Amazon RDS uses mixed mode for Windows Authentication. This approach means that the master user (the name and password used to create your SQL Server DB instance) uses SQL Authentication. Because the master user account is a privileged credential, you should restrict access to this account.

To get Windows Authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust. The trust can be one-way or two-way. For more information on setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

To set up Windows authentication for a SQL Server DB instance, do the following steps, explained in greater detail in Setting up Windows Authentication for SQL Server DB instances (p. 1005):

1. Use AWS Managed Microsoft AD, either from the AWS Management Console or AWS Directory Service API, to create an AWS Managed Microsoft AD directory.
2. If you use the AWS CLI or Amazon RDS API to create your SQL Server DB instance, create an AWS Identity and Access Management (IAM) role. This role uses the managed IAM policy AmazonRDSDirectoryServiceAccess and allows Amazon RDS to make calls to your directory. If you use the console to create your SQL Server DB instance, AWS creates the IAM role for you.
   
   For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.
3. Create and configure users and groups in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users and groups in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.
4. If you plan to locate the directory and the DB instance in different VPCs, enable cross-VPC traffic.
5. Use Amazon RDS to create a new SQL Server DB instance either from the console, AWS CLI, or Amazon RDS API. In the create request, you provide the domain identifier ("d-*" identifier) that was generated when you created your directory and the name of the role you created. You can also modify an existing SQL Server DB instance to use Windows Authentication by setting the domain and IAM role parameters for the DB instance.
6. Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users from the Active Directory users and groups in their domain. (These are known as SQL Server "Windows" logins.) Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.
Creating the endpoint for Kerberos authentication

Kerberos-based authentication requires that the endpoint be the customer-specified host name, a period, and then the fully qualified domain name (FQDN). For example, the following is an example of an endpoint you might use with Kerberos-based authentication. In this example, the SQL Server DB instance host name is `ad-test` and the domain name is `corp-ad.company.com`.

```
ad-test.corp-ad.company.com
```

If you want to make sure your connection is using Kerberos, run the following query:

```
SELECT net_transport, auth_scheme
FROM sys.dm_exec_connections
WHERE session_id = @@SPID;
```

Setting up Windows Authentication for SQL Server DB instances

You use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Windows Authentication for a SQL Server DB instance. To set up Windows Authentication, take the following steps.

Step 1: Create a directory using the AWS Directory Service for Microsoft Active Directory

AWS Directory Service creates a fully managed, Microsoft Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name Service (DNS) servers on your behalf. The directory servers are created in two subnets in two different Availability Zones within a VPC. This redundancy helps ensure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up a Microsoft Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.
  
  **Note**
  
  Be sure to save this password. AWS Directory Service doesn't store this password, and you can't retrieve or reset it.
- Creates a security group for the directory controllers.

When you launch an AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all your directory's objects. This OU, which has the NetBIOS name that you typed when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The `admin` account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users, groups, and computers.
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users and groups in your OU.
- Create additional OUs and containers.
- Delegate authority.
• Create and link group policies.
• Restore deleted objects from the Active Directory Recycle Bin.
• Run AD and DNS Windows PowerShell modules on the Active Directory Web Service.

The admin account also has rights to perform the following domain-wide activities:
• Manage DNS configurations (add, remove, or update records, zones, and forwarders).
• View DNS event logs.
• View security event logs.

To create a directory with AWS Managed Microsoft AD

1. In the AWS Directory Service console navigation pane, choose Directories and choose Set up directory.
2. Choose AWS Managed Microsoft AD. This is the only option currently supported for use with Amazon RDS.
3. Choose Next.
4. On the Enter directory information page, provide the following information:

   **Edition**
   
   Choose the edition that meets your requirements.

   **Directory DNS name**
   
   The fully qualified name for the directory, such as corp.example.com. Names longer than 47 characters aren’t supported by SQL Server.

   **Directory NetBIOS name**
   
   An optional short name for the directory, such as CORP.

   **Directory description**
   
   An optional description for the directory.

   **Admin password**
   
   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

   The directory administrator password can’t include the word admin. The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   • Lowercase letters (a-z)
   • Uppercase letters (A-Z)
   • Numbers (0-9)
   • Non-alphanumeric characters (~!#$%^&*_-+=`\|(){}[]:;"'<>,.?/)

   **Confirm password**
   
   Retype the administrator password.

5. Choose Next.
6. On the Choose VPC and subnets page, provide the following information:

   **VPC**
   
   Choose the VPC for the directory.
Note
You can locate the directory and the DB instance in different VPCs, but if you do so, make sure to enable cross-VPC traffic. For more information, see Step 4: Enable cross-VPC traffic between the directory and the DB instance (p. 1010).

Subnets
Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose Next.
8. Review the directory information. If changes are needed, choose Previous. When the information is correct, choose Create directory.

It takes several minutes for the directory to be created. When it has been successfully created, the Status value changes to Active.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the Directory ID. You need this value when you create or modify your SQL Server DB instance.
Step 2: Create the IAM role for use by Amazon RDS

If you use the console to create your SQL Server DB instance, you can skip this step. If you use the CLI or RDS API to create your SQL Server DB instance, you must create an IAM role that uses the AmazonRDSDirectoryServiceAccess managed IAM policy. This role allows Amazon RDS to make calls to the AWS Directory Service for you.

If you are using a custom policy for joining a domain, rather than using the AWS-managed AmazonRDSDirectoryServiceAccess policy, make sure that you allow the ds:GetAuthorizedApplicationDetails action. This requirement is effective starting July 2019, due to a change in the AWS Directory Service API.

The following IAM policy, AmazonRDSDirectoryServiceAccess, provides access to AWS Directory Service.

Example IAM policy for providing access to AWS Directory Service

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": [
            "ds:DescribeDirectories",
            "ds:AuthorizeApplication",
            "ds:UnauthorizeApplication",
            "ds:GetAuthorizedApplicationDetails"
         ]
      }
   ]
}
```
We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For Windows Authentication, make sure to include the DB instances, as shown in the following example.

**Example trust relationship with global condition context key for Windows Authentication**

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": [
                        "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
                    ]
                }
            }
        }
    ]
}
```

Create an IAM role using this IAM policy and trust relationship. For more information about creating IAM roles, see Creating customer managed policies in the IAM User Guide.

**Step 3: Create and configure users and groups**

You can create users and groups with the Active Directory Users and Computers tool. This tool is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory. Groups are very useful for giving or denying privileges to groups of users, rather than having to apply those privileges to each individual user.

To create users and groups in an AWS Directory Service directory, you must be connected to a Windows EC2 instance that is a member of the AWS Directory Service directory. You must also be logged in as a user that has privileges to create users and groups. For more information, see Add users and groups (Simple AD and AWS Managed Microsoft AD) in the AWS Directory Service Administration Guide.
Step 4: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 5: Create or modify a SQL Server DB instance (p. 1010).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 5: Create or modify a SQL Server DB instance

Create or modify a SQL Server DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.
  
  For instructions, see Creating an Amazon RDS DB instance (p. 175).
- Modify an existing SQL Server DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.
  
  For instructions, see Modifying an Amazon RDS DB instance (p. 309).
- Restore a SQL Server DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.
  
  For instructions, see Restoring from a DB snapshot (p. 432).
- Restore a SQL Server DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.
  
  For instructions, see Restoring a DB instance to a specified time (p. 480).

Windows Authentication is only supported for SQL Server DB instances in a VPC.

For the DB instance to be able to use the domain directory that you created, the following is required:
For **Directory**, you must choose the domain identifier (d-ID) generated when you created the directory.

Make sure that the VPC security group has an outbound rule that lets the DB instance communicate with the directory.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier (d-ID) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role that you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --domain d-ID \
  --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --domain d-ID ^
  --domain-iam-role-name role-name
```

**Important**

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

**Step 6: Create Windows Authentication SQL Server logins**

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users. You do this from the Active Directory users and groups in your domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.
For an Active Directory user to authenticate with SQL Server, a SQL Server Windows login must exist for the user or a group that the user is a member of. Fine-grained access control is handled through granting and revoking permissions on these SQL Server logins. A user that doesn't have a SQL Server login or belong to a group with such a login can't access the SQL Server DB instance.

The ALTER ANY LOGIN permission is required to create an Active Directory SQL Server login. If you haven't created any logins with this permission, connect as the DB instance's master user using SQL Server Authentication.

Run a data definition language (DDL) command such as the following example to create a SQL Server login for an Active Directory user or group.

```
USE [master]
GO
CREATE LOGIN [mydomain\myuser] FROM WINDOWS WITH DEFAULT_DATABASE = [master],
  DEFAULT_LANGUAGE = [us_english];
GO
```

For more information, see CREATE LOGIN (Transact-SQL) in the Microsoft Developer Network documentation.

Users (both humans and applications) from your domain can now connect to the RDS for SQL Server instance from a domain-joined client machine using Windows authentication.

**Managing a DB instance in a Domain**

You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a domain join for a failed membership, use the ModifyDBInstance API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the ModifyDBInstance API operation and specify the current membership's directory ID and the new IAM role.
- To remove a DB instance from a domain, use the ModifyDBInstance API operation and specify none as the domain parameter.
- To move a DB instance from one domain to another, use the ModifyDBInstance API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the DescribeDBInstances API operation.

**Understanding Domain membership**

After you create or modify your DB instance, the instance becomes a member of the domain. The AWS console indicates the status of the domain membership for the DB instance. The status of the DB instance can be one of the following:

- **joined** – The instance is a member of the domain.
- **joining** – The instance is in the process of becoming a member of the domain.
- **pending-join** – The instance membership is pending.
• **pending-maintenance-join** – AWS will attempt to make the instance a member of the domain during the next scheduled maintenance window.
• **pending-removal** – The removal of the instance from the domain is pending.
• **pending-maintenance-removal** – AWS will attempt to remove the instance from the domain during the next scheduled maintenance window.
• **failed** – A configuration problem has prevented the instance from joining the domain. Check and fix your configuration before reissuing the instance modify command.
• **removing** – The instance is being removed from the domain.

A request to become a member of a domain can fail because of a network connectivity issue or an incorrect IAM role. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the domain.

### Connecting to SQL Server with Windows authentication

To connect to SQL Server with Windows Authentication, you must be logged into a domain-joined computer as a domain user. After launching SQL Server Management Studio, choose **Windows Authentication** as the authentication type, as shown following.

![Connect to Server](image)

### Restoring a SQL Server DB instance and then adding it to a domain

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to a domain. Once the DB instance is restored, modify the instance using the process explained in Step 5: Create or modify a SQL Server DB instance (p. 1010) to add the DB instance to a domain.
Integrating an Amazon RDS for SQL Server DB instance with Amazon S3

You can transfer files between a DB instance running Amazon RDS for SQL Server and an Amazon S3 bucket. By doing this, you can use Amazon S3 with SQL Server features such as BULK INSERT. For example, you can download .csv, .xml, .txt, and other files from Amazon S3 to the DB instance host and import the data from D:\S3\ into the database. All files are stored in D:\S3\ on the DB instance.

The following limitations apply:

- Files in the D:\S3 folder are deleted on the standby replica after a failover on Multi-AZ instances. For more information, see Multi-AZ limitations for S3 integration (p. 1026).
- The DB instance and the S3 bucket must be in the same AWS Region.
- If you run more than one S3 integration task at a time, the tasks run sequentially, not in parallel.

  Note
  S3 integration tasks share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. Therefore, two running native backup and restore tasks will block any S3 integration tasks.
- You must re-enable the S3 integration feature on restored instances. S3 integration isn't propagated from the source instance to the restored instance. Files in D:\S3 are deleted on a restored instance.
- Downloading to the DB instance is limited to 100 files. In other words, there can't be more than 100 files in D:\S3\.
- Only files without file extensions or with the following file extensions are supported for download: .abf, .asdatabase, .bcp, .configsettings, .csv, .dat, .deploymentoptions, .deploymenttargets, .fmt, .info, .isp, and .xmla.
- The S3 bucket must have the same owner as the related AWS Identity and Access Management (IAM) role. Therefore, cross-account S3 integration isn't supported.
- The S3 bucket can't be open to the public.
- The file size for uploads from RDS to S3 is limited to 50 GB per file.
- The file size for downloads from S3 to RDS is limited to the maximum supported by S3.

For more information on working with files in Amazon S3, see Getting started with Amazon Simple Storage Service.

Prerequisites for integrating RDS for SQL Server with S3

Before you begin, find or create the S3 bucket that you want to use. Also, add permissions so that the RDS DB instance can access the S3 bucket. To configure this access, you create both an IAM policy and an IAM role.
To create an IAM policy for access to Amazon S3

1. In the IAM Management Console, choose Policies in the navigation pane.
2. Create a new policy, and use the Visual editor tab for the following steps.
3. For Service, enter S3 and then choose the S3 service.
4. For Actions, choose the following to grant the access that your DB instance requires:
   - ListAllMyBuckets – required
   - ListBucket – required
   - GetBucketACL – required
   - GetBucketLocation – required
   - GetObject – required for downloading files from S3 to D:\S3\n   - PutObject – required for uploading files from D:\S3\ to S3
   - ListMultipartUploadParts – required for uploading files from D:\S3\ to S3
   - AbortMultipartUpload – required for uploading files from D:\S3\ to S3
5. For Resources, the options that display depend on which actions you choose in the previous step. You might see options for bucket, object, or both. For each of these, add the appropriate Amazon Resource Name (ARN).

   For bucket, add the ARN for the bucket that you want to use. For example, if your bucket is named example-bucket, set the ARN to arn:aws:s3:::example-bucket.

   For object, enter the ARN for the bucket and then choose one of the following:
   - To grant access to all files in the specified bucket, choose Any for both Bucket name and Object name.
   - To grant access to specific files or folders in the bucket, provide ARNs for the specific buckets and objects that you want SQL Server to access.
6. Follow the instructions in the console until you finish creating the policy.

The preceding is an abbreviated guide to setting up a policy. For more detailed instructions on creating IAM policies, see Creating IAM policies in the IAM User Guide.

To create an IAM role that uses the IAM policy from the previous procedure

1. In the IAM Management Console, choose Roles in the navigation pane.
2. Create a new IAM role, and choose the following options as they appear in the console:
   - AWS service
   - RDS
   - RDS – Add Role to Database

   Then choose Next:Permissions at the bottom.
3. For Attach permissions policies, enter the name of the IAM policy that you previously created. Then choose the policy from the list.
4. Follow the instructions in the console until you finish creating the role.

The preceding is an abbreviated guide to setting up a role. If you want more detailed instructions on creating roles, see IAM roles in the IAM User Guide.
AWS CLI

To grant Amazon RDS access to an Amazon S3 bucket, use the following process:

1. Create an IAM policy that grants Amazon RDS access to an S3 bucket.
2. Create an IAM role that Amazon RDS can assume on your behalf to access your S3 buckets.

   For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.
3. Attach the IAM policy that you created to the IAM role that you created.

To create the IAM policy

Include the appropriate actions to grant the access your DB instance requires:

- ListAllMyBuckets – required
- ListBucket – required
- GetBucketACL – required
- GetBucketLocation – required
- GetObject – required for downloading files from S3 to D:\S3\n- PutObject – required for uploading files from D:\S3\ to S3
- ListMultipartUploadParts – required for uploading files from D:\S3\ to S3
- AbortMultipartUpload – required for uploading files from D:\S3\ to S3

1. The following AWS CLI command creates an IAM policy named rds-s3-integration-policy with these options. It grants access to a bucket named bucket_name.

Example

For Linux, macOS, or Unix:

```
aws iam create-policy \
   --policy-name rds-s3-integration-policy \
   --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Action": "s3:ListAllMyBuckets",
   "Resource": "*"
   },
   {
   "Effect": "Allow",
   "Action": [
   "s3:ListBucket",
   "s3:GetBucketACL",
   "s3:GetBucketLocation"
   ],
   "Resource": "arn:aws:s3:::bucket_name"
   },
   {
   "Effect": "Allow",
   "Action": [
   "s3:GetObject",
   "s3:PutObject",
   "s3:ListMultipartUploadParts",
   "s3:AbortMultipartUpload"
   ],
```
"Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
],
}

For Windows:

Make sure to change the line endings to the ones supported by your interface (^ instead of \). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the policy.json file with the following permission policy:

```
{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
   },
   {
      "Effect": "Allow",
      "Action": [
      "s3:ListBucket",
      "s3:GetBucketACL",
      "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::bucket_name"
   },
   {
      "Effect": "Allow",
      "Action": [
      "s3:GetObject",
      "s3:PutObject",
      "s3:ListMultipartUploadParts",
      "s3:AbortMultipartUpload"
      ],
      "Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
   }
   ]
}
```

Then use the following command to create the policy:

```
aws iam create-policy ^
--policy-name rds-s3-integration-policy ^
--policy-document file://file_path/assume_role_policy.json
```

2. After the policy is created, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a later step.

To create the IAM role

- The following AWS CLI command creates the rds-s3-integration-role IAM role for this purpose.

**Example**

For Linux, macOS, or Unix:

```
```
aws iam create-role \
  --role-name rds-s3-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
      }
    ]
  }'

For Windows:

Make sure to change the line endings to the ones supported by your interface (\ instead of \\). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the assume_role_policy.json file with the following policy:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": ["rds.amazonaws.com"]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Then use the following command to create the IAM role:

```bash
aws iam create-role ^
  --role-name rds-s3-integration-role ^
  --assume-role-policy-document file://file_path/assume_role_policy.json
```

Example of using the global condition context key to create the IAM role

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service’s permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.
In the policy, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For S3 integration, make sure to include the DB instance ARNs, as shown in the following example.

For Linux, macOS, or Unix:

```bash
aws iam create-role \
  --role-name rds-s3-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
        "Condition": {
          "StringEquals": {
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
          }
        }
      }
    ]
  }
}
```

For Windows:

Add the global condition context key to `assume_role_policy.json`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": ["rds.amazonaws.com"]
      },
      "Action": "sts:AssumeRole"
      "Condition": {
        "StringEquals": {
          "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier"
        }
      }
    }
  ]
}
```

**To attach the IAM policy to the IAM role**

- The following AWS CLI command attaches the policy to the role named `rds-s3-integration-role`. Replace `your-policy-arn` with the policy ARN that you noted in a previous step.
Example

For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
  --policy-arn your-policy-arn \
  --role-name rds-s3-integration-role
```

For Windows:

```
aws iam attach-role-policy ^
  --policy-arn your-policy-arn ^
  --role-name rds-s3-integration-role
```

Enabling RDS for SQL Server integration with S3

In the following section, you can find how to enable Amazon S3 integration with Amazon RDS for SQL Server. To work with S3 integration, your DB instance must be associated with the IAM role that you previously created before you use the `S3_INTEGRATION` feature-name parameter.

Note

To add an IAM role to a DB instance, the status of the DB instance must be available.

Console

To associate your IAM role with your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the IAM role to add for Add IAM roles to this instance.
4. For Feature, choose S3_INTEGRATION.

5. Choose Add role.

AWS CLI

To add the IAM role to the RDS for SQL Server DB instance

- The following AWS CLI command adds your IAM role to an RDS for SQL Server DB instance named mydbinstance.
Example

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance \
  --db-instance-identifier mydbinstance \
  --feature-name S3_INTEGRATION \
  --role-arn your-role-arn
```

For Windows:

```bash
aws rds add-role-to-db-instance ^
  --db-instance-identifier mydbinstance ^
  --feature-name S3_INTEGRATION ^
  --role-arn your-role-arn
```

Replace `your-role-arn` with the role ARN that you noted in a previous step. `S3_INTEGRATION` must be specified for the `--feature-name` option.

Transferring files between RDS for SQL Server and Amazon S3

You can use Amazon RDS stored procedures to download and upload files between Amazon S3 and your RDS DB instance. You can also use Amazon RDS stored procedures to list and delete files on the RDS instance.

The files that you download from and upload to S3 are stored in the D:\S3 folder. This is the only folder that you can use to access your files. You can organize your files into subfolders, which are created for you when you include the destination folder during download.

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your S3 bucket and file. The format for your ARN is `arn:aws:s3:::bucket_name/file_name`. Amazon S3 doesn't require an account number or AWS Region in ARNs.

S3 integration tasks run sequentially and share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. It can take up to five minutes for the task to begin processing.

Downloading files from an Amazon S3 bucket to a SQL Server DB instance

To download files from an S3 bucket to an RDS for SQL Server DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_download_from_s3` with the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@s3_arn_of_file</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The S3 ARN of the file to download, for example: <code>arn:aws:s3:::bucket_name/mydata.csv</code></td>
</tr>
<tr>
<td>@rds_file_path</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Optional</td>
<td>The file path for the RDS instance. If not specified, the file path is <code>D:\S3\&lt;filename in s3&gt;</code>. RDS supports absolute paths and relative paths.</td>
</tr>
</tbody>
</table>
Amazon S3 integration

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@overwrite_file</td>
<td>INT</td>
<td>0</td>
<td>Optional</td>
<td>Overwrite the existing file: 0 = Don’t overwrite 1 = Overwrite</td>
</tr>
</tbody>
</table>

You can download files without a file extension and files with the following file extensions: .bcp, .csv, .dat, .fmt, .info, .lst, .tbl, .txt, and .xml.

**Note**
Files with the .ispac file extension are supported for download when SQL Server Integration Services is enabled. For more information on enabling SSIS, see SQL Server Integration Services (p. 1077).
Files with the following file extensions are supported for download when SQL Server Analysis Services is enabled: .abf, .asdatabase, .configsettings, .deploymentoptions, .deploymenttargets, and .xmla. For more information on enabling SSAS, see SQL Server Analysis Services (p. 1059).

The following example shows the stored procedure to download files from S3.

```
exec msdb.dbo.rds_download_from_s3
    @s3_arn_of_file='arn:aws:s3:::bucket_name/bulk_data.csv',
    @rds_file_path='D:\S3\seed_data\data.csv',
    @overwrite_file=1;
```

The example rds_download_from_s3 operation creates a folder named seed_data in D:\S3, if the folder doesn’t exist yet. Then the example downloads the source file bulk_data.csv from S3 to a new file named data.csv on the DB instance. If the file previously existed, it’s overwritten because the @overwrite_file parameter is set to 1.

**Uploading files from a SQL Server DB instance to an Amazon S3 bucket**

To upload files from an RDS for SQL Server DB instance to an S3 bucket, use the Amazon RDS stored procedure msdb.dbo.rds_upload_to_s3 with the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@s3_arn_of_file</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The S3 ARN of the file to be created in S3, for example: arn:aws:s3:::bucket_name/mydata.csv</td>
</tr>
<tr>
<td>@rds_file_path</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The file path of the file to upload to S3. Absolute and relative paths are supported.</td>
</tr>
<tr>
<td>@overwrite_file</td>
<td>INT</td>
<td>–</td>
<td>Optional</td>
<td>Overwrite the existing file: 0 = Don’t overwrite 1 = Overwrite</td>
</tr>
</tbody>
</table>
The following example uploads the file named `data.csv` from the specified location in `D: \S3\seed_data\` to a file `new_data.csv` in the S3 bucket specified by the ARN.

```
exec msdb.dbo.rds_upload_to_s3
    @rds_file_path='D:\S3\seed_data\data.csv',
    @s3_arn_of_file='arn:aws:s3:::bucket_name/new_data.csv',
    @overwrite_file=1;
```

If the file previously existed in S3, it's overwritten because the `@overwrite_file` parameter is set to 1.

**Listing files on the RDS DB instance**

To list the files available on the DB instance, use both a stored procedure and a function. First, run the following stored procedure to gather file details from the files in `D:\S3\`.

```
exec msdb.dbo.rds_gather_file_details;
```

The stored procedure returns the ID of the task. Like other tasks, this stored procedure runs asynchronously. As soon as the status of the task is `SUCCESS`, you can use the task ID in the `rds_fn_list_file_details` function to list the existing files and directories in `D:\S3\`, as shown following.

```
SELECT * FROM msdb.dbo.rds_fn_list_file_details(TASK_ID);
```

The `rds_fn_list_file_details` function returns a table with the following columns.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filepath</td>
<td>Absolute path of the file (for example, <code>D:\S3\mydata.csv</code>)</td>
</tr>
<tr>
<td>size_in_bytes</td>
<td>File size (in bytes)</td>
</tr>
<tr>
<td>last_modified_utc</td>
<td>Last modification date and time in UTC format</td>
</tr>
<tr>
<td>is_directory</td>
<td>Option that indicates whether the item is a directory (true/false)</td>
</tr>
</tbody>
</table>

**Deleting files on the RDS DB instance**

To delete the files available on the DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_delete_from_filesystem` with the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@rds_file_path</td>
<td>NVARCHAR</td>
<td>–</td>
<td>Required</td>
<td>The file path of the file to delete. Absolute and relative paths are supported.</td>
</tr>
<tr>
<td>@force_delete</td>
<td>INT</td>
<td>0</td>
<td>Optional</td>
<td>To delete a directory, this flag must be included and set to 1.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1 = delete a directory</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>This parameter is ignored if you are deleting a file.</td>
</tr>
</tbody>
</table>

To delete a directory, the `@rds_file_path` must end with a backslash (\) and `@force_delete` must be set to 1.

The following example deletes the file D:\S3\delete_me.txt.

```sql
exec msdb.dbo.rds_delete_from_filesystem
    @rds_file_path='D:\S3\delete_me.txt';
```

The following example deletes the directory D:\S3\example_folder\.

```sql
exec msdb.dbo.rds_delete_from_filesystem
    @rds_file_path='D:\S3\example_folder',
    @force_delete=1;
```

**Monitoring the status of a file transfer task**

To track the status of your S3 integration task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to S3 integration. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>For S3 integration, tasks can have the following task types:</td>
</tr>
<tr>
<td></td>
<td>• DOWNLOAD_FROM_S3</td>
</tr>
<tr>
<td></td>
<td>• UPLOAD_TO_S3</td>
</tr>
<tr>
<td></td>
<td>• LIST_FILES_ON_DISK</td>
</tr>
<tr>
<td></td>
<td>• DELETE_FILES_ON_DISK</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
</tbody>
</table>
### Amazon S3 integration

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>duration(mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – After you call one of the S3 integration stored procedures, a task is created and the status is set to CREATED.</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS.</td>
</tr>
<tr>
<td></td>
<td>• SUCCESS – After a task completes, the status is set to SUCCESS.</td>
</tr>
<tr>
<td></td>
<td>• ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column.</td>
</tr>
<tr>
<td></td>
<td>• CANCEL_REQUESTED – After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED.</td>
</tr>
<tr>
<td></td>
<td>• CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.</td>
</tr>
<tr>
<td>task_info</td>
<td>Additional information about the task. If an error occurs during processing, this column contains information about the error.</td>
</tr>
<tr>
<td>last_updated</td>
<td>The date and time that the task status was last updated.</td>
</tr>
<tr>
<td>created_at</td>
<td>The date and time that the task was created.</td>
</tr>
<tr>
<td>S3_object_arn</td>
<td>The ARN of the S3 object downloaded from or uploaded to.</td>
</tr>
<tr>
<td>overwrite_S3_backup_file</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
<tr>
<td>KMS_master_key_arn</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
<tr>
<td>filepath</td>
<td>The file path on the RDS DB instance.</td>
</tr>
<tr>
<td>overwrite_file</td>
<td>An option that indicates if an existing file is overwritten.</td>
</tr>
<tr>
<td>task_metadata</td>
<td>Not applicable to S3 integration tasks.</td>
</tr>
</tbody>
</table>

### Canceling a task

To cancel S3 integration tasks, use the msdb.dbo.rds_cancel_task stored procedure with the task_id parameter. Delete and list tasks that are in progress can’t be cancelled. The following example shows a request to cancel a task.

```sql
exec msdb.dbo.rds_cancel_task @task_id = 1234;
```
To get an overview of all tasks and their task IDs, use the `rds_fn_task_status` function as described in Monitoring the status of a file transfer task (p. 1024).

**Multi-AZ limitations for S3 integration**

On Multi-AZ instances, files in the `D:\S3` folder are deleted on the standby replica after a failover. A failover can be planned, for example, during DB instance modifications such as changing the instance class or upgrading the engine version. Or a failover can be unplanned, during an outage of the primary.

**Note**

We don't recommend using the `D:\S3` folder for file storage. The best practice is to upload created files to Amazon S3 to make them durable, and download files when you need to import data.

To determine the last failover time, you can use the `msdb.dbo.rds_failover_time` stored procedure. For more information, see Determining the last failover time (p. 1122).

**Example of no recent failover**

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

Therefore, all files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host. Files downloaded before that time might also be available.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>null</td>
</tr>
</tbody>
</table>

**Example of recent failover**

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

All files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host.

<table>
<thead>
<tr>
<th>errorlog_available_from</th>
<th>recent_failover_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-04-29 23:59:00.0100000</td>
<td>2020-05-05 18:57:51.8900000</td>
</tr>
</tbody>
</table>

**Disabling RDS for SQL Server integration with S3**

Following, you can find how to disable Amazon S3 integration with Amazon RDS for SQL Server. Files in `D:\S3\` aren't deleted when disabling S3 integration.

**Note**

To remove an IAM role from a DB instance, the status of the DB instance must be available.

**Console**

**To disassociate your IAM role from your DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/)
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the IAM role to remove.
4. Choose Delete.

AWS CLI

To remove the IAM role from the RDS for SQL Server DB instance

- The following AWS CLI command removes the IAM role from a RDS for SQL Server DB instance named mydbinstance.

**Example**

For Linux, macOS, or Unix:

```
aws rds remove-role-from-db-instance \
   --db-instance-identifier mydbinstance \
   --feature-name S3_INTEGRATION \
   --role-arn your-role-arn
```

For Windows:

```
aws rds remove-role-from-db-instance ^
   --db-instance-identifier mydbinstance ^
   --feature-name S3_INTEGRATION ^
   --role-arn your-role-arn
```

Replace *your-role-arn* with the appropriate IAM role ARN for the *--feature-name* option.
Using Database Mail on Amazon RDS for SQL Server

You can use Database Mail to send email messages to users from your Amazon RDS on SQL Server database instance. The messages can contain files and query results. Database Mail includes the following components:

- **Configuration and security objects** – These objects create profiles and accounts, and are stored in the `msdb` database.
- **Messaging objects** – These objects include the `sp_send_dbmail` stored procedure used to send messages, and data structures that hold information about messages. They're stored in the `msdb` database.
- **Logging and auditing objects** – Database Mail writes logging information to the `msdb` database and the Microsoft Windows application event log.
- **Database Mail executable** – `DatabaseMail.exe` reads from a queue in the `msdb` database and sends email messages.

RDS supports Database Mail for all SQL Server versions on the Web, Standard, and Enterprise Editions.

Limitations

The following limitations apply to using Database Mail on your SQL Server DB instance:

- Database Mail isn't supported for SQL Server Express Edition.
- Modifying Database Mail configuration parameters isn't supported. To see the preset (default) values, use the `sysmail_help_configure_sp` stored procedure.
- File attachments aren't fully supported. For more information, see Working with file attachments (p. 1037).
- The maximum file attachment size is 1 MB.
- Database Mail requires additional configuration on Multi-AZ DB instances. For more information, see Considerations for Multi-AZ deployments (p. 1038).
- Configuring SQL Server Agent to send email messages to predefined operators isn't supported.

Enabling Database Mail

Use the following process to enable Database Mail for your DB instance:

1. Create a new parameter group.
2. Modify the parameter group to set the `database mail xps` parameter to 1.
3. Associate the parameter group with the DB instance.

Creating the parameter group for Database Mail

Create a parameter group for the `database mail xps` parameter that corresponds to the SQL Server edition and version of your DB instance.

**Note**

You can also modify an existing parameter group. Follow the procedure in Modifying the parameter that enables Database Mail (p. 1029).

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.
To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
   a. For Parameter group family, choose sqlserver-se-13.0.
   b. For Group name, enter an identifier for the parameter group, such as dbmail-sqlserver-se-13.
   c. For Description, enter Database Mail XPs.
5. Choose Create.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
   --db-parameter-group-name dbmail-sqlserver-se-13 \
   --db-parameter-group-family "sqlserver-se-13.0" \
   --description "Database Mail XPs"
```

For Windows:

```
aws rds create-db-parameter-group ^
   --db-parameter-group-name dbmail-sqlserver-se-13 ^
   --db-parameter-group-family "sqlserver-se-13.0" ^
   --description "Database Mail XPs"
```

Modifying the parameter that enables Database Mail

Modify the database mail xps parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

To enable Database Mail, set the database mail xps parameter to 1.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as dbmail-sqlserver-se-13.
4. Under Parameters, filter the parameter list for mail.
5. Choose database mail xps.
6. Choose Edit parameters.
7. Enter 1.
8. Choose Save changes.

**CLI**

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name dbmail-sqlserver-se-13 \
  --parameters "ParameterName='database mail xps',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name dbmail-sqlserver-se-13 ^
  --parameters "ParameterName='database mail xps',ParameterValue=1,ApplyMethod=immediate"
```

**Associating the parameter group with the DB instance**

You can use the AWS Management Console or the AWS CLI to associate the Database Mail parameter group with the DB instance.

**Console**

You can associate the Database Mail parameter group with a new or existing DB instance.

- For a new DB instance, associate it when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
- For an existing DB instance, associate it by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**CLI**

You can associate the Database Mail parameter group with a new or existing DB instance.

**To create a DB instance with the Database Mail parameter group**

- Specify the same DB engine type and major version as you used when creating the parameter group.
Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --db-instance-class db.m5.2xlarge
   --engine sqlserver-se
   --engine-version 13.00.5426.0.v1
   --allocated-storage 100
   --master-user-password secret123
   --master-username admin
   --storage-type gp2
   --license-model li
   --db-parameter-group-name dbmail-sqlserver-se-13
```

For Windows:

```bash
aws rds create-db-instance
   --db-instance-identifier mydbinstance
   --db-instance-class db.m5.2xlarge
   --engine sqlserver-se
   --engine-version 13.00.5426.0.v1
   --allocated-storage 100
   --master-user-password secret123
   --master-username admin
   --storage-type gp2
   --license-model li
   --db-parameter-group-name dbmail-sqlserver-se-13
```

To modify a DB instance and associate the Database Mail parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --db-parameter-group-name dbmail-sqlserver-se-13
   --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance
   --db-instance-identifier mydbinstance
   --db-parameter-group-name dbmail-sqlserver-se-13
   --apply-immediately
```

Configuring Database Mail

You perform the following tasks to configure Database Mail:

1. Create the Database Mail profile.
2. Create the Database Mail account.
3. Add the Database Mail account to the Database Mail profile.
4. Add users to the Database Mail profile.

**Note**

To configure Database Mail, make sure that you have execute permission on the stored procedures in the `msdb` database.

### Creating the Database Mail profile

To create the Database Mail profile, you use the `sysmail_add_profile_sp` stored procedure. The following example creates a profile named `Notifications`.

**To create the profile**

- Use the following SQL statement.

```sql
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_profile_sp
    @profile_name         = 'Notifications',
    @description          = 'Profile used for sending outgoing notifications using Amazon SES.';
GO
```

### Creating the Database Mail account

To create the Database Mail account, you use the `sysmail_add_account_sp` stored procedure. The following example creates an account named `SES` that uses Amazon Simple Email Service.

Using Amazon SES requires the following parameters:

- `@email_address` – An Amazon SES verified identity. For more information, see Verified identities in Amazon SES.
- `@mailserver_name` – An Amazon SES SMTP endpoint. For more information, see Connecting to an Amazon SES SMTP endpoint.
- `@username` – An Amazon SES SMTP user name. For more information, see Obtaining Amazon SES SMTP credentials.
- `@password` – An Amazon SES SMTP password. For more information, see Obtaining Amazon SES SMTP credentials.

Don't use an AWS Identity and Access Management user name.

**To create the account**

- Use the following SQL statement.

```sql
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_account_sp
    @account_name        = 'SES',
    @description         = 'Mail account for sending outgoing notifications.',
GO
```
Adding the Database Mail account to the Database Mail profile

To add the Database Mail account to the Database Mail profile, you use the `sysmail_add_profileaccount_sp` stored procedure. The following example adds the SES account to the `Notifications` profile.

To add the account to the profile

- Use the following SQL statement.

```sql
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_profileaccount_sp
    @profile_name        = 'Notifications',
    @account_name        = 'SES',
    @sequence_number     = 1;
GO
```

Adding users to the Database Mail profile

To grant permission for an `msdb` database principal to use a Database Mail profile, you use the `sysmail_add_principalprofile_sp` stored procedure. A `principal` is an entity that can request SQL Server resources. The database principal must map to a SQL Server authentication user, a Windows Authentication user, or a Windows Authentication group.

The following example grants public access to the `Notifications` profile.

To add a user to the profile

- Use the following SQL statement.

```sql
USE msdb
GO
EXECUTE msdb.dbo.sysmail_add_principalprofile_sp
    @profile_name       = 'Notifications',
    @principal_name     = 'public',
    @is_default         = 1;
GO
```

Amazon RDS stored procedures and functions for Database Mail

Microsoft provides stored procedures for using Database Mail, such as creating, listing, updating, and deleting accounts and profiles. In addition, RDS provides the stored procedures and functions for Database Mail shown in the following table.
<table>
<thead>
<tr>
<th>Procedure/Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rds_fn_sysmail_allitems</td>
<td>Shows sent messages, including those submitted by other users.</td>
</tr>
<tr>
<td>rds_fn_sysmail_event_log</td>
<td>Shows events, including those for messages submitted by other users.</td>
</tr>
<tr>
<td>rds_fn_sysmail_mailattachments</td>
<td>Shows attachments, including those to messages submitted by other users.</td>
</tr>
<tr>
<td>rds_sysmail_control</td>
<td>Starts and stops the mail queue (DatabaseMail.exe process).</td>
</tr>
<tr>
<td>rds_sysmail_delete_mailitems_sp</td>
<td>Deletes email messages sent by all users from the Database Mail internal tables.</td>
</tr>
</tbody>
</table>

## Sending email messages using Database Mail

You use the `sp_send_dbmail` stored procedure to send email messages using Database Mail.

### Usage

```sql
EXEC msdb.dbo.sp_send_dbmail
    @profile_name = 'profile_name',
    @recipients = 'recipient1@example.com[; recipient2; ... recipientn]',
    @subject = 'subject',
    @body = 'message_body',
    [@body_format = 'HTML'],
    [@file_attachments = 'file_path1; file_path2; ... file_pathn'],
    [@query = 'SQL_query'],
    [@attach_query_result_as_file = 0|1];
```

The following parameters are required:
- `@profile_name` – The name of the Database Mail profile from which to send the message.
- `@recipients` – The semicolon-delimited list of email addresses to which to send the message.
- `@subject` – The subject of the message.
- `@body` – The body of the message. You can also use a declared variable as the body.

The following parameters are optional:
- `@body_format` – This parameter is used with a declared variable to send email in HTML format.
- `@file_attachments` – The semicolon-delimited list of message attachments. File paths must be absolute paths.
- `@query` – A SQL query to run. The query results can be attached as a file or included in the body of the message.
- `@attach_query_result_as_file` – Whether to attach the query result as a file. Set to 0 for no, 1 for yes. The default is 0.

### Examples

The following examples demonstrate how to send email messages.
Example of sending a message to a single recipient

```
USE msdb
GO
EXEC msdb.dbo.sp_send_dbmail
    @profile_name       = 'Notifications',
    @recipients         = 'nobody@example.com',
    @subject            = 'Automated DBMail message - 1',
    @body               = 'Database Mail configuration was successful.';
GO
```

Example of sending a message to multiple recipients

```
USE msdb
GO
EXEC msdb.dbo.sp_send_dbmail
    @profile_name       = 'Notifications',
    @recipients         = 'recipient1@example.com;recipient2@example.com',
    @subject            = 'Automated DBMail message - 2',
    @body               = 'This is a message.';
GO
```

Example of sending a SQL query result as a file attachment

```
USE msdb
GO
EXEC msdb.dbo.sp_send_dbmail
    @profile_name       = 'Notifications',
    @recipients         = 'nobody@example.com',
    @subject            = 'Test SQL query',
    @body               = 'This is a SQL query test.',
    @query              = 'SELECT * FROM abc.dbo.test',
    @attach_query_result_as_file = 1;
GO
```

Example of sending a message in HTML format

```
USE msdb
GO
DECLARE @HTML_Body as NVARCHAR(500) = 'Hi, <h4> Heading </h4> </br> See the report. <b>
    Regards </b>'';
EXEC msdb.dbo.sp_send_dbmail
    @profile_name       = 'Notifications',
    @recipients         = 'nobody@example.com',
    @subject            = 'Test HTML message',
    @body               = @HTML_Body,
    @body_format        = 'HTML';
GO
```

Example of sending a message using a trigger when a specific event occurs in the database

```
USE AdventureWorks2017
GO
IF OBJECT_ID ('Production.iProductNotification', 'TR') IS NOT NULL
    DROP TRIGGER Purchasing.iProductNotification
```
GO

CREATE TRIGGER iProductNotification ON Production.Product
  FOR INSERT
  AS
  DECLARE @ProductInformation nvarchar(255);
  SELECT
    @ProductInformation = 'A new product, ' + Name + ', is now available for $' +
    CAST(StandardCost AS nvarchar(20)) + '!
  FROM INSERTED i;

EXEC msdb.dbo.sp_send_dbmail
  @profile_name       = 'Notifications',
  @recipients         = 'nobody@example.com',
  @subject            = 'New product information',
  @body               = @ProductInformation;
GO

Viewing messages, logs, and attachments

You use RDS stored procedures to view messages, event logs, and attachments.

To view all email messages

- Use the following SQL query.

  ```sql
  SELECT * FROM msdb.dbo.rds_fn_sysmail_allitems(); --WHERE sent_status='sent' or
  'failed' or 'unsent'
  ```

To view all email event logs

- Use the following SQL query.

  ```sql
  SELECT * FROM msdb.dbo.rds_fn_sysmail_event_log();
  ```

To view all email attachments

- Use the following SQL query.

  ```sql
  SELECT * FROM msdb.dbo.rds_fn_sysmail_mailattachments();
  ```

Deleting messages

You use the `rds_sysmail_delete_mailitems_sp` stored procedure to delete messages.

**Note**

RDS automatically deletes mail table items when DBMail history data reaches 1 GB in size, with
a retention period of at least 24 hours.

If you want to keep mail items for a longer period, you can archive them. For more information,
see Create a SQL Server Agent job to archive Database Mail messages and event logs in the
Microsoft documentation.

To delete all email messages

- Use the following SQL statement.
To delete all email messages with a particular status

- Use the following SQL statement to delete all failed messages.

```sql
DECLARE @GETDATE datetime
SET @GETDATE = GETDATE();
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_status = 'failed';
GO
```

Starting the mail queue

You use the `rds_sysmail_control` stored procedure to start the Database Mail process.

**Note**

Enabling Database Mail automatically starts the mail queue.

**To start the mail queue**

- Use the following SQL statement.

```sql
EXECUTE msdb.dbo.rds_sysmail_control start;
GO
```

Stopping the mail queue

You use the `rds_sysmail_control` stored procedure to stop the Database Mail process.

**To stop the mail queue**

- Use the following SQL statement.

```sql
EXECUTE msdb.dbo.rds_sysmail_control stop;
GO
```

Working with file attachments

The following file attachment extensions aren't supported in Database Mail messages from RDS on SQL Server: .ade, .adp, .apk, .appx, .appxbundle, .bat, .bak, .cab, .chm, .cmd, .com, .cpl, .dll, .dmg, .exe, .hta, .inf, .ins, .isp, .js, and .wsh.

Database Mail uses the Microsoft Windows security context of the current user to control access to files. Users who log in with SQL Server Authentication can't attach files using the `@file_attachments` parameter with the `sp_send_dbmail` stored procedure. Windows doesn't allow SQL Server to provide credentials from a remote computer to another remote computer. Therefore, Database Mail can't attach files from a network share when the command is run from a computer other than the computer running SQL Server.
However, you can use SQL Server Agent jobs to attach files. For more information on SQL Server Agent, see Using SQL Server Agent (p. 1127) and SQL Server Agent in the Microsoft documentation.

Considerations for Multi-AZ deployments

When you configure Database Mail on a Multi-AZ DB instance, the configuration isn't automatically propagated to the secondary. We recommend converting the Multi-AZ instance to a Single-AZ instance, configuring Database Mail, and then converting the DB instance back to Multi-AZ. Then both the primary and secondary nodes have the Database Mail configuration.

If you create a read replica from your Multi-AZ instance that has Database Mail configured, the replica inherits the configuration, but without the password to the SMTP server. Update the Database Mail account with the password.
Instance store support for the tempdb database on Amazon RDS for SQL Server

An instance store provides temporary block-level storage for your DB instance. This storage is located on disks that are physically attached to the host computer. These disks have Non-Volatile Memory Express (NVMe) instance storage that is based on solid-state drives (SSDs). This storage is optimized for low latency, very high random I/O performance, and high sequential read throughput.

By placing tempdb data files and tempdb log files on the instance store, you can achieve lower read and write latencies compared to standard storage based on Amazon EBS.

**Note**
SQL Server database files and database log files aren't placed on the instance store.

Enabling the instance store

When RDS provisions DB instances with one of the following instance classes, the tempdb database is automatically placed onto the instance store:

- db.m5d
- db.r5d

To enable the instance store, do one of the following:

- Create a SQL Server DB instance using one of these instance types. For more information, see Creating an Amazon RDS DB instance (p. 175).
- Modify an existing SQL Server DB instance to use one of them. For more information, see Modifying an Amazon RDS DB instance (p. 309).

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the db.m5d and db.r5d instance classes, see DB instance classes (p. 9). For more information on the instance classes supported by Amazon RDS for SQL Server, see DB instance class support for Microsoft SQL Server (p. 925).

File location and size considerations

On instances without an instance store, RDS stores the tempdb data and log files in the D:\rds\db\DATA directory. Both files start at 8 MB by default.

On instances with an instance store, RDS stores the tempdb data and log files in the T:\rds\db\DATA directory.

When tempdb has only one data file (tempdb.mdf) and one log file (templog.ldf), templog.ldf starts at 8 MB by default and tempdb.mdf starts at 80% or more of the instance's storage capacity. Twenty percent of the storage capacity or 200 GB, whichever is less, is kept free to start. Multiple tempdb data files split the 80% disk space evenly, while log files always have an 8-MB initial size.

For example, if you modify your DB instance class from db.m5.2xlarge to db.m5d.2xlarge, the size of tempdb data files increases from 8 MB each to 234 GB in total.

**Note**
Besides the tempdb data and log files on the instance store (T:\rds\db\DATA), you can still create extra tempdb data and log files on the data volume (D:\rds\db\DATA). Those files always have an 8 MB initial size.
Backup considerations

You might need to retain backups for long periods, incurring costs over time. The tempdb data and log blocks can change very often depending on the workload. This can greatly increase the DB snapshot size.

When tempdb is on the instance store, snapshots don’t include temporary files. This means that snapshot sizes are smaller and consume less of the free backup allocation compared to EBS-only storage.

Disk full errors

If you use all of the available space in the instance store, you might receive errors such as the following:

- The transaction log for database ‘tempdb’ is full due to ‘ACTIVE_TRANSACTION’.
- Could not allocate space for object ‘dbo.SORT temporary run storage: 140738941419520’ in database ‘tempdb’ because the ‘PRIMARY’ filegroup is full. Create disk space by deleting unneeded files, dropping objects in the filegroup, adding additional files to the filegroup, or setting autogrowth on for existing files in the filegroup.

You can do one or more of the following when the instance store is full:

- Adjust your workload or the way you use tempdb.
- Scale up to use a DB instance class with more NVMe storage.
- Stop using the instance store, and use an instance class with only EBS storage.
- Use a mixed mode by adding secondary data or log files for tempdb on the EBS volume.

Removing the instance store

To remove the instance store, modify your SQL Server DB instance to use an instance type that doesn’t support instance store, such as db.m5 or db.r5.

Note
When you remove the instance store, the temporary files are moved to the D:\rdsdbdata \DATA directory and reduced in size to 8 MB.
Using extended events with Amazon RDS for Microsoft SQL Server

You can use extended events in Microsoft SQL Server to capture debugging and troubleshooting information for Amazon RDS for SQL Server. Extended events replace SQL Trace and Server Profiler, which have been deprecated by Microsoft. Extended events are similar to profiler traces but with more granular control on the events being traced. Extended events are supported for SQL Server versions 2012 and later on Amazon RDS. For more information, see Extended events overview in the Microsoft documentation.

Extended events are turned on automatically for users with master user privileges in Amazon RDS for SQL Server.

Topics
- Limitations and recommendations (p. 1041)
- Configuring extended events on RDS for SQL Server (p. 1041)
- Considerations for Multi-AZ deployments (p. 1042)
- Querying extended event files (p. 1043)

Limitations and recommendations

When using extended events on RDS for SQL Server, the following limitations apply:

- Extended events are supported only for the Enterprise and Standard Editions.
- You can't alter default extended event sessions.
- Make sure to set the session memory partition mode to NONE.
- Session event retention mode can be either ALLOW_SINGLE_EVENT_LOSS or ALLOW_MULTIPLE_EVENT_LOSS.
- Event Tracing for Windows (ETW) targets aren't supported.
- Make sure that file targets are in the `D:\rdsdbdata\log` directory.
- For pair matching targets, set the `respond_to_memory_pressure` property to 1.
- Ring buffer target memory can't be greater than 4 MB.
- The following actions aren't supported:
  - `debug_break`
  - `create_dump_all_threads`
  - `create_dump_single_threads`
- The `rpc_completed` event is supported on the following versions and later: 15.0.4083.2, 14.0.3370.1, 13.0.5865.1, 12.0.6433.1, 11.0.7507.2.

Configuring extended events on RDS for SQL Server

On RDS for SQL Server, you can configure the values of certain parameters of extended event sessions. The following table describes the configurable parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xe_session_max_memory</code></td>
<td>Specifies the maximum amount of memory to allocate to the session for event buffering. This value corresponds to the <code>max_memory</code> setting of the event session.</td>
</tr>
<tr>
<td><code>xe_session_max_event_size</code></td>
<td>Specifies the maximum memory size allowed for large events. This value corresponds to the <code>max_event_size</code> setting of the event session.</td>
</tr>
</tbody>
</table>
### Parameter name | Description
--- | ---
xe_session_max_dispatch_latency | Specifies the amount of time that events are buffered in memory before being dispatched to extended event session targets. This value corresponds to the `max_dispatch_latency` setting of the event session.
xe_file_target_size | Specifies the maximum size of the file target. This value corresponds to the `max_file_size` setting of the file target.
xe_file_retention | Specifies the retention time in days for files generated by the file targets of event sessions.

**Note**
Setting `xe_file_retention` to zero causes .xel files to be removed automatically after the lock on these files is released by SQL Server. The lock is released whenever an .xel file reaches the size limit set in `xe_file_target_size`.

You can use the `rdsadmin.dbo.rds_show_configuration` stored procedure to show the current values of these parameters. For example, use the following SQL statement to view the current setting of `xe_session_max_memory`.

```sql
exec rdsadmin..rds_show_configuration 'xe_session_max_memory'
```

You can use the `rdsadmin.dbo.rds_set_configuration` stored procedure to modify them. For example, use the following SQL statement to set `xe_session_max_memory` to 4 MB.

```sql
exec rdsadmin..rds_set_configuration 'xe_session_max_memory', 4
```

### Considerations for Multi-AZ deployments

When you create an extended event session on a primary DB instance, it doesn't propagate to the standby replica. You can fail over and create the extended event session on the new primary DB instance. Or you can remove and then re-add the Multi-AZ configuration to propagate the extended event session to the standby replica. RDS stops all nondefault extended event sessions on the standby replica, so that these sessions don't consume resources on the standby. Because of this, after a standby replica becomes the primary DB instance, make sure to manually start the extended event sessions on the new primary.

**Note**
This approach applies to both Always On Availability Groups and Database Mirroring.

You can also use a SQL Server Agent job to track the standby replica and start the sessions if the standby becomes the primary. For example, use the following query in your SQL Server Agent job step to restart event sessions on a primary DB instance.

```sql
BEGIN
IF (DATABASEPROPERTYEX('rdsadmin','Updateability')='READ_WRITE'
  AND DATABASEPROPERTYEX('rdsadmin','status')='ONLINE'
  AND (DATABASEPROPERTYEX('rdsadmin','Collation') IS NOT NULL OR
      DATABASEPROPERTYEX('rdsadmin','IsAutoClose')=1)
  )
BEGIN
  IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe1')
    ALTER EVENT SESSION xe1 ON SERVER STATE=START
  IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe2')
    ALTER EVENT SESSION xe2 ON SERVER STATE=START
END
END
```

This query restarts the event sessions `xe1` and `xe2` on a primary DB instance if these sessions are in a stopped state. You can also add a schedule with a convenient interval to this query.
Querying extended event files

You can either use SQL Server Management Studio or the `sys.fn_xe_file_target_read_file` function to view data from extended events that use file targets. For more information on this function, see `sys.fn_xe_file_target_read_file (Transact-SQL)` in the Microsoft documentation.

Extended event file targets can only write files to the `D:\rdsdbdata\log` directory on RDS for SQL Server.

As an example, use the following SQL query to list the contents of all files of extended event sessions whose names start with `xe`.

```
SELECT * FROM sys.fn_xe_file_target_read_file('d:\rdsdbdata\log\xe*', null, null, null);
```
Options for the Microsoft SQL Server database engine

In this section, you can find descriptions for options that are available for Amazon RDS instances running the Microsoft SQL Server DB engine. To enable these options, you add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups (p. 262).

If you're looking for optional features that aren't added through RDS option groups (such as SSL, Microsoft Windows Authentication, and Amazon S3 integration), see Additional features for Microsoft SQL Server on Amazon RDS (p. 995).

Amazon RDS supports the following options for Microsoft SQL Server DB instances.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Engine editions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Native backup and restore</td>
<td>SQLSERVER_BACKUP_RESTORE</td>
<td>SQL Server Enterprise Edition</td>
</tr>
<tr>
<td>(p. 1046)</td>
<td></td>
<td>SQL Server Standard Edition</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SQL Server Web Edition</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SQL Server Express Edition</td>
</tr>
<tr>
<td>Transparent Data Encryption</td>
<td>TRANSPARENT_DATA_ENCRYPTION (RDS console)</td>
<td>SQL Server 2012–2019 Enterprise Edition</td>
</tr>
<tr>
<td>(p. 1049)</td>
<td>TDE (AWS CLI and RDS API)</td>
<td>SQL Server 2019 Standard Edition</td>
</tr>
<tr>
<td>SQL Server Audit (p. 1052)</td>
<td>SQLSERVER_AUDIT</td>
<td>In RDS, starting with SQL Server 2012, all editions of SQL Server support server-level audits, and Enterprise Edition also supports database-level audits.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Starting with SQL Server SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For more information, see SQL Server Audit (database engine) in the SQL Server documentation.</td>
</tr>
<tr>
<td>SQL Server Analysis Services</td>
<td>SSAS</td>
<td>SQL Server Enterprise Edition</td>
</tr>
<tr>
<td>(p. 1059)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Listing the available options for SQL Server versions and editions

You can use the `describe-option-group-options` AWS CLI command to list the available options for SQL Server versions and editions, and the settings for those options.

The following example shows the options and option settings for SQL Server 2019 Enterprise Edition. The `--engine-name` option is required.

```bash
aws rds describe-option-group-options --engine-name sqlserver-ee --major-engine-version 15.00
```

The output resembles the following:

```json
{
  "OptionGroupOptions": [
    {
      "Name": "MSDTC",
      "Description": "Microsoft Distributed Transaction Coordinator",
      "EngineName": "sqlserver-ee",
      "MajorEngineVersion": "15.00",
      "MinimumRequiredMinorEngineVersion": "4043.16.v1",
      "PortRequired": true,
      "DefaultPort": 5000,
      "OptionsDependedOn": [],
      "OptionsConflictsWith": [],
      "Persistent": false,
      "Permanent": false,
      "RequiresAutoMinorEngineVersionUpgrade": false,
      "VpcOnly": false,
      "OptionGroupOptionSettings": [
        {
          "SettingName": "ENABLE_SNA_LU",
          "SettingDescription": "Enable support for SNA LU protocol",
          "DefaultValue": "true",
```

---

<table>
<thead>
<tr>

</tbody>
</table>
Support for native backup and restore in SQL Server

By using native backup and restore for SQL Server databases, you can create a differential or full backup of your on-premises database and store the backup files on Amazon S3. You can then restore to an existing Amazon RDS DB instance running SQL Server. You can also back up an RDS for SQL Server database, store it on Amazon S3, and restore it in other locations. In addition, you can restore the backup to an on-premises server, or a different Amazon RDS DB instance running SQL Server. For more information, see Importing and exporting SQL Server databases (p. 962).

Amazon RDS supports native backup and restore for Microsoft SQL Server databases by using differential and full backup files (.bak files).

Adding the native backup and restore option

The general process for adding the native backup and restore option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLSERVER_BACKUP_RESTORE option to the option group.
3. Associate an AWS Identity and Access Management (IAM) role with the option. The IAM role must have access to an S3 bucket to store the database backups.

That is, the option must have as its option setting a valid Amazon Resource Name (ARN) in the format arn:aws:iam::account-id:role/role-name. For more information, see Amazon Resource Names (ARNs) in the AWS General Reference.

The IAM role must also have a trust relationship and a permissions policy attached. The trust relationship allows RDS to assume the role, and the permissions policy defines the actions that the role can perform. For more information, see Manually creating an IAM role for native backup and restore (p. 964).

4. Associate the option group with the DB instance.

After you add the native backup and restore option, you don't need to restart your DB instance. As soon as the option group is active, you can begin backing up and restoring immediately.
Console

To add the native backup and restore option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Create a new option group or use an existing option group. For information on how to create a custom DB option group, see Creating an option group (p. 264).

To use an existing option group, skip to the next step.
4. Add the SQLSERVER_BACKUP_RESTORE option to the option group. For more information about adding options, see Adding an option to an option group (p. 266).
5. Do one of the following:

   • To use an existing IAM role and Amazon S3 settings, choose an existing IAM role for IAM Role. If you use an existing IAM role, RDS uses the Amazon S3 settings configured for this role.
   • To create a new role and configure Amazon S3 settings, do the following:
     1. For IAM role, choose Create a new role.
     2. For S3 bucket, choose an S3 bucket from the list.
     3. For S3 prefix (optional), specify a prefix to use for the files stored in your Amazon S3 bucket.

This prefix can include a file path but doesn't have to. If you provide a prefix, RDS attaches that prefix to all backup files. RDS then uses the prefix during a restore to identify related files and ignore irrelevant files. For example, you might use the S3 bucket for purposes besides holding backup files. In this case, you can use the prefix to have RDS perform native backup and restore only on a particular folder and its subfolders.

If you leave the prefix blank, then RDS doesn't use a prefix to identify backup files or files to restore. As a result, during a multiple-file restore, RDS attempts to restore every file in every folder of the S3 bucket.

4. Choose the Enable encryption check box to encrypt the backup file. Leave the check box cleared (the default) to have the backup file unencrypted.

   If you chose Enable encryption, choose an encryption key for AWS KMS key. For more information about encryption keys, see Getting started in the AWS Key Management Service Developer Guide.

6. Choose Add option.
7. Apply the option group to a new or existing DB instance:

   • For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   • For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

CLI

This procedure makes the following assumptions:

• You're adding the SQLSERVER_BACKUP_RESTORE option to an option group that already exists. For more information about adding options, see Adding an option to an option group (p. 266).
• You're associating the option with an IAM role that already exists and has access to an S3 bucket to store the backups.
• You’re applying the option group to a DB instance that already exists. For more information, see Modifying an Amazon RDS DB instance (p. 309).

To add the native backup and restore option

1. Add the **SQLSERVER_BACKUP_RESTORE** option to the option group.

   **Example**

   For Linux, macOS, or Unix:

   ```
   aws rds add-option-to-option-group \
   --apply-immediately \
   --option-group-name mybackupgroup \
   --options "OptionName=SQLSERVER_BACKUP_RESTORE, \n   OptionSettings=[{"Name=IAM_ROLE_ARN,Value=arn:aws:iam::account-id:role/role-name"}
   ```

   For Windows:

   ```
   aws rds add-option-to-option-group ^
   --option-group-name mybackupgroup ^
   --options "{"OptionName":"SQLSERVER_BACKUP_RESTORE"," ^
   "OptionSettings": [{"Name":"IAM_ROLE_ARN", ^
   "Value": "arn:aws:iam::account-id:role/role-name"}], ^
   --apply-immediately
   ```

   **Note**
   
   When using the Windows command prompt, you must escape double quotes (" ) in JSON code by prefixing them with a backslash (\).  

2. Apply the option group to the DB instance.

   **Example**

   For Linux, macOS, or Unix:

   ```
   aws rds modify-db-instance \
   --db-instance-identifier mydbinstance \
   --option-group-name mybackupgroup \
   --apply-immediately
   ```

   For Windows:

   ```
   aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --option-group-name mybackupgroup ^
   --apply-immediately
   ```

**Modifying native backup and restore option settings**

After you enable the native backup and restore option, you can modify the settings for the option. For more information about how to modify option settings, see Modifying an option setting (p. 271).
Removing the native backup and restore option

You can turn off native backup and restore by removing the option from your DB instance. After you remove the native backup and restore option, you don’t need to restart your DB instance.

To remove the native backup and restore option from a DB instance, do one of the following:

- Remove the option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).
- Modify the DB instance and specify a different option group that doesn't include the native backup and restore option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Support for Transparent Data Encryption in SQL Server

Amazon RDS supports using Transparent Data Encryption (TDE) to encrypt stored data on your DB instances running Microsoft SQL Server. TDE automatically encrypts data before it is written to storage, and automatically decrypts data when the data is read from storage.

Amazon RDS supports TDE for the following SQL Server versions and editions:

- SQL Server 2019 Standard and Enterprise Editions
- SQL Server 2017 Enterprise Edition
- SQL Server 2016 Enterprise Edition
- SQL Server 2014 Enterprise Edition
- SQL Server 2012 Enterprise Edition

Transparent Data Encryption for SQL Server provides encryption key management by using a two-tier key architecture. A certificate, which is generated from the database master key, is used to protect the data encryption keys. The database encryption key performs the actual encryption and decryption of data on the user database. Amazon RDS backs up and manages the database master key and the TDE certificate.

**Note**

RDS doesn't support importing or exporting TDE certificates.

Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data. For example, you might want to provide data files and backups to a third party, or address security-related regulatory compliance issues. You can't encrypt the system databases for SQL Server, such as the model or master databases.

**Note**

You can create native backups of TDE-enabled databases, but you can't restore those backups to on-premises databases. You can't restore native backups of TDE-enabled, on-premises databases.

A detailed discussion of Transparent Data Encryption is beyond the scope of this guide, but you should understand the security strengths and weaknesses of each encryption algorithm and key. For information about Transparent Data Encryption for SQL Server, see Transparent Data Encryption (TDE) in the Microsoft documentation.
Enabling TDE

To enable Transparent Data Encryption for an RDS for SQL Server DB instance, specify the TDE option in an RDS option group that is associated with that DB instance.

1. Determine whether your DB instance is already associated with an option group that has the TDE option. To view the option group that a DB instance is associated with, you can use the RDS console, the describe-db-instance AWS CLI command, or the API operation DescribeDBInstances.

2. If the DB instance isn't associated with an option group that has TDE enabled, you have two choices. You can create an option group and add the TDE option, or you can modify the associated option group to add it.

   **Note**
   In the RDS console, the option is named **TRANSPARENT_DATA_ENCRYPTION**. In the AWS CLI and RDS API, it's named **TDE**.

   For information about creating or modifying an option group, see Working with option groups (p. 262). For information about adding an option to an option group, see Adding an option to an option group (p. 266).

3. Associate the DB instance with the option group that has the TDE option. For information about associating a DB instance with an option group, see Modifying an Amazon RDS DB instance (p. 309).

Encrypting data

When the TDE option is added to an option group, Amazon RDS generates a certificate that is used in the encryption process. You can then use the certificate to run SQL statements that encrypt data in a database on the DB instance. The following example uses the RDS-created certificate called RDSTDECertificateName to encrypt a database called customerDatabase.

```
---------- Enabling TDE ------------
-- Find a RDSTDECertificate to use
USE [master]
GO
SELECT name FROM sys.certificates WHERE name LIKE 'RDSTDECertificate%'
GO

USE [customerDatabase]
GO
-- Create DEK using one of the certificates from the previous step
CREATE DATABASE ENCRYPTION KEY
WITH ALGORITHM = AES_128
ENCRYPTION BY SERVER CERTIFICATE [RDSTDECertificateName]
GO

-- Enable encryption on the database
ALTER DATABASE [customerDatabase]
SET ENCRYPTION ON
GO

-- Verify that the database is encrypted
USE [master]
GO
SELECT name FROM sys.databases WHERE is_encrypted = 1
GO
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
```
The time that it takes to encrypt a SQL Server database using TDE depends on several factors. These include the size of the DB instance, whether PIOPS is enabled for the instance, the amount of data, and other factors.

**Option group considerations**

The TDE option is a persistent option that you can't remove from an option group unless all DB instances and backups are disassociated from the option group. After you add the TDE option to an option group, the option group can only be associated with DB instances that use TDE. For more information about persistent options in an option group, see Option groups overview (p. 262).

Because the TDE option is a persistent option, you can have a conflict between the option group and an associated DB instance. You can have a conflict between the option group and an associated DB instance in the following situations:

- The current option group has the TDE option, and you replace it with an option group that does not have the TDE option.
- You restore from a DB snapshot to a new DB instance that does not have an option group that contains the TDE option. For more information about this scenario, see Option group considerations (p. 443).

**SQL Server performance considerations**

The performance of a SQL Server DB instance can be impacted by using Transparent Data Encryption.

Performance for unencrypted databases can also be degraded if the databases are on a DB instance that has at least one encrypted database. As a result, we recommend that you keep encrypted and unencrypted databases on separate DB instances.

**Disabling TDE**

To disable TDE for a DB instance, first make sure that there are no encrypted objects left on the DB instance by either decrypting the objects or by dropping them. If any encrypted objects exist on the DB instance, you can't disable TDE for the DB instance. When you use the console to remove the TDE option from an option group, the console indicates that it is processing. In addition, an error event is created if the option group is associated with an encrypted DB instance or DB snapshot.

The following example removes the TDE encryption from a database called `customerDatabase`.

```sql
------------- Removing TDE ----------------
USE [customerDatabase]
GO

-- Disable encryption on the database
ALTER DATABASE [customerDatabase]
SET ENCRYPTION OFF
GO

-- Wait until the encryption state of the database becomes 1. The state is 5 (Decryption in progress) for a while
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO

-- Drop the DEK used for encryption
DROP DATABASE ENCRYPTION KEY
GO

-- Alter to SIMPLE Recovery mode so that your encrypted log gets truncated
USE [master]
GO
```

1051
When all objects are decrypted, you can have two options. You can modify the DB instance to be associated with an option group without the TDE option. Or you can remove the TDE option from the option group.

### SQL Server Audit

In Amazon RDS, you can audit Microsoft SQL Server databases by using the built-in SQL Server auditing mechanism. You can create audits and audit specifications in the same way that you create them for on-premises database servers.

RDS uploads the completed audit logs to your S3 bucket, using the IAM role that you provide. If you enable retention, RDS keeps your audit logs on your DB instance for the configured period of time.

For more information, see [SQL Server Audit (database engine)](https://docs.microsoft.com/en-us/sql/sql-server/auditing/audit-logs) in the Microsoft SQL Server documentation.

**Topics**

- Support for SQL Server Audit (p. 1052)
- Adding SQL Server Audit to the DB instance options (p. 1053)
- Using SQL Server Audit (p. 1054)
- Viewing audit logs (p. 1054)
- Using SQL Server Audit with Multi-AZ instances (p. 1055)
- Configuring an S3 bucket (p. 1055)
- Manually creating an IAM role for SQL Server Audit (p. 1056)

### Support for SQL Server Audit

In Amazon RDS, starting with SQL Server 2012, all editions of SQL Server support server-level audits, and the Enterprise edition also supports database-level audits. Starting with SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see [SQL Server Audit (database engine)](https://docs.microsoft.com/en-us/sql/sql-server/auditing/audit-logs) in the SQL Server documentation.

RDS supports configuring the following option settings for SQL Server Audit.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM_ROLE_ARN</td>
<td>A valid Amazon Resource Name (ARN) in the format arn:aws:iam::account-id:role/role-name.</td>
<td>The ARN of the IAM role that grants access to the S3 bucket where you want to store your audit logs. For more information, see <a href="https://docs.aws.amazon.com/glu/latest/userguide/resource-name-arn.html">Amazon Resource Names (ARNs)</a> in the <a href="https://docs.aws.amazon.com/general/latest/gr/aws-arns-and-namespaces.html">AWS General Reference</a>.</td>
</tr>
<tr>
<td>S3_BUCKET_ARN</td>
<td>A valid ARN in the format arn:aws:s3:::bucket-name or arn:aws:s3:::bucket-name/key-prefix</td>
<td>The ARN for the S3 bucket where you want to store your audit logs.</td>
</tr>
<tr>
<td>ENABLE_COMPRESSION</td>
<td>true or false</td>
<td>Controls audit log compression. By default, compression is enabled (set to true).</td>
</tr>
</tbody>
</table>
RDS supports SQL Server Audit in all AWS Regions except Middle East (Bahrain).

### Adding SQL Server Audit to the DB instance options

Enabling SQL Server Audit requires two steps: enabling the option on the DB instance, and enabling the feature inside SQL Server. The process for adding the SQL Server Audit option to a DB instance is as follows:

1. Create a new option group, or copy or modify an existing option group.
2. Add and configure all required options.
3. Associate the option group with the DB instance.

After you add the SQL Server Audit option, you don't need to restart your DB instance. As soon as the option group is active, you can create audits and store audit logs in your S3 bucket.

### To add and configure SQL Server Audit on a DB instance's option group

1. Choose one of the following:
   - Use an existing option group.
   - Create a custom DB option group and use that option group. For more information, see Creating an option group (p. 264).

2. Add the SQLSERVER_AUDIT option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 266).
   - For IAM role, if you already have an IAM role with the required policies, you can choose that role. To create a new IAM role, choose Create a New Role. For information about the required policies, see Manually creating an IAM role for SQL Server Audit (p. 1056).
   - For Select S3 destination, if you already have an S3 bucket that you want to use, choose it. To create an S3 bucket, choose Create a New S3 Bucket.
   - For Enable Compression, leave this option chosen to compress audit files. Compression is enabled by default. To disable compression, clear Enable Compression.
   - For Audit log retention, to keep audit records on the DB instance, choose this option. Specify a retention time in hours. The maximum retention time is 35 days.

3. Apply the option group to a new or existing DB instance. Choose one of the following:
   - If you are creating a new DB instance, apply the option group when you launch the instance.
   - On an existing DB instance, apply the option group by modifying the instance and then attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

### Modifying the SQL Server Audit option

After you enable the SQL Server Audit option, you can modify the settings. For information about how to modify option settings, see Modifying an option setting (p. 271).
Removing SQL Server Audit from the DB instance options

You can turn off the SQL Server Audit feature by disabling audits and then deleting the option.

To remove auditing

1. Disable all of the audit settings inside SQL Server. To learn where audits are running, query the SQL Server security catalog views. For more information, see Security catalog views in the Microsoft SQL Server documentation.

2. Delete the SQL Server Audit option from the DB instance. Choose one of the following:
   - Delete the SQL Server Audit option from the option group that the DB instance uses. This change affects all DB instances that use the same option group. For more information, see Removing an option from an option group (p. 274).
   - Modify the DB instance, and then choose an option group without the SQL Server Audit option. This change affects only the DB instance that you modify. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

3. After you delete the SQL Server Audit option from the DB instance, you don't need to restart the instance. Remove unneeded audit files from your S3 bucket.

Using SQL Server Audit

You can control server audits, server audit specifications, and database audit specifications the same way that you control them for on-premises database servers.

Creating audits

You create server audits in the same way that you create them for on-premises database servers. For information about how to create server audits, see CREATE SERVER AUDIT in the Microsoft SQL Server documentation.

To avoid errors, adhere to the following limitations:

- Don't exceed the maximum number of supported server audits per instance of 50.
- Instruct SQL Server to write data to a binary file.
- Don't use RDS_ as a prefix in the server audit name.
- For FILEPATH, specify D:\rdsdbdata\SQLAudit.
- For MAXSIZE, specify a size between 2 MB and 50 MB.
- Don't configure MAX_ROLLOVER_FILES or MAX_FILES.
- Don't configure SQL Server to shut down the DB instance if it fails to write the audit record.

Creating audit specifications

You create server audit specifications and database audit specifications the same way that you create them for on-premises database servers. For information about creating audit specifications, see CREATE SERVER AUDIT SPECIFICATION and CREATE DATABASE AUDIT SPECIFICATION in the Microsoft SQL Server documentation.

To avoid errors, don't use RDS_ as a prefix in the name of the database audit specification or server audit specification.

Viewing audit logs

Your audit logs are stored in D:\rdsdbdata\SQLAudit.
After SQL Server finishes writing to an audit log file—when the file reaches its size limit—Amazon RDS uploads the file to your S3 bucket. If retention is enabled, Amazon RDS moves the file into the retention folder: D:\rdsdbdata\SQLAudit\transmitted.

For information about configuring retention, see Adding SQL Server Audit to the DB instance options (p. 1053).

Audit records are kept on the DB instance until the audit log file is uploaded. You can view the audit records by running the following command.

```sql
SELECT *
FROM msdb.dbo.rds_fn_get_audit_file
('D:\rdsdbdata\SQLAudit\*.sqlaudit'
, default
, default )
```

You can use the same command to view audit records in your retention folder by changing the filter to D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit.

```sql
SELECT *
FROM msdb.dbo.rds_fn_get_audit_file
('D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit'
, default
, default )
```

**Using SQL Server Audit with Multi-AZ instances**

For Multi-AZ instances, the process for sending audit log files to Amazon S3 is similar to the process for Single-AZ instances. However, there are some important differences:

- Database audit specification objects are replicated to all nodes.
- Server audits and server audit specifications aren't replicated to secondary nodes. Instead, you have to create or modify them manually.

To capture server audits or a server audit specification from both nodes:

1. Create a server audit or a server audit specification on the primary node.
2. Fail over to the secondary node and create a server audit or a server audit specification with the same name and GUID on the secondary node. Use the `AUDIT_GUID` parameter to specify the GUID.

**Configuring an S3 bucket**

The audit log files are automatically uploaded from the DB instance to your S3 bucket. The following restrictions apply to the S3 bucket that you use as a target for audit files:

- It must be in the same AWS Region as the DB instance.
- It must not be open to the public.
- It can't use S3 Object Lock.
- The bucket owner must also be the IAM role owner.

The target key that is used to store the data follows this naming schema: `bucket-name/key-prefix/instance-name/audit-name/node_file-name.ext`
Note
You set both the bucket name and the key prefix values with the (S3_BUCKET_ARN) option setting.

The schema is composed of the following elements:

- **bucket-name** – The name of your S3 bucket.
- **key-prefix** – The custom key prefix you want to use for audit logs.
- **instance-name** – The name of your Amazon RDS instance.
- **audit-name** – The name of the audit.
- **node** – The identifier of the node that is the source of the audit logs (node1 or node2). There is one node for a Single-AZ instance and two replication nodes for a Multi-AZ instance. These are not primary and secondary nodes, because the roles of primary and secondary change over time. Instead, the node identifier is a simple label.
  - **node1** – The first replication node (Single-AZ has one node only).
  - **node2** – The second replication node (Multi-AZ has two nodes).
- **file-name** – The target file name. The file name is taken as-is from SQL Server.
- **ext** – The extension of the file (zip or sqlaudit):
  - **zip** – If compression is enabled (default).
  - **sqlaudit** – If compression is disabled.

Manually creating an IAM role for SQL Server Audit

Typically, when you create a new option, the AWS Management Console creates the IAM role and the IAM trust policy for you. However, you can manually create a new IAM role to use with SQL Server Audits, so that you can customize it with any additional requirements you might have. To do this, you create an IAM role and delegate permissions so that the Amazon RDS service can use your Amazon S3 bucket. When you create this IAM role, you attach trust and permissions policies. The trust policy allows Amazon RDS to assume this role. The permission policy defines the actions that this role can do. For more information, see Creating a role to delegate permissions to an AWS service in the AWS Identity and Access Management User Guide.

You can use the examples in this section to create the trust relationships and permissions policies you need.

The following example shows a trust relationship for SQL Server Audit. It uses the service principal rds.amazonaws.com to allow RDS to write to the S3 bucket. A service principal is an identifier that is used to grant permissions to a service. Anytime you allow access to rds.amazonaws.com in this way, you are allowing RDS to perform an action on your behalf. For more information about service principals, see AWS JSON policy elements: Principal.

Example trust relationship for SQL Server Audit

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```
We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For SQL Server Audit, make sure to include both the DB option group and the DB instances, as shown in the following example.

