible with PostgreSQL 9.6.11. For more information, see Version 1.4.</td>
<td>May 9, 2019</td>
</tr>
<tr>
<td>Aurora MySQL version 2.04.3 (p. 1129)</td>
<td>Aurora MySQL version 2.04.3 is available.</td>
<td>May 9, 2019</td>
</tr>
<tr>
<td>Aurora MySQL version 1.19.1 (p. 1169)</td>
<td>Aurora MySQL version 1.19.1 is available.</td>
<td>May 9, 2019</td>
</tr>
<tr>
<td>Performance Insights is available for Aurora MySQL 5.7 (p. 1745)</td>
<td>Amazon RDS Performance Insights is now available for Aurora MySQL 2.x versions, which are compatible with MySQL 5.7. For more information, see Using Amazon RDS performance insights.</td>
<td>May 3, 2019</td>
</tr>
<tr>
<td>Aurora MySQL version 2.04.2 (p. 1130)</td>
<td>Aurora MySQL version 2.04.2 is available.</td>
<td>May 2, 2019</td>
</tr>
<tr>
<td>Aurora global databases available in more AWS Regions (p. 1745)</td>
<td>You can now create Aurora global databases in most AWS Regions where Aurora is available. For information about Aurora global databases, see Working with Amazon Aurora global databases.</td>
<td>April 30, 2019</td>
</tr>
<tr>
<td>Minimum capacity of 1 for Aurora Serverless (p. 1745)</td>
<td>The minimum capacity setting you can use for an Aurora Serverless cluster is 1. Formerly, the minimum was 2. For information about specifying Aurora Serverless capacity values, see Setting the capacity of an Aurora Serverless DB cluster.</td>
<td>April 29, 2019</td>
</tr>
<tr>
<td>Aurora Serverless timeout action (p. 1745)</td>
<td>You can now specify the action to take when an Aurora Serverless capacity change times out. For more information, see Timeout action for capacity changes.</td>
<td>April 29, 2019</td>

</tr>
<tr>
<td><strong>Per-second billing</strong> (p. 1745)</td>
<td>Amazon RDS is now billed in 1-second increments in all AWS Regions except AWS GovCloud (US) for on-demand instances. For more information, see DB instance billing for Aurora.</td>
<td>April 25, 2019</td>
</tr>
<tr>
<td><strong>Sharing Aurora Serverless snapshots across AWS Regions</strong> (p. 1745)</td>
<td>With Aurora Serverless, snapshots are always encrypted. If you encrypt the snapshot with your own AWS KMS key, you can now copy or share the snapshot across AWS Regions. For information about snapshots of Aurora Serverless DB clusters, see Aurora Serverless and snapshots.</td>
<td>April 17, 2019</td>
</tr>
<tr>
<td><strong>Restore MySQL 5.7 backups from Amazon S3</strong> (p. 1745)</td>
<td>You can now create a backup of your MySQL version 5.7 database, store it on Amazon S3, and then restore the backup file onto a new Aurora MySQL DB cluster. For more information, see Migrating data from an external MySQL database to an Aurora MySQL DB cluster.</td>
<td>April 17, 2019</td>
</tr>
<tr>
<td><strong>Sharing Aurora Serverless snapshots across regions</strong> (p. 1745)</td>
<td>With Aurora Serverless, snapshots are always encrypted. If you encrypt the snapshot with your own AWS KMS key, you can now copy or share the snapshot across regions. For information about snapshots of Aurora Serverless DB clusters, see Aurora Serverless and snapshots.</td>
<td>April 16, 2019</td>
</tr>
<tr>
<td><strong>Aurora proof-of-concept tutorial</strong> (p. 1745)</td>
<td>You can learn how to perform a proof of concept to try your application and workload with Aurora. For the full tutorial, see Performing an Aurora proof of concept.</td>
<td>April 16, 2019</td>
</tr>
<tr>
<td><strong>Aurora Serverless supports restoring from an Amazon S3 backup</strong> (p. 1745)</td>
<td>You can now import backups from Amazon S3 to an Aurora Serverless cluster. For details about that procedure, see Migrating data from MySQL by using an Amazon S3 bucket.</td>
<td>April 16, 2019</td>
</tr>
<tr>
<td><strong>New modifiable parameters for Aurora Serverless (p. 1745)</strong></td>
<td>You can now modify the following DB parameters for an Aurora Serverless cluster:</td>
<td>April 4, 2019</td>
</tr>
<tr>
<td>------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td></td>
<td><code>innodb_file_format</code>, <code>innodb_file_per_table</code>, <code>innodb_large_prefix</code>, <code>innodb_lock_wait_timeout</code>, <code>innodb_monitor_disable</code>, <code>innodb_monitor_enable</code>, <code>innodb_monitor_reset</code>, <code>innodb_monitor_reset_all</code>, <code>innodb_print_all_deadlocks</code>, <code>log_warnings</code>, <code>net_read_timeout</code>, <code>net_retry_count</code>, <code>net_write_timeout</code>, <code>sql_mode</code>, and <code>tx_isolation</code>. For more information about configuration parameters for Aurora Serverless clusters, see Aurora Serverless and parameter groups.</td>
<td></td>
</tr>
<tr>
<td><strong>Aurora PostgreSQL supports db.r5 DB instance classes (p. 1745)</strong></td>
<td>You can now create Aurora PostgreSQL DB clusters that use the db.r5 DB instance classes. For more information, see DB instance class.</td>
<td>April 4, 2019</td>
</tr>
<tr>
<td><strong>Aurora PostgreSQL logical replication (p. 1745)</strong></td>
<td>You can now use PostgreSQL logical replication to replicate parts of a database for an Aurora PostgreSQL DB cluster. For more information, see Using PostgreSQL logical replication.</td>
<td>March 28, 2019</td>
</tr>
<tr>
<td><strong>GTID support for Aurora MySQL 2.04 (p. 1745)</strong></td>
<td>You can now use replication with the global transaction ID (GTID) feature of MySQL 5.7. This feature simplifies performing binary log (binlog) replication between Aurora MySQL and an external MySQL 5.7-compatible database. The replication can use the Aurora MySQL cluster as the source or the destination. This feature is available for Aurora MySQL 2.04 and higher. For more information about GTID-based replication and Aurora MySQL, see Using GTID-based replication for Aurora MySQL.</td>
<td>March 25, 2019</td>
</tr>
<tr>
<td><strong>Aurora MySQL version 2.04.1 (p. 1132)</strong></td>
<td>Aurora MySQL version 2.04.1 is available.</td>