**Example trust relationship with global condition context key for SQL Server Audit**

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceArn": [
                        "arn:aws:rds:Region:my_account_ID:og:option_group_name"
                    ]
                }
            }
        }
    ]
}
```

In the following example of a permissions policy for SQL Server Audit, we specify an ARN for the Amazon S3 bucket. You can use ARNs to identify a specific account, user, or role that you want grant access to. For more information about using ARNs, see [Amazon resource names (ARNs)](https://docs.aws.amazon.com/articles/).  

**Example permissions policy for SQL Server Audit**

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": ["s3:ListBucket", "s3:GetBucketACL", "s3:GetBucketLocation"
        }
    ]
}
```
"Resource": "arn:aws:s3:::bucket_name"
},
{
 "Effect": "Allow",
 "Action": [
 "s3:PutObject",
 "s3:ListMultipartUploadParts",
 "s3:AbortMultipartUpload"
 ],
 "Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
}]
}

**Note**

The `s3:ListAllMyBuckets` action is required for verifying that the same AWS account owns both the S3 bucket and the SQL Server DB instance. The action lists the names of the buckets in the account.

S3 bucket namespaces are global. If you accidentally delete your bucket, another user can create a bucket with the same name in a different account. Then the SQL Server Audit data is written to the new bucket.
Support for SQL Server Analysis Services in Amazon RDS for SQL Server

Microsoft SQL Server Analysis Services (SSAS) is part of the Microsoft Business Intelligence (MSBI) suite. SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You use SSAS to analyze data to help make business decisions. SSAS differs from the SQL Server relational database because SSAS is optimized for queries and calculations common in a business intelligence environment.

You can turn on SSAS for existing or new DB instances. It's installed on the same DB instance as your database engine. For more information on SSAS, see the Microsoft Analysis services documentation.

Amazon RDS supports SSAS for SQL Server Standard and Enterprise Editions on the following versions:

• Tabular mode:
  • SQL Server 2019, version 15.00.4043.16.v1 and higher
  • SQL Server 2017, version 14.00.3223.3.v1 and higher
  • SQL Server 2016, version 13.00.5426.0.v1 and higher

• Multidimensional mode:
  • SQL Server 2017, version 14.00.3381.3.v1 and higher
  • SQL Server 2016, version 13.00.5882.1.v1 and higher

Topics

• Limitations (p. 1059)
• Turning on SSAS (p. 1060)
• Deploying SSAS projects on Amazon RDS (p. 1064)
• Monitoring the status of a deployment task (p. 1065)
• Using SSAS on Amazon RDS (p. 1066)
• Backing up an SSAS database (p. 1071)
• Restoring an SSAS database (p. 1072)
• Changing the SSAS mode (p. 1072)
• Turning off SSAS (p. 1074)
• Troubleshooting SSAS issues (p. 1074)

Limitations

The following limitations apply to using SSAS on RDS for SQL Server:

• RDS for SQL Server supports running SSAS in Tabular or Multidimensional mode. For more information, see Comparing tabular and multidimensional solutions in the Microsoft documentation.

• You can only use one SSAS mode at a time. Before changing modes, make sure to delete all of the SSAS databases.

  For more information, see Changing the SSAS mode (p. 1072).

• Multidimensional mode isn't supported on SQL Server 2019.

• Multi-AZ instances aren't supported.

• Instances must use AWS Directory Service for Microsoft Active Directory for SSAS authentication.

• Users aren't given SSAS server administrator access, but they can be granted database-level administrator access.
• The only supported port for accessing SSAS is 2383.
• You can't deploy projects directly. We provide an RDS stored procedure to do this. For more information, see Deploying SSAS projects on Amazon RDS (p. 1064).
• Processing during deployment isn't supported.
• Using .xmla files for deployment isn't supported.
• SSAS project input files and database backup output files can only be in the D:\S3 folder on the DB instance.

Turning on SSAS

Use the following process to turn on SSAS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSAS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSAS listener port.
5. Turn on Amazon S3 integration.

Creating an option group for SSAS

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use.

**Note**
You can also use an existing option group if it's for the correct SQL Server engine and version.

**Console**

The following console procedure creates an option group for SQL Server Standard Edition 2017.

**To create the option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group pane, do the following:
   a. For Name, enter a name for the option group that is unique within your AWS account, such as ssas-se-2017. The name can contain only letters, digits, and hyphens.
   b. For Description, enter a brief description of the option group, such as SSAS option group for SQL Server SE 2017. The description is used for display purposes.
   c. For Engine, choose sqlserver-se.
   d. For Major engine version, choose 14.00.
5. Choose Create.

**CLI**

The following CLI example creates an option group for SQL Server Standard Edition 2017.

**To create the option group**

• Use one of the following commands.
Example

For Linux, macOS, or Unix:

```bash
aws rds create-option-group \
  --option-group-name ssas-se-2017 \
  --engine-name sqlserver-se \
  --major-engine-version 14.00 \
  --option-group-description "SSAS option group for SQL Server SE 2017"
```

For Windows:

```bash
aws rds create-option-group ^
  --option-group-name ssas-se-2017 ^
  --engine-name sqlserver-se ^
  --major-engine-version 14.00 ^
  --option-group-description "SSAS option group for SQL Server SE 2017"
```

Adding the SSAS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSAS option to the option group.

Console

**To add the SSAS option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group that you just created.
4. Choose Add option.
5. Under **Option details**, choose SSAS for **Option name**.
6. Under **Option settings**, do the following:
   a. For **Max memory**, enter a value in the range 10–80.
      
      **Max memory** specifies the upper threshold above which SSAS begins releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.
   b. For **Mode**, choose the SSAS server mode, Tabular or Multidimensional.
      
      If you don't see the **Mode** option setting, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see Limitations (p. 1059).
      
      **Tabular** is the default.
   c. For **Security groups**, choose the VPC security group to associate with the option.

   **Note**
   
   The port for accessing SSAS, 2383, is prepopulated.
7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
8. Choose **Add option**.
To add the SSAS option

1. Create a JSON file, for example ssas-option.json, with the following parameters:

   - **OptionGroupName** – The name of option group that you created or chose previously (ssas-se-2017 in the following example).
   - **Port** – The port that you use to access SSAS. The only supported port is 2383.
   - **VpcSecurityGroupMemberships** – Memberships for VPC security groups for your RDS DB instance.
   - **MAX_MEMORY** – The upper threshold above which SSAS should begin releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.
   - **MODE** – The SSAS server mode, either Tabular or Multidimensional. Tabular is the default.

   If you receive an error that the **MODE** option setting isn't valid, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see Limitations (p. 1059).

   The following is an example of a JSON file with SSAS option settings.

   ```json
   {
   "OptionGroupName": "ssas-se-2017",
   "OptionsToInclude": [
   {
   "OptionName": "SSAS",
   "Port": 2383,
   "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
   "OptionSettings": [{"Name":"MAX_MEMORY","Value":"60"},
   {"Name":"MODE","Value":"Multidimensional"}]
   },
   "ApplyImmediately": true
   }
   }
   ``

2. Add the SSAS option to the option group.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws rds add-option-to-option-group
   --cli-input-json file://ssas-option.json
   --apply-immediately
   ```

   For Windows:

   ```bash
   aws rds add-option-to-option-group ^
   --cli-input-json file://ssas-option.json ^
   --apply-immediately
   ```

**Associating the option group with your DB instance**

You can use the console or the CLI to associate the option group with your DB instance.
Associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group with the DB instance when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
- For an existing DB instance, modify the instance and associate the new option group with it. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**Note**
If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1004).

You can associate your option group with a new or existing DB instance.

**Note**
If you use an existing instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1004).

To create a DB instance that uses the option group

- Specify the same DB engine type and major version that you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-instance
  --db-instance-identifier myssasinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 14.00.3223.3.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --domain-iam-role-name my-directory-iam-role
  --domain my-domain-id
  --option-group-name ssas-se-2017
```

For Windows:

```
aws rds create-db-instance
  --db-instance-identifier myssasinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 14.00.3223.3.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model li
  --domain-iam-role-name my-directory-iam-role
  --domain my-domain-id
  --option-group-name ssas-se-2017
```
To modify a DB instance to associate the option group

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier myssasinstance \
    --option-group-name ssas-se-2017 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier myssasinstance ^
    --option-group-name ssas-se-2017 ^
    --apply-immediately
```

Allowing inbound access to your VPC security group

Create an inbound rule for the specified SSAS listener port in the VPC security group associated with your DB instance. For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

Enabling Amazon S3 integration

To download model configuration files to your host for deployment, use Amazon S3 integration. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1014).

Deploying SSAS projects on Amazon RDS

On RDS, you can't deploy SSAS projects directly by using SQL Server Management Studio (SSMS). To deploy projects, use an RDS stored procedure.

**Note**

Using .xmla files for deployment isn't supported.

Before you deploy projects, make sure of the following:

- Amazon S3 integration is turned on. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1014).
- The Processing Option configuration setting is set to Do Not Process. This setting means that no processing happens after deployment.
- You have both the myssasproject.asdatabase and myssasproject.deploymentoptions files. They're automatically generated when you build the SSAS project.

To deploy an SSAS project on RDS

1. Download the .asdatabase (SSAS model) file from your S3 bucket to your DB instance, as shown in the following example. For more information on the download parameters, see Downloading files from an Amazon S3 bucket to a SQL Server DB instance (p. 1021).
2. Download the .deploymentoptions file from your S3 bucket to your DB instance.

```sql
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.deploymentoptions',
[rds_file_path='D:\S3\myssasproject.deploymentoptions'],
[overwrite_file=1];
```

3. Deploy the project.

```sql
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_DEPLOY_PROJECT',
@file_path='D:\S3\myssasproject.asdatabase';
```

## Monitoring the status of a deployment task

To track the status of your deployment (or download) task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to SSAS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to 0, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>For SSAS, tasks can have the following task types:</td>
</tr>
<tr>
<td></td>
<td>• SSAS_DEPLOY_PROJECT</td>
</tr>
<tr>
<td></td>
<td>• SSAS_ADD_DB_ADMIN_MEMBER</td>
</tr>
<tr>
<td></td>
<td>• SSAS_BACKUP_DB</td>
</tr>
<tr>
<td></td>
<td>• SSAS_RESTORE_DB</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to SSAS tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration (mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
</tbody>
</table>
### Output parameter | Description
---|---
CREATED | After you call one of the SSAS stored procedures, a task is created and the status is set to CREATED.
IN_PROGRESS | After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS.
SUCCESS | After a task completes, the status is set to SUCCESS.
ERROR | If a task fails, the status is set to ERROR. For more information about the error, see the task_info column.
CANCEL_REQUESTED | After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED.
CANCELLED | After a task is successfully canceled, the status of the task is set to CANCELLED.

<table>
<thead>
<tr>
<th>task_info</th>
<th>Additional information about the task. If an error occurs during processing, this column contains information about the error. For more information, see [Troubleshooting SSAS issues](p. 1074).</th>
</tr>
</thead>
<tbody>
<tr>
<td>last_updated</td>
<td>The date and time that the task status was last updated.</td>
</tr>
<tr>
<td>created_at</td>
<td>The date and time that the task was created.</td>
</tr>
<tr>

<td>Not applicable to SSAS tasks.</td>
</tr>
<tr>
<td>overwrite_file</td>
<td>Not applicable to SSAS tasks.</td>
</tr>
<tr>
<td>task_metadata</td>
<td>Metadata associated with the SSAS task.</td>
</tr>
</tbody>
</table>

### Using SSAS on Amazon RDS

After deploying the SSAS project, you can directly process the OLAP database on SSMS.

#### To use SSAS on RDS

1. In SSMS, connect to SSAS using the user name and password for the Active Directory domain.
2. Expand Databases. The newly deployed SSAS database appears.
3. Locate the connection string, and update the user name and password to give access to the source SQL database. Doing this is required for processing SSAS objects.
   a. For Tabular mode, do the following:
1. Expand the **Connections** tab.
2. Open the context (right-click) menu for the connection object, and then choose **Properties**.
3. Update the user name and password in the connection string.

b. For Multidimensional mode, do the following:

1. Expand the **Data Sources** tab.
2. Open the context (right-click) menu for the data source object, and then choose **Properties**.
3. Update the user name and password in the connection string.

4. Open the context (right-click) menu for the SSAS database that you created and choose **Process Database**.

Depending on the size of the input data, the processing operation might take several minutes to complete.

**Topics**
- Setting up a Windows-authenticated user for SSAS (p. 1067)
- Adding a domain user as a database administrator (p. 1068)
- Creating an SSAS proxy (p. 1068)
- Scheduling SSAS database processing using SQL Server Agent (p. 1069)
- Revoking SSAS access from the proxy (p. 1071)

**Setting up a Windows-authenticated user for SSAS**

The main administrator user (sometimes called the master user) can use the following code example to set up a Windows-authenticated login and grant the required procedure permissions. Doing this grants permissions to the domain user to run SSAS customer tasks, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see Credentials (database engine) and Create a SQL Server Agent proxy in the Microsoft documentation.

You can grant some or all of the following permissions as needed to Windows-authenticated users.

**Example**

```
-- Create a server-level domain user login, if it doesn't already exist
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
GO

-- Create domain user, if it doesn't already exist
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
GO

-- Grant necessary privileges to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO

USE [msdb]
GO
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
```
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy to [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\user_name] with grant option
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO

Adding a domain user as a database administrator

You can add a domain user as an SSAS database administrator in the following ways:

- A database administrator can use SSMS to create a role with admin privileges, then add users to that role.
- You can use the following stored procedure.

```sql
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_ADD_DB_ADMIN_MEMBER',
@database_name='myssasdb',
@ssas_role_name='exampleRole',
@ssas_role_member='domain_name\domain_user_name';
```

The following parameters are required:
- `@task_type` - The type of the MSBI task, in this case `SSAS_ADD_DB_ADMIN_MEMBER`.
- `@database_name` - The name of the SSAS database to which you're granting administrator privileges.
- `@ssas_role_name` - The SSAS database administrator role name. If the role doesn't already exist, it's created.
- `@ssas_role_member` - The SSAS database user that you're adding to the administrator role.

Creating an SSAS proxy

To be able to schedule SSAS database processing using SQL Server Agent, create an SSAS credential and an SSAS proxy. Run these procedures as a Windows-authenticated user.

To create the SSAS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```sql
USE [master]
GO
CREATE CREDENTIAL [SSAS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET = N'mysecret'
GO
```

Note

IDENTITY must be a domain-authenticated login. Replace `mysecret` with the password for the domain-authenticated login.
To create the SSAS proxy

1. Use the following SQL statement to create the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
    @proxy_name=N'SSAS_Proxy',
    @credential_name=N'SSAS_Credential',
    @description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
    @proxy_name=N'SSAS_Proxy',
    @login_name=N'\mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSAS subsystem access to the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='GRANT_SUBSYSTEM_ACCESS',
    @proxy_name='SSAS_Proxy',
    @proxy_subsystem='SSAS'
GO
```

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```sql
USE [msdb]
GO
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

Scheduling SSAS database processing using SQL Server Agent

After you create the credential and proxy and grant SSAS access to the proxy, you can create a SQL Server Agent job to schedule SSAS database processing.

To schedule SSAS database processing

- Use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL. You can further configure its job schedule through SSMS or T-SQL.

- The @command parameter outlines the XML for Analysis (XMLA) command to be run by the SQL Server Agent job. This example configures SSAS Multidimensional database processing.

- The @server parameter outlines the target SSAS server name of the SQL Server Agent job.
To call the SSAS service within the same RDS DB instance where the SQL Server Agent job resides, use localhost:2383.

To call the SSAS service from outside the RDS DB instance, use the RDS endpoint. You can also use the Kerberos Active Directory (AD) endpoint (your-DB-instance-name.your-AD-domain-name) if the RDS DB instances are joined by the same domain. For external DB instances, make sure to properly configure the VPC security group associated with the RDS DB instance for a secure connection.

You can further edit the query to support various XMLA operations. Make edits either by directly modifying the T-SQL query or by using the SSMS UI following SQL Server Agent job creation.

```sql
USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'SSAS_Job', @enabled=1,
    @notify_level_eventlog=0,
    @notify_level_email=0,
    @notify_level_netsend=0,
    @notify_level_page=0,
    @category_name=N'[Uncategorized (Local)]',
    @job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver
    @job_name=N'SSAS_Job',
    @server_name = N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'SSAS_Job', @step_name=N'Process_SSAS_Object',
    @step_id=1,
    @cmdexec_success_code=0,
    @on_success_action=1,
    @on_success_step_id=0,
    @on_fail_action=2,
    @on_fail_step_id=0,
    @retry_attempts=0,
    @retry_interval=0,
    @os_run_priority=0, @subsystem=N'ANALYSISCOMMAND',
    @command=N'<Batch xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
      <Parallel>
          <Object>
            <DatabaseID>Your_SSAS_Database_ID</DatabaseID>
```
Revoking SSAS access from the proxy

You can revoke access to the SSAS subsystem and delete the SSAS proxy using the following stored procedures.

To revoke access and delete the proxy

1. Revoke subsystem access.

   ```
   USE [msdb]
   GO
   EXEC msdb.dbo.rds_sqlagent_proxy
   @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
   GO
   ```

2. Revoke the grants on the proxy.

   ```
   USE [msdb]
   GO
   EXEC msdb.dbo.sp_revoke_login_from_proxy
   @proxy_name=N'SSAS_Proxy',@name=N'\mydomain\user_name'
   GO
   ```

3. Delete the proxy.

   ```
   USE [msdb]
   GO
   EXEC dbo.sp_delete_proxy @proxy_name = N'SSAS_Proxy'
   GO
   ```

Backing up an SSAS database

You can create SSAS database backup files only in the D:\S3 folder on the DB instance. To move the backup files to your S3 bucket, use Amazon S3.

You can back up an SSAS database as follows:

- A domain user with the admin role for a particular database can use SSMS to back up the database to the D:\S3 folder.

  For more information, see Adding a domain user as a database administrator (p. 1068).

- You can use the following stored procedure. This stored procedure doesn't support encryption.

   ```
   exec msdb.dbo.rds_msbi_task
   @task_type='SSAS_BACKUP_DB',
   ```
The following parameters are required:

- `@task_type` – The type of the MSBI task, in this case `SSAS_BACKUP_DB`.
- `@database_name` – The name of the SSAS database that you're backing up.
- `@file_path` – The path for the SSAS backup file. The `.abf` extension is required.

The following parameters are optional:

- `@ssas_apply_compression` – Whether to apply SSAS backup compression. Valid values are 1 (Yes) and 0 (No).
- `@ssas_overwrite_file` – Whether to overwrite the SSAS backup file. Valid values are 1 (Yes) and 0 (No).

**Restoring an SSAS database**

Use the following stored procedure to restore an SSAS database from a backup.

You can't restore a database if there is an existing SSAS database with the same name. The stored procedure for restoring doesn't support encrypted backup files.

```sql
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_RESTORE_DB',
@database_name='mynewssasdb',
@file_path='D:\S3\ssas_db_backup.abf';
```

The following parameters are required:

- `@task_type` – The type of the MSBI task, in this case `SSAS_RESTORE_DB`.
- `@database_name` – The name of the new SSAS database that you're restoring to.
- `@file_path` – The path to the SSAS backup file.

**Restoring a DB instance to a specified time**

Point-in-time recovery (PITR) doesn't apply to SSAS databases. If you do PITR, only the SSAS data in the last snapshot before the requested time is available on the restored instance.

To have up-to-date SSAS databases on a restored DB instance

1. Back up your SSAS databases to the `D:\S3` folder on the source instance.
2. Transfer the backup files to the S3 bucket.
3. Transfer the backup files from the S3 bucket to the `D:\S3` folder on the restored instance.
4. Run the stored procedure to restore the SSAS databases onto the restored instance.

You can also reprocess the SSAS project to restore the databases.

**Changing the SSAS mode**

You can change the mode in which SSAS runs, either Tabular or Multidimensional. To change the mode, use the AWS Management Console or the AWS CLI to modify the options settings in the SSAS option.
Important
You can only use one SSAS mode at a time. Make sure to delete all of the SSAS databases before changing the mode, or you receive an error.

Console
The following Amazon RDS console procedure changes the SSAS mode to Tabular and sets the MAX_MEMORY parameter to 70 percent.

To modify the SSAS option
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group with the SSAS option that you want to modify (ssas-se-2017 in the previous examples).
4. Choose Modify option.
5. Change the option settings:
   a. For Max memory, enter 70.
   b. For Mode, choose Tabular.
6. Choose Modify option.

AWS CLI
The following AWS CLI example changes the SSAS mode to Tabular and sets the MAX_MEMORY parameter to 70 percent.

For the CLI command to work, make sure to include all of the required parameters, even if you're not modifying them.

To modify the SSAS option
- Use one of the following commands.

Example
For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
   --option-group-name ssas-se-2017 \ 
   --options "OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=[{Name=MAX_MEMORY,Value=70}, {Name=MODE,Value=Tabular}]" \ 
   --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^ \
   --option-group-name ssas-se-2017 ^ \
   --options OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=[{Name=MAX_MEMORY,Value=70}, {Name=MODE,Value=Tabular}] ^ \
   --apply-immediately
```
Turning off SSAS

To turn off SSAS, remove the SSAS option from its option group.

**Important**
Before you remove the SSAS option, delete your SSAS databases. We highly recommend that you back up your SSAS databases before deleting them and removing the SSAS option.

**Console**

To remove the SSAS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSAS option that you want to remove (ssas-se-2017 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose SSAS for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

**AWS CLI**

To remove the SSAS option from its option group

- Use one of the following commands.

  **Example**

  For Linux, macOS, or Unix:

  ```bash
  aws rds remove-option-from-option-group \
  --option-group-name ssas-se-2017 \
  --options SSAS \
  --apply-immediately
  ```

  For Windows:

  ```bash
  aws rds remove-option-from-option-group ^
  --option-group-name ssas-se-2017 ^
  --options SSAS ^
  --apply-immediately
  ```

**Troubleshooting SSAS issues**

You might encounter the following issues when using SSAS.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Type</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to configure the SSAS option. The requested SSAS mode is <code>new_mode</code>,</td>
<td>RDS event</td>
<td>You can’t change the SSAS mode if you still have SSAS databases that use the current</td>
</tr>
<tr>
<td>Issue</td>
<td>Type</td>
<td>Troubleshooting suggestions</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>but the current DB instance has <code>number current_mode</code> databases. Delete the existing databases before switching to <code>new_mode</code> mode. To regain access to <code>current_mode</code> mode for database deletion, either update the current DB option group, or attach a new option group with <code>%s</code> as the MODE option setting value for the SSAS option.</td>
<td>mode</td>
<td>Delete the SSAS databases, then try again.</td>
</tr>
<tr>
<td>Unable to remove the SSAS option because there are <code>number</code> existing <code>mode</code> databases. The SSAS option can't be removed until all SSAS databases are deleted. Add the SSAS option again, delete all SSAS databases, and try again.</td>
<td>RDS event</td>
<td>You can't turn off SSAS if you still have SSAS databases. Delete the SSAS databases, then try again.</td>
</tr>
<tr>
<td>The SSAS option isn't enabled or is in the process of being enabled. Try again later.</td>
<td>RDS stored procedure</td>
<td>You can't run SSAS stored procedures when the option is turned off, or when it's being turned on.</td>
</tr>
<tr>
<td>The SSAS option is configured incorrectly. Make sure that the option group membership status is &quot;in-sync&quot;, and review the RDS event logs for relevant SSAS configuration error messages. Following these investigations, try again. If errors continue to occur, contact AWS Support.</td>
<td>RDS stored procedure</td>
<td>You can't run SSAS stored procedures when your option group membership isn't in the in-sync status. This puts the SSAS option in an incorrect configuration state.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If your option group membership status changes to <code>failed</code> due to SSAS option modification, there are two possible reasons:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1. The SSAS option was removed without the SSAS databases being deleted.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. The SSAS mode was updated from Tabular to Multidimensional, or from Multidimensional to Tabular, without the existing SSAS databases being deleted.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Reconfigure the SSAS option, because RDS allows only one SSAS mode at a time, and doesn't support SSAS option removal with SSAS databases present.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Check the RDS event logs for configuration errors for your SSAS instance, and resolve the issues accordingly.</td>
</tr>
<tr>
<td>Deployment failed. The change can only be deployed on a server running in <code>deployment_file_mode</code> mode. The current server mode is <code>current_mode</code>.</td>
<td>RDS stored procedure</td>
<td>You can't deploy a Tabular database to a Multidimensional server, or a Multidimensional database to a Tabular server. Make sure that you're using files with the correct mode, and verify that the <code>MODE</code> option setting is set to the appropriate value.</td>
</tr>
<tr>
<td>Issue</td>
<td>Type</td>
<td>Troubleshooting suggestions</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>The restore failed. The backup file can only be restored on a server running in <strong>restore_file_mode</strong> mode. The current server mode is <strong>current_mode</strong>.</td>
<td>RDS stored procedure</td>
<td>You can't restore a Tabular database to a Multidimensional server, or a Multidimensional database to a Tabular server. Make sure that you're using files with the correct mode, and verify that the <strong>MODE</strong> option setting is set to the appropriate value.</td>
</tr>
<tr>
<td>The restore failed. The backup file and the RDS DB instance versions are incompatible.</td>
<td>RDS stored procedure</td>
<td>You can't restore an SSAS database with a version incompatible to the SQL Server instance version. For more information, see Compatibility levels for tabular models and Compatibility level of a multidimensional database in the Microsoft documentation.</td>
</tr>
<tr>
<td>The restore failed. The backup file specified in the restore operation is damaged or is not an SSAS backup file. Make sure that @rds_file_path is correctly formatted.</td>
<td>RDS stored procedure</td>
<td>You can't restore an SSAS database with a damaged file. Make sure that the file isn't damaged or corrupted. This error can also be raised when @rds_file_path isn't correctly formatted (for example, it has double backslashes as in D:\S3\incorrect_format.abf).</td>
</tr>
<tr>
<td>The restore failed. The restored database name can't contain any reserved words or invalid characters: . , ; ' ` : / \ *</td>
<td>? &quot; &amp; % $ ! + = ( ) [ ] { } &lt; &gt;, or be longer than 100 characters.</td>
<td>RDS stored procedure</td>
</tr>
<tr>
<td>An invalid role name was provided. The role name can't contain any reserved strings.</td>
<td>RDS stored procedure</td>
<td>The role name can't contain any reserved strings. For SSAS object naming conventions, see Object naming rules in the Microsoft documentation.</td>
</tr>
<tr>
<td>An invalid role name was provided. The role name can't contain any of the following reserved characters: . , ; ' ` : / \ *</td>
<td>? &quot; &amp; % $ ! + = ( ) [ ] { } &lt; &gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>RDS stored procedure</td>
<td>The role name can't contain any reserved characters. For SSAS object naming conventions, see Object naming rules in the Microsoft documentation.</td>

</tbody>
</table>
Support for SQL Server Integration Services in Amazon RDS for SQL Server

Microsoft SQL Server Integration Services (SSIS) is a component that you can use to perform a broad range of data migration tasks. SSIS is a platform for data integration and workflow applications. It features a data warehousing tool used for data extraction, transformation, and loading (ETL). You can also use this tool to automate maintenance of SQL Server databases and updates to multidimensional cube data.

SSIS projects are organized into packages saved as XML-based .dtsx files. Packages can contain control flows and data flows. You use data flows to represent ETL operations. After deployment, packages are stored in SQL Server in the SSISDB database. SSISDB is an online transaction processing (OLTP) database in the full recovery mode.

Amazon RDS for SQL Server supports running SSIS directly on an RDS DB instance. You can enable SSIS on an existing or new DB instance. SSIS is installed on the same DB instance as your database engine.

RDS supports SSIS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5426.0.v1 and higher

Limitations and recommendations

The following limitations and recommendations apply to running SSIS on RDS for SQL Server:

- The DB instance must use AWS Managed Microsoft AD for SSIS authentication.
- The DB instance must have an associated parameter group with the clr enabled parameter set to 1. For more information, see Modifying the parameter for SSIS (p. 1081).

  **Note**
  If you enable the clr enabled parameter on SQL Server 2017 or 2019, you can't use the common language runtime (CLR) on your DB instance. For more information, see Features not supported and features with limited support (p. 933).

- The following control flow tasks are supported:
  - Analysis Services Execute DDL Task
  - Analysis Services Processing Task
  - Bulk Insert Task
  - Check Database Integrity Task
  - Data Flow Task
  - Data Mining Query Task
  - Data Profiling Task
  - Execute Package Task
  - Execute SQL Server Agent Job Task
  - Execute SQL Task
  - Execute T-SQL Statement Task
  - Notify Operator Task
  - Rebuild Index Task
  - Reorganize Index Task
  - Shrink Database Task
Transfer Database Task
Transfer Jobs Task
Transfer Logins Task
Transfer SQL Server Objects Task
Update Statistics Task
Only project deployment is supported.
Running SSIS packages by using SQL Server Agent is supported.
SSIS log records can be inserted only into user-created databases.
Use only the D:\S3 folder for working with files. Files placed in any other directory are deleted. Be aware of a few other file location details:
Place SSIS project input and output files in the D:\S3 folder.
For the Data Flow Task, change the location for BLOBTempStoragePath and BufferTempStoragePath to a file inside the D:\S3 folder. The file path must start with D:\S3\.
Ensure that all parameters, variables, and expressions used for file connections point to the D:\S3 folder.
On Multi-AZ instances, files created by SSIS in the D:\S3 folder are deleted after a failover. For more information, see Multi-AZ limitations for S3 integration (p. 1026).
Upload the files created by SSIS in the D:\S3 folder to your Amazon S3 bucket to make them durable.
Import Column and Export Column transformations and the Script component on the Data Flow Task aren't supported.
You can't enable dump on running SSIS packages, and you can't add data taps on SSIS packages.
The SSIS Scale Out feature isn't supported.
You can't deploy projects directly. We provide RDS stored procedures to do this. For more information, see Deploying an SSIS project (p. 1085).
Build SSIS project (.ispac) files with the DoNotSavePasswords protection mode for deploying on RDS.
SSIS isn't supported on Always On instances with read replicas.
You can't back up the SSISDB database that is associated with the SSIS option.
Importing and restoring the SSISDB database from other instances of SSIS isn't supported.
Connecting to other database engines, such as Oracle, isn't supported for SSIS on RDS for SQL Server. You can connect only to other SQL Server DB instances.

Enabling SSIS

You enable SSIS by adding the SSIS option to your DB instance. Use the following process:
1. Create a new option group, or choose an existing option group.
2. Add the SSIS option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the clr enabled parameter to 1.
5. Associate the option group and parameter group with the DB instance.
6. Enable Amazon S3 integration.

Note
If a database with the name SSISDB or a reserved SSIS login already exists on the DB instance, you can't enable SSIS on the instance.
Creating the option group for SSIS

To work with SSIS, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group window, do the following:
   a. For Name, enter a name for the option group that is unique within your AWS account, such as ssis-se-2016. The name can contain only letters, digits, and hyphens.
   b. For Description, enter a brief description of the option group, such as SSIS option group for SQL Server SE 2016. The description is used for display purposes.
   c. For Engine, choose sqlserver-se.
   d. For Major engine version, choose 13.00.
5. Choose Create.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \ 
  --option-group-name ssis-se-2016 \ 
  --engine-name sqlserver-se \ 
  --major-engine-version 13.00 \ 
  --option-group-description "SSIS option group for SQL Server SE 2016"
```

For Windows:

```
aws rds create-option-group ^
  --option-group-name ssis-se-2016 ^
  --engine-name sqlserver-se ^
  --major-engine-version 13.00 ^
  --option-group-description "SSIS option group for SQL Server SE 2016"
```

Adding the SSIS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSIS option to your option group.
Console

To add the SSIS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose the option group that you just created, ssis-se-2016 in this example.
4. Choose Add option.
5. Under Option details, choose SSIS for Option name.
6. Under Scheduling, choose whether to add the option immediately or at the next maintenance window.
7. Choose Add option.

CLI

To add the SSIS option

• Add the SSIS option to the option group.

Example

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
   --option-group-name ssis-se-2016 \
   --options OptionName=SSIS \
   --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
   --option-group-name ssis-se-2016 ^
   --options OptionName=SSIS ^
   --apply-immediately
```

Creating the parameter group for SSIS

Create or modify a parameter group for the clr enabled parameter that corresponds to the SQL Server edition and version of the DB instance that you plan to use for SSIS.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose Create parameter group.
4. In the Create parameter group pane, do the following:
For Parameter group family, choose sqlserver-se-13.0.

b. For Group name, enter an identifier for the parameter group, such as ssis-sqlserver-se-13.

c. For Description, enter clr enabled parameter group.

5. Choose Create.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

**To create the parameter group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-parameter-group \
--db-parameter-group-name ssis-sqlserver-se-13 \
--db-parameter-group-family "sqlserver-se-13.0" \
--description "clr enabled parameter group"
```

For Windows:

```bash
aws rds create-db-parameter-group ^
--db-parameter-group-name ssis-sqlserver-se-13 ^
--db-parameter-group-family "sqlserver-se-13.0" ^
--description "clr enabled parameter group"
```

Modifying the parameter for SSIS

Modify the clr enabled parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance. For SSIS, set the clr enabled parameter to 1.

**Console**

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Parameter groups.
3. Choose the parameter group, such as ssis-sqlserver-se-13.
4. Under Parameters, filter the parameter list for clr.
5. Choose clr enabled.
6. Choose Edit parameters.
7. From Values, choose 1.
8. Choose Save changes.
The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
--db-parameter-group-name ssis-sqlserver-se-13 \
--parameters "ParameterName='clr enabled',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name ssis-sqlserver-se-13 ^
  --parameters "ParameterName='clr enabled',ParameterValue=1,ApplyMethod=immediate"
```

**Associating the option group and parameter group with your DB instance**

To associate the SSIS option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI

**Note**

If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1004).

**Console**

To finish enabling SSIS, associate your SSIS option group and parameter group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
- For an existing DB instance, associate them by modifying the instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**CLI**

You can associate the SSIS option group and parameter group with a new or existing DB instance.

**To create an instance with the SSIS option group and parameter group**

- Specify the same DB engine type and major version as you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
```
For Windows:

```bash
aws rds create-db-instance \
  --db-instance-identifier myssisinstance \
  --db-instance-class db.m5.2xlarge \
  --engine sqlserver-se \
  --engine-version 13.00.5426.0.v1 \
  --allocated-storage 100 \
  --master-user-password secret123 \
  --master-username admin \
  --storage-type gp2 \
  --license-model li \
  --domain-iam-role-name my-directory-iam-role \
  --domain my-domain-id \
  --option-group-name ssis-se-2016 \
  --db-parameter-group-name ssis-sqlserver-se-13
```

To modify an instance and associate the SSIS option group and parameter group

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier myssisinstance \
  --option-group-name ssis-se-2016 \
  --db-parameter-group-name ssis-sqlserver-se-13 \
  --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^ \
  --db-instance-identifier myssisinstance ^ \
  --option-group-name ssis-se-2016 ^ \
  --db-parameter-group-name ssis-sqlserver-se-13 ^ \
  --apply-immediately
```

**Enabling S3 integration**

To download SSIS project (.ispac) files to your host for deployment, use S3 file integration. For more information, see Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 (p. 1014).
Administrative permissions on SSISDB

When the instance is created or modified with the SSIS option, the result is an SSISDB database with the ssis_admin and ssis_logreader roles granted to the master user. The master user has the following privileges in SSISDB:

- alter on ssis_admin role
- alter on ssis_logreader role
- alter any user

Because the master user is a SQL-authenticated user, you can't use the master user for executing SSIS packages. The master user can use these privileges to create new SSISDB users and add them to the ssis_admin and ssis_logreader roles. Doing this is useful for giving access to your domain users for using SSIS.

Setting up a Windows-authenticated user for SSIS

The master user can use the following code example to set up a Windows-authenticated login in SSISDB and grant the required procedure permissions. Doing this grants permissions to the domain user to deploy and run SSIS packages, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see Credentials (database engine) and Create a SQL Server Agent proxy in the Microsoft documentation.

**Note**

You can grant some or all of the following permissions as needed to Windows-authenticated users.

**Example**

```sql
USE [SSISDB]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
ALTER ROLE [ssis_admin] ADD MEMBER [mydomain\user_name]
ALTER ROLE [ssis_logreader] ADD MEMBER [mydomain\user_name]
GO

USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_for_subsystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\user_name] WITH GRANT OPTION
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO

USE [master]
GO
```
Deploying an SSIS project

On RDS, you can't deploy SSIS projects directly by using SQL Server Management Studio (SSMS) or SSIS procedures. To download project files from Amazon S3 and then deploy them, use RDS stored procedures.

To run the stored procedures, log in as any user that you granted permissions for running the stored procedures. For more information, see Setting up a Windows-authenticated user for SSIS (p. 1084).

To deploy the SSIS project

1. Download the project (.ispac) file.

   ```sql
   exec msdb.dbo.rds_download_from_s3
   @s3_arn_of_file='arn:aws:s3:::bucket_name/ssisproject.ispac',
   @rds_file_path='D:\S3\ssisproject.ispac',
   @overwrite_file=1;
   ```

2. Submit the deployment task, making sure of the following:
   - The folder is present in the SSIS catalog.
   - The project name matches the project name that you used while developing the SSIS project.

   ```sql
   exec msdb.dbo.rds_msbi_task
   @task_type='SSIS_DEPLOY_PROJECT',
   @folder_name='DEMO',
   @project_name='ssisproject',
   @file_path='D:\S3\ssisproject.ispac';
   ```

Monitoring the status of a deployment task

To track the status of your deployment task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSIS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```sql
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>SSIS_DEPLOY_PROJECT</td>
</tr>
<tr>
<td>Output parameter</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------------------------------------------------------</td>
</tr>
<tr>
<td>database_name</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>% complete</td>
<td>The progress of the task as a percentage.</td>
</tr>
<tr>
<td>duration (mins)</td>
<td>The amount of time spent on the task, in minutes.</td>
</tr>
<tr>
<td>lifecycle</td>
<td>The status of the task. Possible statuses are the following:</td>
</tr>
<tr>
<td></td>
<td>• CREATED – After you call the msdb.dbo.rds_msbi_task stored procedure, a task is created and the status is set to CREATED.</td>
</tr>
<tr>
<td></td>
<td>• IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS.</td>
</tr>
<tr>
<td></td>
<td>• SUCCESS – After a task completes, the status is set to SUCCESS.</td>
</tr>
<tr>
<td></td>
<td>• ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column.</td>
</tr>
<tr>
<td></td>
<td>• CANCEL_REQUESTED – After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED.</td>
</tr>
<tr>
<td></td>
<td>• CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.</td>
</tr>
<tr>
<td>task_info</td>
<td>Additional information about the task. If an error occurs during processing, this column contains information about the error.</td>
</tr>
<tr>
<td>last_updated</td>
<td>The date and time that the task status was last updated.</td>
</tr>

<tr>
<td>KMS_master_key_arn</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>filepath</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>overwrite_file</td>
<td>Not applicable to SSIS tasks.</td>
</tr>
<tr>
<td>task_metadata</td>
<td>Metadata associated with the SSIS task.</td>
</tr>
</tbody>
</table>

**Using SSIS**

After deploying the SSIS project into the SSIS catalog, you can run packages directly from SSMS or schedule them by using SQL Server Agent. You must use a Windows-authenticated login for executing SSIS packages. For more information, see Setting up a Windows-authenticated user for SSIS (p. 1084).
Setting database connection managers for SSIS projects

When you use a connection manager, you can use these types of authentication:

- For local database connections, you can use SQL authentication or Windows authentication. For Windows authentication, use `DB_instance_name.fully_qualified_domain_name` as the server name of the connection string.
  
  An example is `myssisinstance.corp-ad.example.com`, where `myssisinstance` is the DB instance name and `corp-ad.example.com` is the fully qualified domain name.

- For remote connections, always use SQL authentication.

Creating an SSIS proxy

To be able to schedule SSIS packages using SQL Server Agent, create an SSIS credential and an SSIS proxy. Run these procedures as a Windows-authenticated user.

To create the SSIS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```sql
USE [master]
GO
CREATE CREDENTIAL [SSIS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET = N'mysecret'
GO
```

**Note**
IDENTITY must be a domain-authenticated login. Replace `mysecret` with the password for the domain-authenticated login.
Whenever the SSISDB primary host is changed, alter the SSIS proxy credentials to allow the new host to access them.

To create the SSIS proxy

1. Use the following SQL statement to create the proxy.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
@proxy_name=N'SSIS_Proxy',@credential_name=N'SSIS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```sql
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
@proxy_name=N'SSIS_Proxy',@login_name=N'mydomain\user_name'
```
3. Use the following SQL statement to give the SSIS subsystem access to the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```
USE [msdb]
GO
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

Scheduling an SSIS package using SQL Server Agent

After you create the credential and proxy and grant SSIS access to the proxy, you can create a SQL Server Agent job to schedule the SSIS package.

To schedule the SSIS package

- You can use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL.

```
USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'MYSSISJob',
    @enabled=1,
    @notify_level_eventlog=0,
    @notify_level_email=2,
    @notify_level_page=2,
    @delete_level=0,
    @category_name=N'[Uncategorized (Local)]',
    @job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobscheduler @job_name=N'MYSSISJob',@server_name=N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'MYSSISJob',@step_name=N'ExecuteSSISPackage',
    @step_id=1,
    @cmdexec_success_code=0,
    @on_success_action=1,
    @on_fail_action=2,
    @retry_attempts=0,
    @retry_interval=0,
    @os_run_priority=0,
    @subsystem=N'SSIS',
GO`

1088
Revoking SSIS access from the proxy

You can revoke access to the SSIS subsystem and delete the SSIS proxy using the following stored procedures.

To revoke access and delete the proxy

1. Revoke subsystem access.

   ```sql
   USE [msdb]
   GO
   EXEC msdb.dbo.rds_sqlagent_proxy
   @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
   GO
   ```

2. Revoke the grants on the proxy.

   ```sql
   USE [msdb]
   GO
   EXEC msdb.dbo.sp_revoke_login_from_proxy
   @proxy_name=N'SSIS_Proxy',@name=N'mydomain\user_name'
   GO
   ```

3. Delete the proxy.

   ```sql
   USE [msdb]
   GO
   EXEC dbo.sp_delete_proxy @proxy_name = N'SSIS_Proxy'
   GO
   ```

Disabling SSIS

To disable SSIS, remove the SSIS option from its option group.

**Important**
Removing the option doesn't delete the SSISDB database, so you can safely remove the option without losing the SSIS projects. You can re-enable the SSIS option after removal to reuse the SSIS projects that were previously deployed to the SSIS catalog.

Console

The following procedure removes the SSIS option.

To remove the SSIS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSIS option (ssis-se-2016 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSIS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

**CLI**

The following procedure removes the SSIS option.

**To remove the SSIS option from its option group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds remove-option-from-option-group
  --option-group-name ssis-se-2016
  --options SSIS
  --apply-immediately
```

For Windows:

```bash
aws rds remove-option-from-option-group ^
  --option-group-name ssis-se-2016 ^
  --options SSIS ^
  --apply-immediately
```

**Dropping the SSISDB database**

After removing the SSIS option, the SSISDB database isn't deleted. To drop the SSISDB database, use the `rds_drop_ssis_database` stored procedure after removing the SSIS option.

**To drop the SSIS database**

- Use the following stored procedure.

```sql
USE [msdb]
GO
EXEC dbo.rds_drop_ssis_database
GO
```

After dropping the SSISDB database, if you re-enable the SSIS option you get a fresh SSISDB catalog.
Support for SQL Server Reporting Services in Amazon RDS for SQL Server

Microsoft SQL Server Reporting Services (SSRS) is a server-based application used for report generation and distribution. It's part of a suite of SQL Server services that also includes SQL Server Analysis Services (SSAS) and SQL Server Integration Services (SSIS). SSRS is a service built on top of SQL Server. You can use it to collect data from various data sources and present it in a way that's easily understandable and ready for analysis.

Amazon RDS for SQL Server supports running SSRS directly on RDS DB instances. You can enable SSRS for existing or new DB instances.

RDS supports SSRS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, version 15.00.4043.16.v1 and later
- SQL Server 2017, version 14.00.3223.3.v1 and later
- SQL Server 2016, version 13.00.5820.21.v1 and later

Limitations and recommendations

The following limitations and recommendations apply to running SSRS on RDS for SQL Server:

- You can't use SSRS on DB instances that have read replicas.
- Instances must use AWS Managed Microsoft AD for SSRS web portal and web server authentication.
- Importing and restoring report server databases from other instances of SSRS isn't supported.
  
  Make sure to use the databases that are created when the SSRS option is added to the RDS DB instance. For more information, see Report server databases (p. 1095).
- You can't configure SSRS to listen on the default SSL port (443). The allowed values are 1150–49511, except 1234, 1434, 3260, 3343, 3389, and 47001.
- Subscriptions through email or a Microsoft Windows file share aren't supported.
- Using Reporting Services Configuration Manager isn't supported.
- Creating and modifying roles isn't supported.
- Modifying report server properties isn't supported.
- System administrator and system user roles aren't granted.
- You can't edit system-level role assignments through the web portal.

Enabling SSRS

Use the following process to enable SSRS on your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSRS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSRS listener port.

Creating an option group for SSRS

To work with SSRS, create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.
Note
You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group pane, do the following:
   a. For Name, enter a name for the option group that is unique within your AWS account, such as ssrs-se-2017. The name can contain only letters, digits, and hyphens.
   b. For Description, enter a brief description of the option group, such as SSRS option group for SQL Server SE 2017. The description is used for display purposes.
   c. For Engine, choose sqlserver-se.
   d. For Major engine version, choose 14.00.
5. Choose Create.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-option-group
  --option-group-name ssrs-se-2017
  --engine-name sqlserver-se
  --major-engine-version 14.00
  --option-group-description "SSRS option group for SQL Server SE 2017"
```

For Windows:

```bash
aws rds create-option-group
  --option-group-name ssrs-se-2017
  --engine-name sqlserver-se
  --major-engine-version 14.00
  --option-group-description "SSRS option group for SQL Server SE 2017"
```

Adding the SSRS option to your option group

Next, use the AWS Management Console or the AWS CLI to add the SSRS option to your option group.
**Console**

**To add the SSRS option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **SSRS** for **Option name**.
6. Under **Option settings**, do the following:
   a. Enter the port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see **Limitations and recommendations (p. 1091)**.
   b. Enter a value for **Max memory**.

   **Max memory** specifies the upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.
7. For **Security groups**, choose the VPC security group to associate with the option. Use the same security group that is associated with your DB instance.
8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.

**CLI**

**To add the SSRS option**

1. Create a JSON file, for example `ssrs-option.json`, with the following parameters:
   - **OptionGroupName** – The name of option group that you created or chose previously (ssrs-se-2017 in the following example).
   - **Port** – The port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see **Limitations and recommendations (p. 1091)**.
   - **VpcSecurityGroupMemberships** – VPC security group memberships for your RDS DB instance.
   - **MAX_MEMORY** – The upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.

   ```json
   {
     "OptionGroupName": "ssrs-se-2017",
     "OptionsToInclude": [ {
       "OptionName": "SSRS",
       "Port": 8443,
       "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
       "OptionSettings": [{"Name": "MAX_MEMORY","Value": "60"}]
     }],
     "ApplyImmediately": true
   }
   ```
2. Add the SSRS option to the option group.
Example

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
  --cli-input-json file://ssrs-option.json \
  --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --cli-input-json file://ssrs-option.json ^
  --apply-immediately
```

Associating your option group with your DB instance

Use the AWS Management Console or the AWS CLI to associate your option group with your DB instance.

If you use an existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1004).

Console

You can associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
- For an existing DB instance, modify the instance and associate the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

CLI

You can associate your option group with a new or existing DB instance.

To create a DB instance that uses your option group

- Specify the same DB engine type and major version as you used when creating the option group.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-instance-identifier mysrsinstance \
  --db-instance-class db.m5.2xlarge \
  --engine sqlserver-se \
  --engine-version 14.00.3223.3.v1 \
  --allocated-storage 100 \
  --master-user-password secret123 \
  --master-username admin \
  --storage-type gp2 \
  --license-model li \
  --domain-iam-role-name my-directory-iam-role \
  --domain my-domain-id \
```
For Windows:

```
aws rds create-db-instance
  --db-instance-identifier myssrsinstance
  --db-instance-class db.m5.2xlarge
  --engine sqlserver-se
  --engine-version 14.00.3223.3.v1
  --allocated-storage 100
  --master-user-password secret123
  --master-username admin
  --storage-type gp2
  --license-model ll
  --domain-iam-role-name my-directory-iam-role
  --domain my-domain-id
  --option-group-name ssrs-se-2017
```

To modify a DB instance to use your option group

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-instance
  --db-instance-identifier myssrsinstance
  --option-group-name ssrs-se-2017
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance
  --db-instance-identifier myssrsinstance
  --option-group-name ssrs-se-2017
  --apply-immediately
```

Allowing inbound access to your VPC security group

To allow inbound access to the VPC security group associated with your DB instance, create an inbound rule for the specified SSRS listener port. For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

**Report server databases**

When your DB instance is associated with the SSRS option, two new databases are created on your DB instance: rdsadmin_ReportServer and rdsadmin_ReportServerTempDB. These databases act as the ReportServer and ReportServerTempDB databases. SSRS stores its data in the ReportServer database and caches its data in the ReportServerTempDB database. RDS owns and manages these databases, so database operations on them such as ALTER and DROP aren't permitted.

**Accessing the SSRS web portal**

Use the following process to access the SSRS web portal:
1. Enable Secure Sockets Layer (SSL).
2. Grant access to domain users.
3. Access the web portal using a browser and the domain user credentials.

**Enabling SSL on RDS**

SSRS uses the HTTPS SSL protocol for its connections. To work with this protocol, import an SSL certificate into the Microsoft Windows operating system on your client computer.

For more information on SSL certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755). For more information about using SSL with SQL Server, see Using SSL with a Microsoft SQL Server DB instance (p. 996).

**Granting access to domain users**

In a new SSRS activation, there are no role assignments in SSRS. To give a domain user or user group access to the web portal, RDS provides a stored procedure.

**To grant access to a domain user on the web portal**

- Use the following stored procedure.

  ```sql
  exec msdb.dbo.rds_msbi_task
  @task_type='SSRS_GRANT_PORTAL_PERMISSION',
  @ssrs_group_or_username=N'AD_domain\user';
  ``

  The domain user or user group is granted the RDS_SSRS_ROLE system role. This role has the following system-level tasks granted to it:

  - Execute report definitions
  - Manage jobs
  - Manage shared schedules
  - View shared schedules

  The item-level role of Content Manager on the root folder is also granted.

**Accessing the web portal**

After the SSRS_GRANT_PORTAL_PERMISSION task finishes successfully, you have access to the portal using a web browser. The web portal URL has the following format.

```text
https://rds_endpoint:port/Reports
```

In this format, the following applies:

- **rds_endpoint** – The endpoint for the RDS DB instance that you're using with SSRS.

  You can find the endpoint on the Connectivity & security tab for your DB instance. For more information, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 947).

- **port** – The listener port for SSRS that you set in the SSRS option.
To access the web portal

1. Enter the web portal URL in your browser.

   https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/Reports

2. Log in with the credentials for a domain user that you granted access with the SSRS_GRANT_PORTAL_PERMISSION task.

Deploying reports to SSRS

After you have access to the web portal, you can deploy reports to it. You can use the Upload tool in the web portal to upload reports, or deploy directly from SQL Server data tools (SSDT). When deploying from SSDT, ensure the following:

- The user who launched SSDT has access to the SSRS web portal.
- The TargetServerURL value in the SSRS project properties is set to the HTTPS endpoint of the RDS DB instance suffixed with ReportServer, for example:

Revoking system-level permissions

The RDS_SSRS_ROLE system role doesn't have sufficient permissions to delete system-level role assignments. To remove a user or user group from RDS_SSRS_ROLE, use the same stored procedure that you used to grant the role but use the SSRS_REVOKE_PORTAL_PERMISSION task type.

To revoke access from a domain user for the web portal

- Use the following stored procedure.

  ```
  exec msdb.dbo.rds_msbi_task
  @task_type='SSRS_REVOKE_PORTAL_PERMISSION',
  @ssrs_group_or_username=N'AD_domain\user';
  ```

  Doing this deletes the user from the RDS_SSRS_ROLE system role. It also deletes the user from the Content Manager item-level role if the user has it.

Monitoring the status of a task

To track the status of your granting or revoking task, call the rds_fn_task_status function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSRS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 0);
```
The `rds_fn_task_status` function returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_id</td>
<td>The ID of the task.</td>
</tr>
<tr>
<td>task_type</td>
<td>For SSRS, tasks can have the following task types:</td>
</tr>
<tr>
<td></td>
<td>• SSRS_GRANT_PORTAL_PERMISSION</td>

### Disabling SSRS

To disable SSRS, remove the SSRS option from its option group. Removing the option doesn't delete the SSRS databases. For more information, see Deleting the SSRS databases (p. 1100).

You can re-enable SSRS by adding back the SSRS option. If you have also deleted the SSRS databases, re-enabling SSRS on the same DB instance creates new report server databases.

#### Console

**To remove the SSRS option from its option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSRS option (ssrs-se-2017 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose SSRS for **Options to delete**.
6. Under **Apply immediately**, choose Yes to delete the option immediately, or No to delete it at the next maintenance window.
7. Choose **Delete**.

#### CLI

**To remove the SSRS option from its option group**

- Run one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds remove-option-from-option-group \\  --option-group-name ssrs-se-2017 \\  --options SSRS \  --apply-immediately
```

For Windows:

```bash
aws rds remove-option-from-option-group ^  --option-group-name ssrs-se-2017 ^  --options SSRS ^  --apply-immediately
```
Deleting the SSRS databases

Removing the SSRS option doesn't delete the report server databases. To delete them, use the following stored procedure.

To delete the report server databases, be sure to remove the SSRS option first.

**To delete the SSRS databases**

- Use the following stored procedure.

  ```sql
  exec msdb.dbo.rds_drop_ssrs_databases
  ```
Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server

A distributed transaction is a database transaction in which two or more network hosts are involved. RDS for SQL Server supports distributed transactions among hosts, where a single host can be one of the following:

- RDS for SQL Server DB instance
- On-premises SQL Server host
- Amazon EC2 host with SQL Server installed
- Any other EC2 host or RDS DB instance with a database engine that supports distributed transactions

In RDS, starting with SQL Server 2012 (version 11.00.5058.0.v1 and later), all editions of RDS for SQL Server support distributed transactions. The support is provided using Microsoft Distributed Transaction Coordinator (MSDTC). For in-depth information about MSDTC, see Distributed Transaction Coordinator in the Microsoft documentation.

Limitations

The following limitations apply to using MSDTC on RDS for SQL Server:

- MSDTC isn't supported on instances using SQL Server Database Mirroring. For more information, see Transactions - availability groups and database mirroring.
- The in-doubt xact resolution parameter must be set to 1 or 2. For more information, see Modifying the parameter for MSDTC (p. 1105).
- MSDTC requires all hosts participating in distributed transactions to be resolvable using their host names. RDS automatically maintains this functionality for domain-joined instances. However, for standalone instances make sure to configure the DNS server manually.
- Java Database Connectivity (JDBC) XA transactions are supported for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019.
- Distributed transactions that depend on client dynamic link libraries (DLLs) on RDS instances aren't supported.
- Using custom XA dynamic link libraries isn't supported.

Enabling MSDTC

Use the following process to enable MSDTC for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the MSDTC option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the in-doubt xact resolution parameter to 1 or 2.
5. Associate the option group and parameter group with the DB instance.

Creating the option group for MSDTC

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of your DB instance.
Note
You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group
1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Option groups.
3. Choose Create group.
4. In the Create option group pane, do the following:
   a. For Name, enter a name for the option group that is unique within your AWS account, such as msdtc-se-2016. The name can contain only letters, digits, and hyphens.
   b. For Description, enter a brief description of the option group, such as MSDTC option group for SQL Server SE 2016. The description is used for display purposes.
   c. For Engine, choose sqlserver-se.
   d. For Major engine version, choose 13.00.
5. Choose Create.

CLI

The following example creates an option group for SQL Server Standard Edition 2016.

To create the option group
• Use one of the following commands.

Example

For Linux, macOS, or Unix:

```bash
aws rds create-option-group \ 
   --option-group-name msdtc-se-2016 \ 
   --engine-name sqlserver-se \ 
   --major-engine-version 13.00 \ 
   --option-group-description "MSDTC option group for SQL Server SE 2016"
```

For Windows:

```bash
aws rds create-option-group ^ 
   --option-group-name msdtc-se-2016 ^ 
   --engine-name sqlserver-se ^ 
   --major-engine-version 13.00 ^ 
   --option-group-description "MSDTC option group for SQL Server SE 2016"
```

Adding the MSDTC option to the option group

Next, use the AWS Management Console or the AWS CLI to add the MSDTC option to the option group.

The following option settings are required:
• **Port** – The port that you use to access MSDTC. Allowed values are 1150–49151 except for 1234, 1434, 3260, 3343, 3389, and 47001. The default value is 5000.

Make sure that the port you want to use is enabled in your firewall rules. Also, make sure as needed that this port is enabled in the inbound and outbound rules for the security group associated with your DB instance. For more information, see Can't connect to Amazon RDS DB instance (p. 1880).

• **Security groups** – The VPC or DB security group memberships for your RDS DB instance.

• **Authentication type** – The authentication mode between hosts. The following authentication types are supported:
  • Mutual – The RDS instances are mutually authenticated to each other using integrated authentication. If this option is selected, all instances associated with this option group must be domain-joined.
  • None – No authentication is performed between hosts. We don't recommend using this mode in production environments.

• **Transaction log size** – The size of the MSDTC transaction log. Allowed values are 4–1024 MB. The default size is 4 MB.

The following option settings are optional:

• **Enable inbound connections** – Whether to allow inbound MSDTC connections to instances associated with this option group.

• **Enable outbound connections** – Whether to allow outbound MSDTC connections from instances associated with this option group.

• **Enable XA** – Whether to allow XA transactions. For more information on the XA protocol, see XA specification.

• **Enable SNA LU** – Whether to allow the SNA LU protocol to be used for distributed transactions. For more information on SNA LU protocol support, see Managing IBM CICS LU 6.2 transactions in the Microsoft documentation.

**Console**

**To add the MSDTC option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **MSDTC** for **Option name**.
6. Under **Option settings**:
   a. For **Port**, enter the port number for accessing MSDTC. The default is **5000**.
   b. For **Security groups**, choose the VPC or DB security group to associate with the option.
   c. For **Authentication type**, choose **Mutual** or **None**.
   d. For **Transaction log size**, enter a value from 4–1024. The default is **4**.
7. Under **Additional configuration**, do the following:
   a. For **Connections**, as needed choose **Enable inbound connections** and **Enable outbound connections**.
   b. For **Allowed protocols**, as needed choose **Enable XA** and **Enable SNA LU**.
8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.

To add this option, no reboot is required.

**CLI**

**To add the MSDTC option**

1. Create a JSON file, for example `msdtc-option.json`, with the following required parameters.

```json
{
  "OptionGroupName":"msdtc-se-2016",
  "OptionsToInclude": [
    {
      "OptionName":"MSDTC",
      "Port":5000,
      "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
      "OptionSettings": [{
        "Name":"AUTHENTICATION","Value":"MUTUAL"},
        {
        "Name":"TRANSACTION_LOG_SIZE","Value":"4"}
      ]],
      "ApplyImmediately":true
    }
  ]
}
```

2. Add the MSDTC option to the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
  --cli-input-json file://msdtc-option.json \
  --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --cli-input-json file://msdtc-option.json ^
  --apply-immediately
```

No reboot is required.

**Creating the parameter group for MSDTC**

Create or modify a parameter group for the in-doubt xact resolution parameter that corresponds to the SQL Server edition and version of your DB instance.

**Console**

The following example creates a parameter group for SQL Server Standard Edition 2016.

**To create the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
   
   a. For **Parameter group family**, choose `sqlserver-se-13.0`.
   
   b. For **Group name**, enter an identifier for the parameter group, such as `msdtc-sqlserver-se-13`.
   
   c. For **Description**, enter *in-doubt xact resolution*.

5. Choose **Create**.

**CLI**

The following example creates a parameter group for SQL Server Standard Edition 2016.

**To create the parameter group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group
   --db-parameter-group-name msdtc-sqlserver-se-13
   --db-parameter-group-family "sqlserver-se-13.0"
   --description "in-doubt xact resolution"
```

For Windows:

```
aws rds create-db-parameter-group
   --db-parameter-group-name msdtc-sqlserver-se-13
   --db-parameter-group-family "sqlserver-se-13.0"
   --description "in-doubt xact resolution"
```

**Modifying the parameter for MSDTC**

Modify the *in-doubt xact resolution* parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

For MSDTC, set the *in-doubt xact resolution* parameter to one of the following:

- **1** – Presume commit. Any MSDTC in-doubt transactions are presumed to have committed.
- **2** – Presume abort. Any MSDTC in-doubt transactions are presumed to have stopped.

For more information, see *in-doubt xact resolution server configuration option* in the Microsoft documentation.

**Console**

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as `msdtc-sqlserver-se-13`.
4. Under **Parameters**, filter the parameter list for `xact`.
5. Choose **in-doubt xact resolution**.
6. Choose **Edit parameters**.
7. Enter 1 or 2.
8. Choose **Save changes**.

**CLI**

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

**To modify the parameter group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-parameter-group \
  --db-parameter-group-name msdtc-sqlserver-se-13 \ 
  --parameters "ParameterName='in-doubt xact resolution',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-parameter-group ^
  --db-parameter-group-name msdtc-sqlserver-se-13 ^
  --parameters "ParameterName='in-doubt xact resolution',ParameterValue=1,ApplyMethod=immediate"
```

**Associating the option group and parameter group with the DB instance**

You can use the AWS Management Console or the AWS CLI to associate the MSDTC option group and parameter group with the DB instance.

**Console**

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

- For a new DB instance, associate them when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](p. 175).
- For an existing DB instance, associate them by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance](p. 309).

**Note**

If you use an domain-joined existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see [Using Windows Authentication with an Amazon RDS for SQL Server DB instance](p. 1004).
You can associate the MSDTC option group and parameter group with a new or existing DB instance.

**Note**
If you use an existing domain-joined DB instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1004).

**To create a DB instance with the MSDTC option group and parameter group**

- Specify the same DB engine type and major version as you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --db-instance-class db.m5.2xlarge \
  --engine sqlserver-se \
  --engine-version 13.00.5426.0.v1 \
  --allocated-storage 100 \
  --master-user-password secret123 \
  --master-username admin \
  --storage-type gp2 \
  --license-model li \
  --domain-iam-role-name my-directory-iam-role \
  --domain my-domain-id \
  --option-group-name msdtc-se-2016 \
  --db-parameter-group-name msdtc-sqlserver-se-13
```

For Windows:

```bash
aws rds create-db-instance ^ \
  --db-instance-identifier mydbinstance ^ \
  --db-instance-class db.m5.2xlarge ^ \
  --engine sqlserver-se ^ \
  --engine-version 13.00.5426.0.v1 ^ \
  --allocated-storage 100 ^ \
  --master-user-password secret123 ^ \
  --master-username admin ^ \
  --storage-type gp2 ^ \
  --license-model li ^ \
  --domain-iam-role-name my-directory-iam-role ^ \
  --domain my-domain-id ^ \
  --option-group-name msdtc-se-2016 ^ \
  --db-parameter-group-name msdtc-sqlserver-se-13
```

**To modify a DB instance and associate the MSDTC option group and parameter group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
```

For Windows:

```bash
aws rds modify-db-instance ^ \
  --db-instance-identifier mydbinstance ^ \
```

---

1107
Using distributed transactions

In Amazon RDS for SQL Server, you run distributed transactions in the same way as distributed transactions running on-premises:

- Using .NET framework `System.Transactions` promotable transactions, which optimizes distributed transactions by deferring their creation until they're needed.

In this case, promotion is automatic and doesn't require you to make any intervention. If there's only one resource manager within the transaction, no promotion is performed. For more information about implicit transaction scopes, see [Implementing an implicit transaction using transaction scope](#) in the Microsoft documentation.

Promotable transactions are supported with these .NET implementations:

- Starting with ADO.NET 2.0, `System.Data.SqlClient` supports promotable transactions with SQL Server. For more information, see [System.Transactions integration with SQL Server](#) in the Microsoft documentation.

- ODP.NET supports `System.Transactions`. A local transaction is created for the first connection opened in the `TransactionsScope` scope to Oracle Database 11g release 1 (version 11.1) and later. When a second connection is opened, this transaction is automatically promoted to a distributed transaction. For more information about distributed transaction support in ODP.NET, see [Microsoft Distributed Transaction Coordinator integration](#) in the Microsoft documentation.

- Using the `BEGIN DISTRIBUTED TRANSACTION` statement. For more information, see [BEGIN DISTRIBUTED TRANSACTION (Transact-SQL)](#) in the Microsoft documentation.

Using XA transactions

Starting from RDS for SQL Server 2017 version14.00.3223.3, you can control distributed transactions using JDBC. When you set the `Enable` XA option setting to `true` in the `MSDTC` option, RDS automatically enables JDBC transactions and grants the `SqlJDBCXAUser` role to the `guest` user. This allows executing distributed transactions through JDBC. For more information, including a code example, see [Understanding XA transactions](#) in the Microsoft documentation.

Using transaction tracing

RDS supports controlling MSDTC transaction traces and downloading them from the RDS DB instance for troubleshooting. You can control transaction tracing sessions by running the following RDS stored procedure.

```sql
exec msdb.dbo.rds_msdtc_transaction_tracing 'trace_action',
[@traceall='0/1'],
[@traceaborted='0/1'],
```
The following parameter is required:

- trace_action – The tracing action. It can be START, STOP, or STATUS.

The following parameters are optional:

- @traceall – Set to 1 to trace all distributed transactions. The default is 0.
- @traceaborted – Set to 1 to trace canceled distributed transactions. The default is 0.
- @tracelong – Set to 1 to trace long-running distributed transactions. The default is 0.

**Example of START tracing action**

To start a new transaction tracing session, run the following example statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'START',
    @traceall='0',
    @traceaborted='1',
    @tracelong='1';
```

**Note**

Only one transaction tracing session can be active at one time. If a new tracing session START command is issued while a tracing session is active, an error is returned and the active tracing session remains unchanged.

**Example of STOP tracing action**

To stop a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STOP'
```

This statement stops the active transaction tracing session and saves the transaction trace data into the log directory on the RDS DB instance. The first row of the output contains the overall result, and the following lines indicate details of the operation.

The following is an example of a successful tracing session stop.

```
OK: Trace session has been successfully stopped.
Setting log file to: D:\rdsdbdata\MSDTC\Trace\dtctrace.log
Examining D:\rdsdbdata\MSDTC\Trace\dtctrace.log:
OS version 10.0.14393 (Currently running on 6.2.9200)
Start Time <timestamp>
End Time   <timestamp>
Timezone is @tzres.dll,-932 (Bias is 0mins)
BufferSize 16384 B
Maximum File Size 10 MB
Buffers Written Not set (Logger may not have been stopped).
Logger Mode Settings (11000002) ( circular paged
ProcessorCount 1
Processing completed Buffers: 1, Events: 3, EventsLost: 0 :: Format Errors: 0, Unknowns: 3
Event traces dumped to d:\rdsdbdata\Log\msdtc_<timestamp>.log
```

You can use the detailed information to query the name of the generated log file. For more information about downloading log files from the RDS DB instance, see Monitoring Amazon RDS log files (p. 646).
The trace session logs remain on the instance for 35 days. Any older trace session logs are automatically deleted.

**Example of STATUS tracing action**

To trace the status of a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STATUS'
```

This statement outputs the following as separate rows of the result set.

```
OK
SessionStatus: <Started|Stopped>
TraceAll: <True|False>
TraceAborted: <True|False>
TraceLongLived: <True|False>
```

The first line indicates the overall result of the operation: OK or ERROR with details, if applicable. The subsequent lines indicate details about the tracing session status:

- **SessionStatus** can be one of the following:
  - **Started** if a tracing session is running.
  - **Stopped** if no tracing session is running.
- The tracing session flags can be **True** or **False** depending on how they were set in the **START** command.

**Modifying the MSDTC option**

After you enable the **MSDTC** option, you can modify its settings. For information about how to modify option settings, see **Modifying an option setting (p. 271)**.

**Note**

Some changes to MSDTC option settings require the MSDTC service to be restarted. This requirement can affect running distributed transactions.

**Disabling MSDTC**

To disable MSDTC, remove the **MSDTC** option from its option group.

**Console**

**To remove the MSDTC option from its option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the **MSDTC** option (msdtc-se-2016 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **MSDTC** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.
CLI

To remove the MSDTC option from its option group

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group --option-group-name msdtc-se-2016 --options MSDTC --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group --option-group-name msdtc-se-2016 --options MSDTC --apply-immediately
```

Troubleshooting MSDTC for RDS for SQL Server

In some cases, you might have trouble establishing a connection between MSDTC running on a client computer and the MSDTC service running on an RDS for SQL Server DB instance. If so, make sure of the following:

- The inbound rules for the security group associated with the DB instance are configured correctly. For more information, see Can't connect to Amazon RDS DB instance (p. 1880).
- Your client computer is configured correctly.
- The MSDTC firewall rules on your client computer are enabled.

To configure the client computer

1. Open **Component Services**.

   Or, in **Server Manager**, choose **Tools**, and then choose **Component Services**.

2. Expand **Component Services**, expand **Computers**, expand **My Computer**, and then expand **Distributed Transaction Coordinator**.

3. Open the context (right-click) menu for **Local DTC** and choose **Properties**.

4. Choose the **Security** tab.

5. Choose all of the following:

   - Network DTC Access
   - Allow Inbound
   - Allow Outbound

6. Make sure that the correct authentication mode is chosen:

   - Mutual Authentication Required – The client machine is joined to the same domain as other nodes participating in distributed transaction, or there is a trust relationship configured between domains.
   - No Authentication Required – All other cases.
7. Choose **OK** to save your changes.
8. If prompted to restart the service, choose **Yes**.

**To enable MSDTC firewall rules**

1. Open Windows Firewall, then choose **Advanced settings**.

   Or, in **Server Manager**, choose **Tools**, and then choose **Windows Firewall with Advanced Security**.

   **Note**
   Depending on your operating system, Windows Firewall might be called Windows Defender Firewall.

2. Choose **Inbound Rules** in the left pane.
3. Enable the following firewall rules, if they are not already enabled:

   - **Distributed Transaction Coordinator (RPC)**
   - **Distributed Transaction Coordinator (RPC)-EPMAP**
   - **Distributed Transaction Coordinator (TCP-In)**

Common DBA tasks for Microsoft SQL Server

This section describes the Amazon RDS-specific implementations of some common DBA tasks for DB instances that are running the Microsoft SQL Server database engine. In order to deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges.

**Note**
When working with a SQL Server DB instance, you can run scripts to modify a newly created database, but you cannot modify the [model] database, the database used as the model for new databases.

**Topics**
- Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS (p. 1114)
- Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor (p. 1116)
- Collations and character sets for Microsoft SQL Server (p. 1118)
- Creating a database user (p. 1121)
- Determining a recovery model for your Microsoft SQL Server database (p. 1122)
- Determining the last failover time (p. 1122)
- Disabling fast inserts during bulk loading (p. 1123)
- Dropping a Microsoft SQL Server database (p. 1123)
- Renaming a Microsoft SQL Server database in a Multi-AZ deployment (p. 1123)
- Resetting the db_owner role password (p. 1124)
- Restoring license-terminated DB instances (p. 1124)
- Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE (p. 1125)
- Using change data capture (p. 1125)
- Using SQL Server Agent (p. 1127)
- Working with Microsoft SQL Server logs (p. 1129)
- Working with trace and dump files (p. 1130)
Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS

You can access the tempdb database on your Microsoft SQL Server DB instances on Amazon RDS. You can run code on tempdb by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information about connecting to your DB instance, see Connecting to a DB instance running the Microsoft SQL Server database engine (p. 947).

The master user for your DB instance is granted CONTROL access to tempdb so that this user can modify the tempdb database options. The master user isn't the database owner of the tempdb database. If necessary, the master user can grant CONTROL access to other users so that they can also modify the tempdb database options.

Note
You can't run Database Console Commands (DBCC) on the tempdb database.

Modifying tempdb database options

You can modify the database options on the tempdb database on your Amazon RDS DB instances. For more information about which options can be modified, see tempdb database in the Microsoft documentation.

Database options such as the maximum file size options are persistent after you restart your DB instance. You can modify the database options to optimize performance when importing data, and to prevent running out of storage.

Optimizing performance when importing data

To optimize performance when importing large amounts of data into your DB instance, set the SIZE and FILEGROWTH properties of the tempdb database to large numbers. For more information about how to optimize tempdb, see Optimizing tempdb performance in the Microsoft documentation.

The following example demonstrates setting the size to 100 GB and file growth to 10 percent.

```
alter database[tempdb] modify file (NAME = N'templog', SIZE=100GB, FILEGROWTH = 10%)
```

Preventing storage problems

To prevent the tempdb database from using all available disk space, set the MAXSIZE property. The following example demonstrates setting the property to 2048 MB.

```
alter database [tempdb] modify file (NAME = N'templog', MAXSIZE = 2048MB)
```

Shrinking the tempdb database

There are two ways to shrink the tempdb database on your Amazon RDS DB instance. You can use the rds_shrink_tempdbfile procedure, or you can set the SIZE property.

Using the rds_shrink_tempdbfile procedure

You can use the Amazon RDS procedure msdb.dbo.rds_shrink_tempdbfile to shrink the tempdb database. You can only call rds_shrink_tempdbfile if you have CONTROL access to tempdb. When you call rds_shrink_tempdbfile, there is no downtime for your DB instance.
The `rds_shrink_tempdbfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>@temp_filename</code></td>
<td>SYSNAME</td>
<td>—</td>
<td>required</td>
<td>The logical name of the file to shrink.</td>
</tr>
<tr>
<td><code>@target_size</code></td>
<td>int</td>
<td>null</td>
<td>optional</td>
<td>The new size for the file, in megabytes.</td>
</tr>
</tbody>
</table>

The following example gets the names of the files for the `tempdb` database.

```sql
use tempdb;
GO
select name, * from sys.sysfiles;
GO
```

The following example shrinks a `tempdb` database file named `test_file`, and requests a new size of 10 megabytes:

```sql
exec msdb.dbo.rds_shrink_tempdbfile @temp_filename = N'test_file', @target_size = 10;
```

**Setting the SIZE property**

You can also shrink the `tempdb` database by setting the `SIZE` property and then restarting your DB instance. For more information about restarting your DB instance, see Rebooting a DB instance (p. 350).

The following example demonstrates setting the `SIZE` property to 1024 MB.

```sql
alter database [tempdb] modify file (NAME = N'templog', SIZE = 1024MB)
```

**Considerations for Multi-AZ deployments**

If your Amazon RDS DB instance is in a Multi-AZ Deployment for Microsoft SQL Server with Database Mirroring (DBM) or Always On Availability Groups (AGs), there are some things to consider.

The `tempdb` database can't be replicated. No data that you store on your primary instance is replicated to your secondary instance.

If you modify any database options on the `tempdb` database, you can capture those changes on the secondary by using one of the following methods:

- First modify your DB instance and turn Multi-AZ off, then modify tempdb, and finally turn Multi-AZ back on. This method doesn't involve any downtime.
  
  For more information, see Modifying an Amazon RDS DB instance (p. 309).

- First modify `tempdb` in the original primary instance, then fail over manually, and finally modify `tempdb` in the new primary instance. This method involves downtime.

  For more information, see Rebooting a DB instance (p. 350).
Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor

Database Engine Tuning Advisor is a client application provided by Microsoft that analyzes database workload and recommends an optimal set of indexes for your Microsoft SQL Server databases based on the kinds of queries you run. Like SQL Server Management Studio, you run Tuning Advisor from a client computer that connects to your Amazon RDS DB instance that is running SQL Server. The client computer can be a local computer that you run on premises within your own network or it can be an Amazon EC2 Windows instance that is running in the same region as your Amazon RDS DB instance.

This section shows how to capture a workload for Tuning Advisor to analyze. This is the preferred process for capturing a workload because Amazon RDS restricts host access to the SQL Server instance. For more information, see Database Engine Tuning Advisor in the Microsoft documentation.

To use Tuning Advisor, you must provide what is called a workload to the advisor. A workload is a set of Transact-SQL statements that run against a database or databases that you want to tune. Database Engine Tuning Advisor uses trace files, trace tables, Transact-SQL scripts, or XML files as workload input when tuning databases. When working with Amazon RDS, a workload can be a file on a client computer or a database table on an Amazon RDS for SQL Server DB accessible to your client computer. The file or the table must contain queries against the databases you want to tune in a format suitable for replay.

For Tuning Advisor to be most effective, a workload should be as realistic as possible. You can generate a workload file or table by performing a trace against your DB instance. While a trace is running, you can either simulate a load on your DB instance or run your applications with a normal load.

There are two types of traces: client-side and server-side. A client-side trace is easier to set up and you can watch trace events being captured in real-time in SQL Server Profiler. A server-side trace is more complex to set up and requires some Transact-SQL scripting. In addition, because the trace is written to a file on the Amazon RDS DB instance, storage space is consumed by the trace. It is important to track of how much storage space a running server-side trace uses because the DB instance could enter a storage-full state and would no longer be available if it runs out of storage space.

For a client-side trace, when a sufficient amount of trace data has been captured in the SQL Server Profiler, you can then generate the workload file by saving the trace to either a file on your local computer or in a database table on a DB instance that is available to your client computer. The main disadvantage of using a client-side trace is that the trace may not capture all queries when under heavy loads. This could weaken the effectiveness of the analysis performed by the Database Engine Tuning Advisor. If you need to run a trace under heavy loads and you want to ensure that it captures every query during a trace session, you should use a server-side trace.

For a server-side trace, you must get the trace files on the DB instance into a suitable workload file or you can save the trace to a table on the DB instance after the trace completes. You can use the SQL Server Profiler to save the trace to a file on your local computer or have the Tuning Advisor read from the trace table on the DB instance.

Running a client-side trace on a SQL Server DB instance

To run a client-side trace on a SQL Server DB instance

1. Start SQL Server Profiler. It is installed in the Performance Tools folder of your SQL Server instance folder. You must load or define a trace definition template to start a client-side trace.
2. In the SQL Server Profiler File menu, choose New Trace. In the Connect to Server dialog box, enter the DB instance endpoint, port, master user name, and password of the database you would like to run a trace on.
3. In the **Trace Properties** dialog box, enter a trace name and choose a trace definition template. A default template, TSQL_Replay, ships with the application. You can edit this template to define your trace. Edit events and event information under the **Events Selection** tab of the **Trace Properties** dialog box.

For more information about trace definition templates and using the SQL Server Profiler to specify a client-side trace, see Database Engine Tuning Advisor in the Microsoft documentation.

4. Start the client-side trace and watch SQL queries in real-time as they run against your DB instance.

5. Select **Stop Trace** from the **File** menu when you have completed the trace. Save the results as a file or as a trace table on your DB instance.

### Running a server-side trace on a SQL Server DB instance

Writing scripts to create a server-side trace can be complex and is beyond the scope of this document. This section contains sample scripts that you can use as examples. As with a client-side trace, the goal is to create a workload file or trace table that you can open using the Database Engine Tuning Advisor.

The following is an abridged example script that starts a server-side trace and captures details to a workload file. The trace initially saves to the file RDSTrace.trc in the D:\RDSDBDATA\Log directory and rolls-over every 100 MB so subsequent trace files are named RDSTrace_1.trc, RDSTrace_2.trc, etc.

```sql
DECLARE @file_name NVARCHAR(245) = 'D:\RDSDBDATA\Log\RDSTrace';
DECLARE @max_file_size BIGINT = 100;
DECLARE @on BIT = 1
DECLARE @rc INT
DECLARE @traceid INT
EXEC @rc = sp_trace_create @traceid OUTPUT, 2, @file_name, @max_file_size
IF (@rc = 0) BEGIN
  EXEC sp_trace_setevent @traceid, 10, 1, @on
  EXEC sp_trace_setevent @traceid, 10, 2, @on
  EXEC sp_trace_setevent @traceid, 10, 3, @on
  . . .
  EXEC sp_trace_setfilter @traceid, 10, 0, 7, N'SQL Profiler'
  EXEC sp_trace_setstatus @traceid, 1
END
```

The following example is a script that stops a trace. Note that a trace created by the previous script continues to run until you explicitly stop the trace or the process runs out of disk space.

```sql
DECLARE @traceid INT
SELECT @traceid = traceid FROM ::fn_trace_getinfo(default)
WHERE property = 5 AND value = 1 AND traceid <> 1
IF @traceid IS NOT NULL BEGIN
  EXEC sp_trace_setstatus @traceid, 0
  EXEC sp_trace_setstatus @traceid, 2
END
```

You can save server-side trace results to a database table and use the database table as the workload for the Tuning Advisor by using the fn_trace_gettable function. The following commands load the results of all files named RDSTrace.trc in the D:\rdsdbdata\Log directory, including all rollover files like RDSTrace_1.trc, into a table named RDSTrace in the current database.

```sql
SELECT * INTO RDSTrace
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace.trc', default);
```
To save a specific rollover file to a table, for example the RDSTrace_1.trc file, specify the name of the rollover file and substitute 1 instead of default as the last parameter to fn_trace_gettable.

```sql
SELECT * INTO RDSTrace_1
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace_1.trc', 1);
```

**Running Tuning Advisor with a trace**

Once you create a trace, either as a local file or as a database table, you can then run Tuning Advisor against your DB instance. Using Tuning Advisor with Amazon RDS is the same process as when working with a standalone, remote SQL Server instance. You can either use the Tuning Advisor UI on your client machine or use the dta.exe utility from the command line. In both cases, you must connect to the Amazon RDS DB instance using the endpoint for the DB instance and provide your master user name and master user password when using Tuning Advisor.

The following code example demonstrates using the dta.exe command line utility against an Amazon RDS DB instance with an endpoint of `dta.cnazcmklsdei.us-east-1.rds.amazonaws.com`. The example includes the master user name `admin` and the master user password `test`, the example database to tune is named machine named `C:\RDSTrace.trc`. The example command line code also specifies a trace session named `RDSTrace1` and specifies output files to the local machine named `RDSTrace.sql` for the SQL output script, `RDSTrace.txt` for a result file, and `RDSTrace.xml` for an XML file of the analysis. There is also an error table specified on the RDSDTA database named `RDSTraceErrors`.

```plaintext
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -if C:\RDSTrace.trc -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\ RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

Here is the same example command line code except the input workload is a table on the remote Amazon RDS instance named `RDSTrace` which is on the `RDSDTA` database.

```plaintext
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -it RDSDTA.dbo.RDSTrace -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\ RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

For a full list of dta utility command-line parameters, see [dta Utility](#) in the Microsoft documentation.

**Collations and character sets for Microsoft SQL Server**

SQL Server supports collations at multiple levels. You set the default server collation when you create the DB instance. You can override the collation in the database, table, or column level.

**Topics**

- [Server-level collation for Microsoft SQL Server (p. 1118)](#)
- [Database-level collation for Microsoft SQL Server (p. 1121)](#)

**Server-level collation for Microsoft SQL Server**

When you create a Microsoft SQL Server DB instance, you can set the server collation that you want to use. If you don't choose a different collation, the server-level collation defaults to
SQL_Latin1_General_CP1_CI_AS. The server collation is applied by default to all databases and database objects.

**Note**
You can’t change the collation when you restore from a DB snapshot.

Currently, Amazon RDS supports the following server collations:

<table>
<thead>
<tr>
<th>Collation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chinese_PRC_CI_AS</td>
<td>Chinese-PRC, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Chinese_Taiwan_Stroke_CI_AS</td>
<td>Chinese-Taiwan-Stroke, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Finnish_Swedish_CI_AS</td>
<td>Finnish, Swedish, and Swedish (Finland), case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>French_CI_AS</td>
<td>French, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Hebrew_BIN</td>
<td>Hebrew, binary sort</td>
</tr>
<tr>
<td>Hebrew_CI_AS</td>
<td>Hebrew, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Japanese_BIN</td>
<td>Japanese, binary sort</td>
</tr>
<tr>
<td>Japanese_CI_AS</td>
<td>Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Japanese_CS_AS</td>
<td>Japanese, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Korean_Wansung_CI_AS</td>
<td>Korean-Wansung, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Latin1_General_100_BIN</td>
<td>Latin1-General-100, binary sort</td>
</tr>
<tr>
<td>Latin1_General_100_BIN2</td>
<td>Latin1-General-100, binary code point comparison sort</td>
</tr>
<tr>
<td>Latin1_General_100_CI_AS</td>
<td>Latin1-General-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Latin1_General_BIN</td>
<td>Latin1-General, binary sort</td>
</tr>
<tr>
<td>Latin1_General_BIN2</td>
<td>Latin1-General, binary code point comparison sort</td>
</tr>
<tr>
<td>Latin1_General_CI_AI</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Latin1_General_CI_AS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Latin1_General_CI_AS_KS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive</td>
</tr>
<tr>
<td>Collation</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Latin1_General_CS_AS</td>
<td>Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>Modern_Spanish_CI_AS</td>
<td>Modern-Spanish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive</td>
</tr>
<tr>
<td>SQL_1xCompat_CP850_CI_AS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 49 on Code Page 850 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP1_CI_AI</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 54 on Code Page 1252 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP1_CI_AS (default)</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 52 on Code Page 1252 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP1_CS_AS</td>
<td>Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 51 on Code Page 1252 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP437_CI_AI</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 34 on Code Page 437 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP850_BIN2</td>
<td>Latin1-General, binary code point comparison sort for Unicode Data, SQL Server Sort Order 40 on Code Page 850 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP850_CI_AS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 42 on Code Page 850 for non-Unicode Data</td>
</tr>
<tr>
<td>SQL_Latin1_General_CP1256_CI_AS</td>
<td>Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 146 on Code Page 1256 for non-Unicode Data</td>
</tr>
</tbody>
</table>

To choose the collation:

- If you're using the Amazon RDS console, when creating a new DB instance choose **Additional configuration**, then choose the collation from the **Collation** menu under **Database options**. For more information, see *Creating an Amazon RDS DB instance* (p. 175).
- If you're using the AWS CLI, use the `--character-set-name` option with the `create-db-instance` command. For more information, see `create-db-instance`.
- If you're using the Amazon RDS API, use the `CharacterSetName` parameter with the `CreateDBInstance` operation. For more information, see `CreateDBInstance`. 
Database-level collation for Microsoft SQL Server

You can change the default collation at the database, table, or column level by overriding the collation when creating a new database or database object. For example, if your default server collation is SQL_Latin1_General_CP1_CI_AS, you can change it to Mohawk_100_CI_AS for Mohawk collation support. Even arguments in a query can be type-cast to use a different collation if necessary.

For example, the following query would change the default collation for the AccountName column to Mohawk_100_CI_AS

```
CREATE TABLE [dbo].[Account] (
    [AccountID] [nvarchar](10) NOT NULL,
    [AccountName] [nvarchar](100) COLLATE Mohawk_100_CI_AS NOT NULL
) ON [PRIMARY];
```

The Microsoft SQL Server DB engine supports Unicode by the built-in NCHAR, NVARCHAR, and NTEXT data types. For example, if you need CJK support, use these Unicode data types for character storage and override the default server collation when creating your databases and tables. Here are several links from Microsoft covering collation and Unicode support for SQL Server:

- Working with collations
- Collation and international terminology
- Using SQL Server collations
- International considerations for databases and database engine applications

Creating a database user

You can create a database user for your Amazon RDS for Microsoft SQL Server DB instance by running a T-SQL script like the following example. Use an application such as SQL Server Management Suite (SSMS). You log into the DB instance as the master user that was created when you created the DB instance.

```
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
```

For an example of adding a database user to a role, see Adding a user to the SQLAgentUser role (p. 1128).

**Note**

If you get permission errors when adding a user, you can restore privileges by modifying the DB instance master user password. For more information, see Resetting the db_owner role password (p. 1124).
Determining a recovery model for your Microsoft SQL Server database

In Amazon RDS, the recovery model, retention period, and database status are linked.

It's important to understand the consequences before making a change to one of these settings. Each setting can affect the others. For example:

- If you change a database's recovery model to SIMPLE or BULK_LOGGED while backup retention is enabled, Amazon RDS resets the recovery model to FULL within five minutes. This also results in RDS taking a snapshot of the DB instance.
- If you set backup retention to 0 days, RDS sets the recovery mode to SIMPLE.
- If you change a database's recovery model from SIMPLE to any other option while backup retention is set to 0 days, RDS resets the recovery model to SIMPLE.

Important
Never change the recovery model on Multi-AZ instances, even if it seems you can do so—for example, by using ALTER DATABASE. Backup retention, and therefore FULL recovery mode, is required for Multi-AZ. If you alter the recovery model, RDS immediately changes it back to FULL. This automatic reset forces RDS to completely rebuild the mirror. During this rebuild, the availability of the database is degraded for about 30-90 minutes until the mirror is ready for failover. The DB instance also experiences performance degradation in the same way it does during a conversion from Single-AZ to Multi-AZ. How long performance is degraded depends on the database storage size—the bigger the stored database, the longer the degradation.

For more information on SQL Server recovery models, see Recovery models (SQL Server) in the Microsoft documentation.

Determining the last failover time

To determine the last failover time, use the following stored procedure:

execute msdb.dbo.rds_failover_time;

This procedure returns the following information.

<table>
<thead>
<tr>
<th>Output parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errorlog_available_from</td>
<td>Shows the time from when error logs are available in the log directory.</td>
</tr>
<tr>
<td>recent_failover_time</td>
<td>Shows the last failover time if it's available from the error logs. Otherwise it shows null.</td>
</tr>
</tbody>
</table>

Note
The stored procedure searches all of the available SQL Server error logs in the log directory to retrieve the most recent failover time. If the failover messages have been overwritten by SQL Server, then the procedure doesn't retrieve the failover time.

Example of no recent failover
This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.
Disabling fast inserts during bulk loading

Starting with SQL Server 2016, fast inserts are enabled by default. Fast inserts leverage the minimal logging that occurs while the database is in the simple or bulk logged recovery model to optimize insert performance. With fast inserts, each bulk load batch acquires new extents, bypassing the allocation lookup for existing extents with available free space to optimize insert performance.

However, with fast inserts bulk loads with small batch sizes can lead to increased unused space consumed by objects. If increasing batch size isn't feasible, enabling trace flag 692 can help reduce unused reserved space, but at the expense of performance. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes.

You enable trace flag 692 as a startup parameter using DB parameter groups. For more information, see Working with parameter groups (p. 278).

Trace flag 692 is supported for Amazon RDS on SQL Server 2016 and later. For more information on trace flags, see DBCC TRACEON - trace flags in the Microsoft documentation.

Dropping a Microsoft SQL Server database

You can drop a database on an Amazon RDS DB instance running Microsoft SQL Server in a Single-AZ or Multi-AZ deployment. To drop the database, use the following command:

```
--replace your-database-name with the name of the database you want to drop
EXECUTE msdb.dbo.rds_drop_database N'your-database-name'
```

Note
Use straight single quotes in the command. Smart quotes will cause an error.

After you use this procedure to drop the database, Amazon RDS drops all existing connections to the database and removes the database's backup history.

Renaming a Microsoft SQL Server database in a Multi-AZ deployment

To rename a Microsoft SQL Server database instance that uses Multi-AZ, use the following procedure:

1. First, turn off Multi-AZ for the DB instance.
2. Rename the database by running rdsadmin.dbo.rds_modify_db_name.
3. Then, turn on Multi-AZ Mirroring or Always On Availability Groups for the DB instance, to return it to its original state.

For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance (p. 991).

Note
If your instance doesn't use Multi-AZ, you don't need to change any settings before or after running rdsadmin.dbo.rds_modify_db_name.

Example: In the following example, the rdsadmin.dbo.rds_modify_db_name stored procedure renames a database from MOO to ZAR. This is similar to running the statement DDL ALTER DATABASE [MOO] MODIFY NAME = [ZAR].

```
EXEC rdsadmin.dbo.rds_modify_db_name N'MOO', N'ZAR'
GO
```

Resetting the db_owner role password

If you lock yourself out of the db_owner role on your Microsoft SQL Server database, you can reset the db_owner role password by modifying the DB instance master password. By changing the DB instance master password, you can regain access to the DB instance, access databases using the modified password for the db_owner, and restore privileges for the db_owner role that may have been accidentally revoked. You can change the DB instance password by using the Amazon RDS console, the AWS CLI command modify-db-instance, or by using the ModifyDBInstance operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

Restoring license-terminated DB instances

Microsoft has requested that some Amazon RDS customers who did not report their Microsoft License Mobility information terminate their DB instance. Amazon RDS takes snapshots of these DB instances, and you can restore from the snapshot to a new DB instance that has the License Included model.

To restore from a SQL Server snapshot after Amazon RDS has created a final snapshot of your instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot of your SQL Server DB instance. Amazon RDS creates a final snapshot of your DB instance. The name of the terminated instance snapshot is in the format instance_name-final-snapshot. For example, if your DB instance name is mytest.cdgahsklsma.us-east-1.rds.com, the final snapshot is called mytest-final-snapshot and is located in the same AWS Region as the original DB instance.
4. For Actions, choose Restore Snapshot.

The Restore DB Instance window appears.
5. For License Model, choose license-included.
6. Choose the SQL Server DB engine that you want to use.
7. For DB Instance Identifier, enter the name for the restored DB instance.
8. Choose Restore DB Instance.
For more information about restoring from a snapshot, see Restoring from a DB snapshot (p. 432).

## Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE

You can transition your Microsoft SQL Server database on an Amazon RDS DB instance from OFFLINE to ONLINE.

<table>
<thead>
<tr>
<th>SQL Server method</th>
<th>Amazon RDS method</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER DATABASE <code>db_name</code> SET ONLINE;</td>
<td>EXEC rdsadmin.dbo.rds_set_database_online <code>db_name</code></td>
</tr>
</tbody>
</table>

### Using change data capture

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables. It stores metadata about each change, which you can access later. For more information about how CDC works, see Change data capture in the Microsoft documentation.

Before you use CDC with your Amazon RDS DB instances, enable it in the database by running `msdb.dbo.rds_cdc_enable_db`. You must have master user privileges to enable CDC in the Amazon RDS DB instance. After CDC is enabled, any user who is `db_owner` of that database can enable or disable CDC on tables in that database.

**Important**

During restores, CDC will be disabled. All of the related metadata is automatically removed from the database. This applies to snapshot restores, point-in-time restores, and SQL Server Native restores from S3. After performing one of these types of restores, you can re-enable CDC and re-specify tables to track.

To enable CDC for a DB instance, run the `msdb.dbo.rds_cdc_enable_db` stored procedure.

```sql
exec msdb.dbo.rds_cdc_enable_db 'database_name'
```

To disable CDC for a DB instance, run the `msdb.dbo.rds_cdc_disable_db` stored procedure.

```sql
exec msdb.dbo.rds_cdc_disable_db 'database_name'
```

### Topics

- Tracking tables with change data capture (p. 1125)
- Change data capture jobs (p. 1126)
- Change data capture for Multi-AZ instances (p. 1126)

### Tracking tables with change data capture

After CDC is enabled on the database, you can start tracking specific tables. You can choose the tables to track by running `sys.sp_cdc_enable_table`.

```sql
--Begin tracking a table
```
exec sys.sp_cdc_enable_table
    @source_schema           = N' source_schema',
    @source_name             = N' source_name',
    @role_name               = N' role_name'
--The following parameters are optional:
-- , @capture_instance       = ' capture_instance'
-- , @supports_net_changes   = supports_net_changes
-- , @index_name             = ' index_name'
-- , @captured_column_list   = ' captured_column_list'
-- , @filegroup_name         = ' filegroup_name'
-- , @allow_partition_switch = 'allow_partition_switch'
;
To view the CDC configuration for your tables, run sys.sp_cdc_help_change_data_capture.

--View CDC configuration
exec sys.sp_cdc_help_change_data_capture
--The following parameters are optional and must be used together.
--  'schema_name', 'table_name'
;
For more information on CDC tables, functions, and stored procedures in SQL Server documentation, see the following:

- Change data capture stored procedures (Transact-SQL)
- Change data capture functions (Transact-SQL)
- Change data capture tables (Transact-SQL)

Change data capture jobs

When you enable CDC, SQL Server creates the CDC jobs. Database owners (db_owner) can view, create, modify, and delete the CDC jobs. However, the RDS system account owns them. Therefore, the jobs aren’t visible from native views, procedures, or in SQL Server Management Studio.

To control behavior of CDC in a database, use native SQL Server procedures such as sp_cdc_enable_table and sp_cdc_start_job. To change CDC job parameters, like maxtrans and maxscans, you can use sp_cdc_change_job.

To get more information regarding the CDC jobs, you can query the following dynamic management views:

- sys.dm_cdc_errors
- sys.dm_cdc_log_scan_sessions
- sysjobs
- sysjobhistory

Change data capture for Multi-AZ instances

If you use CDC on a Multi-AZ instance, make sure the mirror’s CDC job configuration matches the one on the principal. CDC jobs are mapped to the database_id. If the database IDs on the secondary are different from the principal, then the jobs won't be associated with the correct database. To try to prevent errors after failover, RDS drops and recreates the jobs on the new principal. The recreated jobs use the parameters that the principal recorded before failover.
Although this process runs quickly, it's still possible that the CDC jobs might run before RDS can correct them. Here are three ways to force parameters to be consistent between primary and secondary replicas:

- Use the same job parameters for all the databases that have CDC enabled.
- Before you change the CDC job configuration, convert the Multi-AZ instance to Single-AZ.
- Manually transfer the parameters whenever you change them on the principal.

To view and define the CDC parameters that are used to recreate the CDC jobs after a failover, use `rds_show_configuration` and `rds_set_configuration`.

The following example returns the value set for `cdc_capture_maxtrans`. For any parameter that is set to `RDS_DEFAULT`, RDS automatically configures the value.

```sql
-- Show configuration for each parameter on either primary and secondary replicas.
exec rdsadmin.dbo.rds_show_configuration 'cdc_capture_maxtrans';
```

To set the configuration on the secondary, run `rdsadmin.dbo.rds_set_configuration`. This procedure sets the parameter values for all of the databases on the secondary server. These settings are used only after a failover. The following example sets the `maxtrans` for all CDC capture jobs to 1000:

```sql
--To set values on secondary. These are used after failover.
exec rdsadmin.dbo.rds_set_configuration 'cdc_capture_maxtrans', 1000;
```

To set the CDC job parameters on the principal, use `sys.sp_cdc_change_job` instead.

## Using SQL Server Agent

With Amazon RDS, you can use SQL Server Agent on a DB instance running Microsoft SQL Server Enterprise Edition, Standard Edition, or Web Edition. SQL Server Agent is a Microsoft Windows service that runs scheduled administrative tasks that are called jobs. You can use SQL Server Agent to run T-SQL jobs to rebuild indexes, run corruption checks, and aggregate data in a SQL Server DB instance.

When you create a SQL Server DB instance, the master user name is enrolled in the `SQLAgentUserRole` role.

SQL Server Agent can run a job on a schedule, in response to a specific event, or on demand. For more information, see [SQL Server Agent](https://docs.microsoft.com/en-us/sql-server/sql-server-agent) in the Microsoft documentation.

**Note**

Avoid scheduling jobs to run during the maintenance and backup windows for your DB instance. The maintenance and backup processes that are launched by AWS could interrupt a job or cause it to be canceled.

Multi-AZ deployments have a limit of 100 SQL Server Agent jobs. If you need a higher limit, request an increase by contacting AWS Support. Open the [AWS Support Center](https://aws.amazon.com/support/) page, sign in if necessary, and choose `Create case`. Choose `Service limit increase`. Complete and submit the form.

To view the history of an individual SQL Server Agent job in SQL Server Management Studio (SSMS), open Object Explorer, right-click the job, and then choose `View History`.

Because SQL Server Agent is running on a managed host in a DB instance, some actions aren't supported:

- Running replication jobs and running command-line scripts by using ActiveX, Windows command shell, or Windows PowerShell aren't supported.
- You can't manually start, stop, or restart SQL Server Agent.
• Email notifications through SQL Server Agent aren't available from a DB instance.
• SQL Server Agent alerts and operators aren't supported.
• Using SQL Server Agent to create backups isn't supported. Use Amazon RDS to back up your DB instance.

Adding a user to the SQLAgentUserRole role

To allow an additional login or user to use SQL Server Agent, you must log in as the master user and do the following:

1. Create another server-level login by using the `CREATE LOGIN` command.
2. Create a user in `msdb` using `CREATE USER` command, and then link this user to the login that you created in the previous step.
3. Add the user to the `SQLAgentUserRole` using the `sp_addrolemember` system stored procedure.

For example, suppose your master user name is `admin` and you want to give access to SQL Server Agent to a user named `theirname` with a password `theirpassword`.

To add a user to the SQLAgentUserRole role

1. Log in as the master user.
2. Run the following commands:

```
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
--Added database user theirname in msdb to SQLAgentUserRole in msdb
EXEC sp_addrolemember [SQLAgentUserRole], [theirname];
```

Deleting a SQL Server Agent job

You use the `sp_delete_job` stored procedure to delete SQL Server Agent jobs on Amazon RDS for Microsoft SQL Server.

You can't use SSMS to delete SQL Server Agent jobs. If you try to do so, you get an error message similar to the following:

```
The EXECUTE permission was denied on the object 'xp_regread', database 'mssqlsystemresource', schema 'sys'.
```

As a managed service, RDS is restricted from running procedures that access the Windows registry. When you use SSMS, it tries to run a process (xp_regread) for which RDS isn't authorized.

**Note**

On RDS for SQL Server, you can delete only SQL Server Agent jobs that were created by the same login.
To delete a SQL Server Agent job

- Run the following T-SQL statement:

  ```sql
  EXEC msdb..sp_delete_job @job_name = 'job_name';
  ```

Working with Microsoft SQL Server logs

You can use the Amazon RDS console to view, watch, and download SQL Server Agent logs and Microsoft SQL Server error logs.

Watching log files

If you view a log in the Amazon RDS console, you can see its contents as they exist at that moment. Watching a log in the console opens it in a dynamic state so that you can see updates to it in near-real time.

Only the latest log is active for watching. For example, suppose you have the following logs shown:

<table>
<thead>
<tr>
<th>Name</th>
<th>Last Written</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>log/ERROR</td>
<td>January 14, 2015</td>
<td>6.1 KB</td>
</tr>
<tr>
<td>log/ERROR, 1</td>
<td>January 13, 2015</td>
<td>3.3 KB</td>
</tr>
<tr>
<td>log/ERROR, 2</td>
<td>January 12, 2015</td>
<td>5.9 KB</td>
</tr>
<tr>
<td>log/ERROR, 3</td>
<td>January 11, 2015</td>
<td>5.9 KB</td>
</tr>
<tr>
<td>log/ERROR, 4</td>
<td>January 10, 2015</td>
<td>5.9 KB</td>
</tr>
</tbody>
</table>

Only log/ERROR, as the most recent log, is being actively updated. You can choose to watch others, but they are static and will not update.

Archiving log files

The Amazon RDS console shows logs for the past week through the current day. You can download and archive logs to keep them for reference past that time. One way to archive logs is to load them into an Amazon S3 bucket. For instructions on how to set up an Amazon S3 bucket and upload a file, see Amazon S3 basics in the Amazon Simple Storage Service Getting Started Guide and click Get Started.

Viewing error and agent logs

To view Microsoft SQL Server error and agent logs, use the Amazon RDS stored procedure `rds_read_error_log` with the following parameters:

- `@index` – the version of the log to retrieve. The default value is 0, which retrieves the current error log. Specify 1 to retrieve the previous log, specify 2 to retrieve the one before that, and so on.
- `@type` – the type of log to retrieve. Specify 1 to retrieve an error log. Specify 2 to retrieve an agent log.

Example

The following example requests the current error log.

  ```sql
  EXEC rdsadmin.dbo.rds_read_error_log @index = 0, @type = 1;
  ```

For more information on SQL Server errors, see Database engine errors in the Microsoft documentation.
Working with trace and dump files

This section describes working with trace files and dump files for your Amazon RDS DB instances running Microsoft SQL Server.

Generating a trace SQL query

```sql
declare @rc int
declare @TraceID int
declare @maxfilesize bigint
set @maxfilesize = 5
exec @rc = sp_trace_create @TraceID output, 0, N'D:\rdsdbdata\log\rdstest', @maxfilesize, NULL
```

Viewing an open trace

```sql
select * from ::fn_trace_getinfo(default)
```

Viewing trace contents

```sql
select * from ::fn_trace_gettable('D:\rdsdbdata\log\rdstest.trc', default)
```

Setting the retention period for trace and dump files

Trace and dump files can accumulate and consume disk space. By default, Amazon RDS purges trace and dump files that are older than seven days.

To view the current trace and dump file retention period, use the `rds_show_configuration` procedure, as shown in the following example.

```sql
exec rdsadmin..rds_show_configuration;
```

To modify the retention period for trace files, use the `rds_set_configuration` procedure and set the `tracefile retention` in minutes. The following example sets the trace file retention period to 24 hours.

```sql
exec rdsadmin..rds_set_configuration 'tracefile retention', 1440;
```

To modify the retention period for dump files, use the `rds_set_configuration` procedure and set the `dumpfile retention` in minutes. The following example sets the dump file retention period to 3 days.

```sql
exec rdsadmin..rds_set_configuration 'dumpfile retention', 4320;
```

For security reasons, you cannot delete a specific trace or dump file on a SQL Server DB instance. To delete all unused trace or dump files, set the retention period for the files to 0.
MySQL on Amazon RDS

Amazon RDS supports DB instances running several versions of MySQL. You can use the following major versions:

- MySQL 8.0
- MySQL 5.7
- MySQL 5.6 (Deprecation scheduled for February 1, 2022)

For more information about minor version support, see MySQL on Amazon RDS versions (p. 1133).

You first use the Amazon RDS management tools or interfaces to create an Amazon RDS for MySQL DB instance. You can then resize the DB instance, authorize connections to the DB instance, create and restore from backups or snapshots, create Multi-AZ secondaries, create read replicas, and monitor the performance of the DB instance. You use standard MySQL utilities and applications to store and access the data in the DB instance.

Amazon RDS for MySQL is compliant with many industry standards. For example, you can use RDS for MySQL databases to build HIPAA-compliant applications and to store healthcare related information, including protected health information (PHI) under a Business Associate Agreement (BAA) with AWS. Amazon RDS for MySQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements and has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

For information about the features in each version of MySQL, see The main features of MySQL in the MySQL documentation.

Common management tasks for Amazon RDS for MySQL

The following are the common management tasks you perform with an RDS for MySQL DB instance, with links to relevant documentation for each task.

- Options for MySQL DB instances (p. 1234)
- MySQL on Amazon RDS SQL reference (p. 1264)

## MySQL on Amazon RDS versions

For MySQL, version numbers are organized as version = X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes—for example, going from version 5.7 to 8.0. A version change is considered minor if only the minor version number changes—for example, going from version 5.7.16 to 5.7.21.
Amazon RDS currently supports the following versions of MySQL:

<table>
<thead>
<tr>
<th>Major version</th>
<th>Minor version</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 8.0</td>
<td>• 8.0.28</td>
</tr>
<tr>
<td></td>
<td>• 8.0.27</td>
</tr>
<tr>
<td></td>
<td>• 8.0.26</td>
</tr>
<tr>
<td></td>
<td>• 8.0.25</td>
</tr>
<tr>
<td></td>
<td>• 8.0.23</td>
</tr>
<tr>
<td></td>
<td>• 8.0.21</td>
</tr>
<tr>
<td></td>
<td>• 8.0.20</td>
</tr>
<tr>
<td></td>
<td>• 8.0.19</td>
</tr>
<tr>
<td></td>
<td>• 8.0.17</td>
</tr>
<tr>
<td></td>
<td>• 8.0.16</td>
</tr>
<tr>
<td></td>
<td>• 8.0.15</td>
</tr>
<tr>
<td></td>
<td>• 8.0.13</td>
</tr>
<tr>
<td></td>
<td>• 8.0.11</td>
</tr>
<tr>
<td>MySQL 5.7</td>
<td>• 5.7.37</td>
</tr>
<tr>
<td></td>
<td>• 5.7.36</td>
</tr>
<tr>
<td></td>
<td>• 5.7.34</td>
</tr>
<tr>
<td></td>
<td>• 5.7.33</td>
</tr>
<tr>
<td></td>
<td>• 5.7.31</td>
</tr>
<tr>
<td></td>
<td>• 5.7.30</td>

<tr>
<td></td>
<td>• 5.6.35</td>
</tr>
<tr>
<td></td>
<td>• 5.6.34</td>
</tr>
</tbody>
</table>
You can specify any currently supported MySQL version when creating a new DB instance. You can specify the major version (such as MySQL 5.7), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

The default MySQL version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```
aws rds describe-db-engine-versions --default-only --engine mysql --engine-version major-engine-version --region region --query "*{}.Engine,EngineVersion" --output text
```

Replace `major-engine-version` with the major engine version, and replace `region` with the AWS Region. For example, the following AWS CLI command returns the default MySQL minor engine version for the 5.7 major version and the US West (Oregon) AWS Region (us-west-2):

```
aws rds describe-db-engine-versions --default-only --engine mysql --engine-version 5.7 --region us-west-2 --query "*{}.Engine,EngineVersion" --output text
```

With Amazon RDS, you control when to upgrade your MySQL instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific MySQL versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, your DB instance will be upgraded automatically to new MySQL minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see Upgrading a DB instance engine version (p. 344).

Amazon RDS currently supports the major version upgrades from MySQL version 5.6 to version 5.7, and from MySQL version 5.7 to version 8.0. Because major version upgrades involve some compatibility risk, they do not occur automatically; you must make a request to modify the DB instance. You should thoroughly test any upgrade before upgrading your production instances. For information about upgrading a MySQL DB instance, see Upgrading the MySQL DB engine (p. 1159).

You can test a DB instance against a new version before upgrading by creating a DB snapshot of your existing DB instance, restoring from the DB snapshot to create a new DB instance, and then initiating a version upgrade for the new DB instance. You can then experiment safely on the upgraded clone of your DB instance before deciding whether or not to upgrade your original DB instance.

### Deprecation of MySQL version 5.6

On February 1, 2022, Amazon RDS plans to deprecate support for MySQL 5.6 using the following schedule, which includes upgrade recommendations. We recommend that you upgrade all MySQL 5.6 DB instances to MySQL 5.7 or higher as soon as possible. For more information, see Upgrading the MySQL DB engine (p. 1159).
### MySQL features not supported by Amazon RDS

Amazon RDS doesn't currently support the following MySQL features:

- Authentication Plugin
- Error Logging to the System Log
- Group Replication Plugin
- InnoDB Tablespace Encryption
- Password Strength Plugin
- Persisted system variables
- Semisynchronous replication
- Transportable tablespace
- X Plugin

**Note**

Global transaction IDs are supported for RDS for MySQL 5.7.23 and higher 5.7 versions, and for MySQL 8.0.26 and higher 8.0 versions. Global transaction IDs are not supported for RDS for MySQL 5.6.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, you are assigned to the `db_owner` role for all databases on that instance, and you have all database-level permissions except for those used for backups. Amazon RDS manages backups for you.

<td>Amazon RDS starts automatic upgrades to version 5.7 for any MySQL 5.6 DB instances restored from snapshots.</td>
<td>March 1, 2022</td>
</tr>
</tbody>
</table>

For more information about Amazon RDS for MySQL 5.6 deprecation, see [Announcement: Extending end-of-life process for Amazon RDS for MySQL 5.6](#).
Supported storage engines for RDS for MySQL

While MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. Amazon RDS fully supports the InnoDB storage engine for MySQL DB instances. Amazon RDS features such as Point-In-Time restore and snapshot restore require a recoverable storage engine and are supported for the InnoDB storage engine only. You must be running an instance of MySQL 5.6 or later to use the InnoDB memcached interface. For more information, see MySQL memcached support (p. 1239).

The Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

For user-created schemas, the MyISAM storage engine does not support reliable recovery and can result in lost or corrupt data when MySQL is restarted after a recovery, preventing Point-In-Time restore or snapshot restore from working as intended. However, if you still choose to use MyISAM with Amazon RDS, snapshots can be helpful under some conditions.

Note
System tables in the mysql schema can be in MyISAM storage.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the ALTER TABLE command (for example, alter table TABLE_NAME engine=innodb;). Bear in mind that MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

MySQL 5.1 and 5.5 are no longer supported in Amazon RDS. However, you can restore existing MySQL 5.1 and 5.5 snapshots. When you restore a MySQL 5.1 or 5.5 snapshot, the DB instance is automatically upgraded to MySQL 5.6.

Storage-full behavior for Amazon RDS for MySQL

When storage becomes full for a MySQL DB instance, there can be metadata inconsistencies, dictionary mismatches, and orphan tables. To prevent these issues, Amazon RDS automatically stops a DB instance that reaches the storage-full state.

A MySQL DB instance reaches the storage-full state in the following cases:

- The DB instance has less than 20,000 MiB of storage, and available storage reaches 200 MiB or less.
- The DB instance has more than 102,400 MiB of storage, and available storage reaches 1024 MiB or less.
- The DB instance has between 20,000 MiB and 102,400 MiB of storage, and has less than 1% of storage available.

After Amazon RDS stops a DB instance automatically because it reached the storage-full state, you can still modify it. To restart the DB instance, complete at least one of the following:

- Modify the DB instance to enable storage autoscaling.
  
  For more information about storage autoscaling, see Managing capacity automatically with Amazon RDS storage autoscaling (p. 394).
- Modify the DB instance to increase its storage capacity.
  
  For more information about increasing storage capacity, see Increasing DB instance storage capacity (p. 393).
After you make one of these changes, the DB instance is restarted automatically. For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

MySQL security on Amazon RDS

Security for MySQL DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see Identity and access management in Amazon RDS (p. 1766).
- When you create a DB instance, you use either a VPC security group or a DB security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- To authenticate login and permissions for a MySQL DB instance, you can take either of the following approaches, or a combination of them.

You can take the same approach as with a stand-alone instance of MySQL. Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in on-premises databases, as does directly modifying database schema tables. For information, see Access control and account management in the MySQL documentation.

You can also use IAM database authentication. With IAM database authentication, you authenticate to your DB instance by using an IAM user or IAM role and an authentication token. An authentication token is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786).

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- alter
- alter routine
- create
- create routine
- create temporary tables
- create user
- create view
- delete
- drop
- event
- execute
- grant option
- index
- insert
- lock tables
- process
Using the Password Validation Plugin

MySQL provides the validate_password plugin for improved security. The plugin enforces password policies using parameters in the DB parameter group for your MySQL DB instance. The plugin is supported for DB instances running MySQL version 5.6, 5.7, and 8.0. For more information about the validate_password plugin, see The Password Validation Plugin in the MySQL documentation.

To enable the validate_password plugin for a MySQL DB instance

1. Connect to your MySQL DB instance and run the following command.

   ```sql
   INSTALL PLUGIN validate_password SONAME 'validate_password.so';
   ```

2. Configure the parameters for the plugin in the DB parameter group used by the DB instance.

   For more information about the parameters, see Password Validation Plugin options and variables in the MySQL documentation.

   For more information about modifying DB instance parameters, see Modifying parameters in a DB parameter group (p. 282).

After installing and enabling the password_validate plugin, reset existing passwords to comply with your new validation policies.

Amazon RDS doesn't validate passwords. The MySQL DB instance performs password validation. If you set a user password with the AWS Management Console, the modify-db-instance AWS CLI command, or the ModifyDBInstance RDS API operation, the change can succeed even if the new password
doesn't satisfy your password policies. However, a new password is set in the MySQL DB instance only if it satisfies the password policies. In this case, Amazon RDS records the following event.

"RDS-EVENT-0067" - An attempt to reset the master password for the DB instance has failed.

For more information about Amazon RDS events, see Using Amazon RDS event notification (p. 623).

Using SSL with a MySQL DB instance

Amazon RDS supports Secure Sockets Layer (SSL) connections with DB instances running the MySQL database engine.

Amazon RDS creates an SSL certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

An SSL certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL.

For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755). For more information about using SSL with MySQL, see Updating applications to connect to MySQL DB instances using new SSL/TLS certificates (p. 1154).

MySQL uses yaSSL for secure connections in the following versions:

- MySQL version 5.7.19 and earlier 5.7 versions
- MySQL version 5.6.37 and earlier 5.6 versions

MySQL uses OpenSSL for secure connections in the following versions:

- MySQL version 8.0
- MySQL version 5.7.21 and later 5.7 versions
- MySQL version 5.6.39 and later 5.6 versions

Amazon RDS for MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, and 1.2. The following table shows the TLS support for MySQL versions.

<table>
<thead>
<tr>
<th>MySQL version</th>
<th>TLS 1.0</th>
<th>TLS 1.1</th>
<th>TLS 1.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 8.0</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>MySQL 5.7</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported for MySQL 5.7.21 and later</td>

<td>Supported for MySQL 5.6.46 and later</td>
</tr>
</tbody>
</table>
To encrypt connections using the default `mysql` client, launch the `mysql` client using the `--ssl-ca` parameter to reference the public key, as shown in the examples following.

The following example shows how to launch the client using the `--ssl-ca` parameter for MySQL 5.7 and later.

```
mysql -h myinstance.c9akciq32.rds-us-east-1.amazonaws.com
   --ssl-ca=[full path]global-bundle.pem --ssl-mode=VERIFY_IDENTITY
```

The following example shows how to launch the client using the `--ssl-ca` parameter for MySQL 5.6 and earlier.

```
mysql -h myinstance.c9akciq32.rds-us-east-1.amazonaws.com
   --ssl-ca=[full path]global-bundle.pem --ssl-verify-server-cert
```

For information about downloading certificate bundles, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

You can require SSL connections for specific users accounts. For example, you can use one of the following statements, depending on your MySQL version, to require SSL connections on the user account `encrypted_user`.

For MySQL 5.7 and later, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For MySQL 5.6 and earlier, use the following statement.

```
GRANT USAGE ON *.* TO 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL connections with MySQL, see the Using encrypted connections in the MySQL documentation.

### Using memcached and other options with MySQL

Most Amazon RDS DB engines support option groups that allow you to select additional features for your DB instance. DB instances on MySQL version 5.6 and later support the `memcached` option, a simple, key-based cache. For more information about `memcached` and other options, see Options for MySQL DB instances (p. 1234). For more information about working with option groups, see Working with option groups (p. 262).

### InnoDB cache warming

InnoDB cache warming can provide performance gains for your MySQL DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. The file that stores the saved buffer pool information only stores metadata for the pages that
are in the buffer pool, and not the pages themselves. As a result, the file does not require much storage space. The file size is about 0.2 percent of the cache size. For example, for a 64 GiB cache, the cache warming file size is 128 MiB. For more information on InnoDB cache warming, see Saving and restoring the buffer pool state in the MySQL documentation.

MySQL on Amazon RDS supports InnoDB cache warming for MySQL version 5.6 and later. To enable InnoDB cache warming, set the innodb_buffer_pool_dump_at_shutdown and innodb_buffer_pool_load_at_startup parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group will affect all MySQL DB instances that use that parameter group. To enable InnoDB cache warming for specific MySQL DB instances, you might need to create a new parameter group for those instances. For information on parameter groups, see Working with parameter groups (p. 278).

InnoDB cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you do not commonly see a significant performance benefit.

**Important**

If your MySQL DB instance does not shut down normally, such as during a failover, then the buffer pool state will not be saved to disk. In this case, MySQL loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool prior to the restart. To ensure that you have a recent state of the buffer pool available to warm the InnoDB cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can dump or load the buffer pool on demand if your DB instance is running MySQL version 5.6.19 or later. You can create an event to dump the buffer pool automatically and on a regular interval. For example, the following statement creates an event named periodic_buffer_pool_dump that dumps the buffer pool every hour.

```sql
CREATE EVENT periodic_buffer_pool_dump
ON SCHEDULE EVERY 1 HOUR
DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information on MySQL events, see Event syntax in the MySQL documentation.

### Dumping and loading the buffer pool on demand

For MySQL version 5.6.19 and later, you can save and load the InnoDB cache "on demand."

- To dump the current state of the buffer pool to disk, call the `mysql.rds_innodb_buffer_pool_dump_now` stored procedure.
- To load the saved state of the buffer pool from disk, call the `mysql.rds_innodb_buffer_pool_load_now` stored procedure.
- To cancel a load operation in progress, call the `mysql.rds_innodb_buffer_pool_load_abort` stored procedure.

### Local time zone for MySQL DB instances

By default, the time zone for a MySQL DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see Working with parameter groups (p. 278).
After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

You can set your local time zone to one of the following values.

<table>

Known issues and limitations for Amazon RDS for MySQL

There are some known issues and limitations for working with MySQL on Amazon RDS for MySQL. For more information, see Known issues and limitations for Amazon RDS for MySQL (p. 1260).

Deprecated versions for Amazon RDS for MySQL

Amazon RDS for MySQL version 5.1 and 5.5 are deprecated.

For more information about Amazon RDS for MySQL 5.5 deprecation, see Announcement: Extending end-of-life process for Amazon RDS for MySQL 5.5.
For information about the Amazon RDS deprecation policy for MySQL, see Amazon RDS FAQs.
Connecting to a DB instance running the MySQL database engine

Before you can connect to a DB instance running the MySQL database engine, you must create a DB instance. For information, see Creating an Amazon RDS DB instance (p. 175). After Amazon RDS provisions your DB instance, you can use any standard MySQL client application or utility to connect to the instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

To authenticate to your RDS DB instance, you can use one of the authentication methods for MySQL and AWS Identity and Access Management (IAM) database authentication:

- To learn how to authenticate to MySQL using one of the authentication methods for MySQL, see Authentication method in the MySQL documentation.
- To learn how to authenticate to MySQL using IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786).

You can connect to a MySQL DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see mysql - the MySQL command-line client in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the Download MySQL Workbench page. For information about installing MySQL (including the MySQL command-line client), see Installing and upgrading MySQL.

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on most RPM-based Linux distributions, including Amazon Linux 2, run the following command:

```bash
yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command:

```bash
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command:

```bash
mysql --version
```

To read the MySQL documentation for your current client version, run the following command:

```bash
man mysql
```

To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 1880).

You can use Secure Sockets Layer (SSL) encryption on connections to a MySQL DB instance. For information, see Using SSL with a MySQL DB instance (p. 1140). If you are using AWS Identity and Access Management (IAM) database authentication, make sure to use an SSL connection. For information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786).
You can also connect to a DB instance from a web server. For more information, see Tutorial: Create a web server and an Amazon RDS DB instance (p. 141).

**Note**
For information on connecting to a MariaDB DB instance, see Connecting to a DB instance running the MariaDB database engine (p. 851).

**Topics**
- Finding the connection information for a MySQL DB instance (p. 1147)
- Connecting from the MySQL command-line client (unencrypted) (p. 1149)
- Connecting from the MySQL command-line client with SSL (encrypted) (p. 1150)
- Connecting from MySQL Workbench (p. 1151)
- Connecting with the Amazon Web Services JDBC Driver for MySQL (p. 1152)
- Troubleshooting connections to your MySQL DB instance (p. 1152)

### Finding the connection information for a MySQL DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is `3306`, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify `3306`.
- For user, specify `admin`.

To connect to a DB instance, use any client for the MySQL DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS CLI `describe-db-instances` command, or the Amazon RDS API `DescribeDBInstances` operation to list its details.

**Console**

**To find the connection information for a DB instance in the AWS Management Console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MySQL DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. If you need to find the master user name, choose the Configuration tab and view the Master username value.

AWS CLI

To find the connection information for a MySQL DB instance by using the AWS CLI, call the `describe-db-instances` command. In the call, query for the DB instance ID, endpoint, port, and master user name.
Connecting from the MySQL command-line client (unencrypted)

For Linux, macOS, or Unix:

```bash
aws rds describe-db-instances \
  --filters "Name=engine,Values=mysql" \
  --query "[*].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```bash
aws rds describe-db-instances ^
  --filters "Name=engine,Values=mysql" ^
  --query "[*].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
  [
    "mydb1",
    "mydb1.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ],
  [
    "mydb2",
    "mydb2.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ]
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Connecting from the MySQL command-line client (unencrypted)

Important

Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see Connecting from the MySQL command-line client with SSL (encrypted) (p. 1150).

To connect to a DB instance using the MySQL command-line client, enter the following command at a command prompt to connect to a DB instance using the MySQL command-line client. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

```bash
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com -P 3306 -u mymasteruser -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor.  Commands end with ; or \g.
```
Connecting from the MySQL command-line client with SSL (encrypted)

Amazon RDS creates an SSL certificate for your DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks. To connect to your DB instance using SSL, you can use native password authentication or IAM database authentication. To connect to your DB instance using IAM database authentication, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786). To connect to your DB instance using native password authentication, you can follow these steps:

To connect to a DB instance with SSL using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.
   
   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

2. Enter the following command at a command prompt to connect to a DB instance with SSL using the MySQL command-line client. For the -h parameter, substitute the DNS name (endpoint) for your DB instance. For the --ssl-ca parameter, substitute the SSL certificate file name as appropriate. For the -P parameter, substitute the port for your DB instance. For the -u parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem -P 3306 -u mymasteruser -p
   ```

3. You can require that the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

   For MySQL 5.7 and later:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=VERIFY_IDENTITY -P 3306 -u mymasteruser -p
   ```

   For MySQL 5.6 and earlier:

   ```
   mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-verify-server-cert -P 3306 -u mymasteruser -p
   ```

4. Enter the master user password when prompted.

   You will see output similar to the following.

   ```
   Welcome to the MySQL monitor. Commands end with ; or \g.
   Your MySQL connection id is 350
   Server version: 5.6.40-log MySQL Community Server (GPL)
   ```
Connecting from MySQL Workbench

To connect from MySQL Workbench

1. Download and install MySQL Workbench at Download MySQL Workbench.
2. Open MySQL Workbench.
3. From Database, choose Manage Connections.
4. In the Manage Server Connections window, choose New.
5. In the Connect to Database window, enter the following information:
   - Stored Connection – Enter a name for the connection, such as MyDB.
   - Hostname – Enter the DB instance endpoint.
   - Port – Enter the port used by the DB instance.
   - Username – Enter the user name of a valid database user, such as the master user.
   - Password – Optionally, choose Store in Vault and then enter and save the password for the user.

The window looks similar to the following:
You can use the features of MySQL Workbench to customize connections. For example, you can use the **SSL** tab to configure SSL connections. For information about using MySQL Workbench, see the MySQL Workbench documentation.

6. Optionally, choose **Test Connection** to confirm that the connection to the DB instance is successful.
7. Choose **Close**.
8. From **Database**, choose **Connect to Database**.
9. From **Stored Connection**, choose your connection.
10. Choose **OK**.

### Connecting with the Amazon Web Services JDBC Driver for MySQL

The AWS JDBC Driver for MySQL is a client driver designed for RDS for MySQL. By default, the AWS JDBC Driver for MySQL has optimized settings for use with RDS for MySQL.

The AWS JDBC Driver for MySQL is drop-in compatible with the MySQL Connector/J driver. To install or upgrade your connector, replace the MySQL connector .jar file (located in the application CLASSPATH) with the AWS JDBC Driver for MySQL .jar file, and update the connection URL prefix from `jdbc:mysql://` to `jdbc:mysql:aws://`.

For more information about the AWS JDBC Driver for MySQL and complete instructions for using it, see the [AWS JDBC Driver for MySQL GitHub repository](#).

### Troubleshooting connections to your MySQL DB instance

Two common causes of connection failures to a new DB instance are:
The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MySQL application or utility is running. If the DB instance was created in a VPC, it must have a VPC security group that authorizes the connections. For more information, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.

If the DB instance was created outside of a VPC, it must have a DB security group that authorizes the connections.

The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see Can't connect to Amazon RDS DB instance (p. 1880).
Updating applications to connect to MySQL DB instances using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

**Note**
Some applications are configured to connect to MySQL DB instances only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: disabled, preferred, and required. When you use the preferred SSL mode and the CA certificate doesn't exist or isn't up to date, the following behavior applies:

**Note**
We recommend avoiding preferred mode. In preferred mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

- For newer MySQL minor versions, the connection falls back to not using SSL and connects without encryption.

Because these later versions use the OpenSSL protocol, an expired server certificate doesn't prevent successful connections unless the required SSL mode is specified.

The following MySQL minor versions use the OpenSSL protocol:
- All MySQL 8.0 versions
- MySQL 5.7.21 and later MySQL 5.7 versions
- MySQL 5.6.39 and later MySQL 5.6 versions
- For older MySQL minor versions, an error is returned.

Because these older versions use the yaSSL protocol, certificate verification is strictly enforced and the connection is unsuccessful.

The following MySQL minor versions use the yaSSL protocol:
- MySQL 5.7.19 and earlier MySQL 5.7 versions
- MySQL 5.6.37 and earlier MySQL 5.6 versions

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

**Topics**
- Determining whether any applications are connecting to your MySQL DB instance using SSL (p. 1155)
- Determining whether a client requires certificate verification to connect (p. 1155)
Determining whether any applications are connecting to your MySQL DB instance using SSL

If you are using Amazon RDS for MySQL version 5.7 or 8.0 and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see Performance Schema quick start in the MySQL documentation.

```
mysql> SELECT id, user, host, connection_type
    FROM performance_schema.threads pst
    INNER JOIN information_schema.processlist isp
    ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (admin) and an application logged in as webapp1 are using SSL.

+----+-----------------+------------------+-----------------+
| id | user            | host             | connection_type |
+----+-----------------+------------------+-----------------+
|  8 | admin           | 10.0.4.249:42590 | SSL/TLS         |
|  4 | event_scheduler | localhost        | NULL            |
| 10 | webapp1         | 159.28.1.1:42189 | SSL/TLS         |
+----+-----------------+------------------+-----------------+
3 rows in set (0.00 sec)

If you are using Amazon RDS for MySQL version 5.6, then you can't determine from the server side whether applications are connecting with or without SSL. For those versions, you can determine whether SSL is used by examining the application's connection method. In the following section, you can find more information on examining the client connection configuration.

Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

**JDBC**

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see Configuration properties in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have $$\text{sslMode}$$ set to $$\text{VERIFY_CA}$$ or $$\text{VERIFY_IDENTITY}$$, as in the following example.
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);

**Note**
If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

**MySQL**

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see Client-side configuration for encrypted connections in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```bash
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```bash
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-verify-server-cert
```

**Updating your application trust store**

For information about updating the trust store for MySQL applications, see Installing SSL certificates in the MySQL documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 1764).

**Note**
When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```java
System.setProperty("javax.net.ssl.trustStore", "certs");
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```
When you start the application, set the following properties.

```java
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

### Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```java
class MySQLSSLTest {
    private static final String DB_USER = "username";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void test(String[] args) throws Exception {
        Class.forName("com.mysql.jdbc.Driver");
        System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

        Properties properties = new Properties();
        properties.setProperty("sslMode", "VERIFY_IDENTITY");
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);

        Connection connection = null;
        Statement stmt = null;
        ResultSet rs = null;
        try {
            connection = DriverManager.getConnection("jdbc:mysql://mydatabase.123456789012.us-east-1.rds.amazonaws.com:3306", properties);
            stmt = connection.createStatement();
            rs=stmt.executeQuery("SELECT 1 from dual");
        } finally {
            if (rs != null) {
                try {
                    rs.close();
                    } catch (SQLException e) {
                        }
            }
            if (stmt != null) {
                try {
                    stmt.close();
                } catch (SQLException e) {
            }
            }
            if (connection != null) {
                try {
                    connection.close();
                } catch (SQLException e) {
            }
        }
    }
}
```
Important
After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 1757).
Upgrading the MySQL DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MySQL DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in Major version upgrades for MySQL (p. 1160).

In contrast, minor version upgrades include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the Auto minor version upgrade option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see Upgrading a DB instance engine version (p. 344).

If your MySQL DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the primary and standby replicas are upgraded. Your DB instance will not be available until the upgrade is complete.

Note
Database engine upgrades require downtime. The duration of the downtime varies based on the size of your DB instance.

Topics
- Overview of upgrading (p. 1159)
- Major version upgrades for MySQL (p. 1160)
- Testing an upgrade (p. 1164)
- Upgrading a MySQL DB instance (p. 1164)
- Automatic minor version upgrades for MySQL (p. 1165)
- Using a read replica to reduce downtime when upgrading a MySQL database (p. 1167)

Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:
```
aws rds describe-db-engine-versions \
    --engine mysql \
    --engine-version version-number \
    --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:
```
aws rds describe-db-engine-versions ^
    --engine mysql ^
    --engine-version version-number ^
```
For example, to identify the valid upgrade targets for a MySQL version 5.6.43 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions --engine mysql --engine-version 5.6.43 --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```bash
aws rds describe-db-engine-versions --engine mysql --engine-version 5.6.43 --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases, you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken when the upgrade completes.

Note
--Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 309).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

--Major version upgrades for MySQL

Amazon RDS supports the following in-place upgrades for major versions of the MySQL database engine:

- MySQL 5.6 to MySQL 5.7
- MySQL 5.7 to MySQL 8.0

Note
--You can only create MySQL version 5.7 and 8.0 DB instances with latest-generation and current-generation DB instance classes, in addition to the db.m3 previous-generation DB instance class.
In some cases, you want to upgrade a MySQL version 5.6 DB instance running on a previous-generation DB instance class (other than db.m3) to a MySQL version 5.7 DB instance. In these cases, first modify the DB instance to use a latest-generation or current-generation DB instance class. After you do this, you can then modify the DB instance to use the MySQL version 5.7 database engine. For information on Amazon RDS DB instance classes, see DB instance classes (p. 9).

On February 1, 2022, Amazon RDS plans to deprecate support for MySQL 5.6. Automatic upgrades of MySQL 5.6 DB instances to MySQL 5.7 begin on March 1, 2022. For more information, see Deprecation of MySQL version 5.6 (p. 1135).

Topics

- Overview of MySQL major version upgrades (p. 1161)
- Upgrades to MySQL version 5.7 might be slow (p. 1161)
- Prechecks for upgrades from MySQL 5.7 to 8.0 (p. 1162)
- Rollback after failure to upgrade from MySQL 5.7 to 8.0 (p. 1163)

Overview of MySQL major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically; you must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

To perform a major version upgrade for a MySQL version 5.6 DB instance on Amazon RDS to MySQL version 5.7 or later, first perform any available OS updates. After OS updates are complete, upgrade to each major version: 5.6 to 5.7 and then 5.7 to 8.0. MySQL DB instances created before April 24, 2014, show an available OS update until the update has been applied. For more information on OS updates, see Applying updates for a DB instance (p. 335).

During a major version upgrade of MySQL, Amazon RDS runs the MySQL binary mysql_upgrade to upgrade tables, if necessary. Also, Amazon RDS empties the slow_log and general_log tables during a major version upgrade. To preserve log information, save the log contents before the major version upgrade.

MySQL major version upgrades typically complete in about 10 minutes. Some upgrades might take longer because of the DB instance class size or because the instance doesn't follow certain operational guidelines in Best practices for Amazon RDS (p. 161). If you upgrade a DB instance from the Amazon RDS console, the status of the DB instance indicates when the upgrade is complete. If you upgrade using the AWS Command Line Interface (AWS CLI), use the describe-db-instances command and check the Status value.

Upgrades to MySQL version 5.7 might be slow

MySQL version 5.6.4 introduced a new date and time format for the datetime, time, and timestamp columns that allows fractional components in date and time values. When upgrading a DB instance to MySQL version 5.7, MySQL forces the conversion of all date and time column types to the new format.

Because this conversion rebuilds your tables, it might take a considerable amount of time to complete the DB instance upgrade. The forced conversion occurs for any DB instances that are running a version before MySQL version 5.6.4. It also occurs for any DB instances that were upgraded from a version before MySQL version 5.6.4 to a version other than 5.7.

If your DB instance runs a version before MySQL version 5.6.4, or was upgraded from a version before 5.6.4, we recommend an extra step. In these cases, we recommend that you convert the datetime, time, and timestamp columns in your database before upgrading your DB instance to MySQL version
5.7. This conversion can significantly reduce the amount of time required to upgrade the DB instance to MySQL version 5.7. To upgrade your date and time columns to the new format, issue the `ALTER TABLE <table_name> FORCE;` command for each table that contains date or time columns. Because altering a table locks the table as read-only, we recommend that you perform this update during a maintenance window.

To find all tables in your database that have `datetime`, `time`, or `timestamp` columns and create an `ALTER TABLE <table_name> FORCE;` command for each table, use the following query.

```
SELECT DISTINCT CONCAT('ALTER TABLE `',
  REPLACE(is_tables.TABLE_SCHEMA, '`', '``'), '`.`',
  REPLACE(is_tables.TABLE_NAME, '`', '``'), '` FORCE;')
FROM information_schema.TABLES is_tables
  INNER JOIN information_schema.COLUMNS col ON col.TABLE_SCHEMA =
  is_tables.TABLE_SCHEMA
  AND col.TABLE_NAME = is_tables.TABLE_NAME
  LEFT OUTER JOIN information_schema.INNODB_SYS_TABLES systables ON
  SUBSTRING_INDEX(systables.NAME, '#', 1) =
  CONCAT(is_tables.TABLE_SCHEMA,'/',is_tables.TABLE_NAME)
  LEFT OUTER JOIN information_schema.INNODB_SYS_COLUMNS syscolumns ON
  syscolumns.TABLE_ID = systables.TABLE_ID AND syscolumns.NAME = col.COLUMN_NAME
WHERE col.COLUMN_TYPE IN ('time','timestamp','datetime')
  AND is_tables.TABLE_TYPE = 'BASE TABLE'
  AND is_tables.TABLE_SCHEMA NOT IN ('mysql','information_schema','performance_schema')
  AND (is_tables.ENGINE = 'InnoDB' AND syscolumns.MTYPE = 6);
```

### Prechecks for upgrades from MySQL 5.7 to 8.0

MySQL 8.0 includes a number of incompatibilities with MySQL 5.7. These incompatibilities can cause problems during an upgrade from MySQL 5.7 to MySQL 8.0. So, some preparation might be required on your database for the upgrade to be successful. The following is a general list of these incompatibilities:

- There must be no tables that use obsolete data types or functions.
- There must be no orphan *.frm files.
- Triggers must not have a missing or empty definer or an invalid creation context.
- There must be no partitioned table that uses a storage engine that does not have native partitioning support.
- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.

For more information, see Keywords and reserved words in the MySQL documentation.

- There must be no tables in the MySQL 5.7 `mysql` system database that have the same name as a table used by the MySQL 8.0 data dictionary.
- There must be no obsolete SQL modes defined in your `sql_mode` system variable setting.
- There must be no tables or stored procedures with individual `ENUM` or `SET` column elements that exceed 255 characters or 1020 bytes in length.
- Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared InnoDB tablespaces.
- There must be no queries and stored program definitions from MySQL 8.0.12 or lower that use `ASC` or `DESC` qualifiers for `GROUP BY` clauses.
- Your MySQL 5.7 installation must not use features that are not supported in MySQL 8.0.

For more information, see Features removed in MySQL 8.0 in the MySQL documentation.

- There must be no foreign key constraint names longer than 64 characters.
• For improved Unicode support, consider converting objects that use the utf8mb3 charset to use the utf8mb4 charset. The utf8mb3 character set is deprecated. Also, consider using utf8mb4 for character set references instead of utf8, because currently utf8 is an alias for the utf8mb3 charset.

For more information, see The utf8mb3 character set (3-byte UTF-8 unicode encoding) in the MySQL documentation.

When you start an upgrade from MySQL 5.7 to 8.0, Amazon RDS runs prechecks automatically to detect these incompatibilities. For information about upgrading to MySQL 8.0, see Upgrading MySQL in the MySQL documentation.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

• They enable you to avoid unplanned downtime during the upgrade.
• If there are incompatibilities, Amazon RDS prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to MySQL 8.0 by eliminating the incompatibilities. For detailed information about removing incompatibilities, see Preparing your installation for upgrade in the MySQL documentation and Upgrading to MySQL 8.0? here is what you need to know... on the MySQL Server Blog.

The prechecks include some that are included with MySQL and some that were created specifically by the Amazon RDS team. For information about the prechecks provided by MySQL, see Upgrade checker utility.

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Amazon RDS automatically cancels the upgrade before the DB instance is stopped. Amazon RDS also generates an event for the incompatibility. For more information about Amazon RDS events, see Using Amazon RDS event notification (p. 623).

Amazon RDS records detailed information about each incompatibility in the log file PrePatchCompatibility.log. In most cases, the log entry includes a link to the MySQL documentation for correcting the incompatibility. For more information about viewing log files, see Viewing and listing database log files (p. 646).

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

Note
Amazon RDS runs all of these prechecks only for an upgrade from MySQL 5.7 to MySQL 8.0. For an upgrade from MySQL 5.6 to MySQL 5.7, prechecks are limited to confirming that there are no orphan tables and that there is enough storage space to rebuild tables. Prechecks aren't run for upgrades to releases lower than MySQL 5.7.

Rollback after failure to upgrade from MySQL 5.7 to 8.0

When you upgrade a DB instance from MySQL version 5.7 to MySQL version 8.0, the upgrade can fail. In particular, it can fail if the data dictionary contains incompatibilities that weren't captured by the prechecks. In this case, the database fails to start up successfully in the new MySQL 8.0 version. At this point, Amazon RDS rolls back the changes performed for the upgrade. After the rollback, the MySQL DB instance is running MySQL version 5.7. When an upgrade fails and is rolled back, Amazon RDS generates an event with the event ID RDS-EVENT-0188.

Typically, an upgrade fails because there are incompatibilities in the metadata between the databases in your DB instance and the target MySQL version. When an upgrade fails, you can view the details about these incompatibilities in the upgradeFailure.log file. Resolve the incompatibilities before attempting to upgrade again.
During an unsuccessful upgrade attempt and rollback, your DB instance is restarted. Any pending parameter changes are applied during the restart and persist after the rollback.

For more information about upgrading to MySQL 8.0, see the following topics in the MySQL documentation:

- Preparing Your Installation for Upgrade
- Upgrading to MySQL 8.0? Here is what you need to know...

**Note**
Currently, automatic rollback after upgrade failure is supported only for MySQL 5.7 to 8.0 major version upgrades.

## Testing an upgrade

Before you perform a major version upgrade on your DB instance, thoroughly test your database for compatibility with the new version. In addition, thoroughly test all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

### To test a major version upgrade

1. Review the upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications:
   - Changes in MySQL 5.6
   - Changes in MySQL 5.7
   - Changes in MySQL 8.0
2. If your DB instance is a member of a custom DB parameter group, create a new DB parameter group with your existing settings that is compatible with the new major version. Specify the new DB parameter group when you upgrade your test instance, so your upgrade testing ensures that it works correctly. For more information about creating a DB parameter group, see Working with parameter groups (p. 278).
3. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot (p. 428).
4. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring from a DB snapshot (p. 432).
5. Modify this new test DB instance to upgrade it to the new version, using one of the methods detailed following. If you created a new parameter group in step 2, specify that parameter group.
6. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
7. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
8. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you don't allow write operations to the DB instance until you confirm that everything is working correctly.

## Upgrading a MySQL DB instance

For information about manually or automatically upgrading a MySQL DB instance, see Upgrading a DB instance engine version (p. 344).
Automatic minor version upgrades for MySQL

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

In the AWS Management Console, these settings are under **Additional configuration**. The following image shows the **Auto minor version upgrade** setting.

![Auto minor version upgrade setting](image)

For more information about these settings, see [Settings for DB instances](p. 310).