<tr>
<td>Uploading Aurora Serverless logs to Amazon CloudWatch (p. 1745)</td>
<td>You can now have Aurora upload database logs to CloudWatch for an Aurora Serverless cluster. For more information, see <a href="#">Viewing Aurora Serverless DB clusters</a>. As part of this enhancement, you can now define values for instance-level parameters in a DB cluster parameter group, and those values apply to all DB instances in the cluster unless you override them in the DB parameter group. For more information, see <a href="#">Working with DB parameter groups and DB cluster parameter groups</a>.</td>
<td>February 25, 2019</td>
</tr>
<tr>
<td>Aurora MySQL supports db.t3 DB instance classes (p. 1745)</td>
<td>You can now create Aurora MySQL DB clusters that use the db.t3 DB instance classes. For more information, see <a href="#">DB instance class</a>.</td>
<td>February 25, 2019</td>
</tr>
<tr>
<td>Aurora MySQL supports db.r5 DB instance classes (p. 1745)</td>
<td>You can now create Aurora MySQL DB clusters that use the db.r5 DB instance classes. For more information, see <a href="#">DB instance class</a>.</td>
<td>February 25, 2019</td>
</tr>
<tr>
<td>Performance Insights counters for Aurora MySQL (p. 1745)</td>
<td>You can now add performance counters to your Performance Insights charts for Aurora MySQL DB instances. For more information, see <a href="#">Performance Insights dashboard components</a>.</td>
<td>February 19, 2019</td>
</tr>
<tr>
<td>Aurora PostgreSQL release 2.2.0 (p. 1745)</td>
<td>Release 2.2.0 of Aurora PostgreSQL is available and compatible with PostgreSQL 10.6. For more information, see <a href="#">Version 2.2.0</a>.</td>
<td>February 13, 2019</td>
</tr>
<tr>

</tr>
<tr>
<td><strong>Query plan management in Aurora PostgreSQL (p. 1745)</strong></td>
<td>Aurora PostgreSQL now provides query plan management that you can use to manage PostgreSQL query execution plans. For more information, see Managing query execution plans for Aurora PostgreSQL.</td>
<td>November 20, 2018</td>
</tr>
<tr>
<td><strong>Query editor for Aurora Serverless (beta) (p. 1745)</strong></td>
<td>You can run SQL statements in the Amazon RDS console on Aurora Serverless clusters. For more information, see Using the query editor for Aurora Serverless.</td>
<td>November 20, 2018</td>
</tr>
<tr>
<td><strong>Data API for Aurora Serverless (beta) (p. 1745)</strong></td>
<td>You can access Aurora Serverless clusters with web services-based applications using the Data API. For more information, see Using the Data API for Aurora Serverless.</td>
<td>November 20, 2018</td>
</tr>
<tr>
<td><strong>Aurora PostgreSQL version 2.1 (p. 1745)</strong></td>
<td>Aurora PostgreSQL version 2.1 is available and compatible with PostgreSQL 10.5. For more information, see Version 2.1.</td>
<td>November 20, 2018</td>
</tr>
<tr>
<td><strong>TLS support for Aurora Serverless (p. 1745)</strong></td>
<td>Aurora Serverless clusters support TLS/SSL encryption. For more information, see TLS/SSL for Aurora Serverless.</td>
<td>November 19, 2018</td>
</tr>
<tr>
<td><strong>Custom endpoints (p. 1745)</strong></td>
<td>You can now create endpoints that are associated with an arbitrary set of DB instances. This feature helps with load balancing and high availability for Aurora clusters where some DB instances have different capacity or configuration than others. You can use custom endpoints instead of connecting to a specific DB instance through its instance endpoint. For more information, see Amazon Aurora connection management.</td>
<td>November 12, 2018</td>
</tr>
<tr>
<td><strong>IAM authentication support in Aurora PostgreSQL (p. 1745)</strong></td>
<td>Aurora PostgreSQL now supports IAM authentication. For more information see IAM database authentication.</td>
<td>November 8, 2018</td>
</tr>
<tr>
<td><strong>Aurora MySQL version 2.03.1 (p. 1137)</strong></td>
<td>Aurora MySQL version 2.03.1 is available.</td>