For some RDS for MySQL major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MySQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MySQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```bash
```
Automatic minor version upgrades

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].^{
AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}\n" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
--engine-version 8.0.11 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].\n{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}\n" \
--output table
```

Your output is similar to the following.

```
----------------------------------
|    DescribeDBEngineVersions    |
|--------------+-----------------|
|  AutoUpgrade |  EngineVersion  |
|--------------+-----------------|
|  False       |  8.0.15         |
|  False       |  8.0.16         |
|  False       |  8.0.17         |
|  False       |  8.0.19         |
|  False       |  8.0.20         |
|  False       |  8.0.21         |
|  True        |  8.0.23         |
|  False       |  8.0.25         |
`----------------------------------`

In this example, the AutoUpgrade value is True for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

A MySQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
• The DB instance is running a minor DB engine version that is less than the current automatic upgrade
minor version.

For more information, see Automatically upgrading the minor engine version (p. 346).

Using a read replica to reduce downtime when upgrading a MySQL database

If your MySQL DB instance is currently in use with a production application, you can use the following
procedure to upgrade the database version for your DB instance. This procedure can reduce the amount
of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the
necessary changes during the actual outage. With this technique, you can test and prepare the new DB
instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MySQL version 5.7 to MySQL version 8.0.
You can use the same general steps for upgrades to other major versions.

Note
When you are upgrading from MySQL version 5.7 to MySQL version 8.0, complete the prechecks
before performing the upgrade. For more information, see Prechecks for upgrades from MySQL
5.7 to 8.0 (p. 1162).

To upgrade an MySQL database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://
console.aws.amazon.com/rds/.
2. Create a read replica of your MySQL 5.7 DB instance. This process creates an upgradable copy of
your database. Other read replicas of the DB instance might also exist.
   a. In the console, choose Databases, and then choose the DB instance that you want to upgrade.
   b. For Actions, choose Create read replica.
   c. Provide a value for DB instance identifier for your read replica and ensure that the DB instance
class and other settings match your MySQL 5.7 DB instance.
   d. Choose Create read replica.
3. (Optional) When the read replica has been created and Status shows Available, convert the read
replica into a Multi-AZ deployment and enable backups.

By default, a read replicas is created as a single-AZ deployment with backups disabled. Because the
read replica will ultimately become the production DB instance, it is a best practice to configure a
Multi-AZ deployment and enable backups now.

   a. In the console, choose Databases, and then choose the read replica that you just created.
   b. Choose Modify.
   c. For Multi-AZ deployment, choose Create a standby instance.
   d. For Backup Retention Period, choose a positive nonzero value, for example 3 days, and then
choose Continue.
   e. For Scheduling of modifications, choose Apply immediately.
   f. Choose Modify DB instance.
4. When the read replica Status shows Available, upgrade the read replica to MySQL 8.0:
   a. In the console, choose Databases, and then choose the read replica that you just created.
b. Choose Modify.

c. For DB engine version, choose the MySQL 8.0 version to upgrade to, and then choose Continue.

d. For Scheduling of modifications, choose Apply immediately.

e. Choose Modify DB instance to start the upgrade.

5. When the upgrade is complete and Status shows Available, verify that the upgraded read replica is up-to-date with the source MySQL 5.7 DB instance. You can do this by connecting to the read replica and issuing the SHOW REPLICA STATUS command. If the Seconds_Behind_Master field is 0, then replication is up-to-date.

   Note
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

6. (Optional) Create a read replica of your read replica.

   If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

   a. In the console, choose Databases, and then choose the read replica that you just upgraded.

   b. For Actions, choose Create read replica.

   c. Provide a value for DB instance identifier for your read replica and ensure that the DB instance class and other settings match your MySQL 5.7 DB instance.

   d. Choose Create read replica.

7. (Optional) Configure a custom DB parameter group for the read replica.

   If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now and associate it with the read replica.

   a. Create a custom DB parameter group for MySQL 8.0. For instructions, see Creating a DB parameter group (p. 280).

   b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see Modifying parameters in a DB parameter group (p. 282).

   c. In the console, choose Databases, and then choose the read replica.

   d. Choose Modify.

   e. For DB parameter group, choose the MySQL 8.0 DB parameter group you just created, and then choose Continue.

   f. For Scheduling of modifications, choose Apply immediately.

   g. Choose Modify DB instance to start the upgrade.

8. Make your MySQL 8.0 read replica a standalone DB instance.

   Important
   When you promote your MySQL 8.0 read replica to a standalone DB instance, it no longer is a replica of your MySQL 5.7 DB instance. We recommend that you promote your MySQL 8.0 read replica during a maintenance window when your source MySQL 5.7 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MySQL 8.0 DB instance to ensure that no write operations are lost.

   In addition, we recommend that, before promoting your MySQL 8.0 read replica, you perform all necessary data definition language (DDL) operations on your MySQL 8.0 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MySQL 8.0 read replica after it has been promoted. To promote a read replica, use the following procedure.

   a. In the console, choose Databases, and then choose the read replica that you just upgraded.

   b. For Actions, choose Promote.
c. Choose Yes to enable automated backups for the read replica instance. For more information, see Working with backups (p. 407).

d. Choose Continue.

e. Choose Promote Read Replica.

9. You now have an upgraded version of your MySQL database. At this point, you can direct your applications to the new MySQL 8.0 DB instance.
Upgrading a MySQL DB snapshot

With Amazon RDS, you can create a storage volume DB snapshot of your MySQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your Amazon RDS instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots. For example, you can upgrade DB snapshots created from the MySQL 5.1 engine to DB snapshots for the MySQL 5.5 engine. After restoring a DB snapshot upgraded to a new engine version, you should test that the upgrade was successful. To learn how to test a major version upgrade, see Testing an upgrade (p. 1164). To learn how to restore a DB snapshot, see Restoring from a DB snapshot (p. 432).

Amazon RDS supports upgrading a MySQL DB snapshot from MySQL 5.1 to MySQL 5.5.

You can upgrade manual DB snapshots, which can be encrypted or not encrypted, from MySQL 5.1 to MySQL 5.5 within the same AWS Region. You can't upgrade automated DB snapshots that are created during the automated backup process.

**Console**

**To upgrade a DB snapshot**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.
4. Choose the New engine version to upgrade to.
5. Choose Save changes to upgrade the snapshot.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from available to upgrading, and then changes to active upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to unavailable. You can't recover the snapshot from this state.

**Note**

If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

**AWS CLI**

To upgrade a DB snapshot to a new database engine version, use the AWS CLI modify-db-snapshot command.

**Parameters**

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385).
- `--engine-version` – The engine version to upgrade the DB snapshot to.

**Example**

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot
```

```
To upgrade a DB snapshot to a new database engine version, call the Amazon RDS API `ModifyDBSnapshot` operation.

- **DBSnapshotIdentifier** – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385).
- **EngineVersion** – The engine version to upgrade the DB snapshot to.
## Importing data into a MySQL DB instance

You can use several different techniques to import data into an RDS for MySQL DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

### Overview

Find techniques to import data into an RDS for MySQL DB instance in the following table.

<table>
<thead>
<tr>
<th>Source</th>
<th>Amount of data</th>
<th>One time or ongoing</th>
<th>Applicatio downtime</th>
<th>Technique</th>

**Note**

The 'mysql' system database contains authentication and authorization information required to log in to your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the 'mysql' database in your DB instance can result in error and might render the DB instance and your data inaccessible. If this occurs, you can restore the DB instance from a snapshot using the AWS CLI `restore-db-instance-from-db-snapshot` command. You can recover the DB instance using the AWS CLI `restore-db-instance-to-point-in-time` command.
Importing data considerations

Following, you can find additional technical information related to loading data into MySQL. This information is intended for advanced users who are familiar with the MySQL server architecture. All comments related to LOAD DATA LOCAL INFILE also apply to mysqlimport.

Binary log

Data loads incur a performance penalty and require additional free disk space (up to four times more) when binary logging is enabled versus loading the same data with binary logging turned off. The severity of the performance penalty and the amount of free disk space required is directly proportional to the size of the transactions used to load the data.

Transaction size

Transaction size plays an important role in MySQL data loads. It has a major influence on resource consumption, disk space utilization, resume process, time to recover, and input format (flat files or SQL). This section describes how transaction size affects binary logging and makes the case for disabling binary logging during large data loads. As noted earlier, binary logging is enabled and disabled by setting the Amazon RDS automated backup retention period. Non-zero values enable binary logging, and zero disables it. We also describe the impact of large transactions on InnoDB and why it’s important to keep transaction sizes small.

Small transactions

For small transactions, binary logging doubles the number of disk writes required to load the data. This effect can severely degrade performance for other database sessions and increase the time required to load the data. The degradation experienced depends in part upon the upload rate, other database activity taking place during the load, and the capacity of your Amazon RDS DB instance.

The binary logs also consume disk space roughly equal to the amount of data loaded until they are backed up and removed. Fortunately, Amazon RDS minimizes this by backing up and removing binary logs on a frequent basis.

Large transactions

Large transactions incur a 3X penalty for IOPS and disk consumption with binary logging enabled. This is due to the binary log cache spilling to disk, consuming disk space and incurring additional IO for each write. The cache cannot be written to the binlog until the transaction commits or rolls back, so it consumes disk space in proportion to the amount of data loaded. When the transaction commits, the cache must be copied to the binlog, creating a third copy of the data on disk.

Because of this, there must be at least three times as much free disk space available to load the data compared to loading with binary logging disabled. For example, 10 GiB of data loaded as a single transaction consumes at least 30 GiB disk space during the load. It consumes 10 GiB for the table + 10 GiB for the binary log cache + 10 GiB for the binary log itself. The cache file remains on disk until the session that created it terminates or the session fills its binary log cache again during another transaction. The binary log must remain on disk until backed up, so it might be some time before the extra 20 GiB is freed.

If the data was loaded using LOAD DATA LOCAL INFILE, yet another copy of the data is created if the database has to be recovered from a backup made before the load. During recovery, MySQL extracts the data from the binary log into a flat file. MySQL then runs LOAD DATA LOCAL INFILE, just as in the original transaction. However, this time the input file is local to the database server. Continuing with the example preceding, recovery fails unless there is at least 40 GiB free disk space available.
Disable binary logging

Whenever possible, disable binary logging during large data loads to avoid the resource overhead and addition disk space requirements. In Amazon RDS, disabling binary logging is as simple as setting the backup retention period to zero. If you do this, we recommend that you take a DB snapshot of the database instance immediately before the load. By doing this, you can quickly and easily undo changes made during loading if you need to.

After the load, set the backup retention period back to an appropriate (no zero) value.

You can't set the backup retention period to zero if the DB instance is a source DB instance for read replicas.

InnoDB

The information in this section provides a strong argument for keeping transaction sizes small when using InnoDB.

Undo

InnoDB generates undo to support features such as transaction rollback and MVCC. Undo is stored in the InnoDB system tablespace (usually ibdata1) and is retained until removed by the purge thread. The purge thread cannot advance beyond the undo of the oldest active transaction, so it is effectively blocked until the transaction commits or completes a rollback. If the database is processing other transactions during the load, their undo also accumulates in the system tablespace and cannot be removed even if they commit and no other transaction needs the undo for MVCC. In this situation, all transactions (including read-only transactions) that access any of the rows changed by any transaction (not just the load transaction) slow down. The slowdown occurs because transactions scan through undo that could have been purged if not for the long-running load transaction.

Undo is stored in the system tablespace, and the system tablespace never shrinks in size. Thus, large data load transactions can cause the system tablespace to become quite large, consuming disk space that you can't reclaim without recreating the database from scratch.

Rollback

InnoDB is optimized for commits. Rolling back a large transaction can take a very, very long time. In some cases, it might be faster to perform a point-in-time recovery or restore a DB snapshot.

Input data format

MySQL can accept incoming data in one of two forms: flat files and SQL. This section points out some key advantages and disadvantages of each.

Flat files

Loading flat files with LOAD DATA LOCAL INFILE can be the fastest and least costly method of loading data as long as transactions are kept relatively small. Compared to loading the same data with SQL, flat files usually require less network traffic, lowering transmission costs and load much faster due to the reduced overhead in the database.

One big transaction

LOAD DATA LOCAL INFILE loads the entire flat file as one transaction. This isn't necessarily a bad thing. If the size of the individual files can be kept small, this has a number of advantages:

- Resume capability – Keeping track of which files have been loaded is easy. If a problem arises during the load, you can pick up where you left off with little effort. Some data might have to be retransmitted to Amazon RDS, but with small files, the amount retransmitted is minimal.
• Load data in parallel – If you've got IOPS and network bandwidth to spare with a single file load, loading in parallel might save time.

• Throttle the load rate – Data load having a negative impact on other processes? Throttle the load by increasing the interval between files.

Be careful

The advantages of LOAD DATA LOCAL INFILE diminish rapidly as transaction size increases. If breaking up a large set of data into smaller ones isn't an option, SQL might be the better choice.

SQL

SQL has one main advantage over flat files: it's easy to keep transaction sizes small. However, SQL can take significantly longer to load than flat files and it can be difficult to determine where to resume the load after a failure. For example, mysqldump files are not restartable. If a failure occurs while loading a mysqldump file, the file requires modification or replacement before the load can resume. The alternative is to restore to the point in time before the load and replay the file after the cause of the failure has been corrected.

Take checkpoints using Amazon RDS snapshots

If you have a load that's going to take several hours or even days, loading without binary logging isn't a very attractive prospect unless you can take periodic checkpoints. This is where the Amazon RDS DB snapshot feature comes in very handy. A DB snapshot creates a point-in-time consistent copy of your database instance which can be used restore the database to that point in time after a crash or other mishap.

To create a checkpoint, simply take a DB snapshot. Any previous DB snapshots taken for checkpoints can be removed without affecting durability or restore time.

Snapshots are fast too, so frequent checkpointing doesn't add significantly to load time.

Decreasing load time

Here are some additional tips to reduce load times:

• Create all secondary indexes before loading. This is counter-intuitive for those familiar with other databases. Adding or modifying a secondary index causes MySQL to create a new table with the index changes, copy the data from the existing table to the new table, and drop the original table.

• Load data in PK order. This is particularly helpful for InnoDB tables, where load times can be reduced by 75–80 percent and data file size cut in half.

• Disable foreign key constraints foreign_key_checks=0. For flat files loaded with LOAD DATA LOCAL INFILE, this is required in many cases. For any load, disabling FK checks provides significant performance gains. Just be sure to enable the constraints and verify the data after the load.

• Load in parallel unless already near a resource limit. Use partitioned tables when appropriate.

• Use multi-value inserts when loading with SQL to minimize overhead when running statements. When using mysqldump, this is done automatically.

• Reduce InnoDB log IO innodb Flush_log_at_trx_commit=0

• If you are loading data into a DB instance that does not have read replicas, set the sync_binlog parameter to 0 while loading data. When data loading is complete, set the sync_binlog parameter to back to 1.

• Load data before converting the DB instance to a Multi-AZ deployment. However, if the DB instance already uses a Multi-AZ deployment, switching to a Single-AZ deployment for data loading is not recommended, because doing so only provides marginal improvements.
**Note**
Using `innodb_flush_log_at_trx_commit=0` causes InnoDB to flush its logs every second instead of at each commit. This provides a significant speed advantage, but can lead to data loss during a crash. Use with caution.

**Topics**
- Restoring a backup into a MySQL DB instance (p. 1178)
- Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance (p. 1186)
- Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1188)
- Importing data from any source to a MariaDB or MySQL DB instance (p. 1201)
Restoring a backup into a MySQL DB instance

Amazon RDS supports importing MySQL databases by using backup files. You can create a backup of your database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL.

The scenario described in this section restores a backup of an on-premises database. You can use this technique for databases in other locations, such as Amazon EC2 or non-AWS cloud services, as long as the database is accessible.

You can find the supported scenario in the following diagram.

Importing backup files from Amazon S3 is supported for MySQL version 5.6, 5.7, and 8.0. Importing backup files from Amazon S3 is available in all AWS Regions.

We recommend that you import your database to Amazon RDS by using backup files if your on-premises database can be offline while the backup file is created, copied, and restored. If your database can't be offline, you can use binary log (binlog) replication to update your database after you have migrated to Amazon RDS through Amazon S3 as explained in this topic. For more information, see Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 1222). You can also use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see What is AWS Database Migration Service?

Limitations and recommendations for importing backup files from Amazon S3 to Amazon RDS

The following are some limitations and recommendations for importing backup files from Amazon S3:

- You can only import your data to a new DB instance, not an existing DB instance.
- You must use Percona XtraBackup to create the backup of your on-premises database.
- You can't migrate from a source database that has tables defined outside of the default MySQL data directory.
- You must import your data to the default minor version of your MySQL major version in your AWS Region. For example, if your major version is MySQL 5.6, and the default minor version for your AWS Region is 5.6.51, then you must import your data into a MySQL version 5.6.51 DB instance. You can
upgrade your DB instance after importing. For information about determining the default minor version, see MySQL on Amazon RDS versions (p. 1133).

- Backward migration is not supported for both major versions and minor versions. For example, you can't migrate from version 5.7 to version 5.6, and you can't migrate from version 5.6.39 to version 5.6.37.

- You can't import a MySQL 5.5 database.

- You can't import an on-premises MySQL database from one major version to another. For example, you can't import a MySQL 5.6 database to an Amazon RDS MySQL 5.7 or 8.0 database. Similarly, you can't import a MySQL 5.7 database to an RDS for MySQL 8.0 database. You can upgrade your DB instance after you complete the import.

- You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.

- You can't restore from an encrypted backup in the Amazon S3 bucket.

- You can't restore from an Amazon S3 bucket in a different AWS Region than your Amazon RDS DB instance.

- Importing from Amazon S3 is not supported on the db.t2.micro DB instance class. However, you can restore to a different DB instance class, and change the DB instance class later. For more information about instance classes, see Hardware specifications for DB instance classes (p. 44).

- Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.

- When you restore the database, the backup is copied and then extracted on your DB instance. Therefore, provision storage space for your DB instance that is equal to or greater than the sum of the backup size, plus the original database's size on disk.

- Amazon RDS limits the number of files uploaded to an Amazon S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (.gz), tar (.tar.gz), or Percona xbstream (.xbstream) file to store full and incremental backup files in the Amazon S3 bucket. Percona XtraBackup 8.0 only supports Percona xbstream for compression.

- User accounts are not imported automatically. Save your user accounts from your source database and add them to your new DB instance later.

- Functions are not imported automatically. Save your functions from your source database and add them to your new DB instance later.

- Stored procedures are not imported automatically. Save your stored procedures from your source database and add them to your new DB instance later.

- Time zone information is not imported automatically. Record the time zone information for your source database, and set the time zone of your new DB instance later. For more information, see Local time zone for MySQL DB instances (p. 1142).

- The innodb_data_file_path parameter must be configured with only one data file that uses the default data file name "ibdata1:12M:autoextend". Databases with two data files, or with a data file with a different name, can't be migrated using this method.

The following are examples of file names that are not allowed:

"innodb_data_file_path=ibdata1:50M; ibdata2:50M:autoextend" and
"innodb_data_file_path=ibdata01:50M:autoextend".

- The maximum size of the restored database is the maximum database size supported minus the size of the backup. So, if the maximum database size supported is 64 TiB, and the size of the backup is 30 TiB, then the maximum size of the restored database is 34 TiB, as in the following example:

  \[64 \text{ TiB} - 30 \text{ TiB} = 34 \text{ TiB}\]

For information about the maximum database size supported by Amazon RDS for MySQL, see General Purpose SSD storage (p. 53) and Provisioned IOPS SSD storage (p. 55).
Overview of setting up to import backup files from Amazon S3 to Amazon RDS

These are the components you need to set up to import backup files from Amazon S3 to Amazon RDS:

- An Amazon S3 bucket to store your backup files.
- A backup of your on-premises database created by Percona XtraBackup.
- An AWS Identity and Access Management (IAM) role to allow Amazon RDS to access the bucket.

If you already have an Amazon S3 bucket, you can use that. If you don't have an Amazon S3 bucket, you can create a new one. If you want to create a new bucket, see Creating a bucket.

Use the Percona XtraBackup tool to create your backup. For more information, see Creating your database backup (p. 1180).

If you already have an IAM role, you can use that. If you don't have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you in your account by the wizard when you restore the database by using the AWS Management Console. If you want to create a new IAM role manually, or attach trust and permissions policies to an existing IAM role, see Creating an IAM role manually (p. 1182). If you want to have a new IAM role created for you, follow the procedure in Console (p. 1183).

Creating your database backup

Use the Percona XtraBackup software to create your backup. You can install Percona XtraBackup from Download Percona XtraBackup.

**Warning**
When creating a database backup, XtraBackup might save credentials in the xtrabackup_info file. Make sure you examine that file so that the tool_command setting in it doesn't contain any sensitive information.

**Note**
For MySQL 8.0 migration, you must use Percona XtraBackup 8.0. Percona XtraBackup 8.0.12 and higher versions support migration of all versions of MySQL. If you are migrating to RDS for MySQL 8.0.20 or higher, you must use Percona XtraBackup 8.0.12 or higher.
For MySQL 5.7 migrations, you can also use Percona XtraBackup 2.4. For migrations of earlier MySQL versions, you can also use Percona XtraBackup 2.3 or 2.4.

You can create a full backup of your MySQL database files using Percona XtraBackup. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files.

For more information about backing up your database with Percona XtraBackup, see Percona XtraBackup documentation and The xtrabackup binary on the Percona website.

Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3, use the Percona XtraBackup utility (xtrabackup) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the folder /on-premises/s3-restore/backup folder.

```
xtrabackup --backup --user=myuser --password=password --target-dir=/on-premises/s3-restore/backup
```
If you want to compress your backup into a single file (which can be split later, if needed), you can save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xbstream (.xbstream)

**Note**
Percona XtraBackup 8.0 only supports Percona xbstream for compression.

The following command creates a backup of your MySQL database split into multiple Gzip files.

```bash
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar --target-dir=/on-premises/s3-restore/backup | gzip - | split -d --bytes=500MB -/on-premises/s3-restore/backup/backup.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```bash
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB -/on-premises/s3-restore/backup/backup.tar
```

The following command creates a backup of your MySQL database split into multiple xbstream files.

```bash
xtrabackup --backup --user=<myuser> --password=<password> --stream=xbstream --target-dir=/on-premises/s3-restore/backup | split -d --bytes=500MB -/on-premises/s3-restore/backup/backup.xbstream
```

**Using incremental backups with Percona XtraBackup**

If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files to your Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see Incremental backup.

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Amazon RDS iterates through all files and directories. Amazon RDS uses the `xtrabackup-checkpoints` file that is included with each incremental backup to identify the base directory, and to order incremental backups by log sequence number (LSN) range.

**Backup considerations for Percona XtraBackup**

Amazon RDS consumes your backup files based on the file name. Name your backup files with the appropriate file extension based on the file format—for example, `.xbstream` for files stored using the Percona xbstream format.

Amazon RDS consumes your backup files in alphabetical order and also in natural number order. Use the `split` option when you issue the `xtrabackup` command to ensure that your backup files are written and named in the proper order.

Amazon RDS doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database:
tables, --tables-exclude, --tables-file, --databases, --databases-exclude, or --databases-file.

Amazon RDS supports incremental backups created using Percona XtraBackup. For more information about creating incremental backups using Percona XtraBackup, see Incremental backup.

Creating an IAM role manually

If you don’t have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in Console (p. 1183).

To manually create a new IAM role for importing your database from Amazon S3, create a role to delegate permissions from Amazon RDS to your Amazon S3 bucket. When you create an IAM role, you attach trust and permissions policies. To import your backup files from Amazon S3, use trust and permissions policies similar to the examples following. For more information about creating the role, see Creating a role to delegate permissions to an AWS service.

Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in Console (p. 1183).

The trust and permissions policies require that you provide an Amazon Resource Name (ARN). For more information about ARN formatting, see Amazon Resource Names (ARNs) and AWS service namespaces.

Example Trust policy for importing from Amazon S3

```
{
   "Version": "2012-10-17",
   "Statement":
   [
       {
           "Effect": "Allow",
           "Principal": {"Service": "rds.amazonaws.com"},
           "Action": "sts:AssumeRole"
       }
   ]
}
```

Example Permissions policy for importing from Amazon S3 — IAM user permissions

```
{
   "Version": "2012-10-17",
   "Statement":
   [
       {
           "Sid": "AllowS3AccessRole",
           "Effect": "Allow",
           "Action": "iam:PassRole",
           "Resource": "arn:aws:iam::IAM User ID:role/S3Access"
       }
   ]
}
```

Example Permissions policy for importing from Amazon S3 — role permissions

```
{
   "Version": "2012-10-17",
   "Statement":
   [
       {
           "Sid": "AllowS3AccessRole",
           "Effect": "Allow",
           "Action": "iam:PassRole",
           "Resource": "arn:aws:iam::IAM User ID:role/S3Access"
       }
   ]
}
```
"Statement":
[
  {
    "Effect": "Allow",
    "Action":
      [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
    "Resource": "arn:aws:s3:::bucket_name"
  },
  {
    "Effect": "Allow",
    "Action":
      [
        "s3:GetObject"
      ],
    "Resource": "arn:aws:s3:::bucket_name/prefix*"
  }
]}

Note
If you include a file name prefix, include the asterisk (*) after the prefix. If you don't want to specify a prefix, specify only an asterisk.

Importing data from Amazon S3 to a new MySQL DB instance

You can import data from Amazon S3 to a new MySQL DB instance using the AWS Management Console, AWS CLI, or RDS API.

Console

To import data from Amazon S3 to a new MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB instance. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose Databases.
4. Choose Restore from S3.

The Create database by restoring from S3 page appears.
Create database by restoring from S3

S3 destination

Write audit logs to S3
Enter a destination in Amazon S3 where your audit logs will be stored. Amazon S3 is object storage build to store and retrieve any amount of data from anywhere.

S3 bucket

- test-etu1-bucket

S3 prefix (optional)

Engine options

Engine type

- Amazon Aurora
- MySQL

Edition

- MySQL Community

Source engine version

- 5.6

Version

- MySQL 5.6.44

Known Issues/Limitations

Review the Known Issues/Limitations to learn about potential compatibility issues with specific database versions.

IAM role

IAM role

Choose or create an IAM role to grant write access to your S3 bucket.

Choose an option

Settings

DB instance identifier

Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.
5. Under **S3 destination**:
   a. Choose the **S3 bucket** where to write audit logs.
   b. (Optional) For **S3 folder path prefix**, enter a file path prefix for the files stored in your Amazon S3 bucket.

   If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

   For example, suppose that you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, you specify a prefix of backups/gzip_backup1 to restore from the files in the gzip_backup1 folder.

6. Under **Engine options**:
   a. For **Engine type**, choose **MySQL**.
   b. For **Source engine version**, choose the MySQL major version of your source database.
   c. For **Version**, choose the default minor version of your MySQL major version in your AWS Region.

   In the AWS Management Console, only the default minor version is available. You can upgrade your DB instance after importing.

7. For **IAM role**, you can choose an existing IAM role.

8. (Optional) You can also have a new IAM role created for you by choosing **Create a new role** and entering the **IAM role name**.

9. Specify your DB instance information. For information about each setting, see **Settings for DB instances (p. 178)**.

   **Note**
   Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.
   You can also choose **Enable storage autoscaling** to allow for future growth automatically.

10. Choose additional settings as needed.

11. Choose **Create database**.

**AWS CLI**

To import data from Amazon S3 to a new MySQL DB instance by using the AWS CLI, call the `restore-db-instance-from-s3` command with the following parameters. For information about each setting, see **Settings for DB instances (p. 178)**.

**Note**
Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.
You can also use the `--max-allocated-storage` parameter to enable storage autoscaling and allow for future growth automatically.

- `--allocated-storage`
- `--db-instance-identifier`
- `--db-instance-class`
- `--engine`
- `--master-username`
- `--master-user-password`
- `--s3-bucket-name`
Importing data from an external database

- --s3-ingestion-role-arn
- --s3-prefix
- --source-engine
- --source-engine-version

Example

For Linux, macOS, or Unix:

```bash
aws rds restore-db-instance-from-s3
  --allocated-storage 250
  --db-instance-identifier myidentifier
  --db-instance-class db.m5.large
  --engine mysql
  --master-username admin
  --master-user-password mypassword
  --s3-bucket-name mybucket
  --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename
  --s3-prefix bucketprefix
  --source-engine mysql
  --source-engine-version 5.6.51
  --max-allocated-storage 1000
```

For Windows:

```bash
aws rds restore-db-instance-from-s3
  --allocated-storage 250
  --db-instance-identifier myidentifier
  --db-instance-class db.m5.large
  --engine mysql
  --master-username admin
  --master-user-password mypassword
  --s3-bucket-name mybucket
  --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename
  --s3-prefix bucketprefix
  --source-engine mysql
  --source-engine-version 5.6.51
  --max-allocated-storage 1000
```

RDS API

To import data from Amazon S3 to a new MySQL DB instance by using the Amazon RDS API, call the RestoreDBInstanceFromS3 operation.

Importing data from a MariaDB or MySQL database to a MariaDB or MySQL DB instance

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with mysqldump and piping it directly into the MariaDB or MySQL DB instance. The mysqldump command line utility is commonly used to make backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.

Note

If you are using a MySQL DB instance and your scenario supports it, it's easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance (p. 1178).
A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```
mysqldump -u local_user \
  --databases database_name \
  --single-transaction \
  --compress \
  --order-by-primary \n  -plocal_password | mysql -u RDS_user \
  --port=port_number \
  --host=host_name \n  -pRDS_password
```

**Important**
Make sure not to leave a space between the `-p` option and the entered password.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see Controlling access with security groups (p. 1822).

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases database_name` – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-plocal_password` – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u RDS_user` – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port port_number` – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host host_name` – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `-pRDS_password` – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when...
you run `mysqldump`. To do so, include the following parameters with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

The following example copies the `world` sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```bash
sudo mysqldump -u localuser \
  --databases world \
  --single-transaction \
  --compress \
  --order-by-primary \
  --routines=0 \
  --events=0 \
  -plocalpassword | mysql -u rdsuser \
      --single-transaction \
      --compress \
      --order-by-primary \
      --routines=0 \
      --events=0 \
      -plocalpassword | mysql -u rdsuser \
      --port=3306 \
      --host=myinstance.123456789012.us-east-1.rds.amazonaws.com \
      -prdspassword
```

For Windows, run the following command in a command prompt that has been opened by right-clicking Command Prompt on the Windows programs menu and choosing Run as administrator:

```bash
mysqldump -u localuser ^
  --databases world ^
  --single-transaction ^
  --compress ^
  --order-by-primary ^
  --routines=0 ^
  --events=0 ^
  -plocalpassword | mysql -u rdsuser ^
      --single-transaction ^
      --compress ^
      --order-by-primary ^
      --routines=0 ^
      --events=0 ^
      -plocalpassword | mysql -u rdsuser ^
      --port=3306 ^
      --host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^
      -prdspassword
```

**Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime**

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB or MySQL DB instance. In these cases, you can use the following procedure to minimize the impact on application availability. This procedure can also help if you are working with a very large database. Here, the procedure helps because you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS DB instance. You then use replication to bring the Amazon RDS DB instance up-to-date with your live external instance, before redirecting your application to the Amazon RDS DB instance. You configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, you configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it due to its enhanced crash-safety features. For more information, see Global transaction ID in the MariaDB documentation.

**Note**

If you want to import data into a MySQL DB instance and your scenario supports it, it is easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see Restoring a backup into a MySQL DB instance (p. 1178).
Create a copy of your existing database

The first step in the process of migrating a large amount of data to an Amazon RDS MariaDB or MySQL DB instance with minimal downtime is to create a copy of the source data.

Note
We don't recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5, due to potential replication issues. For more information, see Replication compatibility between MySQL versions in the MySQL documentation.
You can use the mysqldump utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a nonproduction environment to see which method minimizes the amount of time that mysqldump runs.

We also recommend that you weigh mysqldump performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE` command. For more information about choosing a mysqldump format and then loading the data, see Using mysqldump for backups in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

**Note**

Use the `--single-transaction` option with mysqldump because it dumps a consistent state of the database. To ensure a valid dump file, don’t run data definition language (DDL) statements while mysqldump is running. You can schedule a maintenance window for these operations.

Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The mysqldump utility excludes these schemas by default.

To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the `pt-show-grants` utility.

**To set replication options**

1. Edit the `my.cnf` file (this file is usually under `/etc`).

   ```bash
   sudo vi /etc/my.cnf
   ```

   Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

   The following example shows the updated `[mysqld]` section of a `my.cnf` file.

   ```ini
   [mysqld]
   log-bin=mysql-bin
   server-id=1
   ```

   For more information, see the MySQL documentation.

2. Restart the `mysql` service.

   ```bash
   sudo service mysqld restart
   ```

**To create a backup copy of your existing database**

1. Create a backup of your data using the mysqldump utility, specifying either SQL or delimited-text format.

   Specify `--master-data=2` to create a backup file that can be used to start replication between servers. For more information, see the mysqldump documentation.
To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options of `mysqldump`.

To avoid including the MySQL system database in the backup, do not use the `--all-databases` option with `mysqldump`. For more information, see Creating a data snapshot using `mysqldump` in the MySQL documentation.

Use `chmod` if necessary to make sure that the directory where the backup file is being created is writeable.

**Important**

On Windows, run the command window as an administrator.

- To produce SQL output, use the following command.

  For Linux, macOS, or Unix:

  ```bash
  sudo mysqldump
  --databases database_name
  --master-data=2
  --single-transaction
  --order-by-primary
  -r backup.sql
  -u local_user
  -p password
  ```

  For Windows:

  ```bash
  mysqldump
  --databases database_name
  --master-data=2
  --single-transaction
  --order-by-primary
  -r backup.sql
  -u local_user
  -p password
  ```

- To produce delimited-text output, use the following command.

  For Linux, macOS, or Unix:

  ```bash
  sudo mysqldump
  --tab=target_directory
  --fields-terminated-by ','
  --fields-enclosed-by '"'
  --lines-terminated-by 0x0d0a
  database_name
  --master-data=2
  --single-transaction
  --order-by-primary
  -p password
  ```

  For Windows:

  ```bash
  mysqldump
  --tab=target_directory
  --fields-terminated-by ','
  --fields-enclosed-by '"'
  --lines-terminated-by 0x0d0a
  database_name
  ```
importing data to a DB instance with reduced downtime

```bash
--master-data=2
--single-transaction
--order-by-primary
-p password
```

**Note**
Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run mysqldump. To do so, include the following arguments with your mysqldump command: `--routines=0 --triggers=0 --events=0`.

When using the delimited-text format, a `CHANGE MASTER TO` comment is returned when you run mysqldump. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

```bash
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in the `CHANGE MASTER TO` comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```sql
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS DB instance. Take note of the size of the backup file; you need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

- To compress SQL output, use the following command.

  ```bash
gzip backup.sql
  ```

- To compress delimited-text output, use the following command.

  ```bash
tar -zcvf backup.tar.gz target_directory
  ```

Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL DB instance. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS DB instance also reduces network latency during the import.
To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS DB instance to run your MySQL database engine, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. This can be a range of IP addresses (for example, 203.0.113.0/24), or another VPC security group. You can use the Amazon VPC Management Console to create and manage VPCs, subnets, and security groups. For more information, see Getting started with Amazon VPC in the Amazon Virtual Private Cloud Getting Started Guide.

   Note
   Older AWS accounts can also launch instances in EC2-Classic mode. In this case, make sure that the inbound rules in the DB security group for your Amazon RDS instance allow access for your EC2-Classic instance using the Amazon EC2 private IP address. For more information, see Working with DB security groups (EC2-Classic platform) (p. 1827).

2. Open the Amazon EC2 Management Console and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS DB instance. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see Getting started with Amazon EC2 Linux instances in the Amazon Elastic Compute Cloud User Guide for Linux.

3. To connect to your Amazon RDS DB instance from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the Details tab of the Instance pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose Security Groups in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see Adding and removing rules in the Amazon VPC User Guide.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use chmod if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use scp or a Secure Shell (SSH) client to copy the file. The following is an example.
$ scp -r -i key pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz

**Important**  
Be sure to copy sensitive data using a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```
sudo yum update -y
sudo yum install mysql -y
```

For more information, see [Connect to your instance](https://docs.aws.amazon.com/AmazonElasticComputeCloud/latest/UserGuide), in the *Amazon Elastic Compute Cloud User Guide for Linux*.

**Important**  
This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or RedHat Enterprise Linux, this example doesn’t work. For information about installing MySQL, see [Installing and Upgrading MySQL](https://dev.mysql.com/doc/) in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.

   - To decompress SQL output, use the following command.

     ```
     gzip backup.sql.gz -d
     ```

   - To decompress delimited-text output, use the following command.

     ```
     tar xzvf backup.tar.gz
     ```

**Create a MySQL or MariaDB DB instance and import data from your Amazon EC2 instance**

By creating a MariaDB or MySQL DB instance in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.
To create a MariaDB or MySQL DB instance and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS DB instance. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see DB instance classes (p. 9).

2. Determine if Amazon RDS provisioned I/O operations per second (IOPS) is required to support the workloads. Provisioned IOPS storage delivers fast throughput for online transaction processing (OLTP) workloads, which are I/O intensive. For more information, see Provisioned IOPS SSD storage (p. 55).

3. Open the Amazon RDS console. In the upper-right corner, choose the AWS Region that contains your Amazon EC2 instance.

4. In the navigation pane, choose Databases.

5. Choose Create database, and then go through the steps to choose options for your DB instance:
   a. Make sure that Standard Create is chosen.
   b. In the Engine options section, choose MySQL or MariaDB, as appropriate.
   c. For Version, choose the version that is compatible with your source MySQL instance, as follows:
      - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL 5.5.x or greater.
      - If your source instance is MySQL 5.6.x, the Amazon RDS DB instance must be MySQL 5.6.x or MariaDB.
      - If your source instance is MySQL 5.7.x, the Amazon RDS DB instance must be MySQL 5.7.x, 5.6.x, or MariaDB.
      - If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
      - If your source instance is MariaDB 5.5 or greater, the Amazon RDS DB instance must be MariaDB.
   d. In the Templates section, choose Dev/Test to skip configuring Multi-AZ deployment and provisioned IOPS storage.
e. In the **Settings** section, specify the requested **DB instance identifier** and user information.

f. In the **DB instance class** and **Storage** sections, specify the DB instance class and allocated storage size that you want.

g. In the **Availability & durability** section, choose **Do not create a standby instance** for Multi-AZ deployment.

h. In the **Connectivity** section, choose the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Set **Publicly accessible** to **Yes**. To set up replication with your source database as described later, your DB instance must be publicly accessible.

Use the default values for the other settings in this section.

In the **Backup** section, set the backup retention period to **0 days**.

Use the default values for the other settings in this section.

i. Open the **Additional configuration** section, and specify an **Initial database name**.

    Set the **Backup retention period** to **0 days**

Use the default values for the other settings in this section.

j. Choose **Create database**.

    Your new DB instance appears in the **Databases** list with the status **Creating**. Wait for the **Status** of your new DB instance to show as **Available**.

Don’t configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is done, you can set Multi-AZ and backup retention the way that you want them for the production instance. For a detailed walkthrough of creating a DB instance, see Creating an Amazon RDS DB instance (p. 175).

6. Review the default configuration options for the Amazon RDS DB instance. In the RDS console navigation pane, choose **Parameter groups**, and then choose the magnifying glass icon next to the **default.mysqlx.x** or **default.mariadbx.x** parameter group. If this parameter group doesn’t have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see Working with parameter groups (p. 278).

To use a different parameter group than the default, associate it with your Amazon RDS DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).

7. Connect to the new Amazon RDS DB instance as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The host name for the Amazon RDS DB instance is the **Endpoint** value for this instance without including the port number. An example is `mysampledb.claxc2oy9ak1.us-west-2.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

8. Connect to your Amazon EC2 instance. For more information, see Connect to your instance in the Amazon Elastic Compute Cloud User Guide for Linux.

9. Connect to your Amazon RDS DB instance as a remote host from your Amazon EC2 instance using the `mysql` command. The following is an example.

    ```
    mysql -h host_name -P 3306 -u db_master_user -p
    ```

    The host name is the DNS name from the Amazon RDS DB instance endpoint.

10. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:
• For SQL format, use the following command.

```sql
mysql> source backup.sql;
```

• For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS DB instance.

```sql
mysql> create database database_name;
$ mysql> use database_name;
```

Then create the tables.

```sql
mysql> source table1.sql
$ mysql> source table2.sql
etc...
```

Then import the data.

```sql
mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
$ mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY ',' ENCLOSED BY '"' LINES TERMINATED BY '0x0d0a';
etc...
```

To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables get created and then loaded at the same time.

**Note**

If you used any data-formatting options with mysqldump when you initially dumped the table, make sure to use the same options with mysqlimport or LOAD DATA LOCAL INFILE to ensure proper interpretation of the data file contents.

11. Run a simple SELECT query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see Terminating an instance in the Amazon EC2 User Guide.

**Replicate between your external database and new Amazon RDS DB instance**

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL DB instance. That being the case, you can use replication to bring the copied database up-to-date with the source database.
The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the Amazon RDS mysql.rds_set_external_master (p. 1266) command or the mysql.rds_set_external_master_gtid (p. 917) command to configure replication, and the mysql.rds_start_replication (p. 1277) command to start replication between your live database and your Amazon RDS database.

**To start replication**

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS DB instance as a replica with your live database as the source replication instance.

1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance, so that it can communicate with your source instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

**MySQL 5.5, 5.6, and 5.7**

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```
MySQL 8.0

CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';

3. For the source instance, grant REPLICATION_CLIENT and REPLICATION_SLAVE privileges to your replication user. For example, to grant the REPLICATION_CLIENT and REPLICATION_SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

MySQL 5.5, 5.6, and 5.7

GRANT REPLICATION_CLIENT, REPLICATION_SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';

MySQL 8.0

GRANT REPLICATION_CLIENT, REPLICATION_SLAVE ON *.* TO 'repl_user'@'mydomain.com';

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

```bash
cat backup.sql
```

The file includes a CHANGE MASTER TO comment that contains the master log file name and position. This comment is included in the backup file when you use the --master-data option with mysqldump. Note the values for MASTER_LOG_FILE and MASTER_LOG_POS.

```sql
-- Position to start replication or point-in-time recovery from
--
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.

If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at "To create a backup copy of your existing database" in this topic.

5. Make the Amazon RDS DB instance the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the mysql.rds_set_external_master (p. 1266) command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```sql
CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the mysql.rds_set_external_master_gtid (p. 917) command. Use the GTID that you determined in step 2 of the procedure at "To create a backup copy of your existing database" in this topic. The following is an example.
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306, 'ReplicationUser', 'password', 'GTID', 0);

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

6. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication (p. 1277)` command to start replication.

CALL mysql.rds_start_replication;

7. On the Amazon RDS DB instance, run the `SHOW REPLICA STATUS` command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For a MariaDB 10.5 or 10.6 DB instance, run the `mysql.rds_replica_status (p. 916)` procedure instead of the MySQL command.

8. After the Amazon RDS DB instance is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS DB instance using the Amazon RDS Management Console. For more information, see Working with backups (p. 407).

Redirect your live application to your Amazon RDS instance

After the MariaDB or MySQL DB instance is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.
To redirect your live application to your MariaDB or MySQL DB instance and stop replication

1. To add the VPC security group for the Amazon RDS DB instance, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

2. Verify that the Seconds_Behind_Master field in the SHOW REPLICA STATUS command results is 0, which indicates that the replica is up-to-date with the source replication instance.

   SHOW REPLICA STATUS;

   **Note**
   Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

   For a MariaDB 10.5 or 10.6 DB instance, run the mysql.rds_replica_status (p. 916) procedure instead of the MySQL command.

3. Close all connections to the source when their transactions complete.

4. Update your application to use the Amazon RDS DB instance. This update typically involves changing the connection settings to identify the host name and port of the Amazon RDS DB instance, the user account and password to connect with, and the database to use.

5. Stop replication for the Amazon RDS instance using the mysql.rds_stop_replication (p. 1279) command.

   CALL mysql.rds_stop_replication;

6. Run the mysql.rds_reset_external_master (p. 1273) command on your Amazon RDS DB instance to reset the replication configuration so this instance is no longer identified as a replica.

   CALL mysql.rds_reset_external_master;

7. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see Multi-AZ deployments for high availability (p. 65) and Working with read replicas (p. 354).

Importing data from any source to a MariaDB or MySQL DB instance

If you have more than 1 GiB of data to load, or if your data is coming from somewhere other than a MariaDB or MySQL database, we recommend creating flat files and loading them with mysqlimport. The mysqlimport utility is another command line utility bundled with the MySQL and MariaDB client software. Its purpose is to load flat files into MySQL or MariaDB. For information about mysqlimport, see mysqlimport - a data import program in the MySQL documentation.

We also recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.
The following list shows the steps to take. Each step is discussed in more detail following.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.
5. Load the data using mysqlimport.
6. Enable automated backups again.

### Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is `sales`, the file name might be `sales.csv` or `sales.txt`, but not `sales_01.csv`.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the `split` command. For example, the following command splits the `sales.csv` file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The new files are named `sales.part_00`, `sales.part_01`, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.

### Step 2: Stop any applications accessing the target DB instance

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

### Step 3: Create a DB snapshot

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of the AcmeRDS instance and give the DB snapshot the identifier "preload".

```
For Linux, macOS, or Unix:
```

1202
Importing data from any source

```
aws rds create-db-snapshot
   --db-instance-identifier AcmeRDS
   --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot
   --db-instance-identifier AcmeRDS
   --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, AcmeRDS-2" is the identifier. The example connects to the DB instance using the endpoint associated with AcmeRDS-2.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot
   --db-instance-identifier AcmeRDS-2
   --db-snapshot-identifier preload
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot
   --db-instance-identifier AcmeRDS-2
   --db-snapshot-identifier preload
```

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance
   --db-instance-identifier AcmeRDS
   --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot
   --db-instance-identifier AcmeRDS
   --db-snapshot-identifier preload
```

For Windows:

```
aws rds delete-db-instance
   --db-instance-identifier AcmeRDS
   --final-db-snapshot-identifier AcmeRDS-Final

aws rds restore-db-instance-from-db-snapshot
   --db-instance-identifier AcmeRDS
   --db-snapshot-identifier preload
```

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.
Step 4: Consider turning off Amazon RDS automated backups

Warning
Do not turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.

Use the AWS CLI modify-db-instance command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
--db-instance-identifier AcmeRDS \
--apply-immediately \
--backup-retention-period 0
```

For Windows:

```bash
aws rds modify-db-instance ^
--db-instance-identifier AcmeRDS ^
--apply-immediately ^
--backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI describe-db-instances command. The following example displays the DB instance status of the AcmeRDS DB instance.

```bash
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "[*].
(DBInstanceStatus:DBInstanceStatus)"
```

When the DB instance status is available, you're ready to proceed.

Step 5: Load the data

Use the mysqlimport utility to load the flat files into Amazon RDS. The following example tells mysqlimport to load all of the files named "sales" with an extension starting with "part_". This is a convenient way to load all of the files created in the "split" example.

Use the --compress option to minimize network traffic. The --fields-terminated-by='\"' option is used for CSV files, and the --local option specifies that the incoming data is located on the client. Without the --local option, the Amazon RDS DB instance looks for the data on the database host, so always specify the --local option. For the --host option, specify the DB instance endpoint of the RDS for MySQL DB instance.
For RDS for MySQL version 8.0.15 and higher, run the following statement before using the mysqlimport
utility.

```
GRANT SESSION_VARIABLES_ADMIN ON *.* TO master_user;
```

Replace `master_user` with the master username for your DB instance.

For Linux, macOS, or Unix:

```
mysqlimport --local --compress --user=username --password --host=hostname --fields-terminated-by=',' Acme sales.part_*
```

For Windows:

```
mysqlimport --local --compress --user=username --password --host=hostname --fields-terminated-by="," Acme sales.part_*
```

For very large data loads, take additional DB snapshots periodically between loading files and note
which files have been loaded. If a problem occurs, you can easily resume from the point of the last DB
snapshot, avoiding lengthy reloads.

**Step 6: Turn Amazon RDS automated backups back on**

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention
period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared
for a brief outage.

The following example uses the AWS CLI `modify-db-instance` command to turn on automated
backups for the `AcmeRDS` DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance --db-instance-identifier AcmeRDS --backup-retention-period 1 --apply-immediately
```

For Windows:

```
aws rds modify-db-instance --db-instance-identifier AcmeRDS --backup-retention-period 1 --apply-immediately
```
Working with MySQL replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with read replicas (p. 354). For specific information about working with read replicas on RDS for MySQL, see Working with MySQL read replicas (p. 1206).

You can use global transaction identifiers (GTIDs) for replication with RDS for MySQL. For more information, see Using GTID-based replication for RDS for MySQL (p. 1217).

You can also set up replication between an RDS for MySQL DB instance and a MariaDB or MySQL instance that is external to Amazon RDS. For information about configuring replication with an external source, see Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 1222).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see Configuring MySQL binary logging (p. 669).

Note
You can configure replication to import databases from a MariaDB or MySQL instance that is external to Amazon RDS, or to export databases to such instances. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1188) and Exporting data from a MySQL DB instance by using replication (p. 1229).

- Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 1222)

Working with MySQL read replicas

Following, you can find specific information about working with read replicas on RDS for MySQL. For general information about read replicas and instructions for using them, see Working with read replicas (p. 354).

Topics
- Read replica configuration with MySQL (p. 1207)
- Configuring replication filters with MySQL (p. 1207)
- Configuring delayed replication with MySQL (p. 1213)
- Read replica updates with MySQL (p. 1214)
- Multi-AZ read replica deployments with MySQL (p. 1215)
- Monitoring MySQL read replicas (p. 1215)
- Starting and stopping replication with MySQL read replicas (p. 1215)
- Troubleshooting a MySQL read replica problem (p. 1216)
Read replica configuration with MySQL

Before a MySQL DB instance can serve as a replication source, make sure to enable automatic backups on the source DB instance. To do this, set the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. Automatic backups are supported only for read replicas running any version of MySQL 5.6 and higher. You can configure replication based on binary log coordinates for a MySQL DB instance.

On RDS for MySQL version 5.7.23 and higher MySQL 5.7 versions and RDS for MySQL 8.0.26 and higher 8.0 versions, you can configure replication using global transaction identifiers (GTIDs). For more information, see Using GTID-based replication for RDS for MySQL (p. 1217).

You can create up to five read replicas from one DB instance. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

If a read replica is running any version of MySQL 5.6 and higher, you can specify it as the source DB instance for another read replica. For example, you can create ReadReplica1 from MyDBInstance, and then create ReadReplica2 from ReadReplica1. Updates made to MyDBInstance are replicated to ReadReplica1 and then replicated from ReadReplica1 to ReadReplica2. You can’t have more than four instances involved in a replication chain. For example, you can create ReadReplica1 from MySourceDBInstance, and then create ReadReplica2 from ReadReplica1, and then create ReadReplica3 from ReadReplica2, but you can’t create a ReadReplica4 from ReadReplica3.

If you promote a MySQL read replica that is in turn replicating to other read replicas, those read replicas remain active. Consider an example where MyDBInstance1 replicates to MyDBInstance2, and MyDBInstance2 replicates to MyDBInstance3. If you promote MyDBInstance2, replication from MyDBInstance1 to MyDBInstance2 no longer occurs, but MyDBInstance2 still replicates to MyDBInstance3.

To enable automatic backups on a read replica for RDS for MySQL version 5.6 and higher, first create the read replica. Then modify the read replica to enable automatic backups.

You can run multiple read replica create or delete actions at the same time that reference the same source DB instance. To do this, stay within the limit of five read replicas for each source instance.

A read replica of a MySQL DB instance can’t use a lower DB engine version than its source DB instance.

Preparing MySQL DB instances that use MyISAM

If your MySQL DB instance uses a nontransactional engine such as MyISAM, you need to perform the following steps to successfully set up your read replica. These steps are required to make sure that the read replica has a consistent copy of your data. These steps are not required if all of your tables use a transactional engine such as InnoDB.

1. Stop all data manipulation language (DML) and data definition language (DDL) operations on non-transactional tables in the source DB instance and wait for them to complete. SELECT statements can continue running.
2. Flush and lock the tables in the source DB instance.
3. Create the read replica using one of the methods in the following sections.
4. Check the progress of the read replica creation using, for example, the DescribeDBInstances API operation. Once the read replica is available, unlock the tables of the source DB instance and resume normal database operations.

Configuring replication filters with MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.
The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

**Note**

You can also use replication filters to specify which databases and tables are replicated with a primary MySQL DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 1222).

### Topics

- Replication filtering parameters for RDS for MySQL (p. 1208)
- Replication filtering limitations for RDS for MySQL (p. 1209)
- Replication filtering examples for RDS for MySQL (p. 1209)
- Viewing the replication filters for a read replica (p. 1212)

### Replication filtering parameters for RDS for MySQL

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see Replica Server Options and Variables.
- For information about how database replication filtering parameters are evaluated, see Evaluation of Database-Level Replication and Binary Logging Options.
- For information about how table replication filtering parameters are evaluated, see Evaluation of Table-Level Replication Options.
By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the % and _ wildcard characters in the replicate-wild-do-table and replicate-wild-ignore-table parameters. The % wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the binlog_format parameter determines whether the replication is row-based or statement-based. For more information, see Configuring MySQL binary logging (p. 669).

**Note**
All data definition language (DDL) statements are replicated as statements, regardless of the binlog_format setting on the source DB instance.

### Replication filtering limitations for RDS for MySQL

The following limitations apply to replication filtering for RDS for MySQL:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- The MySQL `--binlog-do-db` and `--binlog-ignore-db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

For more information, see Restrictions on XA Transactions in the MySQL documentation.

- Replication filtering is supported for RDS for MySQL version 8.0.17 and higher 8.0 versions and version 5.7.26 and higher 5.7 versions.
- Replication filtering isn't supported for RDS for MySQL version 5.6.

### Replication filtering examples for RDS for MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

**Note**
You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see Working with parameter groups (p. 278).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see Modifying parameters in a DB parameter group (p. 282). When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- Including databases in replication
- Including tables in replication
• Including tables in replication with wildcard characters
• Escaping wildcard characters in names
• Excluding databases from replication
• Excluding tables from replication
• Excluding tables from replication using wildcard characters

Example Including databases in replication
The following example includes the mydb1 and mydb2 databases in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \\
--db-parameter-group-name myparametergroup \\
--parameters "["ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "["ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod":"immediate"]"
```

Example Including tables in replication
The following example includes the table1 and table2 tables in database mydb1 in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \\
--db-parameter-group-name myparametergroup \\
--parameters "["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "["ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"]"
```

Example Including tables in replication using wildcard characters
The following example includes tables with names that begin with orders and returns in database mydb in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \\
--db-parameter-group-name myparametergroup \\
--parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"]"
```
For Windows:

```
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue":
   "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"]"
```

**Example Escaping wildcard characters in names**

The following example shows you how to use the escape character `\` to escape a wildcard character that is part of a name.

Assume that you have several table names in database `mydb1` that start with `my_table`, and you want to include these tables in replication. The table names include an underscore, which is also a wildcard character, so the example escapes the underscore in the table names.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table %", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters "["ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table %", "ApplyMethod":"immediate"]"
```

**Example Excluding databases from replication**

The following example excludes the `mydb1` and `mydb2` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters "["ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod":"immediate"]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
   --db-parameter-group-name myparametergroup ^
   --parameters "["ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod":"immediate"]"
```

**Example Excluding tables from replication**

The following example excludes tables `table1` and `table2` in database `mydb1` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name myparametergroup \
   --parameters "["ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,table1", "ApplyMethod":"immediate"]"
```
aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"]"

For Windows:

aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "["ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"]"

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with orders and returns in database mydb from replication.

For Linux, macOS, or Unix:

aws rds modify-db-parameter-group \
  --db-parameter-group-name myparametergroup \
  --parameters "["ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"]"

For Windows:

aws rds modify-db-parameter-group ^
  --db-parameter-group-name myparametergroup ^
  --parameters "["ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"]"

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

  For instructions, see Viewing parameter values for a DB parameter group (p. 289).

- In a MySQL client, connect to the read replica and run the SHOW REPLICA STATUS statement.

  In the output, the following fields show the replication filters for the read replica:
  - Replicate_Do_DB
  - Replicate_Ignore_DB
  - Replicate_Do_Table
  - Replicate_Ignore_Table
  - Replicate_Wild_Do_Table
  - Replicate_Wild_Ignore_Table

  For more information about these fields, see Checking Replication Status in the MySQL documentation.

  **Note**
  Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.
Configuring delayed replication with MySQL

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.
  
  Use the `mysql.rds_stop_replication` stored procedure to stop replication.
- Start replication and specify that replication stops automatically at a log file location.
  
  You specify a location just before the disaster using the `mysql.rds_start_replication_until` stored procedure.
- Promote the read replica to be the new source DB instance by using the instructions in Promoting a read replica to be a standalone DB instance.

**Note**

- On RDS for MySQL 8.0, delayed replication is supported for MySQL 8.0.26 and higher. On RDS for MySQL 5.7, delayed replication is supported for MySQL 5.7.22 and higher. On RDS for MySQL 5.6, delayed replication is supported for MySQL 5.6.40 and higher.
- Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
- On RDS for MySQL 5.7.23 and higher MySQL 5.7 versions and RDS for MySQL 8.0.26 and higher 8.0 versions, you can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration. If you use GTID-based replication, use the `mysql.rds_start_replication_until_gtid` stored procedure instead of the `mysql.rds_start_replication_until` stored procedure. For more information about GTID-based replication, see Using GTID-based replication for RDS for MySQL (p. 1217).

**Topics**

- Configuring delayed replication during read replica creation (p. 1213)
- Modifying delayed replication for an existing read replica (p. 1214)
- Setting a location to stop replication to a read replica (p. 1214)
- Promoting a read replica (p. 1214)

**Configuring delayed replication during read replica creation**

To configure delayed replication for any future read replica created from a DB instance, run the `mysql.rds_set_configuration` stored procedure with the target delay parameter.

To configure delayed replication during read replica creation

1. Using a MySQL client, connect to the MySQL DB instance to be the source for read replicas as the master user.
2. Run the `mysql.rds_set_configuration` stored procedure with the target delay parameter.

For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

```sql
call mysql.rds_set_configuration('target delay', 3600);
```
Note
After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

Modifying delayed replication for an existing read replica
To modify delayed replication for an existing read replica, run the `mysql.rds_set_source_delay` stored procedure.

To modify delayed replication for an existing read replica
1. Using a MySQL client, connect to the read replica as the master user.
2. Use the `mysql.rds_stop_replication` stored procedure to stop replication.
3. Run the `mysql.rds_set_source_delay` stored procedure.
   
   For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

   ```sql
   call mysql.rds_set_source_delay(3600);
   ```

4. Use the `mysql.rds_start_replication` stored procedure to start replication.

Setting a location to stop replication to a read replica
After stopping replication to the read replica, you can start replication and then stop it at a specified binary log file location using the `mysql.rds_start_replication_until` stored procedure.

To start replication to a read replica and stop replication at a specific location
1. Using a MySQL client, connect to the source MySQL DB instance as the master user.
2. Run the `mysql.rds_start_replication_until` stored procedure.

   The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location 120 is just before the disaster.

   ```sql
   call mysql.rds_start_replication_until('mysql-bin-changelog.000777', 120);
   ```

Replication stops automatically when the stop point is reached. The following RDS event is generated:
Replication has been stopped since the replica reached the stop point specified by the rds_start_replication_until stored procedure.

Promoting a read replica
After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see Promoting a read replica to be a standalone DB instance (p. 361).

Read replica updates with MySQL
Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to optimize the specific types of queries accessing the replica. You
can enable updates by setting the `read_only` parameter to 0 in the DB parameter group for the read replica. Be careful when disabling read-only on a read replica because it can cause problems if the read replica becomes incompatible with the source DB instance. Change the value of the `read_only` parameter back to 1 as soon as possible.

**Multi-AZ read replica deployments with MySQL**

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see Multi-AZ deployments for high availability (p. 65).

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

**Note**

To create a read replica as a Multi-AZ DB instance, the DB instance must be MySQL 5.6 or higher.

**Monitoring MySQL read replicas**

For MySQL read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW REPLICA STATUS` command.

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

Common causes for replication lag for MySQL are the following:

- A network outage.
- Writing to tables that have different indexes on a read replica. If the `read_only` parameter is set to 0 on the read replica, replication can break if the read replica becomes incompatible with the source DB instance. After you've performed maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to 1.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, then replication is currently not active. `ReplicaLag = -1` is equivalent to `Seconds_Behind_Master = NULL`.

**Starting and stopping replication with MySQL read replicas**

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures `mysql.rds_stop_replication` (p. 1279) and `mysql.rds_start_replication` (p. 1277). You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1188) and Exporting data from a MySQL DB instance by using replication (p. 1229).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS terminates replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The
read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is terminated. You can create a new read replica for the source DB instance to reestablish replication.

**Troubleshooting a MySQL read replica problem**

For MySQL DB instances, in some cases read replicas present replication errors or data inconsistencies (or both) between the read replica and its source DB instance. This problem occurs when some binary log (binlog) events or InnoDB redo logs aren't flushed during a failure of the read replica or the source DB instance. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: sync_binlog=1 and innodb_flush_log_at_trx_commit=1. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

**Warning**

In the parameter group associated with the source DB instance, we recommend keeping these parameters values: sync_binlog=1 and innodb_flush_log_at_trx_commit=1. These parameters are dynamic. If you don't want to use these settings, we recommend temporarily setting those values before executing any operation on the source DB instance that might cause it to restart. These operations include, but are not limited to, rebooting, rebooting with failover, upgrading the database version, and changing the DB instance class or its storage. The same recommendation applies to creating new read replicas for the source DB instance. Failure to follow this guidance increases the risk of read replicas presenting replication errors or data inconsistencies (or both) between the read replica and its source DB instance.

The replication technologies for MySQL are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MySQL documentation, see Replication implementation details.

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the Replication State field of the read replica instance to Error if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MySQL engine by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 630), RDS-EVENT-0046 (p. 630), and RDS-EVENT-0047 (p. 628). For more information about events and subscribing to events, see Using Amazon RDS event notification (p. 623). If a MySQL error message is returned, review the error number in the MySQL error message documentation.

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. You use `max_allowed_packet` to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` value in the DB parameter group associated with a read replica is smaller than the `max_allowed_packet` value in the DB parameter.
group associated with the source DB instance. In these cases, the replication process can throw the error
Packet bigger than 'max_allowed_packet' bytes and stop replication. To fix the error, have
the source DB instance and read replica use DB parameter groups with the same max_allowed_packet
parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. In some cases, you might create indexes on a read replica that are
different from the indexes on the source DB instance. If you do, set the read_only parameter to 0
to create the indexes. If you write to tables on the read replica, it might break replication if the read
replica becomes incompatible with the source DB instance. After you perform maintenance tasks on
the read replica, we recommend that you set the read_only parameter back to 1.
- Using a non-transactional storage engine such as MyISAM. Read replicas require a transactional
storage engine. Replication is only supported for the InnoDB storage engine on MySQL.
- Using unsafe nondeterministic queries such as SYSDATE(). For more information, see Determination
of safe and unsafe statements in binary logging.

If you decide that you can safely skip an error, you can follow the steps described in the section Skipping
the current replication error (p. 1245). Otherwise, you can first delete the read replica. Then you create
an instance using the same DB instance identifier so that the endpoint remains the same as that of your
old read replica. If a replication error is fixed, the Replication State changes to replicating.

Using GTID-based replication for RDS for MySQL

Following, you can learn how to use global transaction identifiers (GTIDs) with binary log (binlog)
replication among RDS for MySQL DB instances.

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see Replication
with global transaction identifiers in the MySQL documentation for background.

GTID-based replication is supported for RDS for MySQL version 5.7.23 and higher MySQL 5.7 versions,
and RDS for MySQL version 8.0.26 and higher MySQL 8.0 versions. All MySQL DB instances in a
replication configuration must meet this requirement. GTID-based replication isn't supported for RDS for
MySQL 5.6.

Topics
- Overview of global transaction identifiers (GTIDs) (p. 1217)
- Parameters for GTID-based replication (p. 1218)
- Configuring GTID-based replication for new read replicas (p. 1219)
- Configuring GTID-based replication for existing read replicas (p. 1219)
- Disabling GTID-based replication for a MySQL DB instance with read replicas (p. 1221)

Note
For information about configuring GTID-based replication with an external database, see
Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 1222).

Overview of global transaction identifiers (GTIDs)

Global transaction identifiers (GTIDs) are unique identifiers generated for committed MySQL transactions.
You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

MySQL uses two different types of transactions for binlog replication:

- GTID transactions – Transactions that are identified by a GTID.
- Anonymous transactions – Transactions that don't have a GTID assigned.
In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You can use GTID-based replication to replicate data with Amazon RDS MySQL read replicas or with an external MySQL database. For RDS for MySQL read replicas, you can configure GTID-based replication when you are creating new read replicas, or you can convert existing read replicas to use GTID-based replication.

You can also use GTID-based replication in a delayed replication configuration with RDS for MySQL. For more information, see Configuring delayed replication with MySQL (p. 1213).

Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gtid_mode</td>
<td>OFF, OFF_PERMISSIVE, ON_PERMISSIVE, ON</td>
<td>OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated. OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated. ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated. ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.</td>
</tr>
<tr>
<td>enforce_gtid_consistency</td>
<td>OFF, ON, WARN</td>
<td>OFF allows transactions to violate GTID consistency. ON prevents transactions from violating GTID consistency. WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.</td>
</tr>
</tbody>
</table>

Note

In the AWS Management Console, the gtid_mode parameter appears as gtid-mode.

For GTID-based replication, use these settings for the parameter group for your DB instance or read replica:

- ON and ON_PERMISSIVE apply only to outgoing replication from an RDS DB instance or Aurora MySQL cluster. Both of these values cause your RDS DB instance or Aurora DB cluster to use GTIDs for transactions that are replicated to an external database. ON requires that the external database also use GTID-based replication. ON_PERMISSIVE makes GTID-based replication optional on the external database.
• **OFF_PERMISSIVE**, if set, means that your RDS DB instances or Aurora DB cluster can accept incoming replication from an external database. It can do this whether the external database uses GTID-based replication or not.

• **OFF**, if set, means that your RDS DB instances or Aurora DB cluster only accept incoming replication from external databases that don't use GTID-based replication.

For more information about parameter groups, see Working with parameter groups (p. 278).

### Configuring GTID-based replication for new read replicas

When GTID-based replication is enabled for an RDS for MySQL DB instance, GTID-based replication is configured automatically for read replicas of the DB instance.

**To enable GTID-based replication for new read replicas**

1. Make sure that the parameter group associated with the DB instance has the following parameter settings:
   - **gtid_mode** – ON or ON_PERMISSIVE
   - **enforce_gtid_consistency** – ON

   For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 278).

2. If you changed the parameter group of the DB instance, reboot the DB instance. For more information on how to do so, see Rebooting a DB instance (p. 350).

3. Create one or more read replicas of the DB instance. For more information on how to do so, see Creating a read replica (p. 359).

Amazon RDS attempts to establish GTID-based replication between the MySQL DB instance and the read replicas using the `MASTER_AUTO_POSITION`. If the attempt fails, Amazon RDS uses log file positions for replication with the read replicas. For more information about the `MASTER_AUTO_POSITION`, see GTID auto-positioning in the MySQL documentation.

### Configuring GTID-based replication for existing read replicas

For an existing MySQL DB instance with read replicas that doesn't use GTID-based replication, you can configure GTID-based replication between the DB instance and the read replicas.

**To enable GTID-based replication for existing read replicas**

1. If the DB instance or any read replica is using an RDS for MySQL version that doesn't support GTID-based replication, upgrade the engine version:
   - If the DB instance or any read replica is using an 8.0 version of RDS for MySQL version lower than 8.0.26, upgrade the DB instance or read replica to 8.0.26 or a higher MySQL 8.0 version.
   - If the DB instance or any read replica is using a 5.7 version of RDS for MySQL version lower than 5.7.23, upgrade the DB instance or read replica to 5.7.23 or a higher MySQL 5.7 version.

   For more information, see Upgrading the MySQL DB engine (p. 1159).

2. (Optional) Reset the GTID parameters and test the behavior of the DB instance and read replicas:
   a. Make sure that the parameter group associated with the DB instance and each read replica has the `enforce_gtid_consistency` parameter set to WARN.
Using GTID-based replication

For more information about setting configuration parameters using parameter groups, see Working with parameter groups (p. 278).

b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

For more information, see Rebooting a DB instance (p. 350).

c. Run your DB instance and read replicas with your normal workload and monitor the log files.

If you see warnings about GTID-incompatible transactions, adjust your application so that it only uses GTID-compatible features. Make sure that the DB instance is not generating any warnings about GTID-incompatible transactions before proceeding to the next step.

3. Reset the GTID parameters for GTID-based replication that allows anonymous transactions until the read replicas have processed all of them.

a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:
   - gtid_mode – ON_PERMISSIVE
   - enforce_gtid_consistency – ON

b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

4. Wait for all of your anonymous transactions to be replicated. To check that these are replicated, do the following:

a. Run the following statement on your source DB instance.

   ```sql
   SHOW MASTER STATUS;
   ```

   Note the values in the File and Position columns.

b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

   ```sql
   SELECT MASTER_POS_WAIT('file', position);
   ```

   For example, if the file name is `mysql-bin-changelog.000031` and the position is 107, run the following statement.

   ```sql
   SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
   ```

   If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. Proceed to the next step when the query returns for all read replicas.

5. Reset the GTID parameters for GTID-based replication only.

a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:
   - gtid_mode – ON
   - enforce_gtid_consistency – ON

b. Reboot the DB instance and each read replica.

6. On each read replica, run the following procedure.

   ```sql
   CALL mysql.rds_set_master_auto_position(1);
   ```
Disabling GTID-based replication for a MySQL DB instance with read replicas

You can disable GTID-based replication for a MySQL DB instance with read replicas.

To disable GTID-based replication for a MySQL DB instance with read replicas

1. On each read replica, run the following procedure.

   Call mysql.rds_set_master_auto_position(0); (Aurora MySQL version 1 and 2)
   Call mysql.rds_set_source_auto_position(0); (Aurora MySQL version 3 and higher)

2. Reset the gtid_mode to ON_PERMISSIVE.

   a. Make sure that the parameter group associated with the MySQL DB instance and each read
      replica has gtid_mode set to ON_PERMISSIVE.
      
      For more information about setting configuration parameters using parameter groups, see
      Working with parameter groups (p. 278).
   
   b. Reboot the MySQL DB instance and each read replica. For more information about rebooting,
      see Rebooting a DB instance (p. 350).

3. Reset the gtid_mode to OFF_PERMISSIVE:

   a. Make sure that the parameter group associated with the MySQL DB instance and each read
      replica has gtid_mode set to OFF_PERMISSIVE.
   
   b. Reboot the MySQL DB instance and each read replica.

4. Wait for all of the GTID transactions to be applied on all of the read replicas. To check that these are
   applied, do the following:

   Wait for all of the GTID transactions to be applied on the Aurora primary instance. To check that
   these are applied, do the following:

   a. On the MySQL DB instance, run the SHOW MASTER STATUS command.
      
      Your output should be similar to the following.

      File                        Position
      -------------------------------
      mysql-bin-changelog.000031      107
      -------------------------------

      Note the file and position in your output.
   
   b. On each read replica, use the file and position information from its source instance in the
      previous step to run the following query.

   SELECT MASTER_POS_WAIT('file', position);

   For example, if the file name is mysql-bin-changelog.000031 and the position is 107, run
   the following statement.

   SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);

   If the read replica is past the specified position, the query returns immediately. Otherwise, the
   function waits. When the query returns for all read replicas, go to the next step.
5. Reset the GTID parameters to disable GTID-based replication:
   a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has the following parameter settings:
      - gtid_mode – OFF
      - enforce_gtid_consistency – OFF
   b. Reboot the MySQL DB instance and each read replica.

Replication with a MariaDB or MySQL instance running external to Amazon RDS

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS.

Topics
- Before you begin (p. 899)
- Configuring binary log file position replication with an external source instance (p. 899)
- Configuring GTID-based replication with an external source instance (p. 902)

Before you begin

You can configure replication using the binary log file position of replicated transactions. On RDS for MySQL 5.7.23 and higher MySQL 5.7 versions and RDS for MySQL 8.0.26 and higher 8.0 versions, you can also configure replication using global transaction identifiers (GTIDs).

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS mysql.rds_set_external_master (p. 1266) and mysql.rds_start_replication (p. 1277) commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the binlog_format parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify binlog_format settings. We recommend that you use the default setting for binlog_format, which is MIXED. However, you can also set binlog_format to ROW or STATEMENT if you need a specific binlog format. Reboot your DB instance for the change to take effect.

For information about setting the binlog_format parameter, see Configuring MySQL binary logging (p. 669). For information about the implications of different MySQL replication types, see Advantages and disadvantages of statement-based and row-based replication in the MySQL documentation.

Note
Use the procedure in this topic to configure replication in all cases except when the external instance is MariaDB version 10.0.24 or higher and the Amazon RDS instance is MariaDB. In that case, use the procedure at Using GTID-based replication into a MariaDB DB instance (p. 896) to set up GTID-based replication.

Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:
• Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Using Amazon RDS event notification (p. 623).

• Maintain the binary logs (binlogs) on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.

• Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see Backing up and restoring an Amazon RDS DB instance (p. 406).

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

   You receive output similar to the following example.

   ```
   File                        Position
   ------------------------------------
   mysql-bin-changelog.000031      107
   ------------------------------------
   ```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`.
   For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1188).

   For Linux, macOS, or Unix:

   ```
   mysqldump --databases database_name \
   --single-transaction \
   --compress \
   --order-by-primary \
   -u local_user \
   -plocal_password | mysql \
   --host=hostname \
   --port=3306 \
   -u RDS_user_name \
   -pRDS_password
   ```

   For Windows:

   ```
   mysqldump --databases database_name ^
   --single-transaction ^
   --compress ^
   --order-by-primary ^
   -u local_user ^
   -plocal_password | mysql ^
   --host=hostname ^
   --port=3306 ^
   -u RDS_user_name ^
   -pRDS_password
   ```
Note
Make sure that there isn't a space between the --p option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the --host, --user (-u), --port and --p options in the mysql command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example myinstance.123456789012.us-east-1.rds.amazonaws.com. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the host command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication, and restrict it to your domain to improve security. The following is an example.

**MySQL 5.5, 5.6, and 5.7**

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

**MySQL 8.0**

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
```

7. For the external instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

**MySQL 5.5, 5.6, and 5.7**
8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the `mysql.rds_set_external_master` command. Use the master log file name and master log position that you determined in step 2. The following is an example.

```sql
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

Note
On RDS for MySQL, you can choose to use delayed replication by running the `mysql.rds_set_external_master_with_delay` stored procedure instead.

On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the `mysql.rds_start_replication_until` stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the `mysql.rds_start_replication` command to start replication.

```sql
CALL mysql.rds_start_replication;
```

---

**Configuring GTID-based replication with an external source instance**

When you set up an external source instance and a replica on Amazon RDS, monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see Using Amazon RDS event notification (p. 623).

**Important**
GTID-based replication is only supported on RDS for MySQL version 5.7.23 and higher MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions. GTID-based replication isn’t supported for RDS for MySQL 5.6.

**To configure GTID-based replication with an external source instance**

1. Prepare for GTID-based replication:
   a. Make sure that the external MySQL or MariaDB database has GTID-based replication enabled. To do so, make sure that the external database has the following parameters set to the specified values:

   ```
   gtid_mode = ON
   enforce_gtid_consistency = ON
   ```

   For more information, see Replication with global transaction identifiers in the MySQL documentation or Global transaction ID in the MariaDB documentation.
b. Make sure that the parameter group associated with the DB instance has the following parameter settings:

- **gtid_mode** – ON, ON_PERMISSIVE, or OFF_PERMISSIVE
- **enforce_gtid_consistency** – ON

For more information about parameter groups, see Working with parameter groups (p. 278).

c. If you changed the parameter group of the DB instance, reboot the DB instance. For more information, see Rebooting a DB instance (p. 350).

2. Make the source MySQL or MariaDB instance read-only.

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in Importing data to an Amazon RDS MariaDB or MySQL DB instance with reduced downtime (p. 1188).

   For Linux, macOS, or Unix:

   ```
   mysqldump --databases database_name \
   --single-transaction \
   --compress \
   --order-by-primary \
   -u local_user \
   -plocal_password | mysql  \
   --host=hostname \
   --port=3306 \
   -u RDS_user_name \
   -pRDS_password
   ```

   For Windows:

   ```
   mysqldump --databases database_name ^
   --single-transaction ^
   --compress ^
   --order-by-primary ^
   -u local_user ^
   -plocal_password | mysql ^
   --host=hostname ^
   --port=3306 ^
   -u RDS_user_name ^
   -pRDS_password
   ```

   **Note**
   Make sure that there isn’t a space between the `-p` option and the entered password.

   To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user` (`-u`), `--port` and `--password` options in the `mysql` command. The host name is the DNS name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

   ```
   mysql> SET GLOBAL read_only = OFF;
   mysql> UNLOCK TABLES;
   ```
For more information on making backups for use with replication, see the MySQL documentation.

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the VPC security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see Security groups for your VPC in the Amazon Virtual Private Cloud User Guide.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the host command:

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication, and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

7. For the external instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the replication primary instance by using the mysql.rds_set_external_master_with_auto_position (p. 1271) command. The following is an example.

```
CALL mysql.rds_set_external_master_with_auto_position ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 0, 0);
```

**Note**

On RDS for MySQL, you can choose to use delayed replication by running the mysql.rds_set_external_master_with_delay (p. 1268) stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to enable disaster recovery with the mysql.rds_start_replication_until_gtid (p. 1278) stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the mysql.rds_start_replication_until_gtid procedure.

9. On the Amazon RDS DB instance, issue the mysql.rds_start_replication (p. 1277) command to start replication.
CALL mysql.rds_start_replication;
Exporting data from a MySQL DB instance by using replication

To export data from a MySQL 5.6 or later DB instance to a MySQL instance running external to Amazon RDS, you can use replication. In this scenario, the MySQL DB instance is the source MySQL DB instance, and the MySQL instance running external to Amazon RDS is the external MySQL database.

The source MySQL DB instance must be running version 5.6.13 or later. The external MySQL database can run either on-premises in your data center, or on an Amazon EC2 instance. The external MySQL database must run the same version as the source MySQL DB instance, or a later version.

Replication to an external MySQL database is only supported during the time it takes to export a database from the source MySQL DB instance. The replication should be terminated when the data has been exported and applications can start accessing the external MySQL instance.

The following list shows the steps to take. Each step is discussed in more detail in later sections.

1. Prepare an external MySQL DB instance.
2. Prepare the source MySQL DB instance for replication.
3. Use the mysqldump utility to transfer the database from the source MySQL DB instance to the external MySQL database.
4. Start replication to the external MySQL database.
5. After the export completes, stop replication.

Prepare an external MySQL database

Perform the following steps to prepare the external MySQL database.

To prepare the external MySQL database

1. Install the external MySQL database.
2. Connect to the external MySQL database as the master user. Then create the users required to support the administrators, applications, and services that access the database.
3. Follow the directions in the MySQL documentation to prepare the external MySQL database as a replica. For more information, see the MySQL documentation.
4. Configure an egress rule for the external MySQL database to operate as a read replica during the export. The egress rule allows the external MySQL database to connect to the source MySQL DB instance during replication. Specify an egress rule that allows Transmission Control Protocol (TCP) connections to the port and IP address of the source MySQL DB instance.

Specify the appropriate egress rules for your environment:

- If the external MySQL database is running in an Amazon EC2 instance in a virtual private cloud (VPC) based on the Amazon VPC service, specify the egress rules in a VPC security group. For more information, see Controlling access with security groups (p. 1822).
- If the external MySQL database is running in an Amazon EC2 instance that is not in a VPC, specify the egress rules in an EC2-Classic security group.
- If the external MySQL database is installed on-premises, specify the egress rules in a firewall.
5. If the external MySQL database is running in a VPC, configure rules for the VPC access control list (ACL) rules in addition to the security group egress rule:

- Configure an ACL ingress rule allowing TCP traffic to ports 1024–65535 from the IP address of the source MySQL DB instance.
• Configure an ACL egress rule allowing outbound TCP traffic to the port and IP address of the source MySQL DB instance.

For more information about Amazon VPC network ACLs, see Network ACLs in Amazon VPC User Guide.

6. (Optional) Set the max_allowed_packet parameter to the maximum size to avoid replication errors. We recommend this setting.

Prepare the source MySQL DB instance

Perform the following steps to prepare the source MySQL DB instance as the replication source.

To prepare the source MySQL DB instance

1. Ensure that your client computer has enough disk space available to save the binary logs while setting up replication.

2. Connect to the source MySQL DB instance, and create a replication account by following the directions in Creating a user for replication in the MySQL documentation.

3. Configure ingress rules on the system running the source MySQL DB instance to allow the external MySQL database to connect during replication. Specify an ingress rule that allows TCP connections to the port used by the source MySQL DB instance from the IP address of the external MySQL database.

4. Specify the egress rules:
   • If the source MySQL DB instance is running in a VPC, specify the ingress rules in a VPC security group. For more information, see Controlling access with security groups (p. 1822).
   • If the source MySQL DB instance isn't running in a VPC, specify the ingress rules in a DB security group. For more information, see Authorizing network access to a DB security group from an IP range (p. 1831).

5. If source MySQL DB instance is running in a VPC, configure VPC ACL rules in addition to the security group ingress rule:
   • Configure an ACL ingress rule to allow TCP connections to the port used by the Amazon RDS instance from the IP address of the external MySQL database.
   • Configure an ACL egress rule to allow TCP connections from ports 1024–65535 to the IP address of the external MySQL database.

For more information about Amazon VPC network ACLs, see Network ACLs in the Amazon VPC User Guide.

6. Ensure that the backup retention period is set long enough that no binary logs are purged during the export. If any of the logs are purged before the export has completed, you must restart replication from the beginning. For more information about setting the backup retention period, see Working with backups (p. 407).

7. Use the mysql.rds_set_configuration stored procedure to set the binary log retention period long enough that the binary logs aren't purged during the export. For more information, see Accessing MySQL binary logs (p. 671).

8. Create an Amazon RDS read replica from the source MySQL DB instance to further ensure that the binary logs of the source MySQL DB instance are not purged. For more information, see Creating a read replica (p. 359).

9. After the Amazon RDS read replica has been created, call the mysql.rds_stop_replication stored procedure to stop the replication process. The source MySQL DB instance no longer purges its binary log files, so they are available for the replication process.
10. (Optional) Set both the `max_allowed_packet` parameter and the `slave_max_allowed_packet` parameter to the maximum size to avoid replication errors. The maximum size for both parameters is 1 GB. We recommend this setting for both parameters. For information about setting parameters, see Modifying parameters in a DB parameter group (p. 282).

## Copy the database

Perform the following steps to copy the database.

**To copy the database**

1. Connect to the RDS read replica of the source MySQL DB instance, and run the MySQL `SHOW REPLICA STATUS` statement. Note the values for the following:
   - `Master_Host`
   - `Master_Port`
   - `Master_Log_File`
   - `Exec_Master_Log_Pos`

   **Note**
   Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

2. Use the `mysqldump` utility to create a snapshot, which copies the data from Amazon RDS to your local client computer. Then run another utility to load the data into the external MySQL database. Ensure that your client computer has enough space to hold the `mysqldump` files from the databases to be replicated. This process can take several hours for very large databases. Follow the directions in Creating a data snapshot using mysqldump in the MySQL documentation.

   The following example runs `mysqldump` on a client, and then pipes the dump into the `mysql` client utility, which loads the data into the external MySQL database.

   For Linux, macOS, or Unix:
   ```
   mysqldump -h source_MySQL_DB_instance_endpoint \
   -u user \
   -ppassword \
   --port=3306 \
   --single-transaction \
   --routines \
   --triggers \
   --databases database database2 \
   --compress \
   --port 3306
   ```

   For Windows:
   ```
   mysqldump ^h source_MySQL_DB_instance_endpoint ^
   ^-u user ^
   ^-ppassword ^
   ^--port=3306 ^
   ^--single-transaction ^
   ^--routines ^
   ^--triggers ^
   ^--databases database database2 ^
   ^--compress ^
   ^--port 3306
   ```
The following example runs `mysqldump` on a client and writes the dump to a file.

For Linux, macOS, or Unix:

```
mysqldump -h source_MySQL_DB_instance_endpoint \
  -u user \
  -ppassword \
  --port=3306 \
  --single-transaction \
  --routines \
  --triggers \
  --databases database database2 > path/rds-dump.sql
```

For Windows:

```
mysqldump -h source_MySQL_DB_instance_endpoint ^
  -u user ^
  -ppassword ^
  --port=3306 ^
  --single-transaction ^
  --routines ^
  --triggers ^
  --databases database database2 > path\rds-dump.sql
```

**Complete the export**

Perform the following steps to complete the export.

**To complete the export**

1. Use the MySQL `CHANGE MASTER` statement to configure the external MySQL database. Specify the ID and password of the user granted `REPLICATION SLAVE` permissions. Specify the `Master_Host`, `Master_Port`, `Relay_Master_Log_File`, and `Exec_Master_Log_Pos` values that you got from the MySQL `SHOW REPLICA STATUS\G` statement that you ran on the RDS read replica. For more information, see the MySQL documentation.

   **Note**
   
   Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

2. Use the MySQL `START REPLICA` command to initiate replication from the source MySQL DB instance to the external MySQL database.

   Doing this starts replication from the source MySQL DB instance and exports all source changes that have occurred after you stopped replication from the Amazon RDS read replica.

   **Note**
   
   Previous versions of MySQL used `START SLAVE` instead of `START REPLICA`. If you are using a MySQL version before 8.0.23, then use `START SLAVE`.

3. Run the MySQL `SHOW REPLICA STATUS\G` command on the external MySQL database to verify that it is operating as a read replica. For more information about interpreting the results, see the MySQL documentation.

4. After replication on the external MySQL database has caught up with the source MySQL DB instance, use the MySQL `STOP REPLICA` command to stop replication from the source MySQL DB instance.

   **Note**
   
   Previous versions of MySQL used `STOP SLAVE` instead of `STOP REPLICA`. If you are using a MySQL version before 8.0.23, then use `STOP SLAVE`. 

---

1232
5. On the Amazon RDS read replica, call the `mysql.rds_start_replication` stored procedure. Doing this allows Amazon RDS to start purging the binary log files from the source MySQL DB instance.
Options for MySQL DB instances

This appendix describes options, or additional features, that are available for Amazon RDS instances running the MySQL DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see Working with option groups (p. 262).

Amazon RDS supports the following options for MySQL:

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Engine versions</th>
</tr>
</thead>
</table>
| MariaDB Audit Plugin support (p. 1235) | MARIADB_AUDIT_PLUGIN | MySQL 8.0.25 and higher 8.0 versions  
                                      |                                   | MySQL 5.7.16 and higher 5.7 versions 
                                      |                                   | All MySQL 5.6 versions            |
| MySQL memcached support (p. 1239) | MEMCACHED          | All MySQL 5.6, 5.7, and 8.0 versions       |
MariaDB Audit Plugin support

Amazon RDS supports using the MariaDB Audit Plugin on MySQL database instances. The MariaDB Audit Plugin records database activity such as users logging on to the database, queries run against the database, and more. The record of database activity is stored in a log file.

**Note**
Currently, the MariaDB Audit Plugin is only supported for the following RDS for MySQL versions:

- MySQL 8.0.25 and higher 8.0 versions
- MySQL 5.7.16 and higher 5.7 versions
- All 5.6 versions

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_AUDIT_FILE_PATH</td>
<td>/rdsdbdata/log/audit/</td>
<td>/rdsdbdata/log/audit/</td>
<td>The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS. For more information, see Viewing and listing database log files (p. 646) and MySQL database log files (p. 664).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATE_SIZE</td>
<td>1–100000000</td>
<td>1000000</td>
<td>The size in bytes that when reached, causes the file to rotate. For more information, see Overview of MySQL database logs (p. 664).</td>
</tr>
<tr>
<td>SERVER_AUDIT_FILE_ROTATIONS</td>
<td>0–100</td>
<td>9</td>
<td>The number of log rotations to save. For more information, see Overview of MySQL database logs (p. 664) and Downloading a database log file (p. 647).</td>
</tr>
<tr>
<td>SERVER_AUDIT_EVENTS</td>
<td>CONNECT, QUERY, QUERY_DDL, QUERY_DML, QUERY_DML_NO_SELECT, QUERY_DCL</td>
<td>CONNECT, QUERY</td>
<td>The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged.</td>
</tr>
</tbody>
</table>

- **CONNECT**: Log successful and unsuccessful connections to the database, and disconnections from the database.
- **QUERY**: Log the text of all queries run against the database.
- **QUERY_DDL**: Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).
- **QUERY_DML**: Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT).
- **QUERY_DML_NO_SELECT**: Similar to the QUERY_DML event, but doesn’t log SELECT queries.

The **QUERY_DML_NO_SELECT** setting is supported only for RDS for MySQL 5.7.34 and
<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
</table>
| higher 5.7 versions, and 8.0.25 and higher 8.0 versions.  
• QUERY_DCL: Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on). | | | For MySQL, TABLE is not supported. |
| SERVER_AUDIT_INCL_USERS | Multipler comma-separated values | None | Include only activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_INCL_USERS, make sure no values are added to SERVER_AUDIT_EXCL_USERS. |
| SERVER_AUDIT_EXCL_USERS | Multipler comma-separated values | None | Exclude activity from the specified users. By default, activity is recorded for all users. SERVER_AUDIT_INCL_USERS and SERVER_AUDIT_EXCL_USERS are mutually exclusive. If you add values to SERVER_AUDIT_EXCL_USERS, make sure no values are added to SERVER_AUDIT_INCL_USERS. The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list.  
**Note**  
CONNECT activity is always recorded for all users, even if the user is specified for this option setting. |
| SERVER_AUDIT_LOGGING | ON | Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin (p. 1238). |
| SERVER_AUDIT_QUERY_LOG_LIMIT | 0–2147483647 | 1024 | The limit on the length of the query string in a record. |

### Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

- Create a new option group, or copy or modify an existing option group
- Add the option to the option group
• Associate the option group with the DB instance

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

**Important**
Adding the MariaDB Audit Plugin to a DB instance might cause an outage. We recommend adding the MariaDB Audit Plugin during a maintenance window or during a time of low database workload.

**To add the MariaDB Audit Plugin**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group. Choose `mysql` for Engine, and choose `5.6` or `5.7` for Major engine version. For more information, see Creating an option group (p. 264).
2. Add the `MARIADB_AUDIT_PLUGIN` option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 266). For more information about each setting, see Audit Plugin option settings (p. 1235).
3. Apply the option group to a new or existing DB instance.
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**Audit log format**

Log files are represented as comma-separated variable (CSV) files in UTF-8 format. The audit log is stored separately on the local (ephemeral) storage of each RDS for MySQL DB instance.

**Tip**
Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.

To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see Monitoring Amazon RDS for Oracle with Database Activity Streams (p. 690).

The audit log files include the following comma-delimited information in rows, in the specified order:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>The Unix time stamp for the logged event with microsecond precision.</td>
</tr>
<tr>
<td>serverhost</td>
<td>The name of the instance that the event is logged for.</td>
</tr>
<tr>
<td>username</td>
<td>The connected user name of the user.</td>
</tr>
<tr>
<td>host</td>
<td>The host that the user connected from.</td>
</tr>
<tr>
<td>connectionid</td>
<td>The connection ID number for the logged operation.</td>
</tr>
<tr>
<td>queryid</td>
<td>The query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines are added.</td>
</tr>
</tbody>
</table>
### MariaDB Audit Plugin

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operation</td>
<td>The recorded action type. Possible values are: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, and DROP.</td>
</tr>
<tr>
<td>database</td>
<td>The active database, as set by the USE command.</td>
</tr>
<tr>
<td>object</td>
<td>For QUERY events, this value indicates the query that the database performed. For TABLE events, it indicates the table name.</td>
</tr>
<tr>
<td>retcode</td>
<td>The return code of the logged operation.</td>
</tr>
</tbody>
</table>
| connection_type | The security state of the connection to the server. Possible values are:  
  • 0 – Undefined  
  • 1 – TCP/IP  
  • 2 – Socket  
  • 3 – Named pipe  
  • 4 – SSL/TLS  
  • 5 – Shared memory  

This field is included only for RDS for MySQL version 5.7.34 and higher 5.7 versions, and all 8.0 versions.

### Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`. For information about viewing the log file in the console, see Viewing and listing database log files (p. 646). For information about downloading the log file, see Downloading a database log file (p. 647).

### Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify the settings. For more information about how to modify option settings, see Modifying an option setting (p. 271). For more information about each setting, see Audit Plugin option settings (p. 1235).

### Removing the MariaDB Audit Plugin

Amazon RDS doesn’t support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274)
- Modify the DB instance and specify a different option group that doesn’t include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
MySQL memcached support

Amazon RDS supports using the memcached interface to InnoDB tables that was introduced in MySQL 5.6. The memcached API enables applications to use InnoDB tables in a manner similar to NoSQL key-value data stores.

The memcached interface is a simple, key-based cache. Applications use memcached to insert, manipulate, and retrieve key-value data pairs from the cache. MySQL 5.6 introduced a plugin that implements a daemon service that exposes data from InnoDB tables through the memcached protocol. For more information about the MySQL memcached plugin, see InnoDB integration with memcached.

To enable memcached support for an RDS for MySQL 5.6 or later instance

1. Determine the security group to use for controlling access to the memcached interface. If the set of applications already using the SQL interface are the same set that will access the memcached interface, you can use the existing VPC or DB security group used by the SQL interface. If a different set of applications will access the memcached interface, define a new VPC or DB security group. For more information about managing security groups, see Controlling access with security groups (p. 1822).
2. Create a custom DB option group, selecting MySQL as the engine type and a 5.6 or later version. For more information about creating an option group, see Creating an option group (p. 264).
3. Add the MEMCACHED option to the option group. Specify the port that the memcached interface will use, and the security group to use in controlling access to the interface. For more information about adding options, see Adding an option to an option group (p. 266).
4. Modify the option settings to configure the memcached parameters, if necessary. For more information about how to modify option settings, see Modifying an option setting (p. 271).
5. Apply the option group to an instance. Amazon RDS enables memcached support for that instance when the option group is applied:
   - You enable memcached support for a new instance by specifying the custom option group when you launch the instance. For more information about launching a MySQL instance, see Creating an Amazon RDS DB instance (p. 175).
   - You enable memcached support for an existing instance by specifying the custom option group when you modify the instance. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).
6. Specify which columns in your MySQL tables can be accessed through the memcached interface. The memcached plug-in creates a catalog table named containers in a dedicated database named innodb_memcache. You insert a row into the containers table to map an InnoDB table for access through memcached. You specify a column in the InnoDB table that is used to store the memcached key values, and one or more columns that are used to store the data values associated with the key. You also specify a name that a memcached application uses to refer to that set of columns. For details on inserting rows in the containers table, see InnoDB memcached plugin internals. For an example of mapping an InnoDB table and accessing it through memcached, see Writing applications for the InnoDB memcached plugin.
7. If the applications accessing the memcached interface are on different computers or EC2 instances than the applications using the SQL interface, add the connection information for those computers to the VPC or DB security group associated with the MySQL instance. For more information about managing security groups, see Controlling access with security groups (p. 1822).

You turn off the memcached support for an instance by modifying the instance and specifying the default option group for your MySQL version. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).
MySQL memcached security considerations

The memcached protocol does not support user authentication. For more information about MySQL memcached security considerations, see memcached deployment and Using memcached as a MySQL caching layer.

You can take the following actions to help increase the security of the memcached interface:

- Specify a different port than the default of 11211 when adding the MEMCACHED option to the option group.
- Ensure that you associate the memcached interface with either a VPC or DB security group that limits access to known, trusted client addresses or EC2 instances. For more information about managing security groups, see Controlling access with security groups (p. 1822).

MySQL memcached connection information

To access the memcached interface, an application must specify both the DNS name of the Amazon RDS instance and the memcached port number. For example, if an instance has a DNS name of my-cache-instance.cg034hpkmjmt.region.rds.amazonaws.com and the memcached interface is using port 11212, the connection information specified in PHP would be:

```php
<?php
$cache = new Memcache;
$cache->connect('my-cache-instance.cg034hpkmjmt.region.rds.amazonaws.com',11212);
?>
```

To find the DNS name and memcached port of a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top right corner of the AWS Management Console, select the region that contains the DB instance.
3. In the navigation pane, choose Databases.
4. Choose the MySQL DB instance name to display its details.
5. In the Connect section, note the value of the Endpoint field. The DNS name is the same as the endpoint. Also, note that the port in the Connect section is not used to access the memcached interface.
6. In the Details section, note the name listed in the Option Group field.
7. In the navigation pane, choose Option groups.
8. Choose the name of the option group used by the MySQL DB instance to show the option group details. In the Options section, note the value of the Port setting for the MEMCACHED option.

MySQL memcached option settings

Amazon RDS exposes the MySQL memcached parameters as option settings in the Amazon RDS MEMCACHED option.

MySQL memcached parameters

- DAEMON_MEMCACHED_R_BATCH_SIZE – an integer that specifies how many memcached read operations (get) to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.
• **DAEMON\_MEMCACHED\_W\_BATCH\_SIZE** – an integer that specifies how many memcached write operations, such as add, set, or incr, to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.

• **INNODB\_API\_BK\_COMMIT\_INTERVAL** – an integer that specifies how often to auto-commit idle connections that use the InnoDB memcached interface. The allowed values are 1 to 1073741824; the default is 5. The option takes effect immediately, without requiring that you restart the instance.

• **INNODB\_API\_DISABLE\_ROWLOCK** – a Boolean that disables (1 (true)) or enables (0 (false)) the use of row locks when using the InnoDB memcached interface. The default is 0 (false). The option does not take effect until the instance is restarted.

• **INNODB\_API\_ENABLE\_MDL** – a Boolean that when set to 0 (false) locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. The default is 0 (false). The option does not take effect until the instance is restarted.

• **INNODB\_API\_TRX\_LEVEL** – an integer that specifies the transaction isolation level for queries processed by the memcached interface. The allowed values are 0 to 3. The default is 0. The option does not take effect until the instance is restarted.

Amazon RDS configures these MySQL memcached parameters, and they cannot be modified: DAEMON\_MEMCACHED\_LIB\_NAME, DAEMON\_MEMCACHED\_LIB\_PATH, and INNODB\_API\_ENABLE\_BINLOG. The parameters that MySQL administrators set by using daemon_memcached_options are available as individual MEMCACHED option settings in Amazon RDS.

**MySQL daemon_memcached_options parameters**

• **BINDING\_PROTOCOL** – a string that specifies the binding protocol to use. The allowed values are auto, ascii, or binary. The default is auto, which means the server automatically negotiates the protocol with the client. The option does not take effect until the instance is restarted.

• **BACKLOG\_QUEUE\_LIMIT** – an integer that specifies how many network connections can be waiting to be processed by memcached. Increasing this limit may reduce errors received by a client that is not able to connect to the memcached instance, but does not improve the performance of the server. The allowed values are 1 to 2048; the default is 1024. The option does not take effect until the instance is restarted.

• **CAS\_DISABLED** – a Boolean that enables (1 (true)) or disables (0 (false)) the use of compare and swap (CAS), which reduces the per-item size by 8 bytes. The default is 0 (false). The option does not take effect until the instance is restarted.

• **CHUNK\_SIZE** – an integer that specifies the minimum chunk size, in bytes, to allocate for the smallest item's key, value, and flags. The allowed values are 1 to 48. The default is 48 and you can significantly improve memory efficiency with a lower value. The option does not take effect until the instance is restarted.

• **CHUNK\_SIZE\_GROWTH\_FACTOR** – a float that controls the size of new chunks. The size of a new chunk is the size of the previous chunk times CHUNK\_SIZE\_GROWTH\_FACTOR. The allowed values are 1 to 2; the default is 1.25. The option does not take effect until the instance is restarted.

• **ERROR\_ON\_MEMORY\_EXHAUSTED** – a Boolean that when set to 1 (true) specifies that memcached will return an error rather than evicting items when there is no more memory to store items. If set to 0 (false), memcached will evict items if there is no more memory. The default is 0 (false). The option does not take effect until the instance is restarted.

• **MAX\_SIMULTANEOUS\_CONNECTIONS** – an integer that specifies the maximum number of concurrent connections. Setting this value to anything under 10 prevents MySQL from starting. The allowed values are 10 to 1024; the default is 1024. The option does not take effect until the instance is restarted.

• **VERBOSITY** – a string that specifies the level of information logged in the MySQL error log by the memcached service. The default is v. The option does not take effect until the instance is restarted. The allowed values are:
• `v` – Logs errors and warnings while running the main event loop.
• `vv` – In addition to the information logged by `v`, also logs each client command and the response.
• `vvv` – In addition to the information logged by `vv`, also logs internal state transitions.

Amazon RDS configures these MySQL `DAEMON_MEMCACHED_OPTIONS` parameters, they cannot be modified: `DAEMON_PROCESS`, `LARGE_MEMORY_PAGES`, `MAXIMUM_CORE_FILE_LIMIT`, `MAX_ITEM_SIZE`, `LOCK_DOWN_PAGE_MEMORY`, `MASK`, `IDFILE`, `REQUESTS_PER_EVENT`, `SOCKET`, and `USER`. 
Parameters for MySQL

By default, a MySQL DB instance uses a DB parameter group that is specific to a MySQL database. This parameter group contains parameters for the MySQL database engine. For information about working with parameter groups and setting parameters, see Working with parameter groups (p. 278).

RDS for MySQL parameters are set to the default values of the storage engine that you have selected. For more information about MySQL parameters, see the MySQL documentation. For more information about MySQL storage engines, see Supported storage engines for RDS for MySQL (p. 1137).

You can view the parameters available for a specific RDS for MySQL version using the RDS console or the AWS CLI. For information about viewing the parameters in a MySQL parameter group in the RDS console, see Viewing parameter values for a DB parameter group (p. 289).

Using the AWS CLI, you can view the parameters for an RDS for MySQL version by running the describe-engine-default-parameters command. Specify one of the following values for the --db-parameter-group-family option:

- mysql8.0
- mysql5.7
- mysql5.6

For example, to view the parameters for RDS for MySQL version 8.0, run the following command.

```bash
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0
```

Your output looks similar to the following.

```json
{
   "EngineDefaults": {
      "Parameters": [
         {
            "ParameterName": "activate_all_roles_on_login",
            "ParameterValue": "0",
            "Description": "Automatically set all granted roles as active after the user has authenticated successfully.",
            "Source": "engine-default",
            "ApplyType": "dynamic",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": true
         },
         {
            "ParameterName": "allow-suspicious-udfs",
            "Description": "Controls whether user-defined functions that have only an xxx symbol for the main function can be loaded",
            "Source": "engine-default",
            "ApplyType": "static",
            "DataType": "boolean",
            "AllowedValues": "0,1",
            "IsModifiable": false
         },
         {
            "ParameterName": "auto_generate_certs",
            "Description": "Controls whether the server autogenerates SSL key and certificate files in the data directory, if they do not already exist.",
            "Source": "engine-default",
            "ApplyType": "static",
            "DataType": "boolean",
            "IsModifiable": true
         }
      ]
   }
}```
To list only the modifiable parameters for RDS for MySQL version 8.0, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0
  --query 'EngineDefaults.Parameters[?IsModifiable==`true`]'
```

For Windows:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0
  --query "EngineDefaults.Parameters[?IsModifiable==`true`]"
```
Common DBA tasks for MySQL DB instances

Following, you can find descriptions of the Amazon RDS–specific implementations of some common DBA tasks for DB instances running the MySQL database engine. To deliver a managed service experience, Amazon RDS doesn’t provide shell access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges.

For information about working with MySQL log files on Amazon RDS, see MySQL database log files (p. 664).

Topics
- Ending a session or query (p. 1245)
- Skipping the current replication error (p. 1245)
- Working with InnoDB tablespaces to improve crash recovery times (p. 1246)
- Managing the global status history (p. 1248)

Ending a session or query

You can end user sessions or queries on DB instances by using the rds_kill and rds_kill_query commands. First connect to your MySQL DB instance, then issue the appropriate command as shown following. For more information, see Connecting to a DB instance running the MySQL database engine (p. 1146).

```
CALL mysql.rds_kill(thread-ID)
CALL mysql.rds_kill_query(thread-ID)
```

For example, to end the session that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill(99);
```

To end the query that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill_query(99);
```

Skipping the current replication error

You can skip an error on your read replica if the error is causing your read replica to stop responding and the error doesn’t affect the integrity of your data.

**Note**
First verify that the error in question can be safely skipped. In a MySQL utility, connect to the read replica and run the following MySQL command.

```
SHOW REPLICA STATUS\G
```

For information about the values returned, see the MySQL documentation. Previous versions of and MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

You can skip an error on your read replica in the following ways.

Topics
Calling the mysql.rds_skip_repl_error procedure

Amazon RDS provides a stored procedure that you can call to skip an error on your read replicas. First connect to your read replica, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine (p. 1146).

To skip the error, issue the following command.

```
CALL mysql.rds_skip_repl_error;
```

This command has no effect if you run it on the source DB instance, or on a read replica that hasn't encountered a replication error.

For more information, such as the versions of MySQL that support mysql.rds_skip_repl_error, see mysql.rds_skip_repl_error (p. 1281).

Important

If you attempt to call mysql.rds_skip_repl_error and encounter the following error:

```
ERROR 1305 (42000): PROCEDURE mysql.rds_skip_repl_error does not exist
```

then upgrade your MySQL DB instance to the latest minor version or one of the minimum minor versions listed in mysql.rds_skip_repl_error (p. 1281).

Setting the slave_skip_errors parameter

To skip one or more errors, you can set the slave_skip_errors static parameter on the read replica. You can set this parameter to skip one or more specific replication error codes. Currently, you can set this parameter only for RDS for MySQL 5.7 DB instances. After you change the setting for this parameter, make sure to reboot your DB instance for the new setting to take effect. For information about setting this parameter, see the MySQL documentation.

We recommend setting this parameter in a separate DB parameter group. You can associate this DB parameter group only with the read replicas that need to skip errors. Following this best practice reduces the potential impact on other DB instances and read replicas.

Important

Setting a nondefault value for this parameter can lead to replication inconsistency. Only set this parameter to a nondefault value if you have exhausted other options to resolve the problem and you are sure of the potential impact on your read replica's data.

Working with InnoDB tablespaces to improve crash recovery times

Every table in MySQL consists of a table definition, data, and indexes. The MySQL storage engine InnoDB stores table data and indexes in a `tablespace`. InnoDB creates a global shared tablespace that contains a data dictionary and other relevant metadata, and it can contain table data and indexes. InnoDB can also create separate tablespaces for each table and partition. These separate tablespaces are stored in files with a `.ibd` extension and the header of each tablespace contains a number that uniquely identifies it.

Amazon RDS provides a parameter in a MySQL parameter group called `innodb_file_per_table`. This parameter controls whether InnoDB adds new table data and indexes to the shared tablespace (by setting the parameter value to 0) or to individual tablespaces (by setting the parameter value to 1). Amazon RDS sets the default value for `innodb_file_per_table` parameter to 1, which allows you to
drop individual InnoDB tables and reclaim storage used by those tables for the DB instance. In most use cases, setting the `innodb_file_per_table` parameter to 1 is the recommended setting.

You should set the `innodb_file_per_table` parameter to 0 when you have a large number of tables, such as over 1000 tables when you use standard (magnetic) or general purpose SSD storage or over 10,000 tables when you use Provisioned IOPS storage. When you set this parameter to 0, individual tablespaces are not created and this can improve the time it takes for database crash recovery.

MySQL processes each metadata file, which includes tablespaces, during the crash recovery cycle. The time it takes MySQL to process the metadata information in the shared tablespace is negligible compared to the time it takes to process thousands of tablespace files when there are multiple tablespaces. Because the tablespace number is stored within the header of each file, the aggregate time to read all the tablespace files can take up to several hours. For example, a million InnoDB tablespaces on standard storage can take from five to eight hours to process during a crash recovery cycle. In some cases, InnoDB can determine that it needs additional cleanup after a crash recovery cycle so it will begin another crash recovery cycle, which will extend the recovery time. Keep in mind that a crash recovery cycle also entails rolling-back transactions, fixing broken pages, and other operations in addition to the processing of tablespace information.

Since the `innodb_file_per_table` parameter resides in a parameter group, you can change the parameter value by editing the parameter group used by your DB instance without having to reboot the DB instance. After the setting is changed, for example, from 1 (create individual tables) to 0 (use shared tablespace), new InnoDB tables will be added to the shared tablespace while existing tables continue to have individual tablespaces. To move an InnoDB table to the shared tablespace, you must use the `ALTER TABLE` command.

### Migrating multiple tablespaces to the shared tablespace

You can move an InnoDB table’s metadata from its own tablespace to the shared tablespace, which will rebuild the table metadata according to the `innodb_file_per_table` parameter setting. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine (p. 1146).

```sql
ALTER TABLE table_name ENGINE = InnoDB, ALGORITHM=COPY;
```

For example, the following query returns an `ALTER TABLE` statement for every InnoDB table that is not in the shared tablespace.

**For MySQL 5.6 and 5.7 DB instances:**

```sql
SELECT CONCAT('ALTER TABLE `',
               REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), '`.`',
               REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), ``,
               ' ENGINE=InnoDB,
               ` ENGINE=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ("mysql",
```

**For MySQL 8.0 DB instances:**

```sql
SELECT CONCAT('ALTER TABLE `',
               REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), '`.`',
               REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), ``,
               ' ENGINE=InnoDB,
               ` ENGINE=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ("mysql",
```

Rebuilding a MySQL table to move the table's metadata to the shared tablespace requires additional storage space temporarily to rebuild the table, so the DB instance must have storage space available.
During rebuilding, the table is locked and inaccessible to queries. For small tables or tables not frequently accessed, this might not be an issue. For large tables or tables frequently accessed in a heavily concurrent environment, you can rebuild tables on a read replica.

You can create a read replica and migrate table metadata to the shared tablespace on the read replica. While the ALTER TABLE statement blocks access on the read replica, the source DB instance is not affected. The source DB instance will continue to generate its binary logs while the read replica lags during the table rebuilding process. Because the rebuilding requires additional storage space and the replay log file can become large, you should create a read replica with storage allocated that is larger than the source DB instance.

To create a read replica and rebuild InnoDB tables to use the shared tablespace, take the following steps:

1. Make sure that backup retention is enabled on the source DB instance so that binary logging is enabled.
2. Use the AWS Management Console or AWS CLI to create a read replica for the source DB instance. Because the creation of a read replica involves many of the same processes as crash recovery, the creation process can take some time if there is a large number of InnoDB tablespaces. Allocate more storage space on the read replica than is currently used on the source DB instance.
3. When the read replica has been created, create a parameter group with the parameter settings read_only = 0 and innodb_file_per_table = 0. Then associate the parameter group with the read replica.
4. Issue the following SQL statement for all tables that you want migrated on the replica:

   ```sql
   ALTER TABLE name ENGINE = InnoDB
   ```
5. When all of your ALTER TABLE statements have completed on the read replica, verify that the read replica is connected to the source DB instance and that the two instances are in sync.
6. Use the console or CLI to promote the read replica to be the instance. Make sure that the parameter group used for the new standalone DB instance has the innodb_file_per_table parameter set to 0. Change the name of the new standalone DB instance, and point any applications to the new standalone DB instance.

---

**Managing the global status history**

MySQL maintains many status variables that provide information about its operation. Their value can help you detect locking or memory issues on a DB instance. The values of these status variables are cumulative since last time the DB instance was started. You can reset most status variables to 0 by using the `FLUSH STATUS` command.

To allow for monitoring of these values over time, Amazon RDS provides a set of procedures that will snapshot the values of these status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure, called Global Status History (GoSH), is installed on all MySQL DB instances starting with versions 5.5.23. GoSH is disabled by default.

To enable GoSH, you first enable the event scheduler from a DB parameter group by setting the parameter event_scheduler to ON. For information about creating and modifying a DB parameter group, see Working with parameter groups (p. 278).

You can then use the procedures in the following table to enable and configure GoSH. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see Connecting to a DB instance running the MySQL database engine (p. 1146). For each procedure, type the following:

```sql
CALL procedure-name;
```
Where `procedure-name` is one of the procedures in the table.

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql.rds_enable_gsh_collector</code></td>
<td>Enables GoSH to take default snapshots at intervals specified by <code>rds_set_gsh_collector</code>.</td>
</tr>
<tr>
<td><code>mysql.rds_set_gsh_collector</code></td>
<td>Specifies the interval, in minutes, between snapshots. Default value is 5.</td>
</tr>
<tr>
<td><code>mysql.rds_disable_gsh_collector</code></td>
<td>Disables snapshots.</td>
</tr>
<tr>
<td><code>mysql.rds_collect_global_status</code></td>
<td>Takes a snapshot on demand.</td>
</tr>
<tr>
<td><code>mysql.rds_enable_gsh_rotation</code></td>
<td>Enables rotation of the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> at intervals specified by <code>rds_set_gsh_rotation</code>.</td>
</tr>
<tr>
<td><code>mysql.rds_set_gsh_rotation</code></td>
<td>Specifies the interval, in days, between table rotations. Default value is 7.</td>
</tr>
<tr>
<td><code>mysql.rds_disable_gsh_rotation</code></td>
<td>Disables table rotation.</td>
</tr>
<tr>
<td><code>mysql.rds_rotate_global_status</code></td>
<td>Rotates the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> on demand.</td>
</tr>
</tbody>
</table>

When GoSH is running, you can query the tables that it writes to. For example, to query the hit ratio of the Innodb buffer pool, you would issue the following query:

```
select a.collection_end, a.collection_start, (( a.variable_Delta-b.variable_delta)/a.variable_delta)*100 as "HitRatio"
from mysql.rds_global_status_history as a join mysql.rds_global_status_history as b on a.collection_end = b.collection_end
where a. variable_name = 'Innodb_buffer_pool_read_requests' and b.variable_name = 'Innodb_buffer_pool_reads'
```
Using Kerberos authentication for MySQL

You can use Kerberos authentication to authenticate users when they connect to your MySQL DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

Amazon RDS supports Kerberos authentication for MySQL DB instances in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Stockholm)
- South America (São Paulo)
- China (Beijing)
- China (Ningxia)

To set up Kerberos authentication for a MySQL DB instance, complete the following general steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service to create the directory. For details about doing so, see Create your AWS Managed Microsoft AD directory in the AWS Directory Service Administration Guide.

2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. The role allows Amazon RDS to make calls to your directory.

   For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS managed Microsoft AD in the AWS Directory Service Administration Guide.

4. Create or modify a MySQL DB instance. If you use either the CLI or RDS API in the create request, specify a domain identifier with the Domain parameter. Use the d-* identifier that was generated when you created your directory and the name of the role that you created.
If you modify an existing MySQL DB instance to use Kerberos authentication, set the domain and IAM role parameters for the DB instance. Locate the DB instance in the same VPC as the domain directory.

5. Use the Amazon RDS master user credentials to connect to the MySQL DB instance. Create the user in MySQL using the `CREATE USER` clause `IDENTIFIED WITH 'auth_pam'`. Users that you create this way can log in to the MySQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for MySQL DB instances

You use AWS Managed Microsoft AD to set up Kerberos authentication for a MySQL DB instance. To set up Kerberos authentication, you take the following steps.

**Step 1: Create a directory using AWS Managed Microsoft AD**

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.
  
  **Note**
  
  Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs
To create a directory with AWS Managed Microsoft AD

2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

   **Directory DNS name**
   
   The fully qualified name for the directory, such as `corp.example.com`.

   **Directory NetBIOS name**
   
   The short name for the directory, such as `CORP`.

   **Directory description**
   
   (Optional) A description for the directory.

   **Admin password**
   
   The password for the directory administrator. The directory creation process creates an administrator account with the user name `Admin` and this password.

   The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   - Lowercase letters (a–z)
   - Uppercase letters (A–Z)
   - Numbers (0–9)
   - Non-alphanumeric characters (~!@#$%^&*_-+=`|(){}[]:;"'<>,.?/)  

   **Confirm password**
   
   The administrator password retyped.

5. Choose **Next**.
6. Enter the following information in the **Networking** section and then choose **Next**:

   **VPC**
   
   The VPC for the directory. Create the MySQL DB instance in this same VPC.

   **Subnets**
   
   Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.
It takes several minutes for the directory to be created. When it has been successfully created, the Status value changes to Active.

To see information about your directory, choose the directory name in the directory listing. Note the Directory ID value because you need this value when you create or modify your MySQL DB instance.
Step 2: Create the IAM role for use by Amazon RDS

For Amazon RDS to call AWS Directory Service for you, an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess` is required. This role allows Amazon RDS to make calls to the AWS Directory Service.

When a DB instance is created using the AWS Management Console and the console user has the `iam:CreateRole` permission, the console creates this role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

**Note**

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for MySQL.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. In this case, the IAM role must have the following IAM trust policy.

```json
{ }
```
Step 3: Create and configure users

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to an Amazon EC2 instance based on Microsoft Windows. This instance must be a member of the AWS Directory Service directory and be logged in as a user that has privileges to create users. For more information, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

Step 4: Create or modify a MySQL DB instance

Create or modify a MySQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new MySQL DB instance using the console, the `create-db-instance` CLI command, or the CreateDBInstance RDS API operation.

  For instructions, see Creating an Amazon RDS DB instance (p. 175).

- Modify an existing MySQL DB instance using the console, the `modify-db-instance` CLI command, or the ModifyDBInstance RDS API operation.

  For instructions, see Modifying an Amazon RDS DB instance (p. 309).

- Restore a MySQL DB instance from a DB snapshot using the console, the `restore-db-instance-from-db-snapshot` CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.
For instructions, see Restoring from a DB snapshot (p. 432).

- Restore a MySQL DB instance to a point-in-time using the console, the `restore-db-instance-to-point-in-time` CLI command, or the `RestoreDBInstanceToPointInTime` RDS API operation.

For instructions, see Restoring a DB instance to a specified time (p. 480).

Kerberos authentication is only supported for MySQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows egress within the directory's VPC so the DB instance can communicate with the directory.

When you use the console to create a DB instance, choose Password and Kerberos authentication in the Database authentication section. Choose Browse Directory and then select the directory, or choose Create a new directory.

When you use the console to modify or restore a DB instance, choose the directory in the Kerberos authentication section, or choose Create a new directory.

Use the CLI or RDS API to associate a DB instance with a directory. The following parameters are required for the DB instance to be able to use the domain directory you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:
aws rds modify-db-instance \
   --db-instance-identifier mydbinstance \
   --domain d-ID \
   --domain-iam-role-name role-name

For Windows:

aws rds modify-db-instance ^
   --db-instance-identifier mydbinstance ^
   --domain d-ID ^
   --domain-iam-role-name role-name

Important
If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 5: Create Kerberos authentication MySQL logins

Use the Amazon RDS master user credentials to connect to the MySQL DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision MySQL logins and users from the Active Directory users in your domain. Database permissions are managed through standard MySQL permissions that are granted to and revoked from these logins.

You can allow an Active Directory user to authenticate with MySQL. To do this, first use the Amazon RDS master user credentials to connect to the MySQL DB instance as with any other DB instance. After you’re logged in, create an externally authenticated user with PAM (Pluggable Authentication Modules) in MySQL as shown following.

CREATE USER 'testuser'@'%' IDENTIFIED WITH 'auth_pam';

Replace testuser with the user name. Users (both humans and applications) from your domain can now connect to the DB instance from a domain joined client machine using Kerberos authentication.

Important
We strongly recommended that clients use SSL/TLS connections when using PAM authentication. If they don't use SSL/TLS connections, the password might be sent as clear text in some cases. To require an SSL/TLS encrypted connection for your AD user, run the following command:

UPDATE mysql.user SET ssl_type = 'any' WHERE ssl_type = '' AND PLUGIN = 'auth_pam' 
   and USER = 'testuser';
FLUSH PRIVILEGES;

For more information, see Using SSL with a MySQL DB instance (p. 1140).

Managing a DB instance in a domain

You can use the CLI or the RDS API to manage your DB instance and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:
• To reattempt enabling Kerberos authentication for a failed membership, use the ModifyDBInstance API operation and specify the current membership's directory ID.
• To update the IAM role name for membership, use the ModifyDBInstance API operation and specify the current membership's directory ID and the new IAM role.
• To disable Kerberos authentication on a DB instance, use the ModifyDBInstance API operation and specify none as the domain parameter.
• To move a DB instance from one domain to another, use the ModifyDBInstance API operation and specify the domain identifier of the new domain as the domain parameter.
• To list membership for each DB instance, use the DescribeDBInstances API operation.

Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership for the DB instance by running the describe-db-instances CLI command. The status of the DB instance can be one of the following:

• kerberos-enabled – The DB instance has Kerberos authentication enabled.
• enabling-kerberos – AWS is in the process of enabling Kerberos authentication on this DB instance.
• pending-enable-kerberos – The enabling of Kerberos authentication is pending on this DB instance.
• pending-maintenance-enable-kerberos – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
• pending-disable-kerberos – The disabling of Kerberos authentication is pending on this DB instance.
• pending-maintenance-disable-kerberos – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
• enable-kerberos-failed – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Check and fix your configuration before reissuing the DB instance modify command.
• disabling-kerberos – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB instance or modify an existing DB instance and the attempt to enable Kerberos authentication fails. If this happens, re-issue the modify command or modify the newly created DB instance to join the domain.

Connecting to MySQL with Kerberos authentication

To connect to MySQL with Kerberos authentication, you must log in using the Kerberos authentication type.

To create a database user that you can connect to using Kerberos authentication, use an IDENTIFIED WITH clause on the CREATE USER statement. For instructions, see Step 5: Create Kerberos authentication MySQL logins (p. 1257).

To avoid errors, use the MariaDB mysql client. You can download MariaDB software at https://downloads.mariadb.org/.

At a command prompt, connect to one of the endpoints associated with your MySQL DB instance. Follow the general procedures in Connecting to a DB instance running the MySQL database engine (p. 1146). When you're prompted for the password, enter the Kerberos password associated with that user name.
Restoring a MySQL DB instance and adding it to a domain

You can restore a DB snapshot or complete a point-in-time restore for a MySQL DB instance and then add it to a domain. After the DB instance is restored, modify the DB instance using the process explained in Step 4: Create or modify a MySQL DB instance (p. 1255) to add the DB instance to a domain.

Kerberos authentication MySQL limitations

The following limitations apply to Kerberos authentication for MySQL:

- Only an AWS Managed Microsoft AD is supported. However, you can join RDS for MySQL DB instances to shared Managed Microsoft AD domains owned by different accounts in the same AWS Region.
- Kerberos authentication is supported for the following Amazon RDS for MySQL versions:
  - Amazon RDS for MySQL version 8.0.13 and higher 8.0 versions
  - Amazon RDS for MySQL version 5.7.24 and higher 5.7 versions
- You must reboot the DB instance after enabling the feature.
- The domain name length can't be longer than 61 characters.
- You can't enable Kerberos authentication and IAM authentication at the same time. Choose one authentication method or the other for your MySQL DB instance.
- Don't modify the DB instance port after enabling the feature.
- Don't use Kerberos authentication with read replicas.
- If you have auto minor version upgrade turned on for a MySQL DB instance that is using Kerberos authentication, you must turn off Kerberos authentication and then turn it back on after an automatic upgrade. For more information about auto minor version upgrades, see Automatic minor version upgrades for MySQL (p. 1165).
- To delete a DB instance with this feature enabled, first disable the feature. To do this, use the modify-db-instance CLI command for the DB instance and specify `none` for the `--domain` parameter.

If you use the CLI or RDS API to delete a DB instance with this feature enabled, expect a delay.
Known issues and limitations for Amazon RDS for MySQL

Known issues and limitations for working with Amazon RDS for MySQL are as follows.

Topics
- InnoDB reserved word (p. 1260)
- Inconsistent InnoDB buffer pool size (p. 1260)
- Index merge optimization returns wrong results (p. 1260)
- Log file size (p. 1261)
- MySQL parameter exceptions for Amazon RDS DB instances (p. 1261)
- MySQL file size limits in Amazon RDS (p. 1262)
- MySQL Keyring Plugin not supported (p. 1263)

InnoDB reserved word

InnoDB is a reserved word for RDS for MySQL. You can't use this name for a MySQL database.

Inconsistent InnoDB buffer pool size

For MySQL 5.7, there is currently a bug in the way that the InnoDB buffer pool size is managed. MySQL 5.7 might adjust the value of the innodb_buffer_pool_size parameter to a large value that can result in the InnoDB buffer pool growing too large and using up too much memory. This effect can cause the MySQL database engine to stop running or can prevent the MySQL database engine from starting. This issue is more common for DB instance classes that have less memory available.

To resolve this issue, set the value of the innodb_buffer_pool_size parameter to a multiple of the product of the innodb_buffer_pool_instances parameter value and the innodb_buffer_pool_chunk_size parameter value. For example, you might set the innodb_buffer_pool_size parameter value to a multiple of eight times the product of the innodb_buffer_pool_instances and innodb_buffer_pool_chunk_size parameter values, as shown in the following example.

\[
\text{innodb_buffer_pool_chunk_size} = 536870912 \\
\text{innodb_buffer_pool_instances} = 4 \\
\text{innodb_buffer_pool_size} = (536870912 \times 4) \times 8 = 17179869184
\]

For details on this MySQL 5.7 bug, go to https://bugs.mysql.com/bug.php?id=79379 in the MySQL documentation.

Index merge optimization returns wrong results

Queries that use index merge optimization might return wrong results due to a bug in the MySQL query optimizer that was introduced in MySQL 5.5.37. When you issue a query against a table with multiple indexes the optimizer scans ranges of rows based on the multiple indexes, but does not merge the results together correctly. For more information on the query optimizer bug, go to http://bugs.mysql.com/bug.php?id=72745 and http://bugs.mysql.com/bug.php?id=68194 in the MySQL bug database.

For example, consider a query on a table with two indexes where the search arguments reference the indexed columns.

1260
SELECT * FROM table1
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';

In this case, the search engine will search both indexes. However, due to the bug, the merged results are incorrect.

To resolve this issue, you can do one of the following:

- Set the optimizer_switch parameter to index_merge=off in the DB parameter group for your MySQL DB instance. For information on setting DB parameter group parameters, see Working with parameter groups (p. 278).
- Upgrade your MySQL DB instance to MySQL version 5.6, 5.7, or 8.0. For more information, see Upgrading a MySQL DB snapshot (p. 1170).
- If you cannot upgrade your instance or change the optimizer_switch parameter, you can work around the bug by explicitly identifying an index for the query, for example:

SELECT * FROM table1
USE INDEX covering_index
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';

For more information, go to Index merge optimization.

Log file size

For MySQL, there is a size limit on BLOBs written to the redo log. To account for this limit, ensure that the innodb_log_file_size parameter for your MySQL DB instance is 10 times larger than the largest BLOB data size found in your tables, plus the length of other variable length fields (VARCHAR, VARBINARY, TEXT) in the same tables. For information on how to set parameter values, see Working with parameter groups (p. 278). For information on the redo log BLOB size limit, go to Changes in MySQL 5.6.20.

MySQL parameter exceptions for Amazon RDS DB instances

Some MySQL parameters require special considerations when used with an Amazon RDS DB instance.

lower_case_table_names

Because Amazon RDS uses a case-sensitive file system, setting the value of the lower_case_table_names server parameter to 2 ("names stored as given but compared in lowercase") is not supported. The following are the supported values for Amazon RDS for MySQL DB instances:

- 0 ("names stored as given and comparisons are case-sensitive") is supported for all Amazon RDS for MySQL versions.
- 1 ("names stored in lowercase and comparisons are not case-sensitive") is supported for Amazon RDS for MySQL version 5.6, version 5.7, and version 8.0.19 and higher 8.0 versions.

Set the lower_case_table_names parameter in a custom DB parameter group before creating a DB instance. Then, specify the custom DB parameter group when you create the DB instance.

When a parameter group is associated with a MySQL DB instance with a version lower than 8.0, we recommend that you avoid changing the lower_case_table_names parameter in the parameter
group. Doing so could cause inconsistencies with point-in-time recovery backups and read replica DB instances.

When a parameter group is associated with a version 8.0 MySQL DB instance, you can't modify the `lower_case_table_names` parameter in the parameter group.

Read replicas should always use the same `lower_case_table_names` parameter value as the source DB instance.

**long_query_time**

You can set the `long_query_time` parameter to a floating point value which allows you to log slow queries to the MySQL slow query log with microsecond resolution. You can set a value such as 0.1 seconds, which would be 100 milliseconds, to help when debugging slow transactions that take less than one second.

### MySQL file size limits in Amazon RDS

For MySQL DB instances, the maximum provisioned storage limit constrains the size of a table to a maximum size of 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) is set by default for MySQL DB instances.

**Note**

Some existing DB instances have a lower limit. For example, MySQL DB instances created before April 2014 have a file and table size limit of 2 TB. This 2 TB file size limit also applies to DB instances or read replicas created from DB snapshots taken before April 2014, regardless of when the DB instance was created.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, go to File-per-table tablespaces in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking a large table up into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, go to Partitioning in the MySQL documentation.

**To determine the file size of a table**

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

  ```sql
  SELECT TABLE_SCHEMA, TABLE_NAME,
  round(((DATA_LENGTH + INDEX_LENGTH) / 1024 / 1024), 2) As "Approximate size (MB)"
  FROM information_schema.TABLES
  WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema');
  ```

**To enable InnoDB file-per-table tablespaces**

- To enable InnoDB file-per-table tablespaces, set the `innodb_file_per_table` parameter to 1 in the parameter group for the DB instance.
To disable InnoDB file-per-table tablespaces

- To disable InnoDB file-per-table tablespaces, set the `innodb_file_per_table` parameter to 0 in the parameter group for the DB instance.

For information on updating a parameter group, see Working with parameter groups (p. 278).

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an `ALTER TABLE` command to move a table from the global tablespace to its own tablespace, or from its own tablespace to the global tablespace as shown in the following example:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

MySQL Keyring Plugin not supported

Currently, Amazon RDS for MySQL does not support the MySQL `keyring_aws` Amazon Web Services Keyring Plugin.
MySQL on Amazon RDS SQL reference

This appendix describes system stored procedures that are available for Amazon RDS instances running the MySQL DB engine.

Overview

The following system stored procedures are supported for Amazon RDS DB instances running MySQL. The master user must run these procedures.

Replication

- `mysql.rds_set_master_auto_position` (p. 1265)
- `mysql.rds_set_external_master` (p. 1266)
- `mysql.rds_set_external_master_with_delay` (p. 1268)
- `mysql.rds_set_external_master_with_auto_position` (p. 1271)
- `mysql.rds_reset_external_master` (p. 1273)
- `mysql.rds-import_binlog_ssl_material` (p. 1274)
- `mysql.rds_remove_binlog_ssl_material` (p. 1276)
- `mysql.rds_set_source_delay` (p. 1276)
- `mysql.rds_start_replication` (p. 1277)
- `mysql.rds_start_replication_until` (p. 1277)
- `mysql.rds_start_replication_until_gtid` (p. 1278)
- `mysql.rds_stop_replication` (p. 1279)
- `mysql.rds_skip_transaction_with_gtid` (p. 1280)
- `mysql.rds_skip_repl_error` (p. 1281)
- `mysql.rds_next_master_log` (p. 1281)

InnoDB cache warming

- `mysql.rds_innodb_buffer_pool_dump_now` (p. 1283)
- `mysql.rds_innodb_buffer_pool_load_now` (p. 1284)
- `mysql.rds_innodb_buffer_pool_load_abort` (p. 1284)

Managing additional configuration (for example, binlog file retention)

- `mysql.rds-set_configuration` (p. 1284)
- `mysql.rds-show_configuration` (p. 1286)

Ending a session or query

- `mysql.rds-kill` (p. 1287)
- `mysql.rds-kill_query` (p. 1287)

Logging

- `mysql.rds_rotate_general_log` (p. 1288)
- `mysql.rds_rotate_slow_log` (p. 1288)
Managing the global status history

- `mysql.rds_enable_gsh_collector (p. 1288)`
- `mysql.rds_set_gsh_collector (p. 1289)`
- `mysql.rds_disable_gsh_collector (p. 1289)`
- `mysql.rds_collect_global_status_history (p. 1289)`
- `mysql.rds_enable_gsh_rotation (p. 1289)`
- `mysql.rds_set_gsh_rotation (p. 1289)`
- `mysql.rds_disable_gsh_rotation (p. 1290)`
- `mysql.rds_rotate_global_status_history (p. 1290)`

SQL reference conventions

Following, you can find explanations for the conventions that are used to describe the syntax of the system stored procedures and tables described in the SQL reference section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPPERCASE</td>
<td>Words in uppercase are keywords.</td>
</tr>
<tr>
<td>[ ]</td>
<td>Square brackets indicate optional arguments.</td>
</tr>
<tr>
<td>{ }</td>
<td>Braces indicate that you are required to choose one of the arguments inside the braces.</td>
</tr>
<tr>
<td></td>
<td>Pipes separate arguments that you can choose.</td>
</tr>
<tr>
<td><em>italics</em></td>
<td>Words in italics indicate placeholders. You must insert the appropriate value in place of the word in italics.</td>
</tr>
<tr>
<td>...</td>
<td>An ellipsis indicates that you can repeat the preceding element.</td>
</tr>
<tr>
<td>'</td>
<td>Words in single quotes indicate that you must type the quotes.</td>
</tr>
</tbody>
</table>

`mysql.rds_set_master_auto_position`

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

**Syntax**

```sql
CALL mysql.rds_set_master_auto_position (auto_position_mode);
```

**Parameters**

- `auto_position_mode`

  A value that indicates whether to use log file position replication or GTID-based replication:
  - 0 – Use the replication method based on binary log file position. The default is 0.
1 – Use the GTID-based replication method.

Usage notes

The master user must run the `mysql.rds_set_master_auto_position` procedure.

For RDS for MySQL 5.7, this procedure is supported for MySQL 5.7.23 and higher 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions. This procedure isn't supported for RDS for MySQL 5.6.

**mysql.rds_set_external_master**

Configures a MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

**Important**

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group (p. 282).

**Note**

You can use the `mysql.rds_set_external_master_with_delay` (p. 1268) stored procedure to configure an external source database instance and delayed replication.

**Syntax**

```sql
CALL mysql.rds_set_external_master (
    host_name
    , host_port
    , replication_user_name
    , replication_user_password
    , mysql_binary_log_file_name
    , mysql_binary_log_file_location
    , ssl_encryption
);
```

**Parameters**

`host_name`

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

`host_port`

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

`replication_user_name`

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

`replication_user_password`

The password of the user ID specified in `replication_user_name`. 
**mysql_binary_log_file_name**

The name of the binary log on the source database instance that contains the replication information.

**mysql_binary_log_file_location**

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

**ssl_encryption**

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

**Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

**Usage notes**

The master user must run the `mysql.rds_set_external_master` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify `replication_user_name` and `replication_user_password` values that indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

**To configure an external instance of MySQL as a source database instance**

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   **MySQL 5.6 and 5.7**

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
   ```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   **MySQL 5.6 and 5.7**

   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**
To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the `mysql.rds_import_binlog_ssl_material` procedure.

**Note**
We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with read replicas.

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of set master in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

**Examples**

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```sql
call mysql.rds_set_external_master(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'password',
    'mysql-bin-changelog.0777',
    120,
    0);
```

**mysql.rds_set_external_master_with_delay**

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS and configures delayed replication.

**Important**
To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group.

**Syntax**

```sql
CALL mysql.rds_set_external_master_with_delay (host_name, host_port, replication_user_name)
```
Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS that will become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

mysql_binary_log_file_name

The name of the binary log on the source database instance contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the mysql.rds_set_external_master_with_delay procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.
Before you run `mysql.rds_set_external_master_with_delay`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

### To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `repl_user` user for your domain.

   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   ```

   For more information, see [Replication with a MariaDB or MySQL instance running external to Amazon RDS](p. 1222).

   **Note**

   We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with read replicas](p. 354).

After calling `mysql.rds_set_external_master_with_delay` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_master` to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_delay`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_delay` procedure. After the `mysql.rds_start_replication_until` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](p. 361).

To use the `mysql.rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication for RDS for MySQL](p. 1217).

The `mysql.rds_set_external_master_with_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
MySQL 5.7.22 and higher 5.7 versions
MySQL 5.6.40 and higher 5.6 versions

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn’t applied on the MySQL DB instance read replica for at least one hour.

```sql
call mysql.rds_set_external_master_with_delay(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'SomePassW0rd',
    'mysql-bin-changelog.000777',
    120,
    0,
    3600);
```

mysql.rds_set_external_master_with_auto_position

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).

**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](p. 282).

Syntax

```sql
CALL mysql.rds_set_external_master_with_auto_position (
    host_name
    , host_port
    , replication_user_name
    , replication_user_password
    , ssl_encryption
    , delay
);
```

Parameters

`host_name`

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

`host_port`

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.
replication_user_name

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).

Usage notes

The master user must run the mysql.rds_set_external_master_with_auto_position procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

For RDS for MySQL 5.7, this procedure is supported for MySQL 5.7.23 and higher MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions. This procedure isn't supported for RDS for MySQL 5.6.

Before you run mysql.rds_set_external_master_with_auto_position, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for replication_user_name and replication_user_password. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'

For more information, see Replication with a MariaDB or MySQL instance running external to Amazon RDS (p. 1222).
Note
We recommend that you use read replicas to manage replication between two Amazon RDS
DB instances when possible. When you do so, we recommend that you use only this and
other replication-related stored procedures. These practices enable more complex replication
topologies between Amazon RDS DB instances. We offer these stored procedures primarily to
enable replication with MySQL instances running external to Amazon RDS. For information
about managing replication between Amazon RDS DB instances, see Working with read
replicas (p. 354).

After calling `mysql.rds_set_external_master_with_auto_position` to configure an Amazon
RDS DB instance as a read replica, you can call `mysql.rds_start_replication` (p. 1277) on the read replica
to start the replication process. You can call `mysql.rds_reset_external_master` (p. 1273) to remove the
read replica configuration.

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS
records the time, the user, and an action of `set master` in the `mysql.rds_history` and
`mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` (p. 1277)
or `mysql.rds_start_replication_until_gtid` (p. 1278) stored procedure. To roll forward
changes to a delayed read replica to the time just before a disaster, you can run the
`mysql.rds_set_external_master_with_auto_position` procedure. After the
`mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read
replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a
standalone DB instance (p. 361).

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication
must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can
use the `mysql.rds_skip_transaction_with_gtid` (p. 1280) stored procedure. For more information about
working with GTID-based replication, see Using GTID-based replication for RDS for MySQL (p. 1217).

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica
of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one
hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance
running external to Amazon RDS isn’t applied on the MySQL DB instance read replica for at least one
hour.

```sql
call mysql.rds_set_external_master_with_auto_position(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'SomePassW0rd',
    0,
    3600);
```

`mysql.rds_reset_external_master`

Reconfigures a MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

Important
To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit`
parameter to 1. For information about modifying parameters, see Modifying parameters in a DB
parameter group (p. 282).

Syntax
CALL mysql.rds_reset_external_master;

Usage notes

The master user must run the `mysql.rds_reset_external_master` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

**Note**
We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see Working with read replicas (p. 354).

For more information about using replication to import data from an instance of MySQL running external to Amazon RDS, see Restoring a backup into a MySQL DB instance (p. 1178).

`mysql.rds_import_binlog_ssl_material`

Imports the certificate authority certificate, client certificate, and client key into an Aurora MySQL DB cluster. The information is required for SSL communication and encrypted replication.

**Note**
Currently, this procedure is only supported for Aurora MySQL version 5.6.

Syntax

```sql
CALL mysql.rds_import_binlog_ssl_material (ssl_material);
```

Parameters

`ssl_material`

JSON payload that contains the contents of the following .pem format files for a MySQL client:

- "ssl_ca":"Certificate authority certificate"
- "ssl_cert":"Client certificate"
- "ssl_key":"Client key"

Usage notes

Prepare for encrypted replication before you run this procedure:

- If you don't have SSL enabled on the external MySQL source database instance and don't have a client key and client certificate prepared, enable SSL on the MySQL database server and generate the required client key and client certificate.
- If SSL is enabled on the external source database instance, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora
MySQL DB cluster. To sign the client certificate, you must have the certificate authority key you used to configure SSL on the external MySQL source database instance.

For more information, see Creating SSL certificates and keys using openssl in the MySQL documentation.

**Important**

After you prepare for encrypted replication, use an SSL connection to run this procedure. The client key must not be transferred across an insecure connection.

This procedure imports SSL information from an external MySQL database into an Aurora MySQL DB cluster. The SSL information is in .pem format files that contain the SSL information for the Aurora MySQL DB cluster. During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

You can copy the information from these files into the `ssl_material` parameter in the correct JSON payload. To support encrypted replication, import this SSL information into the Aurora MySQL DB cluster.

The JSON payload must be in the following format.

```
{"ssl_ca": "-----BEGIN CERTIFICATE-----
ssl_ca_pem_body_code
-----END CERTIFICATE-----",
"ssl_cert": "-----BEGIN CERTIFICATE-----
ssl_cert_pem_body_code
-----END CERTIFICATE-----",
"ssl_key": "-----BEGIN RSA PRIVATE KEY-----
ssl_key_pem_body_code
-----END RSA PRIVATE KEY-----"}
```

**Examples**

The following example imports SSL information into an Aurora MySQL DB cluster. In .pem format files, the body code typically is longer than the body code shown in the example.

```
call mysql.rds_import_binlog_ssl_material(
    '{"ssl_ca": "-----BEGIN CERTIFICATE-----
AAAAB3NzaC1yc2EAAAADAQABAAABAADg4TAgAAAAH2Nob3d0eD9yX3Rw
-----END CERTIFICATE-----
"},
    '{"ssl_cert": "-----BEGIN CERTIFICATE-----
AAAAB3NzaC1yc2EAAAADAQABAAABAADg4TAgAAAAH2Nob3d0eD9yX3Rw
-----END CERTIFICATE-----
"},
    '{"ssl_key": "-----BEGIN RSA PRIVATE KEY-----
AAAAB3NzaC1yc2EAAAADAQABAAABAADg4TAgAAAAH2Nob3d0eD9yX3Rw
-----END RSA PRIVATE KEY-----
"})
```

**Note**

For information about using Amazon Aurora, see the [Amazon Aurora User Guide](https://docs.aws.amazon.com/aurora/latest/userguide).
mysql.rds_remove_binlog_ssl_material

Removes the certificate authority certificate, client certificate, and client key for SSL communication and encrypted replication. This information is imported by using mysql.rds_import_binlog_ssl_material (p. 1274).

**Note**
Currently, this procedure is only supported for Aurora MySQL version 5.6.

Syntax

```sql
CALL mysql.rds_remove_binlog_ssl_material;
```

mysql.rds_set_source_delay

Sets the minimum number of seconds to delay replication from source database instance to the current read replica. Use this procedure when you are connected to a read replica to delay replication from its source database instance.

Syntax

```sql
CALL mysql.rds_set_source_delay(
    delay
);
```

**Parameters**

delay

The minimum number of seconds to delay replication from the source database instance.

The limit for this parameter is one day (86400 seconds).

**Usage notes**

The master user must run the `mysql.rds_set_source_delay` procedure.

For disaster recovery, you can use this procedure with the `mysql.rds_start_replication_until` (p. 1277) stored procedure or the `mysql.rds_start_replication_until_gtid` (p. 1278) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_source_delay` procedure. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 361).

To use the `mysql.rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid` (p. 1280) stored procedure. For more information on GTID-based replication, see Using GTID-based replication for RDS for MySQL (p. 1217).

The `mysql.rds_set_source_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
• MySQL 5.7.22 and higher 5.7 versions
• MySQL 5.6.40 and higher 5.6 versions

Examples

To delay replication from source database instance to the current read replica for at least one hour (3,600 seconds), you can call `mysql.rds_set_source_delay` with the following parameter:

```sql
CALL mysql.rds_set_source_delay(3600);
```

`mysql.rds_start_replication`

Initiates replication from a MySQL DB instance.

**Note**

You can use the `mysql.rds_start_replication_until` (p. 1277) or `mysql.rds_start_replication_until_gtid` (p. 1278) stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

**Syntax**

```sql
CALL mysql.rds_start_replication;
```

**Usage notes**

The master user must run the `mysql.rds_start_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_start_replication` on the read replica to start the replication process after you have called `mysql.rds_set_external_master` (p. 1266) to build the replication configuration. For more information, see Restoring a backup into a MySQL DB instance (p. 1178).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see Exporting data from a MySQL DB instance by using replication (p. 1229).

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication` (p. 1279). For more information, see Working with read replicas (p. 354).

`mysql.rds_start_replication_until`

Initiates replication from an RDS for MySQL DB instance and stops replication at the specified binary log file location.

**Syntax**

```sql
CALL mysql.rds_start_replication_until (
replication_log_file
, replication_stop_point
);`
Parameters

replication_log_file

The name of the binary log on the source database instance contains the replication information.

replication_stop_point

The location in the replication_log_file binary log at which replication will stop.

Usage notes

The master user must run the mysql.rds_start_replication_until procedure.

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 361).

You can configure delayed replication using the following stored procedures:

- mysql.rds_set_configuration (p. 1284)
- mysql.rds_set_external_master_with_delay (p. 1268)
- mysql.rds_set_source_delay (p. 1276)

The file name specified for the replication_log_file parameter must match the source database instance binlog file name.

When the replication_stop_point parameter specifies a stop location that is in the past, replication is stopped immediately.

The mysql.rds_start_replication_until procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- MySQL 5.7.22 and higher 5.7 versions
- MySQL 5.6.40 and higher 5.6 versions

Examples

The following example initiates replication and replicates changes until it reaches location 120 in the mysql-bin-changelog.000777 binary log file.

```sql
call mysql.rds_start_replication_until('mysql-bin-changelog.000777', 120);
```

**mysql.rds_start_replication_until_gtid**

Initiates replication from an RDS for MySQL DB instance and stops replication immediately after the specified global transaction identifier (GTID).
Syntax

CALL mysql.rds_start_replication_until_gtid (gtid);

Parameters

 gtid
The GTID after which replication is to stop.

Usage notes

The master user must run the mysql.rds_start_replication_until_gtid procedure.

For RDS for MySQL 5.7, this procedure is supported for MySQL 5.7.23 and higher MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions. This procedure isn't supported for RDS for MySQL 5.6.

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 361).

You can configure delayed replication using the following stored procedures:

- mysql.rds_set_configuration (p. 1284)
- mysql.rds_set_external_master_with_auto_position (p. 1271)
- mysql.rds_set_source_delay (p. 1276)

When the gtid parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

Examples

The following example initiates replication and replicates changes until it reaches GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

call mysql.rds_start_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');

mysql.rds_stop_replication

Stops replication from a MySQL DB instance.

Syntax

CALL mysql.rds_stop_replication;
Usage notes

The master user must run the `mysql.rds_stop_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process after the import has completed. For more information, see Restoring a backup into a MySQL DB instance (p. 1178).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see Exporting data from a MySQL DB instance by using replication (p. 1229).

You can also use `mysql.rds_stop_replication` to stop replication between two Amazon RDS DB instances. You typically stop replication to perform a long running operation on the read replica, such as creating a large index on the read replica. You can restart any replication process that you stopped by calling `mysql.rds_start_replication` (p. 1277) on the read replica. For more information, see Working with read replicas (p. 354).

`mysql.rds_skip_transaction_with_gtid`

Skips replication of a transaction with the specified global transaction identifier (GTID) on a MySQL DB instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

Syntax

```
CALL mysql.rds_skip_transaction_with_gtid (
    gtid_to_skip
);
```

Parameters

`gtid_to_skip`

The GTID of the replication transaction to skip.

Usage notes

The master user must run the `mysql.rds_skip_transaction_with_gtid` procedure.

This procedure is supported for RDS for MySQL 5.7.23 and higher MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions. This procedure isn't supported for RDS for MySQL 5.6.

Examples

The following example skips replication of the transaction with the GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.
call mysql.rds_skip_transaction_with_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');

**mysql.rds_skip_repl_error**

Skips and deletes a replication error on a MySQL DB instance.

**Syntax**

```plaintext
CALL mysql.rds_skip_repl_error;
```

**Usage notes**

The master user must run the `mysql.rds_skip_repl_error` procedure.

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS\G` command. If a replication error isn't critical, you can run `mysql.rds_skip_repl_error` to skip the error. If there are multiple errors, `mysql.rds_skip_repl_error` deletes the first error, then warns that others are present. You can then use `SHOW REPLICA STATUS\G` to determine the correct course of action for the next error. For information about the values returned, see the MySQL documentation.

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For more information about addressing replication errors with Amazon RDS, see Troubleshooting a MySQL read replica problem (p. 1216).

**Replication stopped error**

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that the replica is down or disabled.

This error message appears because replication has stopped and could not be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error due to binlog files being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration (p. 1284)` procedure and specify a configuration parameter of `'binlog retention hours'` along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```plaintext
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

**mysql.rds_next_master_log**

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.
Syntax

CALL mysql.rds_next_master_log(
curr_master_log
);

Parameters

curr_master_log

The index of the current master log file. For example, if the current file is named mysql-bin-changelog.012345, then the index is 12345. To determine the current master log file name, run the SHOW REPLICA STATUS command and view the Master_Log_File field.

Note

Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

Usage notes

The master user must run the mysql.rds_next_master_log procedure.

Warning

Call mysql.rds_next_master_log only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the Last_IO_Errno field of SHOW REPLICA STATUS reports I/O error 1236. Calling mysql.rds_next_master_log may result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred. You can reduce the chance of this happening by configuring the source instance parameters sync_binlog = 1 and innodb_support_xa = 1, although this may reduce performance. For more information, see Working with read replicas (p. 354).

Examples

Assume replication fails on an Amazon RDS read replica. Running SHOW REPLICA STATUS\G on the read replica returns the following result:

```
*************************** 1. row ***************************
Replica_IO_State:        1
Source_Host:             myhost.XXXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
Source_User:             MasterUser
Source_Port:             3306
Connect_Retry:           10
Source_Log_File:         mysql-bin-changelog.012345
Read_Source_Log_Pos:     1219393
Relay_Log_File:          relaylog.012340
Relay_Log_Pos:           30223388
Relay_Source_Log_File:   mysql-bin-changelog.012345
Replica_IO_Running:      No
Replica_SQL_Running:     Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
Last_Errno:              0
```
The Last_IO_Errno field shows that the instance is receiving I/O error 1236. The Master_Log_File field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_master_log` with the following parameter:

```sql
CALL mysql.rds_next_master_log(12345);
```

### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

### mysql.rds_innodb_buffer_pool_dump_now

Dumps the current state of the buffer pool to disk. For more information, see InnoDB cache warming (p. 1141).

#### Syntax

```sql
CALL mysql.rds_innodb_buffer_pool_dump_now();
```

#### Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_dump_now` procedure.

The `mysql.rds_innodb_buffer_pool_dump_now` procedure is available in these versions of RDS for MySQL:

- MySQL 5.6
- MySQL 5.7
- MySQL 8.0
**mysql.rds_innodb_buffer_pool_load_now**

Loads the saved state of the buffer pool from disk. For more information, see InnoDB cache warming (p. 1141).

**Syntax**

```sql
CALL mysql.rds_innodb_buffer_pool_load_now();
```

**Usage notes**

The master user must run the `mysql.rds_innodb_buffer_pool_load_now` procedure.

The `mysql.rds_innodb_buffer_pool_load_now` procedure is available in these versions of RDS for MySQL:

- MySQL 5.6
- MySQL 5.7
- MySQL 8.0

**mysql.rds_innodb_buffer_pool_load_abort**

Cancels a load of the saved buffer pool state while in progress. For more information, see InnoDB cache warming (p. 1141).

**Syntax**

```sql
CALL mysql.rds_innodb_buffer_pool_load_abort();
```

**Usage notes**

The master user must run the `mysql.rds_innodb_buffer_pool_load_abort` procedure.

The `mysql.rds_innodb_buffer_pool_load_abort` procedure is available in these versions of RDS for MySQL:

- MySQL 5.6
- MySQL 5.7
- MySQL 8.0

**mysql.rds_set_configuration**

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

**Syntax**

```sql
CALL mysql.rds_set_configuration(name, value);
```
Parameters

name

The name of the configuration parameter to set.

value

The value of the configuration parameter.

Usage notes

The `mysql.rds_set_configuration` stored procedure is available in these versions of RDS for MySQL:

- MySQL 5.6
- MySQL 5.7
- MySQL 8.0

The `mysql.rds_set_configuration` procedure supports the following configuration parameters:

- Binlog retention hours (p. 1285)
- Target delay (p. 1285)

Binlog retention hours

The binlog retention hours parameter is used to specify the number of hours to retain binary log files. Amazon RDS normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to Amazon RDS. The default value of binlog retention hours is NULL. This default value is interpreted as follows:

- For RDS for MySQL, NULL means binary logs are not retained (0 hours).
- For Aurora MySQL, NULL means binary logs are cleaned up lazily. Aurora MySQL binary logs might remain in the system for a certain period, usually not longer than a day.

To specify the number of hours for Amazon RDS to retain binary logs on a DB instance, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

```sql
CALL mysql.rds_set_configuration('binlog retention hours', 24);
```

For MySQL DB instances, the maximum binlog retention hours value is 168 (7 days).

After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

Target delay

Use the target delay parameter to specify the number of seconds to delay replication from source database instance to the read replica. The specified delay applies to new replicas created from the current DB instance. Amazon RDS normally replicates changes as soon as possible, but some environments might want to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to recover it quickly. The default value of target delay is 0 (don't delay replication).
For disaster recovery, you can use this configuration parameter with the `mysql.rds_start_replication_until (p. 1277)` stored procedure or the `mysql.rds_start_replication_until_gtid (p. 1278)` stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_configuration` procedure with this parameter set. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in Promoting a read replica to be a standalone DB instance (p. 361).

To use the `mysql.rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the `mysql.rds_skip_transaction_with_gtid (p. 1280)` stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication for RDS for MySQL (p. 1217).

To specify the number of seconds for Amazon RDS to delay replication to a read replica, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay replication. The following example specifies that replication is delayed by at least one hour (3,600 seconds).

```sql
call mysql.rds_set_configuration('target delay', 3600);
```

The limit for the `target delay` parameter is one day (86400 seconds).

**Note**
The `target delay` parameter is only supported for RDS for MySQL.
The `target delay` parameter isn't supported for RDS for MySQL version 8.0.

### mysql.rds_show_configuration

The number of hours that binary logs are retained.

**Syntax**

```sql
CALL mysql.rds_show_configuration;
```

**Usage notes**

To verify the number of hours that Amazon RDS retains binary logs, use the `mysql.rds_show_configuration` stored procedure.

The `mysql.rds_show_configuration` procedure is available in these versions of RDS for MySQL:

- MySQL 5.6
- MySQL 5.7
- MySQL 8.0

**Examples**

The following example displays the retention period:

```sql
call mysql.rds_show_configuration;
```

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog retention</td>
<td>24</td>
<td>duration in hours before binary logs are automatically deleted.</td>
</tr>
</tbody>
</table>
mysql.rds_kill

Ends a connection to the MySQL server.

Syntax

```
CALL mysql.rds_kill(processID);
```

Parameters

`processID`

The identity of the connection thread to be ended.

Usage notes

Each connection to the MySQL server runs in a separate thread. To end a connection, use the `mysql.rds_kill` procedure and pass in the thread ID of that connection. To obtain the thread ID, use the MySQL `SHOW PROCESSLIST` command.

Examples

The following example ends a connection with a thread ID of 4243:

```
call mysql.rds_kill(4243);
```

mysql.rds_kill_query

Ends a query running against the MySQL server.

Syntax

```
CALL mysql.rds_kill_query(queryID);
```

Parameters

`queryID`

The identity of the query to be ended.

Usage notes

To stop a query running against the MySQL server, use the `mysql_rds_kill_query` procedure and pass in the ID of that query. To obtain the query ID, query the MySQL `INFORMATION_SCHEMA PROCESSTLIST` table. The connection to the MySQL server is retained.

Examples

The following example stops a query with a thread ID of 230040:
call mysql.rds_kill_query(230040);

**mysql.rds_rotate_general_log**

Rotates the mysql.general_log table to a backup table. For more information, see MySQL database log files (p. 664).

**Syntax**

```
CALL mysql.rds_rotate_general_log;
```

**Usage notes**

You can rotate the mysql.general_log table to a backup table by calling the mysql.rds_rotate_general_log procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the mysql.general_log table is named mysql.general_log_backup.

**mysql.rds_rotate_slow_log**

Rotates the mysql.slow_log table to a backup table. For more information, see MySQL database log files (p. 664).

**Syntax**

```
CALL mysql.rds_rotate_slow_log;
```

**Usage notes**

You can rotate the mysql.slow_log table to a backup table by calling the mysql.rds_rotate_slow_log procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the mysql.slow_log table is named mysql.slow_log_backup.

**mysql.rds_enable_gsh_collector**

Enables the Global Status History (GoSH) to take default snapshots at intervals specified by rds_set_gsh_collector. For more information, see Managing the global status history (p. 1248).

**Syntax**

```
CALL mysql.rds_enable_gsh_collector;
```
mysql.rds_set_gsh_collector

Specifies the interval, in minutes, between snapshots taken by the Global Status History (GoSH). Default value is For more information, see Managing the global status history (p. 1248).

Syntax

```
CALL mysql.rds_set_gsh_collector(intervalPeriod);
```

Parameters

`intervalPeriod`

The interval, in minutes, between snapshots. Default value is

mysql.rds_disable_gsh_collector

Disables snapshots taken by the Global Status History (GoSH). For more information, see Managing the global status history (p. 1248).

Syntax

```
CALL mysql.rds_disable_gsh_collector;
```

mysql.rds_collect_global_status_history

Takes a snapshot on demand for the Global Status History (GoSH). For more information, see Managing the global status history (p. 1248).

Syntax

```
CALL mysql.rds_collect_global_status_history;
```

mysql.rds_enable_gsh_rotation

Enables rotation of the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` at intervals specified by `rds_set_gsh_rotation`. For more information, see Managing the global status history (p. 1248).

Syntax

```
CALL mysql.rds_enable_gsh_rotation;
```

mysql.rds_set_gsh_rotation

Specifies the interval, in days, between rotations of the `mysql.global_status_history` table. Default value is 7. For more information, see Managing the global status history (p. 1248).
Syntax

```
CALL mysql.rds_set_gsh_rotation(intervalPeriod);
```

Parameters

`intervalPeriod`

The interval, in days, between table rotations. Default value is 7.

### `mysql.rds_disable_gsh_rotation`

Disables rotation of the `mysql.global_status_history` table. For more information, see Managing the global status history (p. 1248).

Syntax

```
CALL mysql.rds_disable_gsh_rotation;
```

### `mysql.rds_rotate_global_status_history`

Rotates the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` on demand. For more information, see Managing the global status history (p. 1248).

Syntax

```
CALL mysql.rds_rotate_global_status_history;
```
Oracle on Amazon RDS

Amazon RDS supports DB instances that run the following versions and editions of Oracle Database:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

**Note**
Oracle Database 12c is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 12c Release 1 (12.1) and Oracle Database 12c Release 2 (12.2) after their end-of-support dates. For more information, see Oracle Database 12c Release 2 (12.2.0.1) with Amazon RDS (p. 1298).

RDS for Oracle Database 11g and Oracle Database 18c (18.0.0.0) are legacy versions that are no longer supported.

Before creating a DB instance, complete the steps in the Setting up for Amazon RDS (p. 93) section of this guide. When you create a DB instance using your master account, the account gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts. You can’t use SYS, SYSTEM, or other Oracle-supplied administrative accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running Oracle inside a VPC. You can also add features to your Oracle DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution.

**Important**
To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as Oracle SQL*Plus. However, you can’t access the host directly by using Telnet or Secure Shell (SSH).

**Topics**

Overview of Oracle on Amazon RDS

The following video is a useful introduction to running Oracle on Amazon RDS for a production workload.

Topics
- RDS for Oracle features (p. 1292)
- Oracle versions on Amazon RDS (p. 1295)
- Oracle licensing options (p. 1299)
- RDS for Oracle instance classes (p. 1302)
- RDS for Oracle architecture (p. 1305)
- RDS for Oracle parameters (p. 1306)
- RDS for Oracle character sets (p. 1306)
- RDS for Oracle limitations (p. 1309)

RDS for Oracle features

Amazon RDS for Oracle supports most of the features and capabilities of Oracle Database. Some features might have limited support or restricted privileges. Some features are only available in Enterprise Edition, and some require additional licenses. For more information about Oracle Database features for specific Oracle Database versions, see the Oracle Database Licensing Information User Manual for the version you're using.

You can filter new Amazon RDS features on the What's New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as Oracle 2022.

Note
The following lists are not exhaustive.

Topics
- New features in RDS for Oracle (p. 1292)
- Supported features in RDS for Oracle (p. 1292)
- Unsupported features in RDS for Oracle (p. 1294)

New features in RDS for Oracle

To see new Oracle features, use the following techniques:

- Search Document history (p. 1895) for the keyword Oracle.
- You can filter new Amazon RDS features on the What's New with Database? page. For Products, choose Amazon RDS. Then search for Oracle YYYY, where YYYY is a year such as 2022.

The following video shows a recent video from re:Invent about Oracle new features.

Supported features in RDS for Oracle

Amazon RDS Oracle supports the following Oracle Database features:

- Advanced Compression
- Application Express (APEX)

For more information, see Oracle Application Express (APEX) (p. 1465).
• Automatic Memory Management
• Automatic Undo Management
• Automatic Workload Repository (AWR)

For more information, see Generating performance reports with Automatic Workload Repository (AWR) (p. 1371).
• Active Data Guard with Maximum Performance in the same AWS Region or across AWS Regions

For more information, see Working with Oracle replicas for Amazon RDS (p. 1443).
• Blockchain tables (Oracle Database 21c and higher)

For more information, see Managing Blockchain Tables in the Oracle Database documentation.
• Continuous Query Notification (version 12.1.0.2.v7 and higher)

For more information, see Using Continuous Query Notification (CQN) in the Oracle documentation.
• Data Redaction
• Database Change Notification

For more information, see Database Change Notification in the Oracle documentation.

Note
This feature changes to Continuous Query Notification in Oracle Database 12c Release 1 (12.1) and higher.
• Database In-Memory (Oracle Database 12c and higher)
• Distributed Queries and Transactions
• Edition-Based Redefinition

For more information, see Setting the default edition for a DB instance (p. 1375).
• EM Express (12c and higher)

For more information, see Oracle Enterprise Manager (p. 1479).
• Fine-Grained Auditing
• Flashback Table, Flashback Query, Flashback Transaction Query
• Gradual password rollover for applications (Oracle Database 21c and higher)

For more information, see Managing Gradual Database Password Rollover for Applications in the Oracle Database documentation.
• HugePages

For more information, see Enabling HugePages for an Oracle DB instance (p. 1424).
• Import/export (legacy and Data Pump) and SQL*Loader

For more information, see Importing data into Oracle on Amazon RDS (p. 1429).
• Java Virtual Machine (JVM)

For more information, see Oracle Java virtual machine (p. 1476).
• JavaScript (Oracle Database 21c and higher)

For more information, see DBMS_MLE in the Oracle Database documentation.
• Label Security (Oracle Database 12c and higher)

For more information, see Oracle Label Security (p. 1494).
• Locator

For more information, see Oracle Locator (p. 1497).
• Materialized Views
• Multimedia

For more information, see Oracle Multimedia (p. 1500).

• Multitenant (single-tenant architecture only)

This feature is available for all Oracle Database 19c and higher releases. For more information, see RDS for Oracle architecture (p. 1305) and Limitations of a single-tenant CDB (p. 1310).

• Network encryption

For more information, see Oracle native network encryption (p. 1503) and Oracle Secure Sockets Layer (p. 1514).

• Partitioning
• Spatial and Graph

For more information, see Oracle Spatial (p. 1521).

• Star Query Optimization
• Streams and Advanced Queuing
• Summary Management – Materialized View Query Rewrite
• Text (File and URL data store types are not supported)
• Total Recall
• Transparent Data Encryption (TDE)

For more information, see Oracle Transparent Data Encryption (p. 1542).

• Unified Auditing, Mixed Mode

For more information, see Mixed mode auditing in the Oracle documentation.

• XML DB (without the XML DB Protocol Server)

For more information, see Oracle XML DB (p. 1547).

• Virtual Private Database

Unsupported features in RDS for Oracle

Amazon RDS Oracle doesn't support the following Oracle Database features:

• Automatic Storage Management (ASM)
• Database Vault
• Flashback Database
• FTP and SFTP
• Messaging Gateway
• Oracle Enterprise Manager Cloud Control Management Repository
• Real Application Clusters (Oracle RAC)
• Real Application Testing
• Unified Auditing, Pure Mode
• Workspace Manager (WMSYS) schema

Note
The preceding list is not exhaustive.
Warning
In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYS privileges, you can damage the data dictionary and affect the availability of your instance. Use only supported features and schemas that are available in Adding options to Oracle DB instances (p. 1450).

Oracle versions on Amazon RDS

Amazon RDS for Oracle supports the following major database releases.

Topics
- Oracle Database 21c with Amazon RDS (p. 1295)
- Oracle Database 19c with Amazon RDS (p. 1297)
- Oracle Database 12c with Amazon RDS (p. 1298)

Oracle Database 21c with Amazon RDS

Amazon RDS supports Oracle Database 21c, which includes Oracle Enterprise Edition and Oracle Standard Edition Two. Oracle Database 21c (21.0.0.0) includes many new features and updates from the previous version. A key change is that Oracle Database 21c supports only the multitenant architecture: you can no longer create a database as a traditional non-CDB. To learn more about the differences between CDBs and non-CDBs, see Limitations of a single-tenant CDB (p. 1310).

In this section, you can find the features and changes important to using Oracle Database 21c (21.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 21c documentation. For a complete list of features supported by each Oracle Database 21c edition, see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

Amazon RDS parameter changes for Oracle Database 21c (21.0.0.0)

Oracle Database 21c (21.0.0.0) includes several new parameters and parameters with new ranges and new default values.

Topics
- New parameters (p. 1295)
- Changes for the compatible parameter (p. 1297)
- Removed parameters (p. 1297)

New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 21c (21.0.0.0).

<table>
<thead>
<tr>
<th>Name</th>
<th>Range of values</th>
<th>Default value</th>
<th>Modifiable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>blockchain_table_max_no_drop</td>
<td>NONE</td>
<td>0</td>

Changes for the compatible parameter

The `compatible` parameter has a new maximum value for Oracle Database 21c (21.0.0.0) on Amazon RDS. The following table shows the new default value.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Oracle Database 21c (21.0.0.0) maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>compatible</td>
<td>21.0.0</td>
</tr>
</tbody>
</table>

Removed parameters

The following parameters were removed in Oracle Database 21c (21.0.0.0):

- `remote_os_authent`
- `sec_case_sensitive_logon`
- `unified_audit_sga_queue_size`

Oracle Database 19c with Amazon RDS

Amazon RDS supports Oracle Database 19c, which includes Oracle Enterprise Edition and Oracle Standard Edition Two.

Oracle Database 19c (19.0.0.0) includes many new features and updates from the previous version. In this section, you can find the features and changes important to using Oracle Database 19c (19.0.0.0) on Amazon RDS. For a complete list of the changes, see the Oracle database 19c documentation. For a complete list of features supported by each Oracle Database 19c edition, see Permitted features, options, and management packs by Oracle database offering in the Oracle documentation.

Amazon RDS parameter changes for Oracle Database 19c (19.0.0.0)

Oracle Database 19c (19.0.0.0) includes several new parameters and parameters with new ranges and new default values.

Topics

- New parameters (p. 1297)
- Changes to the compatible parameter (p. 1298)
- Removed parameters (p. 1298)

New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 19c (19.0.0.0).
<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Modifiable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_signature_enable</td>
<td>TRUE, FALSE (default)</td>
<td>Y</td>
<td>Enables or disables the LOB locator signature feature.</td>
</tr>
<tr>
<td>max_datapump_parallel_per_job</td>
<td>to 1024, or AUTO</td>
<td>Y</td>
<td>Specifies the maximum number of parallel processes allowed for each Oracle Data Pump job.</td>
</tr>
</tbody>
</table>

**Changes to the compatible parameter**

The `compatible` parameter has a new maximum value for Oracle Database 19c (19.0.0.0) on Amazon RDS. The following table shows the new default value.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Oracle Database 19c (19.0.0.0) maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>compatible</td>
<td>19.0.0</td>
</tr>
</tbody>
</table>

**Removed parameters**

The following parameters were removed in Oracle Database 19c (19.0.0.0):

- `exafusion_enabled`
- `max_connections`
- `d7_dictionary_access`

**Oracle Database 12c with Amazon RDS**

Amazon RDS supports Oracle Database 12c for both Oracle Enterprise Edition and Oracle Standard Edition 2. You can create instances for both Oracle Database 12c Release 1 (12.1) and Oracle Database 12c Release 2 (12.2). However, Oracle Database 12c is on a deprecation path.

**Topics**

- Oracle Database 12c Release 2 (12.2.0.1) with Amazon RDS (p. 1298)
- Oracle Database 12c Release 1 (12.1.0.2) with Amazon RDS (p. 1299)

**Oracle Database 12c Release 2 (12.2.0.1) with Amazon RDS**

Oracle Corporation intends to deprecate support for Oracle Database 12c Release 2 (12.2.0.1) for BYOL and LI on March 31, 2022. The following schedule includes upgrade recommendations. For more information, see Preparing for the automatic upgrade of Oracle Database 12c (p. 1554).

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Oracle Database 12c Release 2 (12.2.0.1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>We recommend that you upgrade Oracle Database 12c Release 2 (12.2.0.1) instances manually to a higher release.</td>
<td>Now–March 31, 2022</td>
</tr>
<tr>
<td>We recommend that you upgrade Oracle Database 12c Release 2 (12.2.0.1) snapshots manually to a higher release.</td>
<td>February 1, 2022</td>
</tr>
</tbody>
</table>
Amazon RDS ends support for Oracle Database 12c Release 2 (12.2.0.1). You can no longer create DB instances for this version. You can continue to restore 12.2.0.1 DB snapshots without being automatically upgraded until March 31, 2022.

Amazon RDS plans to start automatic upgrades of your Oracle Database 12c Release 2 (12.2.0.1) instances to Oracle Database 19c.

Amazon RDS plans to start automatic upgrades to Oracle Database 19c for any Oracle Database 12c Release 2 (12.2.0.1) DB instances restored from snapshots.

Oracle Database 12c Release 1 (12.1.0.2) with Amazon RDS

Oracle Corporation intends to deprecate support for Oracle Database 12c Release 1 (12.1.0.2) for BYOL and LI on June 1, 2022. The following schedule includes upgrade recommendations. For more information, see Preparing for the automatic upgrade of Oracle Database 12c (p. 1554).

Oracle licensing options

Amazon RDS for Oracle has two licensing options: License Included (LI) and Bring Your Own License (BYOL). After you create an Oracle DB instance on Amazon RDS, you can change the licensing model by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).
License Included

In the License Included model, you don't need to purchase Oracle licenses separately. AWS holds the license for the Oracle database software. In this model, if you have an AWS Support account with case support, contact AWS Support for both Amazon RDS and Oracle Database service requests. The License Included model is only supported on Amazon RDS for Oracle Database Standard Edition Two (SE2).

Bring Your Own License (BYOL)

In the BYOL model, you can use your existing Oracle Database licenses to run Oracle deployments on Amazon RDS. You must have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition you wish to run. You must also follow Oracle's policies for licensing Oracle Database software in the cloud computing environment. For more information on Oracle's licensing policy for Amazon EC2, see Licensing Oracle software in the cloud computing environment.

In this model, you continue to use your active Oracle support account, and you contact Oracle directly for Oracle Database service requests. If you have an AWS Support account with case support, you can contact AWS Support for Amazon RDS issues. Amazon Web Services and Oracle have a multi-vendor support process for cases that require assistance from both organizations.

Amazon RDS supports the BYOL model only for Oracle Database Enterprise Edition (EE) and Oracle Database Standard Edition Two (SE2).

Integrating with AWS License Manager

To make it easier to monitor Oracle license usage in the BYOL model, AWS License Manager integrates with Amazon RDS for Oracle. License Manager supports tracking of RDS for Oracle engine editions and licensing packs based on virtual cores (vCPUs). You can also use License Manager with AWS Organizations to manage all of your organizational accounts centrally.

The following table shows the product information filters for RDS for Oracle.

<table>
<thead>
<tr>
<th>Filter</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Engine Edition</td>

<td>See Oracle SQLT (p. 1524)</td>
</tr>
</tbody>
</table>

To track license usage of your Oracle DB instances, you can create a license configuration. In this case, RDS for Oracle resources that match the product information filter are automatically associated with the license configuration. Discovery of Oracle DB instances can take up to 24 hours.
Console

To create a license configuration to track the license usage of your Oracle DB instances

2. Create a license configuration.
   
   For instructions, see Create a license configuration in the AWS License Manager User Guide.

   Add a rule for an RDS Product Information Filter in the Product Information panel.

   For more information, see ProductInformation in the AWS License Manager API Reference.

AWS CLI

To create a license configuration by using the AWS CLI, call the create-license-configuration command. Use the --cli-input-json or --cli-input-yaml parameters to pass the parameters to the command.

Example

The following code creates a license configuration for Oracle Enterprise Edition.

```
aws license-manager create-license-configuration --cli-input-json file://rds-oracle-ee.json
```

The following is the sample rds-oracle-ee.json file used in the example.

```
{
   "Name": "rds-oracle-ee",
   "Description": "RDS Oracle Enterprise Edition",
   "LicenseCountingType": "vCPU",
   "LicenseCountHardLimit": false,
   "ProductInformationList": [
      {
         "ResourceType": "RDS",
         "ProductInformationFilterList": [
            {
               "ProductInformationFilterName": "Engine Edition",
               "ProductInformationFilterValue": ["oracle-ee"],
               "ProductInformationFilterComparator": "EQUALS"
            }
         ]
      }
   ]
}
```

For more information about product information, see Automated discovery of resource inventory in the AWS License Manager User Guide.

For more information about the --cli-input parameter, see Generating AWS CLI skeleton and input parameters from a JSON or YAML input file in the AWS CLI User Guide.

Migrating between Oracle editions

If you have an unused BYOL Oracle license appropriate for the edition and class of DB instance that you plan to run, you can migrate from Standard Edition 2 (SE2) to Enterprise Edition (EE). You can't migrate from Enterprise Edition to other editions.
To change the edition and retain your data

1. Create a snapshot of the DB instance.
   For more information, see Creating a DB snapshot (p. 428).
2. Restore the snapshot to a new DB instance, and select the Oracle database edition you want to use.
   For more information, see Restoring from a DB snapshot (p. 432).
3. (Optional) Delete the old DB instance, unless you want to keep it running and have the appropriate Oracle Database licenses for it.
   For more information, see Deleting a DB instance (p. 401).

Licensing Oracle Multi-AZ deployments

Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution. We recommend Multi-AZ for production workloads. For more information, see Multi-AZ deployments for high availability (p. 65).

If you use the Bring Your Own License model, you must have a license for both the primary DB instance and the standby DB instance in a Multi-AZ deployment.

RDS for Oracle instance classes

The computation and memory capacity of a DB instance is determined by its DB instance class. The DB instance class you need depends on your processing power and memory requirements.

Supported Oracle DB instance classes

The supported Oracle DB instance classes are a subset of the RDS DB instance classes. For the complete list of RDS instance classes, see DB instance classes (p. 9).

RDS for Oracle also offers instance classes that are optimized for workloads that require additional memory, storage, and I/O per vCPU. These instance classes use the following naming convention:

db.r5.instance_size.tpcthreads_per_core.memratio

The following is an example of a supported instance class:

db.r5.4xlarge.tpc2.mem2x

The components of the preceding instance class name are as follows:

- db.r5.4xlarge – The name of the instance class.
- tpc2 – The threads per core. A value of 2 means that multithreading is turned on. If the value is 1, hyperthreading is turned off.
- mem2x – The ratio of additional memory to the standard memory for the instance class. In this example, the optimization provides twice as much memory as a standard db.r5.4xlarge instance.

The following table lists all instance classes supported for Oracle Database. For information about the memory attributes of each type, see Amazon RDS for Oracle instance types.
<table>

**Note**
We encourage all BYOL customers to consult their licensing agreement to assess the impact of Amazon RDS for Oracle deprecations. For more information on the compute capacity of DB instance classes supported by Amazon RDS for Oracle, see DB instance classes (p. 9) and Configuring the processor for a DB instance class (p. 31).

**Note**
If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see Restoring from a DB snapshot (p. 432).

**Deprecated Oracle DB instance classes**

The following DB instance classes are deprecated for Amazon RDS for Oracle:

- db.m1, db.m2, db.m3
- db.t1, db.t2
- db.r1, db.r2, db.r3

The preceding DB instance classes have been replaced by better performing DB instance classes that are generally available at a lower cost. Amazon RDS for Oracle automatically scales DB instances to DB instance classes that are not deprecated.

If you have DB instances that use deprecated DB instance classes, Amazon RDS will modify each one automatically to use a comparable DB instance class that is not deprecated. You can change the DB instance class for a DB instance yourself by modifying the DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).
If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see Restoring from a DB snapshot (p. 432).

RDS for Oracle architecture

The multitenant architecture enables an Oracle database to function as a multitenant container database (CDB). A CDB can include customer-created pluggable databases (PDBs). A non-CDB is an Oracle database that uses the traditional architecture, which can't contain PDBs. For more information about the multitenant architecture, see Oracle Multitenant Administrator’s Guide.

The architecture is a permanent characteristic that you can’t change later. The architecture requirements are as follows:

Oracle Database 21c

You must create the instance as a CDB.

Oracle Database 19c

You can create the instance as either a CDB or non-CDB.

Oracle Database 12c

You must create the instance as a non-CDB.

For more information, see Creating an Amazon RDS DB instance (p. 175).

Currently, RDS for Oracle supports a subset of multitenant architecture called the single-tenant architecture. In this case, your CDB contains only one PDB. The single-tenant architecture uses the same RDS APIs as the non-CDB architecture. Your experience with a non-CDB is mostly identical to your experience with a PDB. You can’t access the CDB itself.

The following sections explain the principal differences between the non-multitenant and single-tenant architectures. For more information, see Limitations of a single-tenant CDB (p. 1310).

Topics

- Database creation and connections in a single-tenant architecture (p. 1305)
- Database upgrades in a single-tenant architecture (p. 1306)
- User accounts and privileges in a single-tenant architecture (p. 1306)
- Parameters in a single-tenant architecture (p. 1306)
- Snapshots in a single-tenant architecture (p. 1306)

Database creation and connections in a single-tenant architecture

When you create a CDB, specify the DB instance identifier just as for a non-CDB. The instance identifier forms the first part of your endpoint. The system identifier (SID) is the name of the CDB. The SID of every CDB is RDSCDB. You can’t choose a different value.

In the single-tenant architecture, you always connect to the PDB rather than the CDB. Specify the endpoint for the PDB just as for a non-CDB. The only difference is that you specify pdb_name for the database name, where pdb_name is the name you chose for your PDB. The following example shows the format for the connection string in SQL*Plus.

```sql
sqlplus 'dbuser@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)(PORT=port))(CONNECT_DATA=(SID=pdb_name)))'
```
Database upgrades in a single-tenant architecture

You can upgrade a CDB to a different Oracle Database release. For example, you can upgrade a DB instance from Oracle Database 19c to Oracle Database 21c. You can't upgrade a non-CDB to a CDB.

User accounts and privileges in a single-tenant architecture

In the Oracle multitenant architecture, all users accounts are either common users or local users. A CDB common user is a database user whose single identity and password are known in the CDB root and in every existing and future PDB. In contrast, a local user exists only in a single PDB.

The RDS master user is a local user account in the PDB. If you create new user accounts, these users will also be local users residing in the PDB. You can't use any user accounts to create new PDBs or modify the state of the existing PDB.

The rdsadmin user is a common user account. You can run Oracle for RDS packages that exist in this account, but you can't log in as rdsadmin. For more information, see About Common Users and Local Users in the Oracle documentation.

Parameters in a single-tenant architecture

CDBs have their own parameter classes and different default parameter values. The CDB parameter classes are as follows:

- oracle-ee-cdb-21
- oracle-se2-cdb-21
- oracle-ee-cdb-19
- oracle-se2-cdb-19

You specify parameters at the CDB level rather than the PDB level. The PDB inherits parameter settings from the CDB. For more information about setting parameters, see Working with DB parameter groups (p. 172).

Snapshots in a single-tenant architecture

Snapshots work the same in a single-tenant and non-multitenant architecture. The only difference is that when you restore a snapshot, you can only rename the PDB, not the CDB. The CDB is always named RDSCDB. For more information, see Oracle Database considerations (p. 434).

RDS for Oracle parameters

In Amazon RDS, you manage parameters using parameter groups. For more information, see Working with parameter groups (p. 278). To view the supported parameters for a specific Oracle Database edition and version, run the AWS CLI describe-engine-default-parameters command.

For example, to view the supported parameters for the Enterprise Edition of Oracle Database 12c Release 2 (12.2), run the following command.

```
aws rds describe-engine-default-parameters
  --db-parameter-group-family oracle-ee-12.2
```

RDS for Oracle character sets

Amazon RDS for Oracle supports two types of character sets: the DB character set and national character set.
DB character set

The Oracle database character set is used in the CHAR, VARCHAR2, and CLOB data types. The database also uses this character set for metadata such as table names, column names, and SQL statements. The Oracle database character set is typically referred to as the DB character set.

You set the character set when you create a DB instance. You can't change the DB character set after you create the database.

Supported DB character sets

The following table lists the Oracle DB character sets that are supported in Amazon RDS. You can use a value from this table with the --character-set-name parameter of the AWS CLI `create-db-instance` command or with the `CharacterSetName` parameter of the Amazon RDS API `CreateDBInstance` operation.

**Note**
The character set for a CDB is always AL32UTF8. You can set a different character set for the PDB only.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AL32UTF8</td>
<td>Unicode 5.0 UTF-8 Universal character set (default)</td>
</tr>
<tr>
<td>AR8ISO8859P6</td>

</tbody>
</table>

**NLS_LANG environment variable**

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. Setting the NLS_LANG environment variable in your client's environment is the simplest way to specify locale behavior for Oracle. This variable sets the language and territory used by the client application and the database server. It also indicates the client's character set, which corresponds to the character set for data entered or displayed by a client application. For more information on NLS_LANG and character sets, see What is a character set or code page? in the Oracle documentation.

**NLS initialization parameters**

You can also set the following National Language Support (NLS) initialization parameters at the instance level for an Oracle DB instance in Amazon RDS:

- `NLS_DATE_FORMAT`
- `NLS_LENGTH_SEMANTICS`
• NLS_NCHAR_CONV_EXCP
• NLS_TIME_FORMAT
• NLS_TIME_TZ_FORMAT
• NLS_TIMESTAMP_FORMAT
• NLS_TIMESTAMP_TZ_FORMAT

For information about modifying instance parameters, see Working with parameter groups (p. 278).

You can set other NLS initialization parameters in your SQL client. For example, the following statement sets the NLS_LANGUAGE initialization parameter to GERMAN in a SQL client that is connected to an Oracle DB instance:

```
ALTER SESSION SET NLS_LANGUAGE=GERMAN;
```

For information about connecting to an Oracle DB instance with a SQL client, see Connecting to your Oracle DB instance (p. 1312).

**National character set**

The national character set is used in the NCHAR, NVARCHAR2, and NCLOB data types. The national character set is typically referred to as the *NCHAR character set*. Unlike the DB character set, the NCHAR character set doesn't affect database metadata.

The NCHAR character set supports the following character sets:

• AL16UTF16 (default)
• UTF8

You can specify either value with the `--nchar-character-set-name` parameter of the `create-db-instance` command (AWS CLI version 2 only). If you use the Amazon RDS API, specify the `NcharCharacterSetName` parameter of `CreateDBInstance` operation. You can't change the national character set after you create the database.

For more information about Unicode in Oracle databases, see Supporting multilingual databases with unicode in the Oracle documentation.

**RDS for Oracle limitations**

Following are important limitations of using Amazon RDS for Oracle.

**Note**
This list is not exhaustive.

**Topics**

• Oracle file size limits in Amazon RDS (p. 1310)
• Public synonyms for Oracle-supplied schemas (p. 1310)
• Schemas for unsupported features (p. 1310)
• Limitations for Oracle DBA privileges (p. 1310)
• Limitations of a single-tenant CDB (p. 1310)
• Deprecation of TLS 1.0 and 1.1 Transport Layer Security (p. 1311)
Oracle file size limits in Amazon RDS

The maximum file size on Amazon RDS Oracle DB instances is 16 TiB (tebibytes). If you try to resize a data file in a bigfile tablespace to a value over the limit, you receive an error such as the following.

| ORA-01237: cannot extend datafile 6 |
| ORA-01110: data file 6: '/rdsdbdata/db/mydir/datafile/myfile.dbf' |
| ORA-27059: could not reduce file size |
| Linux-x86_64 Error: 27: File too large |
| Additional information: 2 |

Public synonyms for Oracle-supplied schemas

Don't create or modify public synonyms for Oracle-supplied schemas, including SYS, SYSTEM, and RDSADMIN. Such actions might result in invalidation of core database components and affect the availability of your DB instance.

You can create public synonyms referencing objects in your own schemas.

Schemas for unsupported features

In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYS privileges, you can damage the data dictionary and affect your instance availability. Use only supported features and schemas that are available in Adding options to Oracle DB instances (p. 1450).

Limitations for Oracle DBA privileges

In the database, a role is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

Use the master user account for administrative tasks such as creating additional user accounts in the database. You can't use SYS, SYSTEM, and other Oracle-supplied administrative accounts.

Limitations of a single-tenant CDB

The following options aren't supported for the single-tenant architecture:

- Database Activity Streams
- Oracle Data Guard
- Oracle Enterprise Manager
• Oracle Enterprise Manager Agent
• Oracle Label Security

The following operations work in a single-tenant CDB, but no customer-visible mechanism can detect the current status of the operations:

• Enabling and disabling block change tracking (p. 1396)
• Enabling auditing for the SYS.AUD$ table (p. 1375)

**Note**
Auditing information isn't available from within the PDB.

**Deprecation of TLS 1.0 and 1.1 Transport Layer Security**

Transport Layer Security protocol versions 1.0 and 1.1 (TLS 1.0 and TLS 1.1) are deprecated. In accordance with security best practices, Oracle has deprecated the use of TLS 1.0 and TLS 1.1. To meet your security requirements, RDS for Oracle strongly recommends that you use TLS 1.2 instead.
Connecting to your Oracle DB instance

After Amazon RDS provisions your Oracle DB instance, you can use any standard SQL client application to connect to the DB instance. In this topic, you connect to a DB instance that is running the Oracle database engine by using Oracle SQL Developer or SQL*Plus.

For an example that walks you through the process of creating and connecting to a sample DB instance, see Creating an Oracle DB instance and connecting to a database on an Oracle DB instance (p. 124).

Topics

- Finding the endpoint of your Oracle DB instance (p. 1312)
- Connecting to your DB instance using Oracle SQL developer (p. 1314)
- Connecting to your DB instance using SQL*Plus (p. 1316)
- Considerations for security groups (p. 1317)
- Considerations for process architecture (p. 1317)
- Troubleshooting connections to your Oracle DB instance (p. 1317)
- Modifying connection properties using sqlnet.ora parameters (p. 1318)

Finding the endpoint of your Oracle DB instance

Each Amazon RDS DB instance has an endpoint, and each endpoint has the DNS name and port number for the DB instance. To connect to your DB instance using a SQL client application, you need the DNS name and port number for your DB instance.

You can find the endpoint for a DB instance using the Amazon RDS console or the AWS CLI.

**Note**

If you are using Kerberos authentication, see Connecting to Oracle with Kerberos authentication (p. 1336).

Console

**To find the endpoint using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the upper-right corner of the console, choose the AWS Region of your DB instance.
3. Find the DNS name and port number for your DB Instance.
   
   a. Choose **Databases** to display a list of your DB instances.
   b. Choose the Oracle DB instance name to display the instance details.
   c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
To find the endpoint of an Oracle DB instance by using the AWS CLI, call the describe-db-instances command.

**Example To find the endpoint using the AWS CLI**

```bash
aws rds describe-db-instances
```

Search for **Endpoint** in the output to find the DNS name and port number for your DB instance. The **Address** line in the output contains the DNS name. The following is an example of the JSON endpoint output.

```
"Endpoint": {
  "HostedZoneId": "Z1PVIF0B656C1W",
  "Port": 3306,
  "Address": "myinstance.123456789012.us-west-2.rds.amazonaws.com"
},
```
Connecting to your DB instance using Oracle SQL developer

In this procedure, you connect to your DB instance by using Oracle SQL Developer. To download a standalone version of this utility, see the Oracle SQL developer downloads page.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your Oracle DB instance (p. 1312).

To connect to a DB instance using SQL developer

1. Start Oracle SQL Developer.
2. On the Connections tab, choose the add (+) icon.
3. In the New/Select Database Connection dialog box, provide the information for your DB instance:
   - For **Connection Name**, enter a name that describes the connection, such as Oracle-RDS.
   - For **Username**, enter the name of the database administrator for the DB instance.
   - For **Password**, enter the password for the database administrator.
   - For **Hostname**, enter the DNS name of the DB instance.
   - For **Port**, enter the port number.
   - For **SID**, enter the Oracle database SID.
The completed dialog box should look similar to the following.

4. Choose Connect.

5. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:

   a. In the Worksheet tab for your connection, enter the following SQL query.

   ```sql
   SELECT NAME FROM V$DATABASE;
   ```

   b. Choose the execute icon to run the query.

   SQL Developer returns the database name.
Connecting to your DB instance using SQL*Plus

You can use a utility like SQL*Plus to connect to an Amazon RDS DB instance running Oracle. To download Oracle Instant Client, which includes a standalone version of SQL*Plus, see Oracle Instant Client Downloads.

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your Oracle DB instance (p. 1312).

**Example To connect to an Oracle DB instance using SQL*Plus**

In the following examples, substitute the user name of your DB instance administrator. Also, substitute the DNS name for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the DB instance's database that you specified when you created the DB instance, and not the name of the DB instance.

For Linux, macOS, or Unix:

```
sqlplus 'user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))
(CONNECT_DATA=(SID=database_name)))'
```

For Windows:

```
sqlplus user_name @(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))
(CONNECT_DATA=(SID=database_name)))
```

You should see output similar to the following.
After you enter the password for the user, the SQL prompt appears.

SQL>

**Note**
The shorter format connection string (Easy connect or EZCONNECT), such as `sqlplus USER/PASSWORD@LONGER-THAN-63-CHARS-RDS-ENDPOINT-HERE:1521/DATABASE_IDENTIFIER`, might encounter a maximum character limit and should not be used to connect.

**Considerations for security groups**

For you to connect to your DB instance, it must be associated with a security group that contains the necessary IP addresses and network configuration. Your DB instance might use the default security group. If you assigned a default, nonconfigured security group when you created the DB instance, the firewall prevents connections.

To create a new security group, security group that you create depends on the Amazon EC2 platform for your DB instance. To determine your platform, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869). In general, if your DB instance is on the EC2-Classic platform, you create a DB security group; if your DB instance is on the VPC platform, you create a VPC security group. For information about creating a new security group, see Controlling access with security groups (p. 1822).

After you create the new security group, you modify your DB instance to associate it with the security group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see Oracle Secure Sockets Layer (p. 1514).

**Considerations for process architecture**

Server processes handle user connections to an Oracle DB instance. By default, the Oracle DB instance uses dedicated server processes. With dedicated server processes, each server process services only one user process. You can optionally configure shared server processes. With shared server processes, each server process can service multiple user processes.

You might consider using shared server processes when a high number of user sessions are using too much memory on the server. You might also consider shared server processes when sessions connect and disconnect very often, resulting in performance issues. There are also disadvantages to using shared server processes. For example, they can strain CPU resources, and they are more complicated to configure and administer.

For more information about dedicated and shared server processes, see About dedicated and shared server processes in the Oracle documentation. For more information about configuring shared server processes on an RDS for Oracle DB instance, see How do I configure Amazon RDS for Oracle database to work with shared servers? in the Knowledge Center.

**Troubleshooting connections to your Oracle DB instance**

The following are issues you might encounter when you try to connect to your Oracle DB instance.
<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to connect to your DB instance.</td>
<td>For a newly created DB instance, the DB instance has a status of <strong>creating</strong> until it is ready to use. When the state changes to <strong>available</strong>, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB instance is available.</td>
</tr>
<tr>
<td>Unable to connect to your DB instance.</td>
<td>If you can't send or receive communications over the port that you specified when you created the DB instance, you can't connect to the DB instance. Check with your network administrator to verify that the port you specified for your DB instance allows inbound and outbound communication.</td>
</tr>
</tbody>
</table>
| Unable to connect to your DB instance. | The access rules enforced by your local firewall and the IP addresses you authorized to access your DB instance in the security group for the DB instance might not match. The problem is most likely the inbound or outbound rules on your firewall.  
You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser. For more information, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).  
For more information about security groups, see Controlling access with security groups (p. 1822).  
To walk through the process of setting up rules for your security group, see Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863). |
| Connect failed because target host or object does not exist – Oracle, Error: ORA-12545 | Make sure that you specified the server name and port number correctly. For **Server name**, enter the DNS name from the console.  
For information about finding the DNS name and port number for a DB instance, see Finding the endpoint of your Oracle DB instance (p. 1312). |
| Invalid username/password; logon denied – Oracle, Error: ORA-01017 | You were able to reach the DB instance, but the connection was refused. This is usually caused by providing an incorrect user name or password. Verify the user name and password, and then retry. |
| TNS:listener does not currently know of SID given in connect descriptor - Oracle, ERROR: ORA-12505 | Ensure the correct SID is entered. The SID is the same as your DB name. Find the DB name in the Configuration tab of the Databases page for your instance. You can also find the DB name using the AWS CLI: `aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier,DBName]' --output text` |

For more information on connection issues, see Can't connect to Amazon RDS DB instance (p. 1880).

**Modifying connection properties using sqlnet.ora parameters**

The sqlnet.ora file includes parameters that configure Oracle Net features on Oracle database servers and clients. Using the parameters in the sqlnet.ora file, you can modify properties for connections in and out of the database.
For more information about why you might set sqlnet.ora parameters, see Configuring profile parameters in the Oracle documentation.

**Setting sqlnet.ora parameters**

Amazon RDS for Oracle parameter groups include a subset of sqlnet.ora parameters. You set them in the same way that you set other Oracle parameters. The sqlnetora. prefix identifies which parameters are sqlnet.ora parameters. For example, in an Oracle parameter group in Amazon RDS, the default_sdu_size sqlnet.ora parameter is sqlnetora.default_sdu_size.

For information about managing parameter groups and setting parameter values, see Working with parameter groups (p. 278).

**Supported sqlnet.ora parameters**

Amazon RDS supports the following sqlnet.ora parameters. Changes to dynamic sqlnet.ora parameters take effect immediately.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Static/Dynamic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqlnetora.default_sdu_size</td>
<td>Oracle 12c –</td>
<td>Dynamic</td>
<td>The session data unit (SDU) size, in bytes. The SDU is the amount of data that is put in a buffer and sent across the network at one time.</td>
</tr>
<tr>
<td></td>
<td>512 to 2097152</td>
<td></td>
<td></td>
</tr>
<tr>
<td>sqlnetora.diag_adr_enabled</td>
<td>ON, OFF</td>
<td>Dynamic</td>
<td>A value that enables or disables Automatic Diagnostic Repository (ADR) tracing. ON specifies that ADR file tracing is used.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>OFF specifies that non-ADR file tracing is used.</td>
</tr>
<tr>
<td>sqlnetora.recv_buf_size</td>
<td>8192 to 268435456</td>
<td>Dynamic</td>
<td>The buffer space limit for receive operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.</td>
</tr>
<tr>
<td>sqlnetora.send_buf_size</td>
<td>8192 to 268435456</td>
<td>Dynamic</td>
<td>The buffer space limit for send operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.allowed_logon_version_client</td>
<td>8</td>
<td>Dynamic</td>
<td>Minimum authentication protocol version allowed for clients, and servers acting as clients, to establish a connection to Oracle DB instances.</td>
</tr>
<tr>
<td></td>
<td>10, 11, 12</td>
<td></td>
<td></td>
</tr>
<tr>
<td>sqlnetora.sqlnet.allowed_logon_version_server</td>
<td>9, 10, 11, 12, 12a</td>
<td>Dynamic</td>
<td>Minimum authentication protocol version allowed to establish a connection to Oracle DB instances.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Modifying Oracle sqlnet.ora parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Static/Dynamic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqlnetora.sqlnet.expire_time</td>
<td>0 to 1440</td>
<td>Dynamic</td>
<td>Time interval, in minutes, to send a check to verify that client-server connections are active.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.inbound_connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to connect with the database server and provide the necessary authentication information.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.outbound_connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to establish an Oracle Net connection to the DB instance.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.recv_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a database server to wait for client data after establishing a connection.</td>
</tr>
<tr>
<td>sqlnetora.sqlnet.send_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a database server to complete a send operation to clients after establishing a connection.</td>
</tr>
<tr>
<td>sqlnetora.tcp.connect_timeout</td>
<td>0 or 10 to 7200</td>
<td>Dynamic</td>
<td>Time, in seconds, for a client to establish a TCP connection to the database server.</td>
</tr>
<tr>
<td>sqlnetora.trace_level_server</td>
<td>0, 4, 10, 16, OFF, USER, ADMIN, SUPPORT</td>
<td>Dynamic</td>
<td>For non-ADR tracing, turns server tracing on at a specified level or turns it off.</td>
</tr>
</tbody>
</table>

The default value for each supported sqlnet.ora parameter is the Oracle default for the release. For information about default values for Oracle Database 12c, see Parameters for the sqlnet.ora file in the Oracle Database 12c documentation.

Viewing sqlnet.ora parameters

You can view sqlnet.ora parameters and their settings using the AWS Management Console, the AWS CLI, or a SQL client.

Viewing sqlnet.ora parameters using the console

For information about viewing parameters in a parameter group, see Working with parameter groups (p. 278).

In Oracle parameter groups, the sqlnetora. prefix identifies which parameters are sqlnet.ora parameters.

Viewing sqlnet.ora parameters using the AWS CLI

To view the sqlnet.ora parameters that were configured in an Oracle parameter group, use the AWS CLI describe-db-parameters command.
To view the all of the sqlnet.ora parameters for an Oracle DB instance, call the AWS CLI `download-db-log-file-portion` command. Specify the DB instance identifier, the log file name, and the type of output.

**Example**

The following code lists all of the sqlnet.ora parameters for `mydbinstance`.

For Linux, macOS, or Unix:

```bash
aws rds download-db-log-file-portion \
    --db-instance-identifier mydbinstance \
    --log-file-name trace/sqlnet-parameters \
    --output text
```

For Windows:

```bash
aws rds download-db-log-file-portion ^
    --db-instance-identifier mydbinstance ^
    --log-file-name trace/sqlnet-parameters ^
    --output text
```

**Viewing sqlnet.ora parameters using a SQL client**

After you connect to the Oracle DB instance in a SQL client, the following query lists the sqlnet.ora parameters.

```sql
SELECT * FROM TABLE
    (rdsadmin.rds_file_util.read_text_file(
        p_directory => 'BDUMP',
        p_filename => 'sqlnet-parameters'));
```

For information about connecting to an Oracle DB instance in a SQL client, see Connecting to your Oracle DB instance (p. 1312).
Securing Oracle DB instance connections

Amazon RDS for Oracle supports SSL/TLS encrypted connections and also the Oracle Native Network Encryption (NNE) option to encrypt connections between your application and your Oracle DB instance. For more information about the Oracle Native Network Encryption option, see Oracle native network encryption (p. 1503).

Topics

• Encrypting client connections with SSL (p. 1322)
• Updating applications to use new SSL/TLS certificates (p. 1322)
• Configuring Kerberos authentication for Amazon RDS for Oracle (p. 1325)
• Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1336)

Encrypting client connections with SSL

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS), but we still often refer to the protocol as SSL. Amazon RDS supports SSL encryption for Oracle DB instances. Using SSL, you can encrypt a connection between your application client and your Oracle DB instance. SSL support is available in all AWS Regions for Oracle.

To enable SSL encryption for an Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. Doing this allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and an Oracle client. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

For more information, see Oracle Secure Sockets Layer (p. 1514).

Note

You can't use both SSL and Oracle native network encryption (NNE) on the same DB instance. Before you can use SSL encryption, you must disable any other connection encryption.

Updating applications to use new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances.

Important

When you change the certificate for an Amazon RDS for Oracle DB instance, only the database listener is restarted. The DB instance isn't restarted. Existing database connections are unaffected, but new connections will encounter errors for a brief period while the listener is restarted.

Note

For client applications that use SSL/TLS to connect to your DB instances, you must update your client application trust stores to include the new CA certificates.
After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 1757). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755). For information about using SSL/TLS with Oracle DB instances, see Oracle Secure Sockets Layer (p. 1514).

Topics
- Finding out whether applications connect using SSL (p. 1323)
- Updating your application trust store (p. 1323)
- Example Java code for establishing SSL connections (p. 1324)

Finding out whether applications connect using SSL

If your Oracle DB instance uses an option group with the SSL option added, you might be using SSL. Check this by following the instructions in Listing the options and option settings for an option group (p. 270). For information about the SSL option, see Oracle Secure Sockets Layer (p. 1514).

Check the listener log to determine whether there are SSL connections. The following is sample output in a listener log.

```
date time * (CONNECT_DATA=(CID=(PROGRAM=program)
(HOST=host)(USER=user)(SID=sid)) *
(ADDRESS=(PROTOCOL=tcps)(HOST=host)(PORT=port)) * establish * ORCL * 0
```

When PROTOCOL has the value tcps for an entry, it shows an SSL connection. However, when HOST is 127.0.0.1, you can ignore the entry. Connections from 127.0.0.1 are a local management agent on the DB instance. These connections aren't external SSL connections. Therefore, you have applications connecting using SSL if you see listener log entries where PROTOCOL is tcps and HOST is not 127.0.0.1.

To check the listener log, you can publish the log to Amazon CloudWatch Logs. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs (p. 676).

Updating your application trust store

You can update the trust store for applications that use SQL*Plus or JDBC for SSL/TLS connections.

Updating your application trust store for SQL*Plus

You can update the trust store for applications that use SQL*Plus for SSL/TLS connections.

Note
When you update the trust store, you can retain older certificates in addition to adding the new certificates.

To update the trust store for SQL*Plus applications

1. Download the 2019 root certificate that works for all AWS Regions and put the file in the ssl_wallet directory.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).
2. Run the following command to update the Oracle wallet.
Using new SSL/TLS certificates

4. Replace the file name with the one that you downloaded.

3. Run the following command to confirm that the wallet was updated successfully.

```bash
prompt> orapki wallet display -wallet $ORACLE_HOME/ssl_wallet
```

Your output should contain the following.

```
Trusted Certificates:
    Subject: CN=Amazon RDS Root 2019 CA,OU=Amazon RDS,O=Amazon Web Services\, Inc.,L=Seattle,ST=Washington,C=US
```

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 1764).

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;
public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "<dns-name-provided-by-amazon-rds>";
    private static final Integer SSL_PORT = "<ssl-option-port-configured-in-option-group>";
    private static final String DB_SID = "<oracle-sid>";
    private static final String DB_USER = "<user name>";
    private static final String DB_PASSWORD = "<password>";
    private static final String KEY_STORE_FILE_PATH = "<file-path-to-keystore>";
    private static final String KEY_STORE_PASS = "<keystore-password>";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format(
            "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))
            (CONNECT_DATA=(SID=%s)))",
            DB_SERVER_NAME, SSL_PORT, DB_SID);
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);
        properties.put("oracle.jdbc.J2EE13Compliant", "true");
        properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
        properties.put("javax.net.ssl.trustStoreType", "JKS");
        properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
        final Connection connection = DriverManager.getConnection(connectionString, properties);
    }
}
```
// If no exception, that means handshake has passed, and an SSL connection can be
opened
}
}

**Important**
After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance](p. 1757).

## Configuring Kerberos authentication for Amazon RDS for Oracle

You can use Kerberos authentication to authenticate users when they connect to your Amazon RDS DB instance running Oracle. In this configuration, your DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD. When users authenticate with an Oracle DB instance joined to the trusting domain, authentication requests are forwarded to the directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple database instances. A directory can also improve your overall security profile.

Amazon RDS supports Kerberos authentication for Oracle DB instances in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Stockholm)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

**Note**
Kerberos authentication isn't supported for DB instance classes that are deprecated for Oracle DB instances. For more information, see [RDS for Oracle instance classes](p. 1302).

**Topics**
- [Setting up Kerberos authentication for Oracle DB instances](p. 1326)
- [Managing a DB instance in a domain](p. 1334)
- [Connecting to Oracle with Kerberos authentication](p. 1336)
Setting up Kerberos authentication for Oracle DB instances

Use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Kerberos authentication for an Oracle DB instance. To set up Kerberos authentication, complete the following steps:

- Step 1: Create a directory using the AWS Managed Microsoft AD (p. 1326)
- Step 2: Create a trust (p. 1329)
- Step 3: Create an IAM role for use by Amazon RDS (p. 1329)
- Step 4: Create and configure users (p. 1330)
- Step 5: Enable cross-VPC traffic between the directory and the DB instance (p. 1331)
- Step 6: Create or modify an Oracle DB instance (p. 1331)
- Step 7: Create Kerberos authentication Oracle logins (p. 1333)
- Step 8: Configure an Oracle client (p. 1333)

Note
During the setup, RDS creates an Oracle database user named managed_service_user@example.com with the CREATE SESSION privilege, where example.com is your domain name. This user corresponds to the user that Directory Service creates inside your Managed Active Directory. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterwards, RDS immediately destroys the ticket cache.

Step 1: Create a directory using the AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

  Note
  Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
• Delegate authority
• Restore deleted objects from the Active Directory Recycle Bin
• Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:
• Manage DNS configurations (add, remove, or update records, zones, and forwarders)
• View DNS event logs
• View security event logs

To create the directory, use the AWS Management Console, the AWS CLI, or the AWS Directory Service API. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the Oracle DB instance.

To create a directory with AWS Managed Microsoft AD
2. In the navigation pane, choose Directories and choose Set up Directory.
3. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:
   Directory DNS name
   The fully qualified name for the directory, such as corp.example.com.
   Directory NetBIOS name
   The short name for the directory, such as CORP.
   Directory description
   (Optional) A description for the directory.
   Admin password
   The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.
   The directory administrator password and can’t include the word “admin.” The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   • Lowercase letters (a–z)
   • Uppercase letters (A–Z)
   • Numbers (0–9)
   • Non-alphanumeric characters (~!#$%^&*_-+=`\(){}[ ]:\;"'<>,.?/)
   Confirm password
   The administrator password retyped.
5. Choose Next.
6. Enter the following information in the Networking section and then choose Next:
   VPC
   The VPC for the directory. Create the Oracle DB instance in this same VPC.
Subnets

Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose Create directory.

It takes several minutes for the directory to be created. When it has been successfully created, the Status value changes to Active.

To see information about your directory, choose the directory name in the directory listing. Note the Directory ID value because you need this value when you create or modify your Oracle DB instance.
Step 2: Create a trust

If you plan to use AWS Managed Microsoft AD only, move on to Step 3: Create an IAM role for use by Amazon RDS (p. 1329).

To get Kerberos authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust or external trust. The trust can be one-way or two-way. For more information about setting up forest trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Step 3: Create an IAM role for use by Amazon RDS

For Amazon RDS to call AWS Directory Service for you, an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess is required. This role allows Amazon RDS to make calls to the AWS Directory Service.

Note

For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

When a DB instance is created using the AWS Management Console and the console user has the iam:CreateRole permission, the console creates this role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, you must create the IAM role
manually. When you create this IAM role, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

**Note**
The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for Oracle.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy AmazonRDSDirectoryServiceAccess. In this case, the IAM role must have the following IAM trust policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ],
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

**Step 4: Create and configure users**

You can create users with the Active Directory Users and Computers tool, which is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, users are individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that is a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information about creating users in your Microsoft Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.
Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify an Oracle DB instance (p. 1331).

If you plan to locate the directory and the DB instance in different AWS accounts or VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway. The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance’s security group can receive inbound traffic from the directory’s security group. For more information, see Best practices for AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify an Oracle DB instance

Create or modify an Oracle DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new Oracle DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation.
  For instructions, see Creating an Amazon RDS DB instance (p. 175).
- Modify an existing Oracle DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation.
  For instructions, see Modifying an Amazon RDS DB instance (p. 309).
- Restore an Oracle DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation.
  For instructions, see Restoring from a DB snapshot (p. 432).
- Restore an Oracle DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation.
  For instructions, see Restoring a DB instance to a specified time (p. 480).

Kerberos authentication is only supported for Oracle DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. When you create or modify the DB instance, do the following:
• Provide the domain identifier (d-* identifier) that was generated when you created your directory.
• Provide the name of the IAM role that you created.
• Ensure that the DB instance security group can receive inbound traffic from the directory security group and send outbound traffic to the directory.

When you use the console to create a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

When you use the console to modify or restore a DB instance, choose the directory in the **Kerberos authentication** section, or choose **Create a new directory**.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

• For the **--domain** parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
• For the **--domain-iam-role-name** parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --domain d-ID \
  --domain-iam-role-name role-name
```
For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --domain d-ID ^
    --domain-iam-role-name role-name
```

**Important**

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

**Note**

`MANAGED_SERVICE_USER` is a service account whose name is randomly generated by Directory Service for RDS. During the Kerberos authentication setup, RDS for Oracle creates a user with the same name and assigns it the `CREATE SESSION` privilege. The Oracle DB user is identified externally as `MANAGED_SERVICE_USER@EXAMPLE.COM`, where `EXAMPLE.COM` is the name of your domain. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterward, RDS immediately destroys the ticket cache.

**Step 7: Create Kerberos authentication Oracle logins**

Use the Amazon RDS master user credentials to connect to the Oracle DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision Oracle logins and users from the Microsoft Active Directory users and groups in your domain. To manage database permissions, you grant and revoke standard Oracle permissions to these logins.

**To allow a Microsoft Active Directory user to authenticate with Oracle**

1. Connect to the Oracle DB instance using your Amazon RDS master user credentials.
2. Create an externally authenticated user in Oracle database.

   In the following example, replace `KRBUSER@CORP.EXAMPLE.COM` with the user name and domain name.

   ```
   CREATE USER "KRBUSER@CORP.EXAMPLE.COM" IDENTIFIED EXTERNALLY;
   GRANT CREATE SESSION TO "KRBUSER@CORP.EXAMPLE.COM";
   ```

   Users (both humans and applications) from your domain can now connect to the Oracle DB instance from a domain joined client machine using Kerberos authentication.

**Step 8: Configure an Oracle client**

To configure an Oracle client, meet the following requirements:

- Create a configuration file named krb5.conf (Linux) or krb5.ini (Windows) to point to the domain. Configure the Oracle client to use this configuration file.
- Verify that traffic can flow between the client host and AWS Directory Service over DNS port 53 over TCP/UDP, Kerberos ports (88 and 464 for managed AWS Directory Service) over TCP, and LDAP port 389 over TCP.
- Verify that traffic can flow between the client host and the DB instance over the database port.

Following is sample content for AWS Managed Microsoft AD.

```plaintext
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
```
Configuring Kerberos authentication

kdc = example.com
admin_server = example.com
{
[domain Realm]
.example.com = CORP.EXAMPLE.COM
test.com = CORP.EXAMPLE.COM
}

Following is sample content for on-premise Microsoft AD. In your krb5.conf or krb5.ini file, replace on-prem-ad-server-name with the name of your on-premises AD server.

[lbddefaults]
default_realm = ONPREM.COM
[realms]
AWSAD.COM = {
kdc = awsad.com
admin_server = awsad.com
}
ONPREM.COM = {
kdc = on-prem-ad-server-name
admin_server = on-prem-ad-server-name
}
[domain Realm]
.awsad.com = AWSAD.COM
awsad.com = AWSAD.COM
.onprem.com = ONPREM.COM
onprem.com = ONPREM.COM

Note
After you configure your krb5.ini or krb5.conf file, we recommend that you reboot the server.

The following is sample sqlnet.ora content for a SQL*Plus configuration:

SQLNET.AUTHENTICATION_SERVICES=(KERBEROS5PRE,KERBEROS5)
SQLNET.KERBEROS5_CONF=path_to_krb5.conf_file

For an example of a SQL Developer configuration, see Document 1609359.1 from Oracle Support.

Managing a DB instance in a domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate a Microsoft Active Directory to enable Kerberos authentication. You can also disassociate a Microsoft Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

• To reattempt enabling Kerberos authentication for a failed membership, use the modify-db-instance CLI command and specify the current membership's directory ID for the --domain option.
• To disable Kerberos authentication on a DB instance, use the modify-db-instance CLI command and specify none for the --domain option.
• To move a DB instance from one domain to another, use the modify-db-instance CLI command and specify the domain identifier of the new domain for the --domain option.

Viewing the status of domain membership

After you create or modify your DB instance, the DB instance becomes a member of the domain. You can view the status of the domain membership for the DB instance in the console or by running the describe-db-instances CLI command. The status of the DB instance can be one of the following:
• **kerberos-enabled** – The DB instance has Kerberos authentication enabled.
• **enabling-kerberos** – AWS is in the process of enabling Kerberos authentication on this DB instance.
• **pending-enable-kerberos** – Enabling Kerberos authentication is pending on this DB instance.
• **pending-maintenance-enable-kerberos** – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
• **pending-disable-kerberos** – Disabling Kerberos authentication is pending on this DB instance.
• **pending-maintenance-disable-kerberos** – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
• **enable-kerberos-failed** – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
• **disabling-kerberos** – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. If the attempt to enable Kerberos authentication fails when you create or modify a DB instance, make sure that you're using the correct IAM role. Then modify the DB instance to join the domain.

**Note**
Only Kerberos authentication with Amazon RDS for Oracle sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running Oracle. For more information about outbound network access with Amazon RDS for Oracle, see Setting up a custom DNS server (p. 1363).

**Force-rotating Kerberos keys**

A secret key is shared between AWS Managed Microsoft AD and Amazon RDS for Oracle DB instance. This key is rotated automatically every 45 days. You can use the following Amazon RDS procedure to force the rotation of this key.

```
SELECT rdsadmin.rdsadmin_kerberos_auth_tasks.rotate_kerberos_keytab AS TASK_ID FROM DUAL;
```

**Note**
In a read replica configuration, this procedure is available only on the source DB instance and not on the read replica.

The SELECT statement returns the ID of the task in a VARCHAR2 data type. You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure.

**Note**
Tasks are executed asynchronously.
Connecting to Oracle with Kerberos authentication

This section assumes that you have set up your Oracle client as described in Step 8: Configure an Oracle client (p. 1333). To connect to the Oracle DB with Kerberos authentication, log in using the Kerberos authentication type. For example, after launching Oracle SQL Developer, choose Kerberos Authentication as the authentication type, as shown following.

To connect to Oracle with Kerberos authentication with SQL*Plus:

1. At a command prompt, run the following command:

   ```
   kinit username
   ```

   Replace `username` with the user name and, at the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. Open SQL*Plus and connect using the DNS name and port number for the Oracle DB instance.

   For more information about connecting to an Oracle DB instance in SQL*Plus, see Connecting to your DB instance using SQL*Plus (p. 1316).

Configuring UTL_HTTP access using certificates and an Oracle wallet

Amazon RDS supports outbound network access on your Oracle DB instances. To connect your DB instance to the network, you can use the following PL/SQL packages:

**UTL_HTTP**

This package makes HTTP calls from SQL and PL/SQL. You can use it to access data on the Internet over HTTP. For more information, see **UTL_HTTP** in the Oracle documentation.
UTL_TCP

This package provides TCP/IP client-side access functionality in PL/SQL. This package is useful to PL/SQL applications that use Internet protocols and email. For more information, see UTL_TCP in the Oracle documentation.

UTL_SMTP

This package provides interfaces to the SMTP commands that enable a client to dispatch emails to an SMTP server. For more information, see UTL_SMTP in the Oracle documentation.

Before configuring your instance for network access, review the following requirements and considerations:

• Outbound network access with UTL_HTTP, UTL_TCP, and UTL_SMTP is supported only for Oracle DB instances in a VPC. To determine whether or not your DB instance is in a VPC, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869). To move a DB instance not in a VPC into a VPC, see Moving a DB instance not in a VPC into a VPC (p. 1873).

• To use SMTP with the UTL_MAIL option, see Oracle UTL_MAIL (p. 1544).

• The Domain Name Server (DNS) name of the remote host can be any of the following:
  • Publicly resolvable.
  • The endpoint of an Amazon RDS DB instance.
  • Resolvable through a custom DNS server. For more information, see Setting up a custom DNS server (p. 1363).
  • The private DNS name of an Amazon EC2 instance in the same VPC or a peered VPC. In this case, make sure that the name is resolvable through a custom DNS server. Alternatively, to use the DNS provided by Amazon, you can enable the enableDnsSupport attribute in the VPC settings and enable DNS resolution support for the VPC peering connection. For more information, see DNS support in your VPC and Modifying your VPC peering connection.

• To connect securely to remote SSL/TLS resources, we recommend that you create and upload customized Oracle wallets. By using the Amazon S3 integration with Amazon RDS for Oracle feature, you can download a wallet from Amazon S3 into Oracle DB instances. For information about Amazon S3 integration for Oracle, see Amazon S3 integration (p. 1452).

• You can establish database links between Oracle DB instances over an SSL/TLS endpoint if the Oracle SSL option is configured for each instance. No further configuration is required. For more information, see Oracle Secure Sockets Layer (p. 1514).

By completing the following tasks, you can configure UTL_HTTP.REQUEST to work with websites that require client authentication certificates during the SSL handshake. You can also configure password authentication for UTL_HTTP access to websites by modifying the Oracle wallet generation commands and the DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE procedure. For more information, see DBMS_NETWORK_ACL_ADMIN in the Oracle Database documentation.

Note
You can adapt the following tasks for UTL_SMTP, which enables you to send emails over SSL/TLS (including Amazon Simple Email Service).

Topics

• Step 1: Get the root certificate for a website (p. 1338)
• Step 2: Create an Oracle wallet (p. 1338)
• Step 3: Download your Oracle wallet to your RDS for Oracle instance (p. 1339)
• Step 4: Grant user permissions for the Oracle wallet (p. 1340)
• Step 5: Configure access to a website from your DB instance (p. 1341)
Step 1: Get the root certificate for a website

For the RDS for Oracle instance to make secure connections to a website, add the root CA certificate. Amazon RDS uses the root certificate to sign the website certificate to the Oracle wallet.

You can get the root certificate in various ways. For example, you can do the following:

1. Use a web server to visit the website secured by the certificate.
2. Download the root certificate that was used for signing.

For AWS services, root certificates typically reside in the Amazon trust services repository.

Step 2: Create an Oracle wallet

Create an Oracle wallet that contains both the web server certificates and the client authentication certificates. The RDS Oracle instance uses the web server certificate to establish a secure connection to the website. The website needs the client certificate to authenticate the Oracle database user.

You might want to configure secure connections without using client certificates for authentication. In this case, you can skip the Java keystore steps in the following procedure.

To create an Oracle wallet

1. Place the root and client certificates in a single directory, and then change into this directory.
2. Convert the .p12 client certificate to the Java keystore.

   **Note**
   
   If you’re not using client certificates for authentication, you can skip this step.

   The following example converts the client certificate named `client_certificate.p12` to the Java keystore named `client_keystore.jks`. The keystore is then included in the Oracle wallet. The keystore password is `P12PASSWORD`.

   ```
   orapki wallet pkcs12_to_jks -wallet ./client_certificate.p12 -jksKeyStoreLoc ./client_keystore.jks -jksKeyStorepwd P12PASSWORD
   ```

3. Create a directory for your Oracle wallet that is different from the certificate directory.

   The following example creates the directory `/tmp/wallet`.

   ```
   mkdir -p /tmp/wallet
   ```

4. Create an Oracle wallet in your wallet directory.

   The following example sets the Oracle wallet password to `P12PASSWORD`, which is the same password used by the Java keystore in a previous step. Using the same password is convenient, but not necessary. The `-auto_login` parameter turns on the automatic login feature, so that you don’t need to specify a password every time you want to access it.

   ```
   orapki wallet create -wallet /tmp/wallet -pwd P12PASSWORD -auto_login
   ```

5. Add the Java keystore to your Oracle wallet.

   **Note**
   
   If you’re not using client certificates for authentication, you can skip this step.
The following example adds the keystore `client_keystore.jks` to the Oracle wallet named `/tmp/wallet`. In this example, you specify the same password for the Java keystore and the Oracle wallet.

```
orapki wallet jks_to_pkcs12 -wallet /tmp/wallet -pwd P12PASSWORD -keystore ./client_keystore.jks -jkspwd P12PASSWORD
```

6. Add the root certificate for your target website to the Oracle wallet.

   The following example adds a certificate named `Root_CA.cer`.

   ```
orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Root_CA.cer -pwd P12PASSWORD
```

7. Add any intermediate certificates.

   The following example adds a certificate named `Intermediate.cer`. Repeat this step as many times as need to load all intermediate certificates.

   ```
orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Intermediate.cer -pwd P12PASSWORD
```

8. Confirm that your newly created Oracle wallet has the required certificates.

   ```
orapki wallet display -wallet /tmp/wallet -pwd P12PASSWORD
```

**Step 3: Download your Oracle wallet to your RDS for Oracle instance**

In this step, you upload your Oracle wallet to Amazon S3, and then download the wallet from Amazon S3 to your RDS for Oracle instance.

**To download your Oracle wallet to your RDS for Oracle DB instance**

1. Complete the prerequisites for Amazon S3 integration with Oracle, and add the `S3_INTEGRATION` option to your Oracle DB instance. Ensure that the IAM role for the option has access to the Amazon S3 bucket you are using.

   For more information, see Amazon S3 integration (p. 1452).

2. Log in to your DB instance as the master user, and then create an Oracle directory to hold the Oracle wallet.

   The following example creates an Oracle directory named `WALLET_DIR`.

   ```
   EXEC rdsadmin.rdsadmin_util.create_directory('WALLET_DIR');
   
   For more information, see Creating and dropping directories in the main data storage space (p. 1418).
   
   3. Upload the Oracle wallet to your Amazon S3 bucket.

   You can use any supported upload technique.

   4. If you're re-uploading an Oracle wallet, delete the existing wallet. Otherwise, skip to the next step.

   The following example removes the existing wallet, which is named `cwallet.sso`. 
5. Download the Oracle wallet from your Amazon S3 bucket to the Oracle DB instance.

The following example downloads the wallet named `cwallet.sso` from the Amazon S3 bucket named `my_s3_bucket` to the DB instance directory named `WALLET_DIR`.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(  
  p_bucket_name => 'my_s3_bucket',  
  p_s3_prefix => 'cwallet.sso',  
  p_directory_name => 'WALLET_DIR')  
AS TASK_ID FROM DUAL;
```

6. (Optional) Download a password-protected Oracle wallet.

Download this wallet only if you want to require a password for every use of the wallet. The following example downloads password-protected wallet `ewallet.p12`.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(  
  p_bucket_name => 'my_s3_bucket',  
  p_s3_prefix => 'ewallet.p12',  
  p_directory_name => 'WALLET_DIR')  
AS TASK_ID FROM DUAL;
```

7. Check the status of your DB task.

Substitute the task ID returned from the preceding steps for `dbtask-1234567890123-4567.log` in the following example.

```sql
SELECT TEXT FROM  
TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-1234567890123-4567.log'));
```

8. Check the contents of the directory that you're using to store the Oracle wallet.

```sql
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

For more information, see Listing files in a DB instance directory (p. 1419).

---

### Step 4: Grant user permissions for the Oracle wallet

You can either create a new database user or configure an existing user. In either case, you must configure the user to access the Oracle wallet for secure connections and client authentication using certificates.

#### To grant user permissions for the Oracle wallet

1. Log in your RDS for Oracle DB instance as the master user.

2. If you don't want to configure an existing database user, create a new user. Otherwise, skip to the next step.

   The following example creates a database user named `my-user`.

   ```sql
   CREATE USER my-user IDENTIFIED BY my-user-pwd;
   GRANT CONNECT TO my-user;
   ```

3. Grant permission to your database user on the directory containing your Oracle wallet.
The following example grants read access to user `my-user` on directory `WALLET_DIR`.

```
GRANT READ ON DIRECTORY WALLET_DIR TO my-user;
```

4. Grant permission to your database user to use the UTL_HTTP package.

The following PL/SQL program grants UTL_HTTP access to user `my-user`.

```
BEGIN
    rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
END;
/
```

5. Grant permission to your database user to use the UTL_FILE package.

The following PL/SQL program grants UTL_FILE access to user `my-user`.

```
BEGIN
    rdsadmin.rdsadmin_util.grant_sys_object('UTL_FILE', UPPER('my-user'));
END;
/
```

Step 5: Configure access to a website from your DB instance

In this step, you configure your Oracle database user so that it can connect to your target website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate. For more information, see Configuring Access Control to an Oracle Wallet in the Oracle Database documentation.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as the master user.
2. Create a Host Access Control Entry (ACE) for your user and the target website on a secure port.

   The following example configures `my-user` to access `secret.encrypted-website.com` on secure port 443.

   ```
   BEGIN
       DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
           host => 'secret.encrypted-website.com',
           lower_port => 443,
           upper_port => 443,
           ace => xs$ace_type(privilege_list => xs$name_list('http'),
                               principal_name => 'my-user',
                               principal_type => xs_acl.ptype_db));
   END;
   /
   ```

   For more information, see Configuring Access Control for External Network Services in the Oracle Database documentation.

3. (Optional) Create an ACE for your user and target website on the standard port.

   You might need to use the standard port if some web pages are served from the standard web server port (80) instead of the secure port (443).

   ```
   BEGIN
       DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
   ```
Configuring UTL_HTTP access

```sql
host       => 'secret.encrypted-website.com',
lower_port => 80,
upper_port => 80,
ace        => xs$ace_type(privilege_list => xs$name_list('http'),
                      principal_name => 'my-user',
                      principal_type => xs_acl.ptype_db));
END;
/
```

4. Confirm that the access control entries exist.

```
SET LINESIZE 150
COLUMN HOST FORMAT A40
COLUMN ACL FORMAT A50
SELECT HOST, LOWER_PORT, UPPER_PORT, ACL
FROM DBA_NETWORK_ACLS
ORDER BY HOST;
```

5. Grant permission to your database user to use the UTL_HTTP package.

The following PL/SQL program grants UTL_HTTP access to user `my-user`.

```
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
END;
/
```

6. Confirm that related access control lists exist.

```
SET LINESIZE 150
COLUMN ACL FORMAT A50
COLUMN PRINCIPAL FORMAT A20
COLUMN PRIVILEGE FORMAT A10
SELECT ACL, PRINCIPAL, PRIVILEGE, IS_GRANT,
     TO_CHAR(START_DATE, 'DD-MON-YYYY') AS START_DATE,
     TO_CHAR(END_DATE, 'DD-MON-YYYY') AS END_DATE
FROM DBA_NETWORK_ACL_PRIVILEGES
ORDER BY ACL, PRINCIPAL, PRIVILEGE;
```

7. Grant permission to your database user to use certificates for client authentication and your Oracle wallet for connections.

**Note**
If you're not using client certificates for authentication, you can skip this step.

```
DECLARE
  l_wallet_path all_directories.directory_path%type;
BEGIN
  SELECT DIRECTORY_PATH
    INTO l_wallet_path
  FROM ALL_DIRECTORIES
  WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE(
    wallet_path => 'file:' || l_wallet_path,
    ace         => xs$ace_type(privilege_list => xs$name_list('use_client_certificates'),
                            principal_name => 'my-user',
                            principal_type => xs_acl.ptype_db));
END;
/
```
Step 6: Test connections from your DB instance to a website

In this step, you configure your database user so that it can connect to the website using UTL_HTTP, your uploaded Oracle Wallet, and the client certificate.

To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as a database user with UTL_HTTP permissions.
2. Confirm that a connection to your target website can resolve the host address.

   The following example gets the host address from secret.encrypted-website.com.

   ```sql
   SELECT UTL_INADDR.GET_HOST_ADDRESS(host => 'secret.encrypted-website.com')
   FROM DUAL;
   ```

3. Test a failed connection.

   The following query fails because UTL_HTTP requires the location of the Oracle wallet with the certificates.

   ```sql
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```

4. Test website access by using UTL_HTTP.SET_WALLET and selecting from DUAL.

   ```sql
   DECLARE
   l_wallet_path all_directories.directory_path%type;
   BEGIN
   SELECT DIRECTORY_PATH INTO l_wallet_path
   FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
   UTL_HTTP.SET_WALLET('file:/' || l_wallet_path);
   END;
   /
   SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
   ```

5. (Optional) Test website access by storing your query in a variable and using EXECUTE IMMEDIATE.

   ```sql
   DECLARE
   l_wallet_path all_directories.directory_path%type;
   v_webpage_sql VARCHAR2(1000);
   v_results     VARCHAR2(32767);
   BEGIN
   SELECT DIRECTORY_PATH INTO l_wallet_path
   FROM ALL_DIRECTORIES
   WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
   v_webpage_sql := 'SELECT UTL_HTTP.REQUEST(''secret.encrypted-website.com'','','',''file:/' ||l_wallet_path||'') FROM DUAL';
   DBMS_OUTPUT.PUT_LINE(v_webpage_sql);
   EXECUTE IMMEDIATE v_webpage_sql INTO v_results;
   DBMS_OUTPUT.PUT_LINE(v_results);
   END;
   /
   ```

6. (Optional) Find the file system location of your Oracle wallet directory.
Use the output from the previous command to make an HTTP request. For example, if the directory is `rdsdbdata/userdirs/01`, run the following query.

```
SELECT UTL_HTTP.REQUEST('https://secret.encrypted-website.com/', '', 'file://rdsdbdata/userdirs/01')
FROM   DUAL;
```
Administering your Oracle DB instance

Following are the common management tasks you perform with an Amazon RDS DB instance. Some tasks are the same for all RDS DB instances. Other tasks are specific to RDS for Oracle.

The following tasks are common to all RDS databases, but Oracle has special considerations. For example, connect to an Oracle Database using the Oracle clients SQL*Plus and SQL Developer.

<table>

</table>

Following, you can find a description for Amazon RDS–specific implementations of common DBA tasks for RDS Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges. In many of the tasks, you run the rdsadmin package, which is an Amazon RDS–specific tool that enables you to administer your database.

The following are common DBA tasks for DB instances running Oracle:

- **System tasks (p. 1353)**

<table>
<thead>
<tr>

    ```

  - **Oracle method:**
    
    ```
    CREATE DIRECTORY
    ```

  - **Amazon RDS method:**
    
    ```
    rdsadmin.rdsadmin_util.drop_directory
    ```

  - **Oracle method:**
    
    ```
    DROP DIRECTORY
    ```

- **Listing files in a DB instance directory (p. 1419)**

  - **Amazon RDS method:**
    
    ```
    rdsadmin.rds_file_util.listdir
    ```

  - **Oracle method:**
    
    No method specified.

- **Reading files in a DB instance directory (p. 1420)**

  - **Amazon RDS method:**
    
    ```
    rdsadmin.rds_file_util.read_text_file
    ```

  - **Oracle method:**
    
    No method specified.

- **Accessing Opatch files (p. 1420)**

  - **Amazon RDS method:**
    
    ```
    rdsadmin.rds_file_util.read_text_file
    ```
    
    or
    
    ```
    rdsadmin.tracefile_listing
    ```

  - **Oracle method:**
    
    ```
    opatch
    ```

- **Setting parameters for advisor tasks (p. 1422)**

  - **Amazon RDS method:**
    
    ```
    rdsadmin.rdsadmin_util.advisor_task_set_parameter
    ```

  - **Oracle method:**
    
    Various stored package procedures.

- **Disabling AUTO_STATS_ADVISOR_TASK (p. 1424)**

  - **Amazon RDS method:**
    
    ```
    rdsadmin.rdsadmin_util.advisor_task_drop
    ```

  - **Oracle method:**
    
    No method specified.

- **Re-enabling AUTO_STATS_ADVISOR_TASK (p. 1424)**

  - **Amazon RDS method:**
    
    ```
    rdsadmin.rdsadmin_util.dbms_stats_init
    ```

  - **Oracle method:**
    
    No method specified.
### Enabling HugePages for an Oracle DB instance (p. 1424) | Amazon RDS method: `use_large_pages` RDS parameter  
| Oracle method: `use_large_pages` initialization parameter

### Enabling extended data types (p. 1426) | Amazon RDS method: `max_string_size` RDS parameter  
| Oracle method: `max_string_size` initialization parameter

You can also use Amazon RDS procedures for Amazon S3 integration with Oracle and for running OEM Management Agent database tasks. For more information, see Amazon S3 integration (p. 1452) and Performing database tasks with the Management Agent (p. 1490).

## Performing common system tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to the system on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

### Topics
- Disconnecting a session (p. 1353)  
- Terminating a session (p. 1354)  
- Canceling a SQL statement in a session (p. 1355)  
- Enabling and disabling restricted sessions (p. 1355)  
- Flushing the shared pool (p. 1356)  
- Flushing the buffer cache (p. 1356)  
- Granting SELECT or EXECUTE privileges to SYS objects (p. 1357)  
- Revoking SELECT or EXECUTE privileges on SYS objects (p. 1358)  
- Granting privileges to non-master users (p. 1359)  
- Creating custom functions to verify passwords (p. 1359)  
- Setting up a custom DNS server (p. 1363)  
- Setting and unsetting system diagnostic events (p. 1364)

### Disconnecting a session

To disconnect the current session by ending the dedicated server process, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.disconnect`. The `disconnect` procedure has the following parameters.
### Parameter name | Data type | Default | Required | Description  
---|---|---|---|---  
**sid** | number | — | Yes | The session identifier.  
**serial** | number | — | Yes | The serial number of the session.  
**method** | varchar | 'IMMEDIATE' | No | Valid values are 'IMMEDIATE' or 'POST_TRANSACTION'.

The following example disconnects a session.

```sql
begin
  rdsadmin.rdsadmin_util.disconnect(
    sid => sid,
    serial => serial_number);
end;
/
```

To get the session identifier and the session serial number, query the `V$SESSION` view. The following example gets all sessions for the user `AWSUSER`.

```sql
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The database must be open to use this method. For more information about disconnecting a session, see `ALTER SYSTEM` in the Oracle documentation.

### Terminating a session

To terminate a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.kill`. The `kill` procedure has the following parameters.

| Parameter name | Data type | Default | Required | Description  
---|---|---|---|---  
**sid** | number | — | Yes | The session identifier.  
**serial** | number | — | Yes | The serial number of the session.  
**method** | varchar | null | No | Valid values are 'IMMEDIATE' or 'PROCESS'.

The following example terminates a session.

```sql
begin
  rdsadmin.rdsadmin_util.kill(
    sid => sid,
    serial => serial_number);
end;
/
```

To get the session identifier and the session serial number, query the `V$SESSION` view. The following example gets all sessions for the user `AWSUSER`.  

1354
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';

You can specify either IMMEDIATE or PROCESS as a value for the method parameter. By specifying PROCESS as the method value, you can terminate the processes associated with a session. Do this only if terminating the session using IMMEDIATE as the method value was unsuccessful.

### Canceling a SQL statement in a session

To cancel a SQL statement in a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.cancel`.

**Note**

This procedure is supported for Oracle Database 19c (19.0.0) and all higher major and minor versions of RDS for Oracle.

The `cancel` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sid</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The session identifier.</td>
</tr>
<tr>
<td>serial</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The serial number of the session.</td>
</tr>
<tr>
<td>sql_id</td>
<td>varchar2</td>
<td>null</td>
<td>No</td>
<td>The SQL identifier of the SQL statement.</td>
</tr>
</tbody>
</table>

The following example cancels a SQL statement in a session.

```sql
begin
  rdsadmin.rdsadmin_util.cancel(
    sid   => sid,
    serial => serial_number,
    sql_id => sql_id);
end;
/```

To get the session identifier, the session serial number, and the SQL identifier of a SQL statement, query the `V$SESSION` view. The following example gets all sessions and SQL identifiers for the user `AWSUSER`.

```sql
select SID, SERIAL#, SQL_ID, STATUS from V$SESSION where USERNAME = 'AWSUSER';
```

### Enabling and disabling restricted sessions

To enable and disable restricted sessions, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.restricted_session`. The `restricted_session` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Yes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_enable</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to enable restricted sessions, false</td>
</tr>
</tbody>
</table>
### Flushing the shared pool

To flush the shared pool, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_shared_pool`. The `flush_shared_pool` procedure has no parameters.

The following example flushes the shared pool.

```
EXEC rdsadmin.rdsadmin_util.flush_shared_pool;
```

### Flushing the buffer cache

To flush the buffer cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_buffer_cache`. The `flush_buffer_cache` procedure has no parameters.

The following example flushes the buffer cache.

```
/* Verify that the database is currently unrestricted. */
SELECT LOGINS FROM V$INSTANCE;
LOGINS
-------
ALLOWED

/* Enable restricted sessions */
EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => true);

/* Verify that the database is now restricted. */
SELECT LOGINS FROM V$INSTANCE;
LOGINS
-------
RESTRICTED

/* Disable restricted sessions */
EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => false);

/* Verify that the database is now unrestricted again. */
SELECT LOGINS FROM V$INSTANCE;
LOGINS
-------
ALLOWED
```
EXEC rdsadmin.rdsadmin_util.flush_buffer_cache;

Granting SELECT or EXECUTE privileges to SYS objects

Usually you transfer privileges by using roles, which can contain many objects. To grant privileges to a single object, use the Amazon RDS procedure rdsadmin.rdsadmin_util.grant_sys_object. The procedure grants only privileges that the master user has already been granted through a role or direct grant.

The grant_sys_object procedure has the following parameters.

**Important**
For all parameter values, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run CREATE USER myuser or CREATE USER MYUSER, the data dictionary stores MYUSER. However, if you use double quotes in CREATE USER "MyUser", the data dictionary stores MyUser.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_obj_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to grant privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they appear in DBA_OBJECTS. Most system objects are defined in uppercase, so we recommend that you try that first.</td>
</tr>
<tr>
<td>p_grantee</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to grant privileges to. The object can be a schema or a role.</td>
</tr>
<tr>
<td>p_privilege</td>
<td>varchar2</td>
<td>null</td>
<td>Yes</td>
<td>—</td>
</tr>
<tr>
<td>p_grant_option</td>
<td>boolean</td>
<td>false</td>
<td>No</td>
<td>Set to true to use the with grant option. The p_grant_option parameter is supported for 12.1.0.2.v4 and later, all 12.2.0.1 versions, and all 19.0.0 versions.</td>
</tr>
</tbody>
</table>

The following example grants select privileges on an object named V_$SESSION to a user named USER1.

```sql
begin
    rdsadmin.rdsadmin_util.grant_sys_object( 
        p_obj_name => 'V_$SESSION',
        p_grantee => 'USER1',
        p_privilege => 'SELECT');
end;
/```
The following example grants select privileges on an object named V_$SESSION to a user named USER1 with the grant option.

```sql
begin
    rdsadmin.rdsadmin_util.grant_sys_object(
        p_obj_name     => 'V_$SESSION',
        p_grantee      => 'USER1',
        p_privilege    => 'SELECT',
        p_grant_option => true);
end;
/
```

To be able to grant privileges on an object, your account must have those privileges granted to it directly with the grant option, or via a role granted using with admin option. In the most common case, you may want to grant SELECT on a DBA view that has been granted to the SELECT_CATALOG_ROLE role. If that role isn't already directly granted to your user using with admin option, then you can't transfer the privilege. If you have the DBA privilege, then you can grant the role directly to another user.

The following example grants the SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE to USER1. Since the with admin option is used, USER1 can now grant access to SYS objects that have been granted to SELECT_CATALOG_ROLE.

```sql
GRANT SELECT_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
GRANT EXECUTE_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
```

Objects already granted to PUBLIC do not need to be re-granted. If you use the grant_sys_object procedure to re-grant access, the procedure call succeeds.

### Revoking SELECT or EXECUTE privileges on SYS objects

To revoke privileges on a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.revoke_sys_object`. The procedure only revokes privileges that the master account has already been granted through a role or direct grant.

The `revoke_sys_object` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_obj_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to revoke privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they appear in DBA_OBJECTS. Most system objects are defined in upper case, so we recommend you try that first.</td>
</tr>
<tr>
<td>p_revokee</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the object to revoke privileges for. The object can be a schema or a role.</td>
</tr>
</tbody>
</table>
The following example revokes select privileges on an object named `V_SESSION` from a user named `USER1`.

```sql
begin
 rdsadmin.rdsadmin_util.revoke_sys_object(
   p_obj_name  => 'V_SESSION',
   p_revokee   => 'USER1',
   p_privilege => 'SELECT');
end;
/
```

**Granting privileges to non-master users**

You can grant select privileges for many objects in the `SYS` schema by using the `SELECT_CATALOG_ROLE` role. The `SELECT_CATALOG_ROLE` role gives users `SELECT` privileges on data dictionary views. The following example grants the role `SELECT_CATALOG_ROLE` to a user named `user1`.

```
GRANT SELECT_CATALOG_ROLE TO user1;
```

You can grant `EXECUTE` privileges for many objects in the `SYS` schema by using the `EXECUTE_CATALOG_ROLE` role. The `EXECUTE_CATALOG_ROLE` role gives users `EXECUTE` privileges for packages and procedures in the data dictionary. The following example grants the role `EXECUTE_CATALOG_ROLE` to a user named `user1`.

```
GRANT EXECUTE_CATALOG_ROLE TO user1;
```

The following example gets the permissions that the roles `SELECT_CATALOG_ROLE` and `EXECUTE_CATALOG_ROLE` allow.

```
SELECT *
FROM ROLE_TAB_PRIVS
WHERE ROLE IN ('SELECT_CATALOG_ROLE','EXECUTE_CATALOG_ROLE')
ORDER BY ROLE, TABLE_NAME ASC;
```

The following example creates a non-master user named `user1`, grants the `CREATE SESSION` privilege, and grants the `SELECT` privilege on a database named `sh.sales`.

```
CREATE USER user1 IDENTIFIED BY PASSWORD;
GRANT CREATE SESSION TO user1;
GRANT SELECT ON sh.sales TO user1;
```

**Creating custom functions to verify passwords**

You can create a custom password verification function in the following ways:

- To use standard verification logic, and to store your function in the `SYS` schema, use the `create_verify_function` procedure. If you want to use custom verification logic, or you don't want to store your function in the `SYS` schema, use the `create_passthrough_verify_fcn` procedure.
- To use custom verification logic, or to avoid storing your function in the `SYS` schema, use the `create_passthrough_verify_fcn` procedure.
The create_verify_function procedure

You can create a custom function to verify passwords by using the Amazon RDS procedure rdsadmin.rdsadmin_password_verify.create_verify_function. The create_verify_function procedure is supported for version 12.1.0.2.v5 and all higher major and minor versions of RDS for Oracle.

The create_verify_function procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_verify_function_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name for your custom function. This function is created for you in the SYS schema. You assign this function to user profiles.</td>
</tr>
<tr>
<td>p_min_length</td>
<td>number</td>
<td>8</td>
<td>No</td>
<td>The minimum number of characters required.</td>
</tr>
<tr>
<td>p_max_length</td>
<td>number</td>
<td>256</td>
<td>No</td>
<td>The maximum number of characters allowed.</td>
</tr>
<tr>
<td>p_min_letters</td>
<td>number</td>
<td>1</td>
<td>No</td>
<td>The minimum number of letters required.</td>
</tr>
<tr>
<td>p_min_uppercase</td>
<td>number</td>
<td>0</td>
<td>No</td>
<td>The minimum number of uppercase letters required.</td>
</tr>
<tr>
<td>p_min_lowercase</td>
<td>number</td>
<td>0</td>
<td>No</td>
<td>The minimum number of lowercase letters required.</td>
</tr>
<tr>
<td>p_min_digits</td>
<td>number</td>
<td>1</td>
<td>No</td>
<td>The minimum number of digits required.</td>
</tr>
<tr>
<td>p_min_special</td>
<td>number</td>
<td>0</td>
<td>No</td>
<td>The minimum number of special characters required.</td>
</tr>
<tr>
<td>p_min_different_chars</td>
<td>number</td>
<td>3</td>
<td>No</td>
<td>The minimum number of different characters required between the old and new password.</td>
</tr>
<tr>
<td>p_disallow_username</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to disallow the user name in the password.</td>
</tr>
<tr>
<td>p_disallow_reverse</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to disallow the reverse of the user name in the password.</td>
</tr>
<tr>
<td>p_disallow_db_name</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to disallow the database or server name in the password.</td>
</tr>
<tr>
<td>p_disallow_simple_string</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to disallow simple strings as the password.</td>
</tr>
</tbody>
</table>
You can create multiple password verification functions.

There are restrictions on the name of your custom function. Your custom function can't have the same name as an existing system object. The name can be no more than 30 characters long. Also, the name must include one of the following strings: PASSWORD, VERIFY, COMPLEXITY, ENFORCE, or STRENGTH.

The following example creates a function named CUSTOM_PASSWORD_FUNCTION. The function requires that a password has at least 12 characters, 2 uppercase characters, 1 digit, and 1 special character, and that the password disallows the @ character.

```sql
begin
    rdsadmin.rdsadmin_password_verify.create_verify_function(
        p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
        p_min_length           => 12,
        p_min_uppercase        => 2,
        p_min_digits           => 1,
        p_min_special          => 1,
        p_disallow_at_sign     => true);
end;
/
```

To see the text of your verification function, query `DBA_SOURCE`. The following example gets the text of a custom password function named CUSTOM_PASSWORD_FUNCTION.

```sql
COL TEXT FORMAT a150
SELECT TEXT
FROM DBA_SOURCE
WHERE OWNER = 'SYS'
  AND NAME = 'CUSTOM_PASSWORD_FUNCTION'
ORDER BY LINE;
```

To associate your verification function with a user profile, use `alter profile`. The following example associates a verification function with the DEFAULT user profile.

```sql
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

To see what user profiles are associated with what verification functions, query `DBA_PROFILES`. The following example gets the profiles that are associated with the custom verification function named CUSTOM_PASSWORD_FUNCTION.

```sql
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD' AND LIMIT = 'CUSTOM_PASSWORD_FUNCTION';
```
The following example gets all profiles and the password verification functions that they are associated with.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD_VERIFY_FUNCTION';
```

<table>
<thead>
<tr>
<th>PROFILE</th>
<th>RESOURCE_NAME</th>
<th>RESOURCE LIMIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>PASSWORD</td>
</tr>
<tr>
<td>CUSTOM_PASSWORD_FUNCTION</td>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>PASSWORD NULL</td>
</tr>
<tr>
<td>RDSADMIN</td>
<td>PASSWORD_VERIFY_FUNCTION</td>
<td>PASSWORD NULL</td>
</tr>
</tbody>
</table>

**The create_passthrough_verify_fcn procedure**

The `create_passthrough_verify_fcn` procedure is supported for version 12.1.0.2.v7 and all higher major and minor versions of RDS for Oracle.

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn`. The `create_passthrough_verify_fcn` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_verify_function_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name for your custom verification function. This is a wrapper function</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>that is created for you in the SYS schema, and it doesn't contain any</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>verification logic. You assign this function to user profiles.</td>
</tr>
<tr>
<td>p_target_owner</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The schema owner for your custom verification function.</td>
</tr>
<tr>
<td>p_target_function_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of your existing custom function that contains the verification</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>logic. Your custom function must return a boolean. Your function should</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>return <code>true</code> if the password is valid and <code>false</code> if the password is invalid.</td>
</tr>
</tbody>
</table>

The following example creates a password verification function that uses the logic from the function named `PASSWORD_LOGIC_EXTRA_STRONG`.

```
begin
    rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn(
```
To associate the verification function with a user profile, use `alter profile`. The following example associates the verification function with the `DEFAULT` user profile.

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

### Setting up a custom DNS server

Amazon RDS supports outbound network access on your DB instances running Oracle. For more information about outbound network access, including prerequisites, see Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1336).

Amazon RDS Oracle allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your Amazon RDS DB instance through your custom DNS server.

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

To set up a custom DNS server for your Amazon RDS for Oracle DB instance, do the following:

- From the DHCP options set attached to your virtual private cloud (VPC), set the `domain-name-servers` option to the IP address of your DNS name server. For more information, see DHCP options sets.
  
  **Note**
  
  The `domain-name-servers` option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

- Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.

- Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.

- Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1024 bytes or less.

- Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that permit UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall allow-listing to permit UDP and TCP inbound traffic on port 53.

  For more information, see Security groups for your VPC and Adding and removing rules.

- Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

  For more information, see Security groups for your VPC and Adding and removing rules.

- The routing path between the Amazon RDS DB instance and the DNS server has to be configured correctly to allow DNS traffic.
  
  - If the Amazon RDS DB instance and the DNS server are not in the same VPC, a peering connection has to be set up between them. For more information, see What is VPC peering?
Setting and unset system diagnostic events

To set and unset diagnostic events at the session level, you can use the Oracle SQL statement `ALTER SESSION SET EVENTS`. However, to set events at the system level you can't use Oracle SQL. Instead, use the system event procedures in the `rdsadmin.rdsadmin_util` package. The system event procedures are available in the following engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 19c versions
  
  For more information, see Version 19.0.0.0.ru-2020-10.rur-2020-10.r1 in the Amazon RDS for Oracle Release Notes.

- 12.2.0.1.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 12c Release 2 (12.2.0.1) versions
  
  For more information, see Version 12.2.0.1.ru-2020-10.rur-2020-10.r1 in the Amazon RDS for Oracle Release Notes.

- 12.1.0.2.v22 and higher Oracle Database 12c Release 1 (12.1.0.2) versions
  
  For more information, see Version 12.1.0.2.v22 in the Amazon RDS for Oracle Release Notes.

**Important**

Internally, the `rdsadmin.rdsadmin_util` package sets events by using the `ALTER SYSTEM SET EVENTS` statement. This `ALTER SYSTEM` statement isn't documented in the Oracle Database documentation. Some system diagnostic events can generate large amounts of tracing information, cause contention, or affect database availability. We recommend that you test specific diagnostic events in your nonproduction database, and only set events in your production database under guidance of Oracle Support.

Listing allowed system diagnostic events

To list the system events that you can set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_allowed_system_events`. This procedure accepts no parameters.

The following example lists all system events that you can set.

```sql
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_allowed_system_events;
```

The following sample output lists event numbers and their descriptions. Use the Amazon RDS procedures `set_system_event` to set these events and `unset_system_event` to unset them.

<table>
<thead>
<tr>
<th>Event Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>604</td>
<td>error occurred at recursive SQL level</td>
</tr>
<tr>
<td>942</td>
<td>table or view does not exist</td>
</tr>
<tr>
<td>1401</td>
<td>inserted value too large for column</td>
</tr>
<tr>
<td>1403</td>
<td>no data found</td>
</tr>
<tr>
<td>1410</td>
<td>invalid ROWID</td>
</tr>
<tr>
<td>1422</td>
<td>exact fetch returns more than requested number of rows</td>
</tr>
<tr>
<td>1426</td>
<td>numeric overflow</td>
</tr>
<tr>
<td>1427</td>
<td>single-row subquery returns more than one row</td>
</tr>
<tr>
<td>1476</td>
<td>divisor is equal to zero</td>
</tr>
<tr>
<td>1483</td>
<td>invalid length for DATE or NUMBER bind variable</td>
</tr>
<tr>
<td>1489</td>
<td>result of string concatenation is too long</td>
</tr>
<tr>
<td>1652</td>
<td>unable to extend temp segment by in tablespace</td>
</tr>
<tr>
<td>1858</td>
<td>a non-numeric character was found where a numeric was expected</td>
</tr>
<tr>
<td>4031</td>
<td>unable to allocate bytes of shared memory (&quot;&quot;,&quot;&quot;,&quot;&quot;,&quot;&quot;)</td>
</tr>
<tr>
<td>4502</td>
<td>PL/SQL: numeric or value error</td>
</tr>
<tr>
<td>10027</td>
<td>Specify Deadlock Trace Information to be Dumped</td>
</tr>
</tbody>
</table>
10046 - enable SQL statement timing
10053 - CBO Enable optimizer trace
10173 - Dynamic Sampling time-out error
10442 - enable trace of kst for ORA-01555 diagnostics
12008 - error in materialized view refresh path
12012 - error on auto execute of job
12504 - TNS:listener was not given the SERVICE_NAME in CONNECT_DATA
14400 - inserted partition key does not map to any partition
31693 - Table data object failed to load/unload and is being skipped due to error:

Note
The list of the allowed system events can change over time. To make sure that you have the most recent list of eligible events, use rdsadmin.rdsadmin_util.list_allowed_system_events.

Setting system diagnostic events

To set a system event, use the Amazon RDS procedure rdsadmin.rdsadmin_util.set_system_event. You can only set events listed in the output of rdsadmin.rdsadmin_util.list_allowed_system_events. The set_system_event procedure accepts the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_event</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The system event number. The value must be one of the event numbers reported by list_allowed_system_events.</td>
</tr>
<tr>
<td>p_level</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The event level. See the Oracle Database documentation or Oracle Support for descriptions of different level values.</td>
</tr>
</tbody>
</table>

The procedure set_system_event constructs and runs the required ALTER SYSTEM SET EVENTS statements according to the following principles:

- The event type (context or errorstack) is determined automatically.
- A statement in the form ALTER SYSTEM SET EVENTS 'event LEVEL event_level' sets the context events. This notation is equivalent to ALTER SYSTEM SET EVENTS 'event TRACE NAME CONTEXT FOREVER, LEVEL event_level'.
- A statement in the form ALTER SYSTEM SET EVENTS 'event ERRORSTACK (event_level)' sets the error stack events. This notation is equivalent to ALTER SYSTEM SET EVENTS 'event TRACE NAME ERRORSTACK LEVEL event_level'.

The following example sets event 942 at level 3, and event 10442 at level 10. Sample output is included.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(942,3);
Setting system event 942 with: alter system set events '942 errorstack (3)'
PL/SQL procedure successfully completed.
SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(10442,10);
Setting system event 10442 with: alter system set events '10442 level 10'
```
PL/SQL procedure successfully completed.

Listing system diagnostic events that are set

To list the system events that are currently set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_set_system_events`. This procedure reports only events set at system level by `set_system_event`.

The following example lists the active system events.

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_set_system_events;
```

The following sample output shows the list of events, the event type, the level at which the events are currently set, and the time when the event was set.

```
942 errorstack (3) - set at 2020-11-03 11:42:27
10442 level 10 - set at 2020-11-03 11:42:41
```

PL/SQL procedure successfully completed.

Unsetting system diagnostic events

To unset a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.unset_system_event`. You can only unset events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `unset_system_event` procedure accepts the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_event</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The system event number. The value must be one of the event numbers reported by <code>list_allowed_system_events</code>.</td>
</tr>
</tbody>
</table>

The following example unsets events 942 and 10442. Sample output is included.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(942);
Unsetting system event 942 with: alter system set events '942 off'
PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(10442);
Unsetting system event 10442 with: alter system set events '10442 off'
PL/SQL procedure successfully completed.
```

Performing common database tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to databases on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide
Changing the global name of a database

To change the global name of a database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.rename_global_name`. The `rename_global_name` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_new_global_name</code></td>
<td><code>varchar2</code></td>
<td>—</td>
<td>Yes</td>
<td>The new global name for the database.</td>
</tr>
</tbody>
</table>

The database must be open for the name change to occur. For more information about changing the global name of a database, see `ALTER DATABASE` in the Oracle documentation.

The following example changes the global name of a database to `new_global_name`.

```sql
EXEC rdsadmin.rdsadmin_util.rename_global_name(p_new_global_name => 'new_global_name');
```

Creating and sizing tablespaces

Amazon RDS only supports Oracle Managed Files (OMF) for data files, log files, and control files. When you create data files and log files, you can’t specify the physical file names.

By default, tablespaces are created with auto-extend enabled, and no maximum size. Because of these default settings, tablespaces can grow to consume all allocated storage. We recommend that you specify...
an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

The following example creates a tablespace named `users2` with a starting size of 1 gigabyte and a maximum size of 10 gigabytes:

```
CREATE TABLESPACE users2 DATAFILE SIZE 1G AUTOEXTEND ON MAXSIZE 10G;
```

The following example creates temporary tablespace named `temp01`:

```
CREATE TEMPORARY TABLESPACE temp01;
```

We recommend that you don't use smallfile tablespaces because you can't resize smallfile tablespaces with Amazon RDS for Oracle. However, you can add a datafile to a smallfile tablespace.

You can resize a bigfile tablespace by using `ALTER TABLESPACE`. You can specify the size in kilobytes (K), megabytes (M), gigabytes (G), or terabytes (T).

The following example resizes a bigfile tablespace named `users2` to 200 MB.

```
ALTER TABLESPACE users2 RESIZE 200M;
```

The following example adds an additional datafile to a smallfile tablespace named `users2`.

```
ALTER TABLESPACE users2 ADD DATAFILE SIZE 100000M AUTOEXTEND ON NEXT 250M MAXSIZE UNLIMITED;
```

### Setting the default tablespace

To set the default tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_tablespace`. The `alter_default_tablespace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the default tablespace.</td>
</tr>
</tbody>
</table>

The following example sets the default tablespace to `users2`:

```
EXEC rdsadmin.rdsadmin_util.alter_default_tablespace(tablespace_name => 'users2');
```

### Setting the default temporary tablespace

To set the default temporary tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_temp_tablespace`. The `alter_default_temp_tablespace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tablespace_name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the default temporary tablespace.</td>
</tr>
</tbody>
</table>
The following example sets the default temporary tablespace to `temp01`.

```sql
EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace(tablespace_name => 'temp01');
```

### Checkpointing a database

To checkpoint the database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.checkpoint`. The checkpoint procedure has no parameters.

The following example checkpoints the database.

```sql
EXEC rdsadmin.rdsadmin_util.checkpoint;
```

### Setting distributed recovery

To set distributed recovery, use the Amazon RDS procedures `rdsadmin.rdsadmin_util.enable_distr_recovery` and `disable_distr_recovery`. The procedures have no parameters.

The following example enables distributed recovery.

```sql
EXEC rdsadmin.rdsadmin_util.enable_distr_recovery;
```

The following example disables distributed recovery.

```sql
EXEC rdsadmin.rdsadmin_util.disable_distr_recovery;
```

### Setting the database time zone

You can set the time zone of your Amazon RDS Oracle database in the following ways:

- **The Timezone option**
  
  The `Timezone` option changes the time zone at the host level and affects all date columns and values such as `SYSDATE`. For more information, see Oracle time zone (p. 1533).

- **The Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_db_time_zone`**
  
  The `alter_db_time_zone` procedure changes the time zone for only certain data types, and doesn’t change `SYSDATE`. There are additional restrictions on setting the time zone listed in the Oracle documentation.

**Note**

You can also set the default time zone for Oracle Scheduler. For more information, see Setting the time zone for Oracle Scheduler jobs (p. 1409).

The `alter_db_time_zone` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_new_tz</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The new time zone as a named region or an absolute offset from Coordinated Universal Time</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>(UTC). Valid offsets range from -12:00 to +14:00.</td>
</tr>
</tbody>
</table>

The following example changes the time zone to UTC plus three hours.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => '+3:00');
```

The following example changes the time zone to the Africa/Algiers time zone.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => 'Africa/Algiers');
```

After you alter the time zone by using the `alter_db_time_zone` procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance (p. 350). For information about upgrading time zones, see Time zone considerations (p. 1553).

### Working with Oracle external tables

**Oracle external tables** are tables with data that is not in the database. Instead, the data is in external files that the database can access. By using external tables, you can access data without loading it into the database. For more information about external tables, see Managing external tables in the Oracle documentation.

With Amazon RDS, you can store external table files in directory objects. You can create a directory object, or you can use one that is predefined in the Oracle database, such as the DATA_PUMP_DIR directory. For information about creating directory objects, see Creating and dropping directories in the main data storage space (p. 1418). You can query the ALL_DIRECTORIES view to list the directory objects for your Amazon RDS Oracle DB instance.

**Note**

Directory objects point to the main data storage space (Amazon EBS volume) used by your instance. The space used—along with data files, redo logs, audit, trace, and other files—counts against allocated storage.

You can move an external data file from one Oracle database to another by using the DBMS_FILE_TRANSFER package or the UTL_FILE package. The external data file is moved from a directory on the source database to the specified directory on the destination database. For information about using DBMS_FILE_TRANSFER, see Importing using Oracle Data Pump (p. 1430).

After you move the external data file, you can create an external table with it. The following example creates an external table that uses the `emp_xt_file1.txt` file in the USER_DIR1 directory.

```
CREATE TABLE emp_xt (    emp_id NUMBER,    first_name VARCHAR2(50),    last_name VARCHAR2(50),    user_name VARCHAR2(20)  ) ORGANIZATION EXTERNAL ( TYPE ORACLE_LOADER DEFAULT DIRECTORY USER_DIR1 ACCESS PARAMETERS (    RECORDS DELIMITED BY NEWLINE    FIELDS TERMINATED BY ','    MISSING FIELD VALUES ARE NULL    (emp_id,first_name,last_name,user_name)  )
```
LOCATION ('emp_xt_file1.txt')
) PARALLEL REJECT LIMIT UNLIMITED;

Suppose that you want to move data that is in an Amazon RDS Oracle DB instance into an external data file. In this case, you can populate the external data file by creating an external table and selecting the data from the table in the database. For example, the following SQL statement creates the `orders_xt` external table by querying the `orders` table in the database.

```sql
CREATE TABLE orders_xt
    ORGANIZATION EXTERNAL
    ( TYPE ORACLE_DATAPUMP
        DEFAULT DIRECTORY DATA_PUMP_DIR
        LOCATION ('orders_xt.dmp')
    )
    AS SELECT * FROM orders;
```

In this example, the data is populated in the `orders_xt.dmp` file in the `DATA_PUMP_DIR` directory.

### Generating performance reports with Automatic Workload Repository (AWR)

To gather performance data and generate reports, Oracle recommends Automatic Workload Repository (AWR). AWR requires Oracle Database Enterprise Edition and a license for the Diagnostics and Tuning packs. To enable AWR, set the `CONTROL_MANAGEMENT_PACK_ACCESS` initialization parameter to either `DIAGNOSTIC` or `DIAGNOSTIC+TUNING`.

### Working with AWR reports in RDS

To generate AWR reports, you can run scripts such as `awrrpt.sql`. These scripts are installed on the database host server. In Amazon RDS, you don't have direct access to the host. However, you can get copies of SQL scripts from another installation of Oracle Database.

You can also use AWR by running procedures in the `SYS.DBMS_WORKLOAD_REPOSITORY` PL/SQL package. You can use this package to manage baselines and snapshots, and also to display ASH and AWR reports. For example, to generate an AWR report in text format run the `DBMS_WORKLOAD_REPOSITORY.AWR_REPORT_TEXT` procedure. However, you can't reach these AWR reports from the AWS Management Console.

When working with AWR, we recommend using the `rdsadmin.rdsadmin_diagnostic_util` procedures. You can use these procedures to generate the following:

- AWR reports
- Active Session History (ASH) reports
- Automatic Database Diagnostic Monitor (ADDM) reports
- Oracle Data Pump Export dump files of AWR data

The `rdsadmin_diagnostic_util` procedures save the reports to the DB instance file system. You can access these reports from the console. You can also access reports using the `rdsadmin.rds_file_util` procedures, and you can access reports that are copied to Amazon S3 using the S3 Integration option. For more information, see Reading files in a DB instance directory (p. 1420) and Amazon S3 integration (p. 1452).

You can use the `rdsadmin_diagnostic_util` procedures in the following Amazon RDS for Oracle DB engine versions:
• All Oracle Database 21c versions
• 19.0.0.0.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 19c versions
• 12.2.0.1.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 12c Release 2 (12.2) versions
• 12.1.0.2.v20 and higher Oracle Database 12c Release 1 (12.1) versions

Common parameters for the diagnostic utility package

You typically use the following parameters when managing AWR and ADDM with the 
rdsadmin_diagnostic_util package.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>begin_snap_id</td>
<td>NUMBER</td>
<td>—</td>
<td>Yes</td>
<td>The ID of the beginning snapshot.</td>
</tr>
<tr>
<td>end_snap_id</td>
<td>NUMBER</td>
<td>—</td>
<td>Yes</td>
<td>The ID of the ending snapshot.</td>
</tr>
<tr>
<td>dump_directory</td>
<td>VARCHAR2</td>
<td>DUMP</td>
<td>No</td>
<td>The directory to write the report or export file to. If you specify a nondefault directory, the user that runs the rdsadmin_diagnostic_util procedures must have write permissions for the directory.</td>
</tr>
<tr>
<td>p_tag</td>
<td>VARCHAR2</td>
<td>—</td>
<td>No</td>
<td>A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as incremental or daily. You can specify up to 30 characters. Valid characters are a–z, A–Z, 0–9, an underscore (_), a dash (–), and a period (.), and a period (.). The tag is not case-sensitive. RMAN always stores tags in uppercase, regardless of the case used when entering them. Tags don’t need to be unique, so multiple backups can have the same tag. If you don’t specify a tag, RMAN assigns a default tag automatically using the format TAGYYYYMMDDTHHMMSS, where YYYY is the year, MM is the month, DD is the day, HH is the hour (in 24-hour format), MM is the minutes, and SS is the seconds. The date and time indicate when RMAN started the backup. For example, a backup with the default tag TAG20190927T214517 indicates a backup that started on 2019-09-27 at 21:45:17. The p_tag parameter is supported for the following RDS for Oracle DB engine versions: • Oracle Database 21c (21.0.0) • Oracle Database 19c (19.0.0), using 19.0.0.0.ru-2021-10.rur-2021-10.r1 and higher • Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2021-10.rur-2021-10.r1 and higher • Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v26 and higher</td>
</tr>
<tr>
<td>report_type</td>
<td>VARCHAR2</td>
<td>HTML</td>
<td>No</td>
<td>The format of the report. Valid values are TEXT and HTML.</td>
</tr>
</tbody>
</table>
| dbid          | NUMBER    | —       | No       | A valid database identifier (DBID) shown in the DBA_HIST_DATABASE_INSTANCE view for Oracle. If this
You typically use the following parameters when managing ASH with the rdsadmin_diagnostic_util package.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>begin_time</td>
<td>DATE</td>
<td>—</td>
<td>Yes</td>
<td>The beginning time of the ASH analysis.</td>
</tr>
<tr>
<td>end_time</td>
<td>DATE</td>
<td>—</td>
<td>Yes</td>
<td>The ending time of the ASH analysis.</td>
</tr>
<tr>
<td>slot_width</td>
<td>NUMBER</td>
<td>0</td>
<td>No</td>
<td>The duration of the slots (in seconds) used in the &quot;Top Activity&quot; section of the ASH report. If this parameter isn't specified, the time interval between <code>begin_time</code> and <code>end_time</code> uses no more than 10 slots.</td>
</tr>
<tr>
<td>sid</td>
<td>NUMBER</td>
<td>Null</td>
<td>No</td>
<td>The session ID.</td>
</tr>
<tr>
<td>sql_id</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The SQL ID.</td>
</tr>
<tr>
<td>wait_class</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The wait class name.</td>
</tr>
<tr>
<td>service_hash</td>
<td>NUMBER</td>
<td>Null</td>
<td>No</td>
<td>The service name hash.</td>
</tr>
<tr>
<td>module_name</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The module name.</td>
</tr>
<tr>
<td>action_name</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The action name.</td>
</tr>
<tr>
<td>client_id</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The application-specific ID of the database session.</td>
</tr>
<tr>
<td>plsql_entry</td>
<td>VARCHAR2</td>
<td>Null</td>
<td>No</td>
<td>The PL/SQL entry point.</td>
</tr>
</tbody>
</table>

Generating an AWR report

To generate an AWR report, use the `rdsadmin.rdsadmin_diagnostic_util.awr_report` procedure.

The following example generates a AWR report for the snapshot range 101–106. The output text file is named `awrrpt_101_106.txt`. You can access this report from the AWS Management Console.

```sql
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(101,106,'TEXT');
```

The following example generates an HTML report for the snapshot range 63–65. The output HTML file is named `awrrpt_63_65.html`. The procedure writes the report to the nondefault database directory named `AWR_RPT_DUMP`.

```sql
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(63,65,'HTML','AWR_RPT_DUMP');
```

Extracting AWR data into a dump file

To extract AWR data into a dump file, use the `rdsadmin.rdsadmin_diagnostic_util.awr_extract` procedure.
The following example extracts the snapshot range 101–106. The output dump file is named awrextract_101_106.dmp. You can access this file through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(101,106);
```

The following example extracts the snapshot range 63–65. The output dump file is named awrextract_63_65.dmp. The file is stored in the nondefault database directory named AWR_RPT_DUMP.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(63,65,'AWR_RPT_DUMP');
```

### Generating an ADDM report

To generate an ADDM report, use the `rdsadmin.rdsadmin_diagnostic_util.addm_report` procedure.

The following example generates an ADDM report for the snapshot range 101–106. The output text file is named addmrpt_101_106.txt. You can access the report through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(101,106);
```

The following example generates an ADDM report for the snapshot range 63–65. The output text file is named addmrpt_63_65.txt. The file is stored in the nondefault database directory named ADDM_RPT_DUMP.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(63,65,'ADDM_RPT_DUMP');
```

### Generating an ASH report

To generate an ASH report, use the `rdsadmin.rdsadmin_diagnostic_util.ash_report` procedure.

The following example generates an ASH report that includes the data from 14 minutes ago until the current time. The name of the output file uses the format `ashrpt_begin_timeend_time.txt`, where `begin_time` and `end_time` use the format `YYYYMMDDHH24MISS`. You can access the file through the console.

```
BEGIN
  rdsadmin.rdsadmin_diagnostic_util.ash_report(
    begin_time     =>     SYSDATE-14/1440,
    end_time       =>     SYSDATE,
    report_type    =>     'TEXT');
END;
```

The following example generates an ASH report that includes the data from November 18, 2019, at 6:07 PM through November 18, 2019, at 6:15 PM. The name of the output HTML report is `ashrpt_20190918180700_20190918181500.html`. The report is stored in the nondefault database directory named AWR_RPT_DUMP.

```
BEGIN
  rdsadmin.rdsadmin_diagnostic_util.ash_report(
    begin_time     =>    TO_DATE('2019-09-18 18:07:00', 'YYYY-MM-DD HH24:MI:SS'),
    end_time       =>    TO_DATE('2019-09-18 18:15:00', 'YYYY-MM-DD HH24:MI:SS'),
    report_type    =>    'html',
    dump_directory =>    'AWR_RPT_DUMP');
END;
```
Accessing AWR reports from the console or CLI

To access AWR reports or export dump files, you can use the AWS Management Console or AWS CLI. For more information, see Downloading a database log file (p. 647).

Adjusting database links for use with DB instances in a VPC

To use Oracle database links with Amazon RDS DB instances inside the same virtual private cloud (VPC) or peered VPCs, the two DB instances should have a valid route between them. Verify the valid route between the DB instances by using your VPC routing tables and network access control list (ACL).

The security group of each DB instance must allow ingress to and egress from the other DB instance. The inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see Updating your security groups to reference peered VPC security groups.

If you have configured a custom DNS server using the DHCP Option Sets in your VPC, your custom DNS server must be able to resolve the name of the database link target. For more information, see Setting up a custom DNS server (p. 1363).

For more information about using database links with Oracle Data Pump, see Importing using Oracle Data Pump (p. 1430).

Setting the default edition for a DB instance

You can redefine database objects in a private environment called an edition. You can use edition-based redefinition to upgrade an application's database objects with minimal downtime.

You can set the default edition of an Amazon RDS Oracle DB instance using the Amazon RDS procedure rdsadmin.rdsadmin_util.alter_default_edition.

The following example sets the default edition for the Amazon RDS Oracle DB instance to RELEASE_V1.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('RELEASE_V1');
```

The following example sets the default edition for the Amazon RDS Oracle DB instance back to the Oracle default.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('ORA$BASE');
```

For more information about Oracle edition-based redefinition, see About editions and edition-based redefinition in the Oracle documentation.

Enabling auditing for the SYS.AUD$ table

To enable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table. The only supported audit property is ALL. You can't audit or not audit individual statements or operations.

Enabling auditing is supported for Oracle DB instances running the following versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1.0.2.v14) and later

The audit_all_sys_aud_table procedure has the following parameters.
### Database tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_by_access</td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to audit BY ACCESS. Set to false to audit BY SESSION.</td>
</tr>
</tbody>
</table>

**Note**

In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. Auditing information isn't available from within the PDB. For more information, see Limitations of a single-tenant CDB (p. 1310).

The following query returns the current audit configuration for SYS.AUD$ for a database.

```sql
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following commands enable audit of ALL on SYS.AUD$ BY ACCESS.

```sql
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table;
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => true);
```

The following command enables audit of ALL on SYS.AUD$ BY SESSION.

```sql
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => false);
```

For more information, see AUDIT (traditional auditing) in the Oracle documentation.

### Disabling auditing for the SYS.AUD$ table

To disable auditing on the database audit trail table SYS.AUD$, use the Amazon RDS procedure rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table. This procedure takes no parameters.

The following query returns the current audit configuration for SYS.AUD$ for a database:

```sql
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following command disables audit of ALL on SYS.AUD$.

```sql
EXEC rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table;
```

For more information, see NOAUDIT (traditional auditing) in the Oracle documentation.

### Cleaning up interrupted online index builds

To clean up failed online index builds, use the Amazon RDS procedure rdsadmin.rdsadmin_dbms_repair.online_index_clean.

The online_index_clean procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_id</td>
<td>binary_integer</td>
<td>ALL_INDEX_ID</td>
<td>No</td>
<td>The object ID of the index. Typically, you can use</td>
</tr>
</tbody>
</table>
### Parameter name | Data type | Default | Required | Description
--- | --- | --- | --- | ---
wait_for_lock | binary_integer | rdsadmin.rdsadmin_dbms_repair.lock_wait | No | Specify `rdsadmin.rdsadmin_dbms_repair.lock_wait`, the default, to try to get a lock on the underlying object and retry until an internal limit is reached if the lock fails. Specify `rdsadmin.rdsadmin_dbms_repair.lock_nowait` to try to get a lock on the underlying object but not retry if the lock fails.

The following example cleans up a failed online index build:

```sql
declare
  is_clean boolean;
begin
  is_clean := rdsadmin.rdsadmin_dbms_repair.online_index_clean(    object_id => 1234567890,
    wait_for_lock => rdsadmin.rdsadmin_dbms_repair.lock_nowait);
end;
/
```

For more information, see [ONLINE_INDEX_CLEAN function](https://docs.oracle.com/en/database/oracle/database/19/sqlrdbms/doc/functions.html#ONLINE_INDEX_CLEAN) in the Oracle documentation.

## Skipping corrupt blocks

To skip corrupt blocks during index and table scans, use the `rdsadmin.rdsadmin_dbms_repair` package.

The following procedures wrap the functionality of the `sys.dbms_repair.admin_table` procedure and take no parameters:

- `rdsadmin.rdsadmin_dbms_repair.create_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table`

The following procedures take the same parameters as their counterparts in the `DBMS_REPAIR` package for Oracle databases:

- `rdsadmin.rdsadmin_dbms_repair.check_object`
- `rdsadmin.rdsadmin_dbms_repair.dump_orphan_keys`
- `rdsadmin.rdsadmin_dbms_repair.fix_corrupt_blocks`
- `rdsadmin.rdsadmin_dbms_repair.rebuild_freelists`
• rdsadmin.rdsadmin_dbms_repair.segment_fix_status
• rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks

For more information about handling database corruption, see **DBMS_REPAIR** in the Oracle documentation.

**Example Responding to corrupt blocks**

This example shows the basic workflow for responding to corrupt blocks. Your steps will depend on the location and nature of your block corruption.

**Important**
Before attempting to repair corrupt blocks, review the **DBMS_REPAIR** documentation carefully.

**To skip corrupt blocks during index and table scans**

1. Run the following procedures to create repair tables if they don’t already exist.

   ```sql
   EXEC rdsadmin.rdsadmin_dbms_repair.create_repair_table;
   EXEC rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table;
   ```

2. Run the following procedures to check for existing records and purge them if appropriate.

   ```sql
   SELECT COUNT(*) FROM SYS.REPAIR_TABLE;
   SELECT COUNT(*) FROM SYS.ORPHAN_KEY_TABLE;
   SELECT COUNT(*) FROM SYS.DBA_REPAIR_TABLE;
   SELECT COUNT(*) FROM SYS.DBA_ORPHAN_KEY_TABLE;
   EXEC rdsadmin.rdsadmin_dbms_repair.purge_repair_table;
   EXEC rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table;
   ```

3. Run the following procedure to check for corrupt blocks.

   ```sql
   SET SERVEROUTPUT ON
   DECLARE v_num_corrupt INT;
   BEGIN
     v_num_corrupt := 0;
     rdsadmin.rdsadmin_dbms_repair.check_object (  
       schema_name => '&corruptionOwner',
       object_name => '&corruptionTable',
       corrupt_count => v_num_corrupt
     );
     dbms_output.put_line('number corrupt: '||to_char(v_num_corrupt));
   END;
   
   COL CORRUPT_DESCRIPTION FORMAT a30
   COL REPAIR_DESCRIPTION FORMAT a30
   SELECT OBJECT_NAME, BLOCK_ID, CORRUPT_TYPE, MARKED_CORRUPT,
   CORRUPT_DESCRIPTION, REPAIR_DESCRIPTION
   FROM   SYS.REPAIR_TABLE;
   SELECT SKIP_CORRUPT
   FROM   DBA_TABLES
   WHERE  OWNER = '&corruptionOwner'
   AND    TABLE_NAME = '&corruptionTable';
   ```

4. Use the **skip_corrupt_blocks** procedure to enable or disable corruption skipping for affected tables. Depending on the situation, you may also need to extract data to a new table, and then drop the table containing the corrupt block.

1378
Run the following procedure to enable corruption skipping for affected tables.

```sql
begin
  rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    object_type => rdsadmin.rdsadmin_dbms_repair.table_object,
    flags => rdsadmin.rdsadmin_dbms_repair.skip_flag);
end;
/

select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name = '&corruptionTable';
```

Run the following procedure to disable corruption skipping.

```sql
begin
  rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    object_type => rdsadmin.rdsadmin_dbms_repair.table_object,
    flags => rdsadmin.rdsadmin_dbms_repair.noskip_flag);
end;
/

select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name = '&corruptionTable';
```

5. When you have completed all repair work, run the following procedures to drop the repair tables.

```sql
EXEC rdsadmin.rdsadmin_dbms_repair.drop_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table;
```

**Resizing the temporary tablespace in a read replica**

By default, Oracle tablespaces are created with auto-extend enabled and no maximum size. Because of these default settings, tablespaces can grow too large in some cases. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

To resize the temporary space in a read replica for an Oracle DB instance, use either the `rdsadmin.rdsadmin_util.resize_temp_tablespace` or the `rdsadmin.rdsadmin_util.resize_temp_file` Amazon RDS procedure.

The `resize_temp_tablespace` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>temp_tbs</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the temporary tablespace to resize.</td>
</tr>
<tr>
<td>size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>You can specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The `resize_temp_file` procedure has the following parameters.
### Database tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_id</td>
<td>binary_integer</td>
<td>—</td>
<td>Yes</td>
<td>The file identifier of the temporary tablespace to resize.</td>
</tr>
<tr>
<td>size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>You can specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The following examples resize a temporary tablespace named TEMP to the size of 4 gigabytes on a read replica.

| EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4G'); |
| EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4096000000'); |

The following example resizes a temporary tablespace based on the tempfile with the file identifier 1 to the size of 2 megabytes on a read replica.

| EXEC rdsadmin.rdsadmin_util.resize_tempfile(1,'2M'); |

For more information about read replicas for Oracle DB instances, see [Working with Oracle replicas for Amazon RDS](p. 1443).

### Purging the recycle bin

When you drop a table, your Oracle database doesn't immediately remove its storage space. The database renames the table and places it and any associated objects in a recycle bin. Purging the recycle bin removes these items and releases their storage space.

To purge the entire recycle bin, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.purge_dba_recyclebin`. However, this procedure can't purge the recycle bin of SYS and RDSADMIN objects. If you need to purge these objects, contact AWS Support.

The following example purges the entire recycle bin.

| EXEC rdsadmin.rdsadmin_util.purge_dba_recyclebin; |

### Setting the Data Redaction policy for full redaction

To change the default displayed values for a Data Redaction policy for full redaction on your Amazon RDS Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val`.

The `dbms_redact_upd_full_rdct_val` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_number_val</td>
<td>number</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NUMBER datatype.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------</td>
<td>---------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_binfloat_val</td>
<td>binary_float</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BINARY_FLOAT datatype.</td>
</tr>
<tr>
<td>p_bindouble_val</td>
<td>binary_double</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BINARY_DOUBLE datatype.</td>
</tr>
<tr>
<td>p_char_val</td>
<td>char</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the CHAR datatype.</td>
</tr>
<tr>
<td>p_varchar_val</td>
<td>varchar2</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the VARCHAR2 datatype.</td>
</tr>
<tr>
<td>p_nchar_val</td>
<td>nchar</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NCHAR datatype.</td>
</tr>
<tr>
<td>pnvarchar_val</td>
<td>nvarchar2</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NVARCHAR2 datatype.</td>
</tr>
<tr>
<td>p_date_val</td>
<td>date</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the DATE datatype.</td>
</tr>
<tr>
<td>p_ts_val</td>
<td>timestamp</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the TIMESTAMP datatype.</td>
</tr>
<tr>
<td>p_tswtz_val</td>
<td>timestamp with time zone</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the TIMESTAMP WITH TIME ZONE datatype.</td>
</tr>
<tr>
<td>p_blob_val</td>
<td>blob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the BLOB datatype.</td>
</tr>
<tr>
<td>p_clob_val</td>
<td>clob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the CLOB datatype.</td>
</tr>
<tr>
<td>p_nclob_val</td>
<td>nclob</td>
<td>Null</td>
<td>No</td>
<td>Modifies the default value for columns of the NCLOB datatype.</td>
</tr>
</tbody>
</table>

The following example changes the default redacted value to * for char datatype:

```sql
EXEC rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(p_char_val => '*');
```

The following example changes the default redacted values for number, date and char datatypes:

```sql
begin
```
After you alter the default values for full redaction with the `dbms_redact_upd_full_rdct_val` procedure, reboot your DB instance for the change to take effect. For more information, see Rebooting a DB instance (p. 350).

### Performing common log-related tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to logging on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

For more information, see Oracle database log files (p. 673).

**Topics**
- Setting force logging (p. 1382)
- Setting supplemental logging (p. 1383)
- Switching online log files (p. 1383)
- Adding online redo logs (p. 1384)
- Dropping online redo logs (p. 1384)
- Resizing online redo logs (p. 1385)
- Retaining archived redo logs (p. 1386)
- Accessing online and archived redo logs (p. 1388)
- Downloading archived redo logs from Amazon S3 (p. 1388)

#### Setting force logging

In force logging mode, Oracle logs all changes to the database except changes in temporary tablespaces and temporary segments (`NOLOGGING` clauses are ignored). For more information, see Specifying FORCE LOGGING mode in the Oracle documentation.

To set force logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.force_logging`. The `force_logging` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Yes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_enable</code></td>
<td>boolean</td>
<td>true</td>
<td>No</td>
<td>Set to true to put the database in force logging mode, false to remove the database from force logging mode.</td>
</tr>
</tbody>
</table>

The following example puts the database in force logging mode.

```
EXEC rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```
Setting supplemental logging

If you enable supplemental logging, LogMiner has the necessary information to support chained rows and clustered tables. For more information, see Supplemental logging in the Oracle documentation.

Oracle Database doesn't enable supplemental logging by default. To enable and disable supplemental logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_supplemental_logging`. For more information about how Amazon RDS manages the retention of archived redo logs for Oracle DB instances, see Retaining archived redo logs (p. 1386).

The `alter_supplemental_logging` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_action</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>'ADD' to add supplemental logging, 'DROP' to drop supplemental logging.</td>
</tr>
<tr>
<td>p_type</td>
<td>varchar2</td>
<td>null</td>
<td>No</td>
<td>The type of supplemental logging. Valid values are 'ALL', 'FOREIGN KEY', 'PRIMARY KEY', 'UNIQUE', or PROCEDURAL.</td>
</tr>
</tbody>
</table>

The following example enables supplemental logging.

```sql
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD');
end;
/
```

The following example enables supplemental logging for all fixed-length maximum size columns.

```sql
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD',
        p_type   => 'ALL');
end;
/
```

The following example enables supplemental logging for primary key columns.

```sql
begin
    rdsadmin.rdsadmin_util.alter_supplemental_logging(
        p_action => 'ADD',
        p_type   => 'PRIMARY KEY');
end;
/
```

Switching online log files

To switch log files, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.switch_logfile`. The `switch_logfile` procedure has no parameters.
The following example switches log files.

```
EXEC rdsadmin.rdsadmin_util.switch_logfile;
```

## Adding online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. To add additional redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_logfile`.

The `add_logfile` procedure has the following parameters.

**Note**

The parameters are mutually exclusive.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bytes</td>
<td>positive</td>
<td>null</td>
<td>No</td>
<td>The size of the log file in bytes.</td>
</tr>
<tr>
<td>p_size</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The size of the log file. You can specify the size in kilobytes (K), megabytes (M), or gigabytes (G).</td>
</tr>
</tbody>
</table>

The following command adds a 100 MB log file.

```
EXEC rdsadmin.rdsadmin_util.add_logfile(p_size => '100M');
```

## Dropping online redo logs

To drop redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_logfile`. The `drop_logfile` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grp</td>
<td>positive</td>
<td>—</td>
<td>Yes</td>
<td>The group number of the log.</td>
</tr>
</tbody>
</table>

The following example drops the log with group number 3.

```
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
```

You can only drop logs that have a status of unused or inactive. The following example gets the statuses of the logs.

```
SELECT GROUP#, STATUS FROM V$LOG;
```

<table>
<thead>
<tr>
<th>GROUP#</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>CURRENT</td>
</tr>
<tr>
<td>2</td>
<td>INACTIVE</td>
</tr>
<tr>
<td>3</td>
<td>INACTIVE</td>
</tr>
</tbody>
</table>
Resizing online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. The following example shows how you can use Amazon RDS procedures to resize your logs from 128 MB each to 512 MB each.

/* Query V$LOG to see the logs. */
/* You start with 4 logs of 128 MB each. */
SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#       BYTES      STATUS
---------- ---------- ----------------
1            134217728  INACTIVE
2            134217728  CURRENT
3            134217728  INACTIVE
4            134217728  INACTIVE

/* Add four new logs that are each 512 MB */
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);

/* Query V$LOG to see the logs. */
/* Now there are 8 logs. */
SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#       BYTES      STATUS
---------- ---------- ----------------
1            134217728  INACTIVE
2            134217728  CURRENT
3            134217728  INACTIVE
4            134217728  INACTIVE
5            536870912  UNUSED
6            536870912  UNUSED
7            536870912  UNUSED
8            536870912  UNUSED

/* Drop each inactive log using the group number. */
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 1);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 4);

/* Query V$LOG to see the logs. */
/* Now there are 5 logs. */
SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#       BYTES      STATUS
---------- ---------- ----------------
2            134217728  CURRENT
5            536870912  UNUSED
6            536870912  UNUSED
7            536870912  UNUSED
Retaining archived redo logs

You can retain archived redo logs locally on your DB instance for use with products like Oracle LogMiner (DBMS_LOGMNR). After you have retained the redo logs, you can use LogMiner to analyze the logs. For more information, see Using LogMiner to analyze redo log files in the Oracle documentation.
To retain archived redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_configuration`. The `set_configuration` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The name of the configuration to update.</td>
</tr>
<tr>
<td>value</td>
<td>varchar</td>
<td>—</td>
<td>Yes</td>
<td>The value for the configuration.</td>
</tr>
</tbody>
</table>

The following example retains 24 hours of redo logs.

```sql
begin
  rdsadmin.rdsadmin_util.set_configuration(
    name  => 'archivelog retention hours',
    value => '24');
end;
/
commit;
```

**Note**
The commit is required for the change to take effect.

To view how long archived redo logs are kept for your DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.show_configuration`.

The following example shows the log retention time.

```sql
set serveroutput on
EXEC rdsadmin.rdsadmin_util.show_configuration;
```

The output shows the current setting for `archivelog retention hours`. The following output shows that archived redo logs are kept for 48 hours.

```
NAME:archivelog retention hours
VALUE:48
DESCRIPTION:ArchiveLog expiration specifies the duration in hours before archive/redo log files are automatically deleted.
```

Because the archived redo logs are retained on your DB instance, ensure that your DB instance has enough allocated storage for the retained logs. To determine how much space your DB instance has used in the last X hours, you can run the following query, replacing X with the number of hours.

```sql
SELECT SUM(BLOCKS * BLOCK_SIZE) bytes
FROM V$ARCHIVED_LOG
WHERE FIRST_TIME >= SYSDATE-(X/24) AND DEST_ID=1;
```

RDS for Oracle only generates archived redo logs when the backup retention period of your DB instance is greater than zero. By default the backup retention period is greater than zero.

When the archived log retention period expires, RDS for Oracle removes the archived redo logs from your DB instance. To support restoring your DB instance to a point in time, Amazon RDS retains the archived redo logs outside of your DB instance based on the backup retention period. To modify the backup retention period, see `Modifying an Amazon RDS DB instance (p. 309)`.
Note
In some cases, you might be using JDBC on Linux to download archived redo logs and experience long latency times and connection resets. In such cases, the issues might be caused by the default random number generator setting on your Java client. We recommend setting your JDBC drivers to use a nonblocking random number generator.

Accessing online and archived redo logs

You might want to access your online and archived redo log files for mining with external tools such as GoldenGate, Attunity, Informatica, and others. To access these files, do the following:

1. Create directory objects that provide read-only access to the physical file paths.
   
   Use `rdsadmin.rdsadmin_master_util.create_archivelog_dir` and `rdsadmin.rdsadmin_master_util.create_onlinelog_dir`.

2. Read the files using PL/SQL.
   
   You can read the files by using PL/SQL. For more information about reading files from directory objects, see Listing files in a DB instance directory (p. 1419) and Reading files in a DB instance directory (p. 1420).

Accessing transaction logs is supported for the following releases:

- Oracle Database 21c
- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1)

The following code creates directories that provide read-only access to your online and archived redo log files:

**Important**
This code also revokes the `DROP ANY DIRECTORY` privilege.

```sql
EXEC rdsadmin.rdsadmin_master_util.create_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.create_onlinelog_dir;
```

The following code drops the directories for your online and archived redo log files.

```sql
EXEC rdsadmin.rdsadmin_master_util.drop_archivelog_dir;
EXEC rdsadmin.rdsadmin_master_util.drop_onlinelog_dir;
```

The following code grants and revokes the `DROP ANY DIRECTORY` privilege.

```sql
EXEC rdsadmin.rdsadmin_master_util.revoke_drop_any_directory;
EXEC rdsadmin.rdsadmin_master_util.grant_drop_any_directory;
```

**Downloading archived redo logs from Amazon S3**

You can download archived redo logs on your DB instance using the `rdsadmin.rdsadmin_archive_log_download` package. If archived redo logs are no longer on your DB instance, you might want to download them again from Amazon S3. Then you can mine the logs or use them to recover or replicate your database.
Note
You can't download archived redo logs on read replica instances.

Downloading archived redo logs: basic steps

The availability of your archived redo logs depends on the following retention policies:

- Backup retention policy – Logs inside of this policy are available in Amazon S3. Logs outside of this
  policy are removed.
- Archived log retention policy – Logs inside of this policy are available on your DB instance. Logs
  outside of this policy are removed.

If logs aren't on your instance but are protected by your backup retention period, use
rdsadmin.rdsadmin_archive_log_download to download them again. RDS for Oracle saves the
logs to the /rdsdbdata/log/arch directory on your DB instance.

To download archived redo logs from Amazon S3

1. Increase your archived redo log retention period so that RDS won't delete the logs that you
   download. Make sure to COMMIT your change.

   To learn how to set the retention policy, see Retaining archived redo logs (p. 1386).

2. Wait up to 5 minutes for the archived log retention policy change to take effect.

3. Download the archived redo logs from Amazon S3 using
   rdsadmin.rdsadmin_archive_log_download.

   For more information, see Downloading a single archived redo log (p. 1389) and Downloading a
   series of archived redo logs (p. 1390).

   Note
   RDS automatically checks the available storage before downloading. If the requested logs
   consume a high percentage of space, you receive an alert.

4. Confirm that the logs were downloaded from Amazon S3 successfully.

   You can view the status of your download task in a bdump file. The bdump files have the path name
   /rdsdbdata/log/trace/dbtask-task-id.log. In the preceding download step, you run a
   SELECT statement that returns the task ID in a VARCHAR2 data type. For more information, see
   similar examples in Monitoring the status of a file transfer (p. 1463).

Downloading a single archived redo log

To download a single archived redo log to the /rdsdbdata/log/arch directory, use
rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum. This procedure has
the following parameter:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seqnum</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The sequence number of the archived redo log.</td>
</tr>
</tbody>
</table>

The following example downloads the log with sequence number 20.

```
SELECT rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum(seqnum => 20)
AS TASK_ID
FROM DUAL;
```
Downloading a series of archived redo logs

To download a series of archived redo logs to the /rdsdbdata/log/arch directory, use `download_logs_in_seqnum_range`. Your download is limited to 300 logs per request. The `download_logs_in_seqnum_range` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start_seq</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The starting sequence number for the series.</td>
</tr>
<tr>
<td>end_seq</td>
<td>number</td>
<td>—</td>
<td>Yes</td>
<td>The ending sequence number for the series.</td>
</tr>
</tbody>
</table>

The following example downloads the logs from sequence 50 to 100.

```sql
SELECT rdsadmin.rdsadmin_archive_log_download.download_logs_in_seqnum_range(start_seq => 50, end_seq => 100)
AS TASK_ID
FROM DUAL;
```

Performing common RMAN tasks for Oracle DB instances

In the following section, you can find how you can perform Oracle Recovery Manager (RMAN) DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges.

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform RMAN backups of your Amazon RDS for Oracle database to disk. The `rdsadmin.rdsadmin_rman_util` package supports full and incremental database file backups, tablespace backups, and archive log backups.

RMAN backups consume storage space on the Amazon RDS DB instance host. When you perform a backup, you specify an Oracle directory object as a parameter in the procedure call. The backup files are placed in the specified directory. You can use default directories, such as `DATA_PUMP_DIR`, or create a new directory. For more information, see Creating and dropping directories in the main data storage space (p. 1418).

After an RMAN backup has finished, you can copy the backup files off the Amazon RDS for Oracle DB instance host. You might do this for the purpose of restoring to a non-RDS host or for long-term storage of backups. For example, you can copy the backup files to an Amazon S3 bucket. For more information, see using Amazon S3 integration (p. 1452).

The backup files for RMAN backups remain on the Amazon RDS DB instance host until you remove them manually. You can use the `UTL_FILE.FREMOVE` Oracle procedure to remove files from a directory. For more information, see FREMOVE procedure in the Oracle documentation.

When backing up archived redo logs or performing a full or incremental backup that includes archived redo logs, redo log retention must be set to a nonzero value. For more information, see Retaining archived redo logs (p. 1386).

Note
For backing up and restoring to another Amazon RDS for Oracle DB instance, you can continue to use the Amazon RDS backup and restore features. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 406). Currently, RMAN restore isn't supported for Amazon RDS for Oracle DB instances.
Common parameters for RMAN procedures

You can use procedures in the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform tasks with RMAN. Several parameters are common to the procedures in the package. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_directory_name</code></td>
<td>varchar2</td>
<td>A valid database directory name.</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory to contain the backup files.</td>
</tr>
</tbody>
</table>
| `p_label` | varchar2 | a-z, A-Z, 0-9, ‘_’, ‘-’, ‘.’ | — | No | A unique string that is included in the backup file names.  
**Note**  
The limit is 30 characters. |
| `p_owner` | varchar2 | A valid owner of the directory specified in `p_directory_name`. | — | Yes | The owner of the directory to contain the backup files. |
| `p_tag` | varchar2 | a-z, A-Z, 0-9, ‘_’, ‘-’, ‘.’ | NULL | No | A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as daily, weekly, or incremental-level backups.  
The limit is 30 characters. The tag is not case-sensitive. Tags are always stored in uppercase, regardless of the case used when entering them.  
Tags don't need to be unique, so multiple backups can have the same tag.  
If you don't specify a tag, then RMAN assigns a default tag automatically using the format `TAGYYYYMMDDTHHMMSS`, where `YYYY` is the year, `MM` is the month, `DD` is the day, `HH` is the hour (in 24-hour format), and `MM` is the minutes,
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_compress</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>Specify TRUE to enable BASIC backup compression. Specify FALSE to disable BASIC backup compression.</td>
</tr>
<tr>
<td>p_include_archive_logs</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>Specify TRUE to include archived redo logs in the backup. Specify FALSE to exclude archived redo logs from the backup.</td>
</tr>
<tr>
<td>p_include_controlfile</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>Specify TRUE to include the control file in the backup. Specify FALSE to exclude the control file from the backup.</td>
</tr>
<tr>
<td>p_optimize</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>TRUE</td>
<td>No</td>
<td>Specify TRUE to enable backup optimization, if archived redo logs are included, to reduce backup size. Specify FALSE to disable backup optimization.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------</td>
<td>----------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>p_parallel</td>
<td>number</td>
<td>A valid integer between 1 and 254 for Oracle Database Enterprise Edition (EE)</td>
<td>1</td>
<td>No</td>
<td>Number of channels.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 for other Oracle Database editions</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>p_rman_to_dbms_output</td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>When TRUE, the RMAN output is sent to the DBMS_OUTPUT package in addition to a file in the BDUMP directory. In SQL*Plus, use SET SERVEROUTPUT ON to see the output. When FALSE, the RMAN output is only sent to a file in the BDUMP directory.</td>
</tr>
<tr>
<td>p_section_size_mb</td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The section size in megabytes (MB). Validates in parallel by dividing each file into the specified section size. When NULL, the parameter is ignored.</td>
</tr>
<tr>
<td>p_validation_type</td>
<td>varchar2</td>
<td>'PHYSICAL', 'PHYSICAL+LOGICAL'</td>
<td>'PHYSICAL'</td>
<td></td>
<td>The level of corruption detection. Specify 'PHYSICAL' to check for physical corruption. An example of physical corruption is a block with a mismatch in the header and footer. Specify 'PHYSICAL+LOGICAL' to check for logical inconsistencies in addition to physical corruption. An example of logical corruption is a corrupt block.</td>
</tr>
</tbody>
</table>

**Validating DB instance files**

You can use the Amazon RDS package rdsadmin.rdsadmin_rman_util to validate Amazon RDS for Oracle DB instance files, such as data files, tablespaces, control files, or server parameter files (SPFILES).

For more information about RMAN validation, see [Validating database files and backups](#) and [VALIDATE](#) in the Oracle documentation.

**Topics**

- Validating a DB instance (p. 1394)
- Validating a tablespace (p. 1394)
- Validating a control file (p. 1395)
- Validating an SPFILE (p. 1395)
Validating a DB instance

To validate all of the relevant files used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_database`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see Common parameters for RMAN procedures (p. 1391).

The following example validates the DB instance using the default values for the parameters.

```
EXEC rdsadmin.rdsadmin_rman_util.validate_database;
```

The following example validates the DB instance using the specified values for the parameters.

```
BEGIN
   rdsadmin.rdsadmin_rman_util.validate_database( 
      p_validation_type     => 'PHYSICAL+LOGICAL',
      p_parallel            => 4,
      p_section_size_mb     => 10,
      p_rman_to_dbms_output => FALSE);
END;
/
```

When the `p_rman_to_dbms_output` parameter is set to `FALSE`, the RMAN output is written to a file in the BDUMP directory.

To view the files in the BDUMP directory, run the following `SELECT` statement.

```
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following `SELECT` statement.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

Validating a tablespace

To validate the files associated with a tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
• p_section_size_mb
• p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures (p. 1391).

Validating a control file

To validate only the control file used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.validate_current_controlfile.

This procedure uses the following common parameter for RMAN tasks:

• p_validation_type
• p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures (p. 1391).

Validating an SPFILE

To validate only the server parameter file (SPFILE) used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.validate_spfile.

This procedure uses the following common parameter for RMAN tasks:

• p_validation_type
• p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures (p. 1391).

Validating a data file

To validate a data file, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.validate_datafile.

This procedure uses the following common parameters for RMAN tasks:

• p_validation_type
• p_parallel
• p_section_size_mb
• p_rman_to_dbms_output

For more information, see Common parameters for RMAN procedures (p. 1391).

This procedure also uses the following additional parameters.
### Parameter Table

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_datafile</td>
<td>varchar2</td>
<td>A valid datafile ID number or a valid datafile name including complete path</td>
<td></td>
<td>Yes</td>
<td>The datafile ID number (from <code>v $datafile.file#</code>) or the full datafile name including the path (from <code>v $datafile.name</code>).</td>
</tr>
<tr>
<td>p_from_block</td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The number of the block where the validation starts within the data file. When this is NULL, 1 is used.</td>
</tr>
<tr>
<td>p_to_block</td>
<td>number</td>
<td>A valid integer</td>
<td>NULL</td>
<td>No</td>
<td>The number of the block where the validation ends within the data file. When this is NULL, the maximum block in the data file is used.</td>
</tr>
</tbody>
</table>

### Enabling and disabling block change tracking

Block changing tracking records changed blocks in a tracking file. This technique can improve the performance of incremental backups. For more information, see Using Block Change Tracking to Improve Incremental Backup Performance in the Oracle Database documentation.

To enable block change tracking for a DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. To disable block change tracking, use `disable_block_change_tracking`. These procedures take no parameters.

Read-only replicas support block change tracking. If you create a read-only replica from a source DB that uses block change tracking, the replica uses block change tracking. You can't enable block change tracking on a mounted replica. If you place a mounted replica in read-only mode, block change tracking isn't enabled, but you can enable it using `enable_block_change_tracking`. If you promote an Oracle replica to a source DB, you can use block change tracking just as for any other Oracle DB instance.

Block change tracking procedures are supported for the following DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

**Note**

In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. See also Limitations of a single-tenant CDB (p. 1310).
To determine whether block change tracking is enabled for your DB instance, run the following query.

```
SELECT STATUS, FILENAME FROM V$BLOCK_CHANGE_TRACKING;
```

The following example enables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.enable_block_change_tracking;
```

The following example disables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.disable_block_change_tracking;
```

## Crosschecking archived redo logs

You can crosscheck archived redo logs using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.crosscheck_archivelog`.

You can use this procedure to crosscheck the archived redo logs registered in the control file and optionally delete the expired logs records. When RMAN makes a backup, it creates a record in the control file. Over time, these records increase the size of the control file. We recommend that you remove expired records periodically.

**Note**

Standard Amazon RDS backups don't use RMAN and therefore don't create records in the control file.

This procedure uses the common parameter `p_rman_to_dbms_output` for RMAN tasks.

For more information, see [Common parameters for RMAN procedures](p. 1391).

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_delete_expired</code></td>
<td>boolean</td>
<td>TRUE, FALSE</td>
<td>TRUE</td>
<td>No</td>
<td>When TRUE, delete expired archived redo log records from the control file.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>When FALSE, retain the expired archived redo log records in the control file.</td>
</tr>
</tbody>
</table>

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example marks archived redo log records in the control file as expired, but does not delete the records.
BEGIN
  rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
    p_delete_expired => FALSE,
    p_rman_to_dbms_output => FALSE);
END;
/

The following example deletes expired archived redo log records from the control file.

BEGIN
  rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
    p_delete_expired => TRUE,
    p_rman_to_dbms_output => FALSE);
END;
/

## Backing up archived redo logs

You can use the Amazon RDS package rdsadmin.rdsadmin_rman_util to back up archived redo logs for an Amazon RDS Oracle DB instance.

The procedures for backing up archived redo logs are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

### Topics

- Backing up all archived redo logs (p. 1398)
- Backing up an archived redo log from a date range (p. 1399)
- Backing up an archived redo log from an SCN range (p. 1400)
- Backing up an archived redo log from a sequence number range (p. 1402)

### Backing up all archived redo logs

To back up all of the archived redo logs for an Amazon RDS Oracle DB instance, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.backup_archivelog_all.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures (p. 1391).
The following example backs up all archived redo logs for the DB instance.

```sql
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_all(
        p_owner => 'SYS',
        p_directory_name => 'MYDIRECTORY',
        p_parallel => 4,
        p_tag => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

**Backing up an archived redo log from a date range**

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a date range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_date`. The date range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#). This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_from_date</code></td>
<td>date</td>
<td>A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be less than or equal to the value</td>
<td>—</td>
<td>Yes</td>
<td>The starting date for the archived log backups.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>--------------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>p_to_date</td>
<td>date</td>
<td>A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_date.</td>
<td>—</td>
<td>Yes</td>
<td>The ending date for the archived log backups.</td>
</tr>
</tbody>
</table>

The following example backs up archived redo logs in the date range for the DB instance.

```sql
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_date(
        p_owner => 'SYS',
        p_directory_name => 'MYDIRECTORY',
        p_from_date => '03/01/2019 00:00:00',
        p_to_date => '03/02/2019 00:00:00',
        p_parallel => 4,
        p_tag => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

### Backing up an archived redo log from an SCN range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a system change number (SCN) range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_scn`. The SCN range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
• p_parallel
• p_compress
• p_rman_to_dbms_output
• p_tag

For more information, see Common parameters for RMAN procedures (p. 1391).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_from_scn</td>
<td>number</td>
<td>An SCN of an archived redo log that exists on disk. The value must be less than or equal to the value specified for p_to_scn.</td>
<td>—</td>
<td>Yes</td>
<td>The starting SCN for the archived log backups.</td>
</tr>
<tr>
<td>p_to_scn</td>
<td>number</td>
<td>An SCN of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_scn.</td>
<td>—</td>
<td>Yes</td>
<td>The ending SCN for the archived log backups.</td>
</tr>
</tbody>
</table>

The following example backs up archived redo logs in the SCN range for the DB instance.

```sql
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_scn(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_from_scn            => 1533835,
        p_to_scn              => 1892447,
        p_parallel            => 4,
        p_tag                 => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
```
BACKING UP AN ARCHIVED REDO LOG FROM A SEQUENCE NUMBER RANGE

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a sequence number range, use the Amazon RDS procedure rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence. The sequence number range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see Common parameters for RMAN procedures (p. 1391).

This procedure also uses the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_from_sequence</code></td>
<td>number</td>
<td>A sequence number an archived redo log that exists on disk. The value must be less than or equal to the value specified for <code>p_to_sequence</code>.</td>
<td>—</td>
<td>Yes</td>
<td>The starting sequence number for the archived log backups.</td>
</tr>
<tr>
<td><code>p_to_sequence</code></td>
<td>number</td>
<td>A sequence number of an archived redo log that exists on disk. The value must be</td>
<td>—</td>
<td>Yes</td>
<td>The ending sequence number for the archived log backups.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Valid values</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>--------------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>greater than or equal to the value specified for <code>p_from_sequence</code>.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example backs up archived redo logs in the sequence number range for the DB instance.

```
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence(
        p_owner => 'SYS',
        p_directory_name => 'MYDIRECTORY',
        p_from_sequence => 11160,
        p_to_sequence => 11160,
        p_parallel => 4,
        p_tag => 'MY_LOG_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

**Performing a full database backup**

You can perform a backup of all blocks of data files included in the backup using Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_full`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures (p. 1391)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_RMAN.html#USER_RMAN.toc).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher
The following example performs a full backup of the DB instance using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_database_full(
    p_owner => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_parallel => 4,
    p_section_size_mb => 10,
    p_tag => 'FULL_DB_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

### Performing an incremental database backup

You can perform an incremental backup of your DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_incremental`.

For more information about incremental backups, see [Incremental backups](#) in the Oracle documentation.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_level</code></td>
<td>number</td>
<td>0, 1</td>
<td>0</td>
<td>No</td>
<td>Specify 0 to enable a full incremental backup.</td>
</tr>
</tbody>
</table>
RMAN tasks

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Specify 1 to enable a non-cumulative incremental backup.</td>
</tr>
</tbody>
</table>

The following example performs an incremental backup of the DB instance using the specified values for the parameters.

```sql
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_database_incremental(
    p_owner => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_level => 1,
    p_parallel => 4,
    p_section_size_mb => 10,
    p_tag => 'MY_INCREMENTAL_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

Backing up a tablespace

You can back up a tablespace using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tablespace`. This procedure uses the following common parameters for RMAN tasks:

- p_owner
- p_directory_name
- p_label
- p_parallel
- p_section_size_mb
- p_include_archive_logs
- p_include_controlfile
- p_optimize
- p_compress
- p_rman_to_dbms_output
- p_tag

For more information, see Common parameters for RMAN procedures (p. 1391).

This procedure also uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tablespace_name</td>
<td>varchar2</td>
<td>A valid tablespace name.</td>
<td>—</td>
<td>Yes</td>
<td>The name of the tablespace to back up.</td>
</tr>
</tbody>
</table>

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:
• Oracle Database 21c (21.0.0)
• Oracle Database 19c (19.0.0)
• Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
• Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example performs a tablespace backup using the specified values for the parameters.

```sql
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_tablespace(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_tablespace_name     => 'MYTABLESPACE',
        p_parallel            => 4,
        p_section_size_mb     => 10,
        p_tag                 => 'MYTABLESPACE_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```

### Backing up a control file

You can back up a control file using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_current_controlfile`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](p. 1391).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2), using 12.2.0.1.ru-2019-01.rur-2019-01.r1 or higher
- Oracle Database 12c Release 1 (12.1), using 12.1.0.2.v15 or higher

The following example backs up a control file using the specified values for the parameters.

```sql
BEGIN
    rdsadmin.rdsadmin_rman_util.backup_controlfile(
        p_owner               => 'SYS',
        p_directory_name      => 'MYDIRECTORY',
        p_label               => 'CONTROL_FILE_BACKUP',
        p_rman_to_dbms_output => FALSE);
END;
/
```
Performing common scheduling tasks for Oracle DB instances

Some scheduler jobs owned by SYS can interfere with normal database operations. Oracle Support recommends you disable these jobs or modify the schedule. To perform tasks for Oracle Scheduler jobs owned by SYS, use the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`.

The `rdsadmin.rdsadmin_dbms_scheduler` procedures are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c
- Oracle Database 12c Release 2 (12.2) on 12.2.0.2.ru-2019-07.rur-2019-07.r1 or higher 12.2 versions
- Oracle Database 12c Release 1 (12.1) on 12.1.0.2.v17 or higher 12.1 versions

Common parameters for Oracle Scheduler procedures

To perform tasks with Oracle Scheduler, use procedures in the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`. Several parameters are common to the procedures in the package. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>varchar2</td>
<td>'SYS.BSLN_MAINTAIN_STATS_JOB', 'SYS.CLEANUP_ONLINE_IND_BUILD'</td>
<td></td>
<td>Yes</td>
<td>The name of the job to modify.</td>
</tr>
</tbody>
</table>

**Note**
Currently, you can only modify `SYS.CLEANUP_ONLINE_IND_BUILD` and `SYS.BSLN_MAINTAIN_STATS_JOB` jobs.

<table>
<thead>
<tr>
<th>attribute</th>
<th>varchar2</th>
<th>'REPEAT_INTERVAL', 'SCHEDULE_NAME'</th>
<th></th>
<th>Yes</th>
<th>Attribute to modify.</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>varchar2</td>
<td>A valid schedule interval or schedule name, depending on</td>
<td></td>
<td>Yes</td>
<td>The new value of the attribute.</td>
</tr>
</tbody>
</table>
Modifying DBMS_SCHEDULER jobs

To modify certain components of Oracle Scheduler, use the Oracle procedure `dbms_scheduler.set_attribute`. For more information, see `DBMS_SCHEDULER` and `SET_ATTRIBUTE` procedure in the Oracle documentation.

When working with Amazon RDS DB instances, prepend the schema name `SYS` to the object name. The following example sets the resource plan attribute for the Monday window object.

```sql
BEGIN
    DBMS_SCHEDULER.SET_ATTRIBUTE(
        name => 'SYS.MONDAY_WINDOW',
        attribute => 'RESOURCE_PLAN',
        value => 'resource_plan_1');
END;
/
```

Modifying AutoTask maintenance windows

Amazon RDS for Oracle instances are created with default settings for maintenance windows. Automated maintenance tasks such as optimizer statistics collection run during these windows. By default, the maintenance windows turn on Oracle Database Resource Manager.

To modify the window, use the `DBMS_SCHEDULER` package. You might need to modify the maintenance window settings for the following reasons:

- You want maintenance jobs to run at a different time, with different settings, or not at all. For example, might want to modify the window duration, or change the repeat time and interval.
- You want to avoid the performance impact of enabling Resource Manager during maintenance. For example, if the default maintenance plan is specified, and if the maintenance window opens while the database is under load, you might see wait events such as `resmgr:cpu quantum`. This wait event is related to Database Resource Manager. You have the following options:
  - Ensure that maintenance windows are active during off-peak times for your DB instance.
  - Disable the default maintenance plan by setting the `resource_plan` attribute to an empty string.
  - Set the `resource_manager_plan` parameter to `FORCE:` in your parameter group. If your instance uses Enterprise Edition, this setting prevents Database Resource Manager plans from activating.

To modify your maintenance window settings

1. Connect to your database using an Oracle SQL client.
2. Query the current configuration for a scheduler window.

The following example queries the configuration for `MONDAY_WINDOW`.

```sql
SELECT ENABLED, RESOURCE_PLAN, DURATION, REPEAT_INTERVAL
FROM   DBA_SCHEDULER_WINDOWS
WHERE  WINDOW_NAME='MONDAY_WINDOW';
```

The following output shows that the window is using the default values.
3. Modify the window using the DBMS_SCHEDULER package.

The following example sets the resource plan to null so that the Resource Manager won't run during the maintenance window.

```sql
BEGIN
  -- disable the window to make changes
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);

  -- specify the empty string to use no plan
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
                                 attribute=>'RESOURCE_PLAN', value=>'');

  -- re-enable the window
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/```

The following example sets the maximum duration of the window to 2 hours.

```sql
BEGIN
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"', attribute=>'DURATION',
                                 value=>'0 2:00:00');
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/```

The following example sets the repeat interval to every Monday at 10 AM.

```sql
BEGIN
  DBMS_SCHEDULER.DISABLE(name=>'"SYS"."MONDAY_WINDOW"',force=>TRUE);
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'"SYS"."MONDAY_WINDOW"',
                                 attribute=>'REPEAT_INTERVAL',
                                 value=>'freq=daily;byday=MON;byhour=10;byminute=0;bysecond=0');
  DBMS_SCHEDULER.ENABLE(name=>'"SYS"."MONDAY_WINDOW"');
END;
/```

### Setting the time zone for Oracle Scheduler jobs

To modify the time zone for Oracle Scheduler, you can use the Oracle procedure dbms_scheduler.set_scheduler_attribute. For more information about the dbms_scheduler package, see [DBMS_SCHEDULER and SET_SCHEDULER_ATTRIBUTE](#) in the Oracle documentation.

### To modify the current time zone setting

1. Connect to the database using a client such as SQL Developer. For more information, see [Connecting to your DB instance using Oracle SQL developer](#) (p. 1314).
2. Set the default time zone as following, substituting your time zone for `time_zone_name`. 
BEGIN
  DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
      attribute => 'default_timezone',
      value => 'time_zone_name'
  );
END;
/

In the following example, you change the time zone to Asia/Shanghai.

Start by querying the current time zone, as shown following.

SELECT VALUE FROM DBA_SCHEDULER_GLOBAL_ATTRIBUTE WHERE ATTRIBUTE_NAME='DEFAULT_TIMEZONE';

The output shows that the current time zone is ETC/UTC.

VALUE
-------
Etc/UTC

Then you set the time zone to Asia/Shanghai.

BEGIN
  DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(
      attribute => 'default_timezone',
      value => 'Asia/Shanghai'
  );
END;
/

For more information about changing the system time zone, see Oracle time zone (p. 1533).

Disabling SYS-owned Oracle Scheduler jobs

To disable a SYS-owned Oracle Scheduler job, use the rdsadmin.rdsadmin_dbms_scheduler.disable procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures (p. 1407).

The following example disables the SYS.CLEANUP_ONLINE_IND_BUILD Oracle Scheduler job.

BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.disable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/

Enabling SYS-owned Oracle Scheduler jobs

To enable a SYS-owned Oracle Scheduler job, use the rdsadmin.rdsadmin_dbms_scheduler.enable procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see Common parameters for Oracle Scheduler procedures (p. 1407).
The following example enables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```sql
BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.enable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/
```

**Modifying the repeat interval for jobs of CALENDAR type**

To modify the repeat interval to modify a SYS-owned Oracle Scheduler job of CALENDAR type, use the `rdsadmin.rdsadmin_dbms_scheduler.disable` procedure. This procedure uses the following common parameters for Oracle Scheduler tasks:

- **name**
- **attribute**
- **value**

For more information, see [Common parameters for Oracle Scheduler procedures](#p.1407).

The following example modifies the repeat interval of the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```sql
BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.set_attribute(
    name => 'SYS.CLEANUP_ONLINE_IND_BUILD',
    attribute => 'repeat_interval',
    value => 'freq=daily;byday=FRI,SAT;byhour=20;byminute=0;bysecond=0');
END;
/
```

**Modifying the repeat interval for jobs of NAMED type**

Some Oracle Scheduler jobs use a schedule name instead of an interval. For this type of jobs, you must create a new named schedule in the master user schema. Use the standard `Oracle sys.dbms_scheduler.create_schedule` procedure to do this. Also, use the `rdsadmin.rdsadmin_dbms_scheduler.set_attribute` procedure to assign the new named schedule to the job.

This procedure uses the following common parameter for Oracle Scheduler tasks:

- **name**
- **attribute**
- **value**

For more information, see [Common parameters for Oracle Scheduler procedures](#p.1407).

The following example modifies the repeat interval of the `SYS.BSLN_MAINTAIN_STATS_JOB` Oracle Scheduler job.

```sql
BEGIN
  DBMS_SCHEDULER.CREATE_SCHEDULE (  
    schedule_name => 'rds_master_user.new_schedule',  
    start_date => SYSTIMESTAMP,
  );
END;
/
Performing common diagnostic tasks for Oracle DB instances

Oracle Database includes a fault diagnosability infrastructure that you can use to investigate database problems. In Oracle terminology, a **problem** is a critical error such as a code bug or data corruption. An **incident** is the occurrence of a problem. If the same error occurs three times, then the infrastructure shows three incidents of this problem. For more information, see Diagnosing and resolving problems in the Oracle Database documentation.

The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. For example, you can use this tool to investigate problems and package diagnostic data. An **incident package** includes diagnostic data for an incident or all incidents that reference a specific problem. You can upload an incident package, which is implemented as a .zip file, to Oracle Support.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to ADRCI. To perform diagnostic tasks for your Oracle instance, instead use the Amazon RDS package rdsadmin.rdsadmin_adrci_util.

By using the functions in rdsadmin_adrci_util, you can list and package problems and incidents, and also show trace files. All functions return a task ID. This ID forms part of the name of the log file that contains the ADRCI output, as in dbtask-**task_id**.log. The log file resides in the BDUMP directory.

**Common parameters for diagnostic procedures**

To perform diagnostic tasks, use functions in the Amazon RDS package rdsadmin.rdsadmin_adrci_util. The package has the following common parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>incident_id</td>
<td>number</td>
<td>A valid incident ID or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all incidents. If the value isn't null and represents a valid incident ID, the function shows the specified incident.</td>
</tr>
<tr>
<td>problem_id</td>
<td>number</td>
<td>A valid problem ID or null</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all problems. If the value</td>
</tr>
</tbody>
</table>
### Listing incidents

To list diagnostic incidents for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents`. You can list incidents in either basic or detailed mode. By default, the function lists the 50 most recent incidents.

This function uses the following common parameters:

- `incident_id`
- `problem_id`

If you specify both of the preceding parameters, `incident_id` overrides `problem_id`. For more information, see Common parameters for diagnostic procedures (p. 1412).

This function uses the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>detail</td>
<td>boolean</td>
<td>TRUE or FALSE</td>
<td>FALSE</td>
<td>No</td>
<td>If TRUE, the function lists incidents in detail mode. If FALSE, the function lists incidents in basic mode.</td>
</tr>
</tbody>
</table>

To list all incidents, query the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments. The query returns the task ID.

```sql
SQL> SELECT rdsadmin.rdsadmin_adrci_util.list_adrci_incidents AS task_id FROM DUAL;
```

```plaintext
TASK_ID
------------------
1590786706158-3126
```

Or call the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments and store the output in a SQL client variable. You can use the variable in other statements.

```sql
SQL> VAR task_id VARCHAR2(80);
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_incidents;
```
PL/SQL procedure successfully completed.

To read the log file, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name. The following output shows three incidents: 53523, 53522, and 53521.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
                      'dbtask-||:task_id||'.log));
```

```
2020-05-29 21:11:46.256 UTC [INFO ]
ADR Home = /rdsdbdata/log/diag/rdbms/orcl_a/ORCL:
*************************************************************************
INCIDENT_ID PROBLEM_KEY                                                 CREATE_TIME
----------- -----------------------------------------------------------

3 rows fetched

2020-05-29 21:11:46.256 UTC [INFO ] The ADRCI incidents were successfully listed.
14 rows selected.
```

To list a particular incident, specify its ID using the `incident_id` parameter. In the following example, you query the log file for incident 53523 only.

```sql
SQL> EXEC :task_id :=
       rdsadmin.rdsadmin_adrci_util.list_adrci_incidents(incident_id=>53523);
```

PL/SQL procedure successfully completed.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
                      'dbtask-||:task_id||'.log));
```

```

Listing problems

To list diagnostic problems for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_problems`.

By default, the function lists the 50 most recent problems.

This function uses the common parameter `problem_id`. For more information, see Common parameters for diagnostic procedures (p. 1412).

To get the task ID for all problems, call the `rdsadmin.rdsadmin_adrci_util.list_adrci_problems` function without any arguments, and store the output in a SQL client variable.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems;
PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file` function, supplying the task ID as part of the file name. In the following output, the log file shows three problems: 1, 2, and 3.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
           'dbtask-''||:task_id||''.log'));
```

```

2020-05-29 21:18:50.829 UTC [INFO ] The ADRCI problems were successfully listed. |
14 rows selected. |

In the following example, you list problem 3 only.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems(problem_id=>3);
PL/SQL procedure successfully completed.
```

To read the log file for problem 3, call `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
                   'dbtask-''||:task_id||''.log'));
```

Creating incident packages

You can create incident packages using the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package`. The output is a .zip file that you can supply to Oracle Support.

This function uses the following common parameters:

- `problem_id`
- `incident_id`

Make sure to specify one of the preceding parameters. If you specify both parameters, `incident_id` overrides `problem_id`. For more information, see Common parameters for diagnostic procedures (p. 1412).

To create a package for a specific incident, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package` with the `incident_id` parameter. The following example creates a package for incident 53523.

```
SQL> EXEC :task_id :=
    2 rdsadmin.rdsadmin_adrci_util.create_adrci_package(incident_id=>53523);
PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file`. You can supply the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212043_COM_1.zip`.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
    2 'dbtask-':||:task_id||'.log'));
```

To package diagnostic data for a particular problem, specify its ID using the `problem_id` parameter. In the following example, you package data for problem 3 only.
Diagnostic tasks

SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.create_adrci_package(problem_id=>3);
PL/SQL procedure successfully completed.

To read the task output, call rdsadmin.rds_file_util.read_text_file, supplying the task ID as part of the file name. The output shows that you generated incident package ORA700EVE_20200529212111_COM_1.zip.

SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log'));

TEXT
------------------------------------------------------------------------------------------------------------------------------------------------------------
2020-05-29 21:21:15.646 UTC [INFO ] Generated package 2 in file /rdsdbdata/log/trace/ORA700EVE_20200529212111_COM_1.zip, mode complete
2020-05-29 21:21:15.646 UTC [INFO ] The ADRCI package was successfully created.

Showing trace files

You can show trace files using the Amazon RDS function rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile.

This function uses the following parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Valid values</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>varchar2</td>
<td>A valid trace file name</td>
<td>Null</td>
<td>No</td>
<td>If the value is null, the function shows all trace files. If it isn't null, the function shows the specified file.</td>
</tr>
</tbody>
</table>

To show the trace file, call the Amazon RDS function rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile with the incident_id parameter.

SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile;
PL/SQL procedure successfully completed.

To list the trace file names, call the Amazon RDS procedure rdsadmin.rds_file_util.read_text_file, supplying the task ID as part of the file name.

SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log')) WHERE TEXT LIKE '%/alert_%';

TEXT
---------------------------------------------------------------
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-28
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-27
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-26
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-25
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-24
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-23
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-22
In the following example, you generate output for alert_ORCL.log.

```sql
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile('diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log');
PL/SQL procedure successfully completed.

To read the log file, call rdsadmin.rds_file_util.read_text_file. Supply the task ID as part of the file name. The output shows the first 10 lines of alert_ORCL.log.

```sql
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-'||:task_id||'.log')) WHERE ROWNUM <= 10;
TEXT

Performing miscellaneous tasks for Oracle DB instances

Following, you can find how to perform miscellaneous DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

Topics
- Creating and dropping directories in the main data storage space (p. 1418)
- Listing files in a DB instance directory (p. 1419)
- Reading files in a DB instance directory (p. 1420)
- Accessing Opatch files (p. 1420)
- Managing advisor tasks (p. 1422)
- Enabling HugePages for an Oracle DB instance (p. 1424)
- Enabling extended data types (p. 1426)

Creating and dropping directories in the main data storage space

To create directories, use the Amazon RDS procedure rdsadmin.rdsadmin_util.create_directory. You can create up to 10,000 directories,
all located in your main data storage space. To drop directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_directory`.

The `create_directory` and `drop_directory` procedures have the following required parameter.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory.</td>
</tr>
</tbody>
</table>

The following example creates a new directory named `PRODUCT_DESCRIPTIONS`.

```sql
EXEC rdsadmin.rdsadmin_util.create_directory(p_directory_name => 'product_descriptions');
```

The data dictionary stores the directory name in uppercase. You can list the directories by querying `DBA_DIRECTORIES`. The system chooses the actual host pathname automatically. The following example gets the directory path for the directory named `PRODUCT_DESCRIPTIONS`:

```sql
SELECT DIRECTORY_PATH
FROM DBA_DIRECTORIES
WHERE DIRECTORY_NAME='PRODUCT_DESCRIPTIONS';
```

```
DIRECTORY_PATH
--------------------------
/rdsdbdata/userdirs/01
```

The master user name for the DB instance has read and write privileges in the new directory, and can grant access to other users. `EXECUTE` privileges are not available for directories on a DB instance. Directories are created in your main data storage space and will consume space and I/O bandwidth.

The following example drops the directory named `PRODUCT_DESCRIPTIONS`.

```sql
EXEC rdsadmin.rdsadmin_util.drop_directory(p_directory_name => 'product_descriptions');
```

**Note**

You can also drop a directory by using the Oracle SQL command `DROP DIRECTORY`.

Dropping a directory doesn't remove its contents. Because the `rdsadmin.rdsadmin_util.create_directory` procedure can reuse pathnames, files in dropped directories can appear in a newly created directory. Before you drop a directory, we recommend that you use `UTL_FILE.FREMOVE` to remove files from the directory. For more information, see `FREMOVE` procedure in the Oracle documentation.

### Listing files in a DB instance directory

To list the files in a directory, use the Amazon RDS procedure `rdsadmin.rds_file_util.listdir`. The `listdir` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_directory</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory to list.</td>
</tr>
</tbody>
</table>

The following example grants read/write privileges on the directory `PRODUCT_DESCRIPTIONS` to user `rdsadmin`, and then lists the files in this directory.
GRANT READ, WRITE ON DIRECTORY PRODUCT_DESCRIPTIONS TO rdsadmin;
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'PRODUCT_DESCRIPTIONS'));

### Reading files in a DB instance directory

To read a text file, use the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The `read_text_file` procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_directory</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the directory that contains the file.</td>
</tr>
<tr>
<td><code>p_filename</code></td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the file to read.</td>
</tr>
</tbody>
</table>

The following example creates the file `rice.txt` in the directory `PRODUCT_DESCRIPTIONS`.

```
declare
  fh sys.utl_file.file_type;
begnin
  fh := utl_file.fopen(location=>'PRODUCT_DESCRIPTIONS', filename=>'rice.txt',
                      open_mode=>'w');
  utl_file.put(file=>fh, buffer=>'AnyCompany brown rice, 15 lbs');
  utl_file.fclose(file=>fh);
end;
/
```

The following example reads the file `rice.txt` from the directory `PRODUCT_DESCRIPTIONS`.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file( 
  p_directory => 'PRODUCT_DESCRIPTIONS',
  p_filename  => 'rice.txt'));
```

### Accessing Opatch files

Opatch is an Oracle utility that enables the application and rollback of patches to Oracle software. The Oracle mechanism for determining which patches have been applied to a database is the `opatch lsinventory` command. To open service requests for Bring Your Own Licence (BYOL) customers, Oracle Support requests the `lsinventory` file and sometimes the `lsinventory_detail` file generated by Opatch.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to Opatch. Instead, the `lsinventory-dbv.txt` in the BDUMP directory contains the patch information related to your current engine version. When you perform a minor or major upgrade, Amazon RDS updates `lsinventory-dbv.txt` within an hour of applying the patch. To verify the applied patches, read `lsinventory-dbv.txt`. This action is similar to running the `opatch lsinventory` command.

**Note**
The examples in this section assume that the BDUMP directory is named `BDUMP`. On a read replica, the BDUMP directory name is different. To learn how to get the BDUMP name by querying `V$DATABASE.DB_UNIQUE_NAME` on a read replica, see Listing files (p. 674).

The inventory files use the Amazon RDS naming convention `lsinventory-dbv.txt` and `lsinventory_detail-dbv.txt`, where `dbv` is the full name of your DB version.
The `lsinventory-dbversion.txt` file is available on all DB versions. The corresponding `lsinventory_detail-dbversion.txt` is available on the following DB versions:

- 19.0.0.0, ru-2020-01.rur-2020-01.r1 or later
- 12.2.0.1, ru-2020-01.rur-2020-01.r1 or later
- 12.1.0.2, v19 or later

For example, if your DB version is 19.0.0.0.ru-2021-07.rur-2021-07.r1, then your inventory files have the following names.

- `lsinventory-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt`
- `lsinventory_detail-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt`

Ensure that you download the files that match the current version of your DB engine.

**Console**

**To download an inventory file using the console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, search for `lsinventory`.
7. Select the file that you want to access, and then choose **Download**.

**SQL**

To read the `lsinventory-dbversion.txt` in a SQL client, you can use a `SELECT` statement. For this technique, use either of the following `rdsadmin` functions: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing`.

In the following sample query, replace `dbversion` with your Oracle DB version. For example, your DB version might be 19.0.0.0.ru-2020-04.rur-2020-04.r1.

```sql
SELECT text
FROM   TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'lsinventory-dbversion.txt'))
```

**PL/SQL**

To read the `lsinventory-dbversion.txt` in a SQL client, you can write a PL/SQL program. This program uses `utl_file` to read the file, and `dbms_output` to print it. These are Oracle-supplied packages.

In the following sample program, replace `dbversion` with your Oracle DB version. For example, your DB version might be 19.0.0.0.ru-2020-04.rur-2020-04.r1.

```sql
SET SERVEROUTPUT ON
DECLARE
    v_file              SYS.UTL_FILE.FILE_TYPE;
    v_line              VARCHAR2(1000);
    v_oracle_home_type  VARCHAR2(1000);
    c_directory         VARCHAR2(30) := 'BDUMP';
    c_output_file       VARCHAR2(30) := 'lsinventory-dbversion.txt';
BEGIN
    v_file := SYSLIB.FILEOPEN(c_directory, c_output_file, 'r');
    v_line := SYSLIB.FILEREADLINE(v_file);
    FOR i IN 1.. LENGTH(v_line)
    LOOP
        dbms_output.put_line(v_line);
    END LOOP;
END;
```
Managing advisor tasks

Oracle Database includes a number of advisors. Each advisor supports automated and manual tasks. You can use procedures in the rdsadmin.rdsadmin_util package to manage some advisor tasks.

The advisor task procedures are available in the following engine versions:

- Oracle Database 21c (21.0.0)
- Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 19c versions

  For more information, see Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 in the Amazon RDS for Oracle Release Notes.

- Version 12.2.0.1.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 12c (Release 2) 12.2.0.1 versions

  For more information, see Version 12.2.0.1.ru-2021-01.rur-2021-01.r1 in the Amazon RDS for Oracle Release Notes.

Topics

- Setting parameters for advisor tasks (p. 1422)
- Disabling AUTO_STATS_ADVISOR_TASK (p. 1424)
- Re-enabling AUTO_STATS_ADVISOR_TASK (p. 1424)

Setting parameters for advisor tasks

To set parameters for some advisor tasks, use the Amazon RDS procedure rdsadmin.rdsadmin_util.advisor_task_set_parameter. The advisor_task_set_parameter procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_task_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the advisor task whose parameters you want to change. The following values are valid:</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Data type</td>
<td>Default</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------</td>
<td>---------</td>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>p_parameter</td>
<td>varchar2</td>
<td></td>
<td>Yes</td>
<td>The name of the task parameter. To find valid parameters for an advisor task, run the following query. Substitute p_task_name with a valid value for p_task_name:</td>
</tr>
</tbody>
</table>
|               |           |         |          | COL PARAMETER_NAME FORMAT a30  
|               |           |         |          | COL PARAMETER_VALUE FORMAT a30  
|               |           |         |          | SELECT PARAMETER_NAME, PARAMETER_VALUE  
|               |           |         |          | FROM DBA_ADVISOR_PARAMETERS  
|               |           |         |          | WHERE TASK_NAME='p_task_name'  
|               |           |         |          | AND PARAMETER_VALUE != 'UNUSED'  
|               |           |         |          | ORDER BY PARAMETER_NAME; |
| p_value       | varchar2 |         | Yes      | The value for a task parameter. To find valid values for task parameters, run the following query. Substitute p_task_name with a valid value for p_task_name: |
|               |           |         |          | COL PARAMETER_NAME FORMAT a30  
|               |           |         |          | COL PARAMETER_VALUE FORMAT a30  
|               |           |         |          | SELECT PARAMETER_NAME, PARAMETER_VALUE  
|               |           |         |          | FROM DBA_ADVISOR_PARAMETERS  
|               |           |         |          | WHERE TASK_NAME='p_task_name'  
|               |           |         |          | AND PARAMETER_VALUE != 'UNUSED'  
|               |           |         |          | ORDER BY PARAMETER_NAME; |

The following PL/SQL program sets ACCEPT PLANS to FALSE for SYS_AUTO_SPM_EVOLVE_TASK. The SQL Plan Management automated task verifies the plans and generates a report of its findings, but does not evolve the plans automatically. You can use a report to identify new SQL plan baselines and accept them manually.

```plsql
BEGIN
rdsadmin.rdsadmin_util.advisor_task_set_parameter(
    p_task_name => 'SYS_AUTO_SPM_EVOLVE_TASK',
    p_parameter => 'ACCEPT_PLANS',
    p_value => 'FALSE');
END;
```

The following PL/SQL program sets EXECUTION DAYS TO EXPIRE to 10 for AUTO_STATS_ADVISOR_TASK. The predefined task AUTO_STATS_ADVISOR_TASK runs automatically in the maintenance window once per day. The example sets the retention period for the task execution to 10 days.

```plsql
BEGIN
rdsadmin.rdsadmin_util.advisor_task_set_parameter(
    p_task_name => 'AUTO_STATS_ADVISOR_TASK',
    p_parameter => 'EXECUTION_DAYS_TO_EXPIRE',
    p_value => '10');
END;
```
Disabling AUTO_STATS_ADVISOR_TASK

To disable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure rdsadmin.rdsadmin_util.advisor_task_drop. The advisor_task_drop procedure accepts the following parameter.

**Note**

This procedure is available in Oracle Database 12c Release 2 (12.2.0.1) and later.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_task_name</td>
<td>varchar2</td>
<td>—</td>
<td>Yes</td>
<td>The name of the advisor task to be disabled. The only valid value is AUTO_STATS_ADVISOR_TASK.</td>
</tr>
</tbody>
</table>

The following command drops AUTO_STATS_ADVISOR_TASK.

```
EXEC rdsadmin.rdsadmin_util.advisor_task_drop('AUTO_STATS_ADVISOR_TASK')
```

You can re-enabling AUTO_STATS_ADVISOR_TASK using rdsadmin.rdsadmin_util.dbms_stats_init.

Re-enabling AUTO_STATS_ADVISOR_TASK

To re-enable AUTO_STATS_ADVISOR_TASK, use the Amazon RDS procedure rdsadmin.rdsadmin_util.dbms_stats_init. The dbms_stats_init procedure takes no parameters.

The following command re-enables AUTO_STATS_ADVISOR_TASK.

```
EXEC rdsadmin.rdsadmin_util.dbms_stats_init()
```

Enabling HugePages for an Oracle DB instance

Amazon RDS for Oracle supports Linux kernel HugePages for increased database scalability. HugePages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. For more information, see Overview of HugePages in the Oracle documentation.

You can use HugePages with the following versions and editions of Oracle Database:

- 19.0.0.0, all editions
- 12.2.0.1, all editions
- 12.1.0.2, all editions

The use_large_pages parameter controls whether HugePages are enabled for a DB instance. The possible settings for this parameter are ONLY, FALSE, and {DBInstanceClassHugePagesDefault}. The use_large_pages parameter is set to {DBInstanceClassHugePagesDefault} in the default DB parameter group for Oracle.

To control whether HugePages are enabled for a DB instance automatically, you can use the DBInstanceClassHugePagesDefault formula variable in parameter groups. The value is determined as follows:
• For the DB instance classes mentioned in the table following, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE` by default, and `use_large_pages` evaluates to `FALSE`. You can enable HugePages manually for these DB instance classes if the DB instance class has at least 14 GiB of memory.

• For DB instance classes not mentioned in the table following, if the DB instance class has less than 14 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE`. Also, `use_large_pages` evaluates to `FALSE`.

• For DB instance classes not mentioned in the table following, if the instance class has at least 14 GiB of memory and less than 100 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `TRUE` by default. Also, `use_large_pages` evaluates to `ONLY`. You can disable HugePages manually by setting `use_large_pages` to `FALSE`.

• For DB instance classes not mentioned in the table following, if the instance class has at least 100 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `TRUE`. Also, `use_large_pages` evaluates to `ONLY` and HugePages can't be disabled.

HugePages are not enabled by default for the following DB instance classes.

<table>
<thead>
<tr>
<th>DB instance class family</th>
<th>DB instance classes with HugePages not enabled by default</th>
</tr>
</thead>
<tbody>
<tr>
<td>db.m5</td>
<td>db.m5.large</td>
</tr>
<tr>
<td>db.m4</td>
<td>db.m4.large, db.m4.xlarge, db.m4.2xlarge, db.m4.4xlarge,</td>
</tr>
<tr>
<td></td>
<td>db.m4.10xlarge</td>
</tr>
<tr>
<td>db.t3</td>
<td>db.t3.micro, db.t3.small, db.t3.medium, db.t3.large</td>
</tr>
</tbody>
</table>

For more information about DB instance classes, see Hardware specifications for DB instance classes (p. 44).

To enable HugePages for new or existing DB instances manually, set the `use_large_pages` parameter to `ONLY`. You can't use HugePages with Oracle Automatic Memory Management (AMM). If you set the parameter `use_large_pages` to `ONLY`, then you must also set both `memory_target` and `memory_max_target` to 0. For more information about setting DB parameters for your DB instance, see Working with parameter groups (p. 278).

You can also set the `sga_target`, `sga_max_size`, and `pga_aggregate_target` parameters. When you set system global area (SGA) and program global area (PGA) memory parameters, add the values together. Subtract this total from the memory available to the database `DBInstanceClassMemory` to determine the free memory beyond the HugePages allocation. You must leave free memory of at least 2 GiB, or 10 percent of the total available instance memory, whichever is smaller.

After you configure your parameters, you must reboot your DB instance for the changes to take effect. For more information, see Rebooting a DB instance (p. 350).

**Note**
The Oracle DB instance defers changes to SGA-related initialization parameters until you reboot the instance without failover. In the Amazon RDS console, choose Reboot but do not choose **Reboot with failover**. In the AWS CLI, call the `reboot-db-instance` command with the `--no-force-failover` parameter. The DB instance does not process the SGA-related parameters during failover or during other maintenance operations that cause the instance to restart.

The following is a sample parameter configuration for HugePages that enables HugePages manually. You should set the values to meet your needs.
memory_target            = 0
memory_max_target        = 0
pga_aggregate_target     = {DBInstanceClassMemory*1/8}
sga_target               = {DBInstanceClassMemory*3/4}
sga_max_size             = {DBInstanceClassMemory*3/4}
use_large_pages          = ONLY

Assume the following parameters values are set in a parameter group.

memory_target            = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
memory_max_target        = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
pga_aggregate_target     = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*1/8}, 0)
sga_target               = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
sga_max_size             = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
use_large_pages          = {DBInstanceClassHugePagesDefault}

The parameter group is used by a db.r4 DB instance class with less than 100 GiB of memory. With these parameter settings and use_large_pages set to {DBInstanceClassHugePagesDefault}, HugePages are enabled on the db.r4 instance.

Consider another example with following parameters values set in a parameter group.

memory_target            = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
memory_max_target        = IF({DBInstanceClassHugePagesDefault}, 0, {DBInstanceClassMemory*3/4})
pga_aggregate_target     = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*1/8}, 0)
sga_target               = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
sga_max_size             = IF({DBInstanceClassHugePagesDefault}, {DBInstanceClassMemory*3/4}, 0)
use_large_pages          = FALSE

The parameter group is used by a db.r4 DB instance class and a db.r5 DB instance class, both with less than 100 GiB of memory. With these parameter settings, HugePages are disabled on the db.r4 and db.r5 instance.

Note
If this parameter group is used by a db.r4 DB instance class or db.r5 DB instance class with at least 100 GiB of memory, the FALSE setting for use_large_pages is overridden and set to ONLY. In this case, a customer notification regarding the override is sent.

After HugePages are active on your DB instance, you can view HugePages information by enabling enhanced monitoring. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 582).

Enabling extended data types

Amazon RDS Oracle Database 12c supports extended data types. With extended data types, the maximum size is 32,767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types. To use extended
data types, set the MAX_STRING_SIZE parameter to EXTENDED. For more information, see Extended data types in the Oracle documentation.

If you don't want to use extended data types, keep the MAX_STRING_SIZE parameter set to STANDARD (the default). When this parameter is set to STANDARD, the size limits are 4,000 bytes for the VARCHAR2 and NVARCHAR2 data types, and 2,000 bytes for the RAW data type.

You can enable extended data types on a new or existing DB instance. For new DB instances, DB instance creation time is typically longer when you enable extended data types. For existing DB instances, the DB instance is unavailable during the conversion process.

The following are considerations for a DB instance with extended data types enabled:

- When you enable extended data types for a DB instance, you can't change the DB instance back to use the standard size for data types. After a DB instance is converted to use extended data types, if you set the MAX_STRING_SIZE parameter back to STANDARD it results in the incompatible-parameters status.
- When you restore a DB instance that uses extended data types, you must specify a parameter group with the MAX_STRING_SIZE parameter set to EXTENDED. During restore, if you specify the default parameter group or any other parameter group with MAX_STRING_SIZE set to STANDARD it results in the incompatible-parameters status.
- We recommend that you don't enable extended data types for Oracle DB instances running on the t2.micro DB instance class.

When the DB instance status is incompatible-parameters because of the MAX_STRING_SIZE setting, the DB instance remains unavailable until you set the MAX_STRING_SIZE parameter to EXTENDED and reboot the DB instance.

**Enabling extended data types for a new DB instance**

**To enable extended data types for a new DB instance**

1. Set the MAX_STRING_SIZE parameter to EXTENDED in a parameter group.
   
   To set the parameter, you can either create a new parameter group or modify an existing parameter group.
   
   For more information, see Working with parameter groups (p. 278).

2. Create a new Amazon RDS Oracle DB instance, and associate the parameter group with MAX_STRING_SIZE set to EXTENDED with the DB instance.
   
   For more information, see Creating an Amazon RDS DB instance (p. 175).

**Enabling extended data types for an existing DB instance**

When you modify a DB instance to enable extended data types, the data in the database is converted to use the extended sizes. The DB instance is unavailable during the conversion. The amount of time it takes to convert the data depends on the DB instance class used by the DB instance and the size of the database.

**Note**

After you enable extended data types, you can't perform a point-in-time restore to a time during the conversion. You can restore to the time immediately before the conversion or after the conversion.

**To enable extended data types for an existing DB instance**

1. Take a snapshot of the database.
If there are invalid objects in the database, Amazon RDS tries to recompile them. The conversion to extended data types can fail if Amazon RDS can't recompile an invalid object. The snapshot enables you to restore the database if there is a problem with the conversion. Always check for invalid objects before conversion and fix or drop those invalid objects. For production databases, we recommend testing the conversion process on a copy of your DB instance first.

For more information, see Creating a DB snapshot (p. 428).

2. Set the MAX_STRING_SIZE parameter to EXTENDED in a parameter group.

To set the parameter, you can either create a new parameter group or modify an existing parameter group.

For more information, see Working with parameter groups (p. 278).

3. Modify the DB instance to associate it with the parameter group with MAX_STRING_SIZE set to EXTENDED.

For more information, see Modifying an Amazon RDS DB instance (p. 309).

4. Reboot the DB instance for the parameter change to take effect.

For more information, see Rebooting a DB instance (p. 350).
Importing data into Oracle on Amazon RDS

How you import data into an Amazon RDS DB instance depends on the following:

- The amount of data you have
- The number of database objects in your database
- The variety of database objects in your database

For example, use the following mechanisms:

- Oracle SQL Developer – Import a simple, 20 MB database.
- Oracle Data Pump – Import complex databases, or databases that are several hundred megabytes or several terabytes in size. You can use Amazon S3 in this task. For example, download Data Pump files from Amazon S3 to the DB instance. For more information, see Amazon S3 integration (p. 1452).
- AWS Database Migration Service (AWS DMS) – Migrate databases without downtime. For more information about AWS DMS, see What is AWS Database Migration Service and the blog post Migrating Oracle databases with near-zero downtime using AWS DMS.

Important
Before you use any of these migration techniques, we recommend that you back up your database. After you import the data, you can back up your Amazon RDS DB instances by creating snapshots. Later, you can restore the snapshots. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 406).

For many database engines, ongoing replication can continue until you are ready to switch over to the target database. You can migrate to Amazon RDS for Oracle from either the same database engine or a different database engine using AWS DMS. If you migrate from a different database engine, you can use the AWS Schema Conversion Tool to migrate schema objects that aren’t migrated by AWS DMS.

The following video summarizes the different Oracle Database migration techniques.

The following video explains how to plan and execute a data migration.

Topics
- Importing using Oracle SQL Developer (p. 1429)
- Importing using Oracle Data Pump (p. 1430)
- Oracle Export/Import utilities (p. 1439)
- Oracle SQL*Loader (p. 1440)
- Oracle materialized views (p. 1441)

Importing using Oracle SQL Developer

For small databases, you can use Oracle SQL Developer, a graphical Java tool distributed without cost by Oracle. You can install this tool on your desktop computer (Windows, Linux, or Mac) or on one of your servers. Oracle SQL Developer provides options for migrating data between two Oracle databases, or for migrating data from other databases, such as MySQL, to Oracle. Oracle SQL Developer is best suited for migrating small databases. We recommend that you read the Oracle SQL Developer product documentation before you begin migrating your data.

After you install SQL Developer, you can use it to connect to your source and target databases. Use the Database Copy command on the Tools menu to copy your data to your Amazon RDS instance.

Oracle also has documentation on how to migrate from other databases, including MySQL and SQL Server. For more information, see http://www.oracle.com/technetwork/database/migration in the Oracle documentation.

**Importing using Oracle Data Pump**

Oracle Data Pump is a long-term replacement for the Oracle Export/Import utilities. Oracle Data Pump is the preferred way to move large amounts of data from an Oracle installation to an Amazon RDS DB instance. You can use Oracle Data Pump for several scenarios:

- Import data from an Oracle database (either on-premises or Amazon EC2 instance) to an Amazon RDS for Oracle DB instance.
- Import data from an RDS for Oracle DB instance to an Oracle database (either on-premises or Amazon EC2 instance).
- Import data between RDS for Oracle DB instances (for example, to migrate data from EC2-Classic to VPC).

To download Oracle Data Pump utilities, see Oracle database software downloads on the Oracle Technology Network website.

For compatibility considerations when migrating between versions of Oracle Database, see the Oracle documentation.

When you import data with Oracle Data Pump, you must transfer the dump file that contains the data from the source database to the target database. You can transfer the dump file using an Amazon S3 bucket or by using a database link between the two databases.

When you use Oracle Data Pump to import data into an Oracle DB instance, we recommend the following best practices:

- Perform imports in schema or table mode to import specific schemas and objects.
- Limit the schemas you import to those required by your application.
- Don't import in full mode.

Because Amazon RDS for Oracle does not allow access to SYS or SYSDBA administrative users, importing in full mode, or importing schemas for Oracle-maintained components, might damage the Oracle data dictionary and affect the stability of your database.

- When loading large amounts of data, do the following:
  1. Transfer the dump file to the target Amazon RDS for Oracle DB instance.
  2. Take a DB snapshot of your instance.
  3. Test the import to verify that it succeeds.

  If database components are invalidated, you can delete the DB instance and re-create it from the DB snapshot. The restored DB instance includes any dump files staged on the DB instance when you took the DB snapshot.

- Don't import dump files that were created using the Oracle Data Pump export parameters TRANSPORT_TABLESPACES, TRANSPORTABLE, or TRANSPORT_FULL_CHECK. Amazon RDS for Oracle DB instances don't support importing these dump files.

- Don't import dump files that contain Oracle Scheduler objects in SYS, SYSTEM, RDSADMIN, RDSSEC, and RDS_DATAGUARD, and belong to the following categories:
Amazon RDS for Oracle DB instances don't support importing these dump files.

**Note**

To exclude unsupported Scheduler objects, use additional directives during the Data Pump export. If you use `DBMS_DATAPUMP`, add an additional `METADATA_FILTER` before the `DBMS_METADATA.START_JOB`:

```sql
DBMS_DATAPUMP.METADATA_FILTER(
  v_hdln,
  'EXCLUDE_NAME_EXPR',
  q'[IN (SELECT NAME FROM SYS.OBJ$
      WHERE TYPE# IN (66,67,74,79,59,62,46)
      AND OWNER# IN
      (SELECT USER# FROM SYS.USER$
        WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
      )
    )',
   'PROCOBJ'
);
```

If you use `expdp`, create a parameter file that contains the exclude directive shown in the following example. Then use `PARFILE=parameter_file` with your `expdp` command.

```sql
exclude=procobj:"IN
 (SELECT NAME FROM sys.OBJ$
  WHERE TYPE# IN (66,67,74,79,59,62,46)
  AND OWNER# IN
  (SELECT USER# FROM SYS.USER$
    WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
  )
 )"
```

The examples in this section show one way to import data into an Oracle database. However, Oracle Data Pump permits many ways to import data. To learn more about Oracle Data Pump, see the Oracle Database documentation.

The examples in this section use the `DBMS_DATAPUMP` package. The same tasks can be accomplished by using the Oracle Data Pump command line utilities `impdp` and `expdp`. You can install these utilities on a remote host as part of an Oracle Client installation, including Oracle Instant Client.

**Topics**

- Importing data with Oracle Data Pump and an Amazon S3 bucket (p. 1432)
- Importing data with Oracle Data Pump and a database link (p. 1435)
Importing data with Oracle Data Pump and an Amazon S3 bucket

The following import process uses Oracle Data Pump and an Amazon S3 bucket. The process exports data on the source database using the Oracle DBMS_DATAPUMP package and puts the dump file in an Amazon S3 bucket. It then downloads the dump file from the Amazon S3 bucket to the DATA_PUMP_DIR directory on the target Amazon RDS for Oracle DB instance. The final step imports the data from the copied dump file into the Amazon RDS for Oracle DB instance using the package DBMS_DATAPUMP.

The process has the following requirements:

- You must have an Amazon S3 bucket available for file transfers, and the Amazon S3 bucket must be in the same AWS Region as the DB instance. For instructions, see Create a bucket in the Amazon Simple Storage Service Getting Started Guide.
- The object that you upload into the Amazon S3 bucket must be 5 TB or less. For more information about working with objects in Amazon S3, see Amazon Simple Storage Service User Guide.

Note
If you dump file exceeds 5 TB, you can run the Oracle Data Pump export with the parallel option. This operation spreads the data into multiple dump files so that you do not exceed the 5 TB limit for individual files.

- You must prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in Configuring IAM permissions for Amazon RDS for Oracle integration with Amazon S3 (p. 1452).
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

Note
This process imports a dump file into the DATA_PUMP_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA_PUMP_DIR directory. To remove the imported dump file, use UTL_FILE.FREMOVE, found on the Oracle website.

The import process using Oracle Data Pump and an Amazon S3 bucket has the following steps.

Topics
- Step 1: Grant privileges to the user on the Amazon RDS target instance (p. 1432)
- Step 2: Use DBMS_DATAPUMP to create a dump file (p. 1433)
- Step 3: Upload the dump file to your Amazon S3 bucket (p. 1434)
- Step 4: Copy the exported dump file from the Amazon S3 bucket to the target DB instance (p. 1434)
- Step 5: Use DBMS_DATAPUMP to import the data file on the target DB instance (p. 1434)
- Step 6: Clean up (p. 1435)

Step 1: Grant privileges to the user on the Amazon RDS target instance

To grant privileges to the user on the RDS target instance, take the following steps:

1. Use SQL Plus or Oracle SQL Developer to connect to the Amazon RDS target Oracle DB instance into which the data will be imported. Connect as the Amazon RDS master user. For information about connecting to the DB instance, see Connecting to your Oracle DB instance (p. 1312).
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces (p. 1367).
3. If the user account into which the data is imported doesn't exist, create the user account and grant the necessary permissions and roles. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following commands create a new user and grant the necessary permissions and roles to import the data into the user’s schema.

```
CREATE USER schema_1 IDENTIFIED BY <password>;
GRANT CREATE SESSION, RESOURCE TO schema_1;
ALTER USER schema_1 QUOTA 100M ON users;
```

This example grants the new user the `CREATE SESSION` privilege and the `RESOURCE` role. Additional privileges and roles might be required depending on the database objects that you import.

**Note**
Replace `schema_1` with the name of your schema in this step and in the following steps.

**Step 2: Use DBMS_DATAPUMP to create a dump file**

Use SQL Plus or Oracle SQL Developer to connect to the source Oracle instance with an administrative user. If the source database is an Amazon RDS for Oracle DB instance, connect with the Amazon RDS master user. Next, use the Oracle Data Pump utility to create a dump file.

The following script creates a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory that contains the `SCHEMA_1` schema. Replace `SCHEMA_1` with the name of the schema that you want to export.

```
DECLARE
  v_hdnl NUMBER;
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT',
    job_mode  => 'SCHEMA',
    job_name  => null
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_dump_file
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample_exp.log',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_log_file
  );
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''
    SCHEMA_1'' )');
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'EXCLUDE_NAME_EXPR',
    q'[[IN (SELECT NAME FROM sys.OBJ$
        WHERE TYPE# IN (66,67,74,79,59,62,46)
        AND OWNER# IN
        (SELECT USER# FROM SYS.USER$
            WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
            )
        )]
    ]'',
    'PROCOBJ'
  );
```

DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/

Note
Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the export log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1420).

Step 3: Upload the dump file to your Amazon S3 bucket

Upload the dump file to the Amazon S3 bucket.

Use the Amazon RDS procedure rdsadmin.rdsadmin_s3_tasks.upload_to_s3 to copy the dump file to the Amazon S3 bucket. The following example uploads all of the files from the DATA_PUMP_DIR directory to an Amazon S3 bucket named mys3bucket.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name   =>  'mys3bucket',
    p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type.

For more information, see Uploading files from an Oracle DB instance to an Amazon S3 bucket (p. 1459).

Step 4: Copy the exported dump file from the Amazon S3 bucket to the target DB instance

Use SQL Plus or Oracle SQL Developer to connect to the Amazon RDS target Oracle DB instance. Next, use the Amazon RDS procedure rdsadmin.rdsadmin_s3_tasks.download_from_s3 to copy the dump file from the Amazon S3 bucket to the target DB instance. The following example downloads all of the files from an Amazon S3 bucket named mys3bucket to the DATA_PUMP_DIR directory.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name   =>  'mys3bucket',
    p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type.

For more information, see Downloading files from an Amazon S3 bucket to an Oracle DB instance (p. 1461).

Step 5: Use DBMS_DATAPUMP to import the data file on the target DB instance

Use Oracle Data Pump to import the schema in the DB instance. Additional options such as METADATA_REMAP might be required.

Connect to the DB instance with the Amazon RDS master user account to perform the import.

```
DECLARE
    v_hdnl NUMBER;
BEGIN
    v_hdnl := DBMS_DATAPUMP.OPEN(
        operation => 'IMPORT',
        job_mode  => 'SCHEMA',
        job_name  => 'import_job',
        job_status => 'RUNNING',
        job_type  => 'FULL',
        job_priority => 'NORMAL',
        job_retention => '60',
        job_copies => 1,
        job_server => 'host1',
        job_process => 'process1',
        job_dsn => 'mydsn',
        job_username => 'myuser',
        job_password => 'mypassword'
    );
END;
/
```
job_name => null);
DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdln,
    filename  => 'sample_copied.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
DBMS_DATAPUMP.ADD_FILE(
    handle    => v_hdln,
    filename  => 'sample_imp.log',
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_log_file);
DBMS_DATAPUMP.METADATA_FILTER(v_hdln,'SCHEMA_EXPR','IN (''
    SCHEMA_1''')');
DBMS_DATAPUMP.START_JOB(v_hdln);
END;
/

Note
Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1420).

You can verify the data import by viewing the user's tables on the DB instance. For example, the following query returns the number of tables for SCHEMA_1.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 6: Clean up
After the data has been imported, you can delete the files that you don't want to keep. You can list the files in the DATA_PUMP_DIR using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

To delete files in the DATA_PUMP_DIR that you no longer require, use the following command.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','<file name>');
```

For example, the following command deletes the file named "sample_copied.dmp".

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

Importing data with Oracle Data Pump and a database link
The following import process uses Oracle Data Pump and the Oracle DBMS_FILE_TRANSFER package. The process connects to a source Oracle instance, which can be an on-premises or Amazon EC2 instance, or an Amazon RDS for Oracle DB instance. The process then exports data using the DBMS_DATAPUMP package. Next, it uses the DBMS_FILE_TRANSFER.PUT_FILE method to copy the dump file from the Oracle instance to the DATA_PUMP_DIR directory on the target Amazon RDS for Oracle DB instance that is connected using a database link. The final step imports the data from the copied dump file into the Amazon RDS for Oracle DB instance using the DBMS_DATAPUMP package.

The process has the following requirements:

- You must have execute privileges on the DBMS_FILE_TRANSFER and DBMS_DATAPUMP packages.
- You must have write privileges to the DATA_PUMP_DIR directory on the source DB instance.
• You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

Note
This process imports a dump file into the `DATA_PUMP_DIR` directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the `DATA_PUMP_DIR` directory. To remove the imported dump file, use `UTL_FILE.FREMOVE`, found on the Oracle website.

The import process using Oracle Data Pump and the `DBMS_FILE_TRANSFER` package has the following steps.

Topics
• Step 1: Grant privileges to the user on the Amazon RDS target instance (p. 1436)
• Step 2: Grant privileges to the user on the source database (p. 1436)
• Step 3: Use `DBMS_DATAPUMP` to create a dump file (p. 1437)
• Step 4: Create a database link to the target DB instance (p. 1438)
• Step 5: Use `DBMS_FILE_TRANSFER` to copy the exported dump file to the target DB instance (p. 1438)
• Step 6: Use `DBMS_DATAPUMP` to import the data file to the target DB instance (p. 1438)
• Step 7: Clean up (p. 1439)

Step 1: Grant privileges to the user on the Amazon RDS target instance

To grant privileges to the user on the RDS target instance, take the following steps:

1. Use SQL Plus or Oracle SQL Developer to connect to the Amazon RDS target Oracle DB instance into which the data will be imported. Connect as the Amazon RDS master user. For information about connecting to the DB instance, see Connecting to your Oracle DB instance (p. 1312).
2. Create the required tablespaces before you import the data. For more information, see Creating and sizing tablespaces (p. 1367).
3. If the user account into which the data is imported doesn't exist, create the user account and grant the necessary permissions and roles. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following commands create a new user and grant the necessary permissions and roles to import the data into the user's schema.

```sql
CREATE USER schema_1 IDENTIFIED BY <password>;
GRANT CREATE SESSION, RESOURCE TO schema_1;
ALTER USER schema_1 QUOTA 100M ON users;
```

This example grants the new user the `CREATE SESSION` privilege and the `RESOURCE` role. Additional privileges and roles might be required depending on the database objects that you import.

Note
Replace `schema_1` with the name of your schema in this step and in the following steps.

Step 2: Grant privileges to the user on the source database

Use SQL*Plus or Oracle SQL Developer to connect to the Oracle instance that contains the data to be imported. If necessary, create a user account and grant the necessary permissions.
Note
If the source database is an Amazon RDS instance, you can skip this step. You use your Amazon RDS master user account to perform the export.

The following commands create a new user and grant the necessary permissions.

```sql
CREATE USER export_user IDENTIFIED BY <password>;
GRANT CREATE SESSION, CREATE TABLE, CREATE DATABASE LINK TO export_user;
ALTER USER export_user QUOTA 100M ON users;
GRANT READ, WRITE ON DIRECTORY data_pump_dir TO export_user;
GRANT EXECUTE ON DBMS_DATAPUMP TO export_user;
GRANT EXECUTE ON DBMS_FILE_TRANSFER TO export_user;
```

Step 3: Use DBMS_DATAPUMP to create a dump file

Use SQL Plus or Oracle SQL Developer to connect to the source Oracle instance with an administrative user or with the user you created in step 2. If the source database is an Amazon RDS for Oracle DB instance, connect with the Amazon RDS master user. Next, use the Oracle Data Pump utility to create a dump file.

The following script creates a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory.

```sql
DECLARE
  v_hdl NUMBER;
BEGIN
  v_hdl := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT',
    job_mode => 'SCHEMA',
    job_name => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdl,
    filename => 'sample.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdl,
    filename => 'sample_exp.log',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdl, 'SCHEMA_EXPR', 'IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdl, 'EXCLUDE_NAME_EXPR', 
    q'[IN (SELECT NAME FROM sys.OBJ$
      WHERE TYPE# IN (66,67,74,79,59,62,46)
      AND OWNER# IN
        (SELECT USER# FROM SYS.USER$
          WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
          )
        )', 'PROCOBJ']);
  DBMS_DATAPUMP.START_JOB(v_hdl);
END;
```
Note
Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the export log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1420).

Step 4: Create a database link to the target DB instance

Create a database link between your source instance and your target DB instance. Your local Oracle instance must have network connectivity to the DB instance in order to create a database link and to transfer your export dump file.

Perform this step connected with the same user account as the previous step.

If you are creating a database link between two DB instances inside the same VPC or peered VPCs, the two DB instances should have a valid route between them. The security group of each DB instance must allow ingress to and egress from the other DB instance. The security group inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see Adjusting database links for use with DB instances in a VPC (p. 1375).

The following command creates a database link named to_rds that connects to the Amazon RDS master user at the target DB instance.

```
CREATE DATABASE LINK to_rds
    CONNECT TO <master_user_account>
    IDENTIFIED BY <password>
    USING '(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<dns or ip address of remote db>)
                   (PORT=<listener port>))(CONNECT_DATA=(SID=<remote SID>)))';
```

Step 5: Use DBMS_FILE_TRANSFER to copy the exported dump file to the target DB instance

Use DBMS_FILE_TRANSFER to copy the dump file from the source database instance to the target DB instance. The following script copies a dump file named sample.dmp from the source instance to a target database link named to_rds (created in the previous step).

```
BEGIN
    DBMS_FILE_TRANSFER.PUT_FILE(
        source_directory_object       => 'DATA_PUMP_DIR',
        source_file_name              => 'sample.dmp',
        destination_directory_object  => 'DATA_PUMP_DIR',
        destination_file_name         => 'sample_copied.dmp',
        destination_database          => 'to_rds');
END;
/
```

Step 6: Use DBMS_DATAPUMP to import the data file to the target DB instance

Use Oracle Data Pump to import the schema in the DB instance. Additional options such as METADATA_REMAP might be required.

Connect to the DB instance with the Amazon RDS master user account to perform the import.

```
DECLARE
    v_hdnl NUMBER;
```
BEGIN
  v_hdnl := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample_copied.dmp',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle => v_hdnl,
    filename => 'sample_imp.log',
    directory => 'DATA_PUMP_DIR',
    filetype => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdnl,'SCHEMA_EXPR','IN (''
SCHEMA_1'' )');
  DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/

Note
Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see Monitoring job status in the Oracle documentation. You can view the contents of the import log by using the rdsadmin.rds_file_util.read_text_file procedure. For more information, see Reading files in a DB instance directory (p. 1420).

You can verify the data import by viewing the user's tables on the DB instance. For example, the following query returns the number of tables for schema_1.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

Step 7: Clean up

After the data has been imported, you can delete the files that you don't want to keep. You can list the files in DATA_PUMP_DIR using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

To delete files in DATA_PUMP_DIR that you no longer require, use the following command.

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','<file name>');
```

For example, the following command deletes the file named "sample_copied.dmp".

```
EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample_copied.dmp');
```

Oracle Export/Import utilities

The Oracle Export/Import utilities are best suited for migrations where the data size is small and data types such as binary float and double are not required. The import process creates the schema objects so you do not need to run a script to create them beforehand, making this process well suited for databases with small tables. The following example demonstrates how these utilities can be used to export and import specific tables.

Export the tables from the source database using the command below. Substitute username/password as appropriate.

```
exp cust_dba@ORCL FILE=exp_file.dmp TABLES=(tab1,tab2,tab3) LOG=exp_file.log
```

The export process creates a binary dump file that contains both the schema and data for the specified tables. Now this schema and data can be imported into a target database using the command:

```
imp cust_dba@targetdb FROMUSER=cust_schema TOUSER=cust_schema \
   TABLES=(tab1,tab2,tab3) FILE=exp_file.dmp LOG=imp_file.log
```

There are other variations of the Export and Import commands that might be better suited to your needs. See Oracle's documentation for full details.

**Oracle SQL*Loader**

Oracle SQL*Loader is well suited for large databases that have a limited number of objects in them. Since the process involved in exporting from a source database and loading to a target database is very specific to the schema, the following example creates the sample schema objects, exports from a source, and then loads it into a target database.

1. Create a sample source table using the command below.

```
CREATE TABLE customer_0 TABLESPACE users
   AS (SELECT ROWNUM id, o.*
       FROM   ALL_OBJECTS o, ALL_OBJECTS x
       WHERE  ROWNUM <= 1000000);
```

2. On the target Amazon RDS instance, create a destination table that is used to load the data. The clause `WHERE 1=2` ensures that you copy the structure of `ALL_OBJECTS`, but don't copy any of the rows.

```
CREATE TABLE customer_1 TABLESPACE users
   AS (SELECT 0 AS ID, OWNER, OBJECT_NAME, CREATED
       FROM   ALL_OBJECTS
       WHERE  1=2);
```

3. The data is exported from the source database to a flat file with delimiters. This example uses SQL*Plus for this purpose. For your data, you will likely need to generate a script that does the export for all the objects in the database.

```
ALTER SESSION SET NLS_DATE_FORMAT = 'YYYY/MM/DD HH24:MI:SS'

SET LINESIZE 800 HEADING OFF FEEDBACK OFF ARRAY 5000 PAGESIZE 0
SPOOL customer_0.out
SET MARKUP HTML PREFORMAT ON
SET COLUMSP ','
SELECT id, owner, object_name, created
FROM   customer_0;
SPOOL OFF
```

4. You need to create a control file to describe the data. Again, depending on your data, you need to build a script that does this step.
cat << EOF > sqlldr_1.ctl
load data
infile customer_0.out
into table customer_1
APPEND
fields terminated by "," optionally enclosed by ""
(
    id           POSITION(01:10)    INTEGER EXTERNAL,
    owner        POSITION(12:41)    CHAR,
    object_name  POSITION(43:72)    CHAR,
    created      POSITION(74:92)    date "YYYY/MM/DD HH24:MI:SS"
)
EOF

If needed, copy the files generated by the preceding code to a staging area, such as an Amazon EC2 instance.

5. Finally, import the data using SQL*Loader with the appropriate username and password for the target database.

    sqlldr cust_dba@targetdb CONTROL=sqlldr_1.ctl BINDSIZE=10485760 READSIZE=10485760 ROWS=1000

Oracle materialized views

You can also make use of Oracle materialized view replication to migrate large datasets efficiently. Replication allows you to keep the target tables in sync with the source on an ongoing basis, so the actual cutover to Amazon RDS can be done later, if needed. The replication is set up using a database link from the Amazon RDS instance to the source database.

One requirement for materialized views is to allow access from the target database to the source database. In the following example, access rules were enabled on the source database to allow the Amazon RDS target database to connect to the source over SQLNet.

1. Create a user account on both source and Amazon RDS target instances that can authenticate with the same password.

    CREATE USER dblink_user IDENTIFIED BY <password>
    DEFAULT TABLESPACE users
    TEMPORARY TABLESPACE temp;
    GRANT CREATE SESSION TO dblink_user;
    GRANT SELECT ANY TABLE TO dblink_user;
    GRANT SELECT ANY DICTIONARY TO dblink_user;

2. Create a database link from the Amazon RDS target instance to the source instance using the newly created dblink_user.

    CREATE DATABASE LINK remote_site
    CONNECT TO dblink_user IDENTIFIED BY <password>
    USING 'description=(address=(protocol=tcp) (host=<myhost>)
    (port=<listener port>)) (connect_data=(sid=<sourcedb sid>))';

3. Test the link:

    SELECT * FROM V$INSTANCE@remote_site;
4. Create a sample table with primary key and materialized view log on the source instance.

```sql
CREATE TABLE customer_0 TABLESPACE users AS (SELECT ROWNUM id, o.* FROM ALL_OBJECTS o, ALL_OBJECTS x WHERE ROWNUM <= 1000000);
ALTER TABLE customer_0 ADD CONSTRAINT pk_customer_0 PRIMARY KEY (id) USING INDEX;
CREATE MATERIALIZED VIEW LOG ON customer_0;
```

5. On the target Amazon RDS instance, create a materialized view.

```sql
CREATE MATERIALIZED VIEW customer_0
BUILD IMMEDIATE REFRESH FAST
AS (SELECT * FROM cust_dba.customer_0@remote_site);
```

6. On the target Amazon RDS instance, refresh the materialized view.

```sql
EXEC DBMS_MV.REFRESH('CUSTOMER_0', 'f');
```

7. Drop the materialized view and include the PRESERVE TABLE clause to retain the materialized view container table and its contents.

```sql
DROP MATERIALIZED VIEW customer_0 PRESERVE TABLE;
```

The retained table has the same name as the dropped materialized view.
Working with Oracle replicas for Amazon RDS

To configure replication between Oracle DB instances, you can create replica databases. For an overview of Amazon RDS read replicas, see Overview of Amazon RDS read replicas (p. 356). For a summary of the differences between Oracle replicas and other DB engines, see Differences between read replicas for different DB engines (p. 357).

Topics
- Overview of Oracle replicas (p. 1443)
- Replica requirements for Oracle (p. 1444)
- Preparing to create an Oracle replica (p. 1446)
- Creating an Oracle replica in mounted mode (p. 1447)
- Modifying the Oracle replica mode (p. 1448)
- Troubleshooting Oracle replicas (p. 1449)

Overview of Oracle replicas

An Oracle replica database is a physical copy of your primary database. An Oracle replica in read-only mode is called a read replica. An Oracle replica in mounted mode is called a mounted replica. Oracle Database doesn't permit writes in a replica, but you can promote a replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.

The following video provides a helpful overview of Oracle disaster recovery. For more information, see the blog post Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups and Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups.

Topics
- Archived log retention (p. 1443)
- Read-only and mounted replicas (p. 1443)
- Outages during replication (p. 1444)

Archived log retention

If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of transaction logs on the source DB instance. This is true regardless of the setting for archiverlog retention hours in rdsadmin.rdsadmin_util.set_configuration. RDS purges logs from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. RDS purges logs from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database.

In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas. For information about rdsadmin.rdsadmin_util.set_configuration, see Retaining archived redo logs (p. 1386).

Read-only and mounted replicas

When creating or modifying an Oracle replica, you can place it in either of the following modes:

Read-only

This is the default. Active Data Guard transmits and applies changes from the source database to all read replica databases.
You can create up to five read replicas from one source DB instance. For general information about read replicas that applies to all DB engines, see Working with read replicas (p. 354). For information about Oracle Data Guard, see Oracle data guard concepts and administration in the Oracle documentation.

Mounted

In this case, replication uses Oracle Data Guard, but the replica database doesn't accept user connections. The primary use for mounted replicas is cross-Region disaster recovery.

A mounted replica can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them, regardless of the archived log retention policy.

You can create a combination of mounted and read-only DB replicas for the same source DB instance. You can change a read-only replica to mounted mode, or change a mounted replica to read-only mode. In either case, the Oracle database preserves the archived log retention setting.

Outages during replication

When you create an Oracle replica, no outage occurs for the source DB instance. Amazon RDS takes a snapshot of the source DB instance. This snapshot becomes the replica. Amazon RDS sets the necessary parameters and permissions for the source DB and replica without service interruption. Similarly, if you delete a replica, no outage occurs.

Replica requirements for Oracle

Before creating an Oracle replica, check the following requirements.

Topics

- Version and licensing requirements for Oracle replicas (p. 1444)
- Option requirements and restrictions for Oracle replicas (p. 1445)
- Miscellaneous requirements and restrictions for Oracle replicas (p. 1445)

Version and licensing requirements for Oracle replicas

Before creating an Oracle replica, check the following version and licensing requirements:

- If the replica is in read-only mode, make sure that you have an Active Data Guard license. If you place the replica in mounted mode, you don't need an Active Data Guard license. Only the Oracle DB engine supports mounted replicas.
- Oracle replicas are only available on the Oracle Enterprise Edition (EE) engine.
- Oracle replicas are available for instances created using version Oracle Database 12c Release 1 (12.1.0.2.v10) and higher 12c releases, and for non-CDB instances of Oracle Database 19c. Replicas of CDBs aren't supported.
- Oracle replicas are available for DB instances only on the EC2-VPC platform.
- Oracle replicas are available for DB instances running only on DB instance classes with two or more vCPUs. A source DB instance can't use the db.t3.micro or db.t3.small instance classes.
- The Oracle DB engine version of the source DB instance and all of its replicas must be the same. Amazon RDS upgrades the replicas immediately after upgrading the source DB instance, regardless of a replica's maintenance window. For major version upgrades of cross-Region replicas, Amazon RDS automatically does the following:
  - Generates an option group for the target version.
  - Copies all options and option settings from the original option group to the new option group.
  - Associates the upgraded cross-Region replica with the new option group.
Option requirements and restrictions for Oracle replicas

Before creating a replica for Oracle, check the requirements and restrictions for option groups:

- If your Oracle replica is in the same AWS Region as its source DB instance, make sure that it belongs to the same option group as the source DB instance. Modifications to the source option group or source option group membership propagate to replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

For more information about option groups, see Working with option groups (p. 262).

- When you create an Oracle cross-Region replica, Amazon RDS creates a dedicated option group for it. You can't remove an Oracle cross-Region replica from its dedicated option group. No other DB instances can use the dedicated option group for an Oracle cross-Region replica.

You can only add or remove the following nonreplicated options from a dedicated option group:
- `NATIVE_NETWORK_ENCRYPTION`
- `OEM`
- `OEM_AGENT`
- `SSL`

To add other options to an Oracle cross-Region replica, add them to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas. For licensed options, make sure that there are sufficient licenses for the replicas.

When you promote an Oracle cross-Region replica, the promoted replica behaves the same as other Oracle DB instances, including the management of its options. You can promote a replica explicitly or implicitly by deleting its source DB instance.

For more information about option groups, see Working with option groups (p. 262).

Miscellaneous requirements and restrictions for Oracle replicas

Before creating an Oracle replica, check the following miscellaneous requirements and restrictions:

- You can't create manual snapshots of Amazon RDS for Oracle read replicas or enable automatic backups for them.
- If a DB instance is a source for one or more cross-Region replicas, the source DB retains its archived redo logs until they are applied on all cross-Region replicas. The archived redo logs might result in increased storage consumption.
- A logon trigger on a primary instance must permit access to the `RDS_DATAGUARD` user and to any user whose `AUTHENTICATED_IDENTITY` value is `RDS_DATAGUARD` or `rdsdb`. Also, the trigger must not set the current schema for the `RDS_DATAGUARD` user.
- To avoid disrupting RDS automation, system triggers must permit specific users to log on to the primary and replica database. System triggers include DDL, logon, and database role triggers. We recommend that you add code to your triggers to exclude the users listed in the following sample code:

```
-- Determine who the user is
```
Preparing to create an Oracle replica

Before you can begin using your replica, perform the following tasks.

Topics

- Enabling automatic backups (p. 1446)
- Enabling force logging mode (p. 1446)
- Changing your logging configuration (p. 1446)
- Setting the MAX_STRING_SIZE parameter (p. 1447)
- Planning compute and storage resources (p. 1447)

Enabling automatic backups

Before a DB instance can serve as a source DB instance, make sure to enable automatic backups on the source DB instance. To learn how to perform this procedure, see Enabling automated backups (p. 409).

Enabling force logging mode

We recommend that you enable force logging mode. In force logging mode, the Oracle database writes redo records even when NOLOGGING is used with data definition language (DDL) statements.

To enable force logging mode

1. Log in to your Oracle database using a client tool such as SQL Developer.
2. Enable force logging mode by running the following procedure.

   ```sql
   exec rdsadmin.rdsadmin_util.force_logging(p_enable => true);
   ```

   For more information about this procedure, see Setting force logging (p. 1382).

Changing your logging configuration

If you want to change your logging configuration, we recommend that you complete the changes before making a DB instance the source for replicas. Also, we recommend that you not modify the logging configuration after you create the replicas. Modifications can cause the online redo logging configuration to get out of sync with the standby logging configuration.

Modify the logging configuration for a DB instance by using the Amazon RDS procedures `rdsadmin.rdsadmin_util.add_logfile` and `rdsadmin.rdsadmin_util.drop_logfile`. For more information, see Adding online redo logs (p. 1384) and Dropping online redo logs (p. 1384).
**Setting the MAX_STRING_SIZE parameter**

Before you create an Oracle replica, ensure that the setting of the MAX_STRING_SIZE parameter is the same on the source DB instance and the replica. You can do this by associating them with the same parameter group. If you have different parameter groups for the source and the replica, you can set MAX_STRING_SIZE to the same value. For more information about setting this parameter, see Enabling extended data types for a new DB instance (p. 1427).

**Planning compute and storage resources**

Ensure that the source DB instance and its replicas are sized properly, in terms of compute and storage, to suit their operational load. If a replica reaches compute, network, or storage resource capacity, the replica stops receiving or applying changes from its source. Amazon RDS for Oracle doesn't intervene to mitigate high replica lag between a source DB instance and its replicas. You can modify the storage and CPU resources of a replica independently from its source and other replicas.

**Creating an Oracle replica in mounted mode**

By default, Oracle replicas are read-only. To create a replica in mounted mode, use the console, the AWS CLI, or the RDS API.

**Console**

To create a mounted replica from a source Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Oracle DB instance that you want to use as the source for a mounted replica.
4. For Actions, choose Create replica.
5. For Replica mode, choose Mounted.
6. Choose the settings that you want to use. For DB instance identifier, enter a name for the read replica. Adjust other settings as needed.
7. For Regions, choose the Region where the mounted replica will be launched.
8. Choose your instance size and storage type. We recommend that you use the same DB instance class and storage type as the source DB instance for the read replica.
9. For Multi-AZ deployment, choose Create a standby instance to create a standby of your replica in another Availability Zone for failover support for the mounted replica. Creating your mounted replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
10. Choose the other settings that you want to use.
11. Choose Create replica.

In the Databases page, the mounted replica has the role Replica.

**AWS CLI**

To create an Oracle replica in mounted mode, set --replica-mode to mounted in the AWS CLI command create-db-instance-read-replica.

**Example**

For Linux, macOS, or Unix:
Modifying the Oracle replica mode

To change a read-only replica to a mounted state, set --replica-mode to mounted in the AWS CLI command `modify-db-instance`. To place a mounted replica in read-only mode, set --replica-mode to open-read-only.

**RDS API**

To create an Oracle replica in mounted mode, specify ReplicaMode=mounted in the RDS API operation `CreateDBInstanceReadReplica`.

**Modifying the Oracle replica mode**

To change the replica mode of an existing replica, use the console, AWS CLI, or RDS API. When you change to mounted mode, the replica disconnects all active connections. When you change to read-only mode, Amazon RDS initializes Active Data Guard.

The change operation can take a few minutes. During the operation, the DB instance status changes to modifying. For more information about status changes, see Viewing Amazon RDS DB instance status (p. 497).

**Console**

To change the replica mode of an Oracle replica from mounted to read-only

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/
2. In the navigation pane, choose Databases.
3. Choose the mounted replica database.
4. Choose Modify.
5. For Replica mode, choose Read-only.
6. Choose the other settings that you want to change.
7. Choose Continue.
8. For Scheduling of modifications, choose Apply immediately.
9. Choose Modify DB instance.

**AWS CLI**

To change a read replica to mounted mode, set --replica-mode to mounted in the AWS CLI command `modify-db-instance`. To change a mounted replica to read-only mode, set --replica-mode to open-read-only.

**Example**

For Linux, macOS, or Unix:
aws rds modify-db-instance \ 
   --db-instance-identifier myreadreplica \ 
   --replica-mode mode

For Windows:

aws rds modify-db-instance ^
   --db-instance-identifier myreadreplica ^
   --replica-mode mode

**RDS API**

To change a read-only replica to mounted mode, set ReplicaMode=mounted in ModifyDBInstance. To change a mounted replica to read-only mode, set ReplicaMode=read-only.

**Troubleshooting Oracle replicas**

This section describes possible replication problems and solutions.

**Replication lag**

To monitor replication lag in Amazon CloudWatch, view the Amazon RDS ReplicaLag metric. For information about replication lag time, see Monitoring read replication (p. 364).

If replication lag is too long, query the following views:

- **V$ARCHIVED_LOG** – Shows which commits have been applied to the read replica.
- **V$DATAGUARD_STATS** – Shows a detailed breakdown of the components that make up the replicaLag metric.
- **V$DATAGUARD_STATUS** – Shows the log output from Oracle's internal replication processes.

**Replication failure after adding or modifying triggers**

If you add or modify any triggers, and if replication fails afterward, the problem may be the triggers. Ensure that the trigger excludes the following user accounts, which are required by RDS for replication:

- User accounts with administrator privileges
- SYS
- SYSTEM
- RDS_DATAGUARD
- rdsdb

For more information, see Miscellaneous requirements and restrictions for Oracle replicas (p. 1445).
Adding options to Oracle DB instances

In Amazon RDS, an option is an additional feature. Following, you can find a description of options that you can add to Amazon RDS instances running the Oracle DB engine.

Topics
- Overview of Oracle DB options (p. 1450)
- Amazon S3 integration (p. 1452)
- Oracle Application Express (APEX) (p. 1465)
- Oracle Java virtual machine (p. 1476)
- Oracle Enterprise Manager (p. 1479)
- Oracle Label Security (p. 1494)
- Oracle Locator (p. 1497)
- Oracle Multimedia (p. 1500)
- Oracle native network encryption (p. 1503)
- Oracle OLAP (p. 1511)
- Oracle Secure Sockets Layer (p. 1514)
- Oracle Spatial (p. 1521)
- Oracle SQLT (p. 1524)
- Oracle Statspack (p. 1530)
- Oracle time zone (p. 1533)
- Oracle time zone file autoupgrade (p. 1537)
- Oracle Transparent Data Encryption (p. 1542)
- Oracle UTL_MAIL (p. 1544)
- Oracle XML DB (p. 1547)

Overview of Oracle DB options

To enable options for your Oracle database, add them to an option group, and then associate the option group with your DB instance. For more information, see Working with option groups (p. 262).

Topics
- Summary of Oracle Database options (p. 1450)
- Options supported for different editions (p. 1451)
- Memory requirements for specific options (p. 1451)

Summary of Oracle Database options

You can add the following options for Oracle DB instances.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon S3 integration (p. 1452)</td>
<td>S3_INTEGRATION</td>
</tr>
<tr>
<td>Oracle Application Express (APEX) (p. 1465)</td>
<td>APEX</td>
</tr>
<tr>
<td></td>
<td>APEX_DEV</td>
</tr>
</tbody>
</table>
### Options supported for different editions

RDS for Oracle prevents you from adding options to an edition if they aren't supported. To find out which RDS options are supported in different Oracle Database editions, use the command `aws rds describe-option-group-options`. The following example lists supported options for Oracle Database 19c Enterprise Edition.

```bash
aws rds describe-option-group-options
  --engine-name oracle-ee
  --major-engine-version 19
```

For more information, see `describe-option-group-options` in the [AWS CLI Command Reference](https://docs.aws.amazon.com/cli/latest/reference/rds/describe-option-group-options.html).

### Memory requirements for specific options

Some options require additional memory to run on your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems due to memory constraints. You can adjust the Oracle parameters so that the database requires less RAM. Alternatively, you can scale up to a larger DB instance.
Amazon S3 integration

You can transfer files between an Amazon RDS for Oracle DB instance and an Amazon S3 bucket. You can use Amazon S3 integration with Oracle features such as Data Pump. For example, you can download Data Pump files from Amazon S3 to the DB instance host.

Note
The DB instance and the Amazon S3 bucket must be in the same AWS Region.

Topics
- Configuring IAM permissions for Amazon RDS for Oracle integration with Amazon S3 (p. 1452)
- Adding the Amazon S3 integration option (p. 1458)
- Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket (p. 1459)
- Removing the Amazon S3 integration option (p. 1464)

Configuring IAM permissions for Amazon RDS for Oracle integration with Amazon S3

For Amazon RDS for Oracle to integrate with Amazon S3, the Amazon RDS DB instance must have access to an Amazon S3 bucket. Prepare for the integration as follows:

1. Create an AWS Identity and Access Management (IAM) policy with the permissions required to transfer files from your bucket to RDS.

   To create the policy, you need the Amazon Resource Name (ARN) value for your bucket. Also, RDS for Oracle supports SSE-KMS and SSE-S3 encryption. If your bucket is encrypted, you need the ARN for your AWS KMS key. For more information, see Protecting data using server-side encryption in the Amazon Simple Storage Service User Guide.

   Note
   An Oracle DB instance can't access Amazon S3 buckets encrypted with SSE-C.

2. Create an IAM role, and then attach your new policy to it.

3. Attach the role to your Oracle DB instance.

   The status of the DB instance must be available.

The Amazon VPC used by your DB instance doesn't need to provide access to the Amazon S3 endpoints.

Console

To create an IAM policy to allow Amazon RDS access to an Amazon S3 bucket

1. Open the IAM Management Console.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose S3.
5. For Actions, choose Expand all, and then choose the bucket permissions and object permissions required to transfer files from an Amazon S3 bucket to Amazon RDS. For example, do the following:
   - Expand List, and then select ListBucket.
   - Expand Read, and then select GetObject.
Object permissions are permissions for object operations in Amazon S3, and must be granted for objects in a bucket, not the bucket itself. For more information about permissions for object operations in Amazon S3, see Permissions for object operations.

6. Choose Resources, and choose Add ARN for bucket.

7. In the Add ARN(s) dialog box, provide the details about your resource, and choose Add.

Specify the Amazon S3 bucket to allow access to. For instance, to allow Amazon RDS to access the Amazon S3 bucket named example-bucket, set the ARN value to arn:aws:s3:::example-bucket.

8. If the object resource is listed, choose Add ARN for object.

9. In the Add ARN(s) dialog box, provide the details about your resource.

For the Amazon S3 bucket, specify the Amazon S3 bucket to allow access to. For the object, you can choose Any to grant permissions to any object in the bucket.

Note
You can set Amazon Resource Name (ARN) to a more specific ARN value to allow Amazon RDS to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

10. (Optional) Choose Add additional permissions to add resources to the policy. For example, do the following:

- If your bucket is encrypted with a custom KMS key, select KMS for the service. Select Encrypt, ReEncrypt, Decrypt, DescribeKey, and GenerateDataKey for actions. Enter the ARN of your custom key as the resource. For more information, see Protecting Data Using Server-Side Encryption with KMS keys Stored in AWS Key Management Service (SSE-KMS) in the Amazon Simple Storage Service User Guide.
- If you want Amazon RDS to access to access other buckets, add the ARNs for these buckets. Optionally, you can also grant access to all buckets and objects in Amazon S3.

11. Choose Next: Tags and then Next: Review.

12. For Name, enter a name for your IAM policy, for example rds-s3-integration-policy. You use this name when you create an IAM role to associate with your DB instance. You can also add an optional Description value.

13. Choose Create policy.

To create an IAM role to allow Amazon RDS access to an Amazon S3 bucket

1. In the navigation pane, choose Roles.

2. Choose Create role.

3. For AWS service, choose RDS.

4. For Select your use case, choose RDS – Add Role to Database.

5. Choose Next: Permissions.

6. For Search under Attach permissions policies, enter the name of the IAM policy you created, and choose the policy when it appears in the list.

7. Choose Next: Tags and then Next: Review.

8. Set Role name to a name for your IAM role, for example rds-s3-integration-role. You can also add an optional Role description value.

9. Choose Create role.
To associate your IAM role with your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases from the navigation pane.
3. If your database instance is unavailable, choose Actions and then Start. When the instance status shows Started, go to the next step.
4. Choose the Oracle DB instance name to display its details.
5. On the Connectivity & security tab, scroll down to the Manage IAM roles section at the bottom of the page.
6. Choose the role to add in the Add IAM roles to this instance section.
7. For Feature, choose S3_INTEGRATION.
8. Choose Add role.

AWS CLI

To grant Amazon RDS access to an Amazon S3 bucket

1. Create an AWS Identity and Access Management (IAM) policy that grants Amazon RDS access to an Amazon S3 bucket.

Include the appropriate actions in the policy based on the type of access required:

- **GetObject** – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- **ListBucket** – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- **PutObject** – Required to transfer files from Amazon RDS to an Amazon S3 bucket.

The following AWS CLI command creates an IAM policy named rds-s3-integration-policy with these options. It grants access to a bucket named your-s3-bucket-arn.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-policy \
    --policy-name rds-s3-integration-policy \
    --policy-document '{
        "Version": "2012-10-17",
        "Statement": [
            {
                "Sid": "s3Integration",
                "Action": ["s3:GetObject", "s3:ListBucket", "s3:PutObject"]
            }
        ]
    }
```
The following example includes permissions for custom KMS keys.

```
aws iam create-policy \
  --policy-name rds-s3-integration-policy \n  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "s3integration",
        "Effect": "Allow",
        "Resource": [ "arn:aws:s3:::your-s3-bucket-arn", "arn:aws:s3:::your-s3-bucket-arn/*", "arn:aws:kms:::your-kms-arn" ]
      }
    ]
  }
```

For Windows:

```
aws iam create-policy ^
  --policy-name rds-s3-integration-policy ^
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "s3integration",
        "Action": [ "s3:GetObject", "s3:ListBucket", "s3:PutObject" ],
        "Effect": "Allow",
        "Resource": [ "arn:aws:s3:::your-s3-bucket-arn", "arn:aws:s3:::your-s3-bucket-arn/*", "arn:aws:s3:::your-s3-bucket-arn/*" ]
      }
    ]
  }
```
The following example includes permissions for custom KMS keys.

```bash
aws iam create-policy
  --policy-name rds-s3-integration-policy
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "s3integration",
        "Action": [
          "s3:GetObject",
          "s3:ListBucket",
          "s3:PutObject",
          "kms:Decrypt",
          "kms:Encrypt",
          "kms:ReEncrypt",
          "kms:GenerateDataKey",
          "kms:DescribeKey",
        ],
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::your-s3-bucket-arn",
          "arn:aws:s3:::your-s3-bucket-arn/*",
          "arn:aws:kms:::your-kms-arn"
        ]
      }
    ]
  }',

2. After the policy is created, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step.

3. Create an IAM role that Amazon RDS can assume on your behalf to access your Amazon S3 buckets.

   We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

   You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

   - Use `aws:SourceArn` if you want cross-service access for a single resource.
   - Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

   In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

   The following AWS CLI command creates the role named `rds-s3-integration-role` for this purpose.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws iam create-role
     --role-name rds-s3-integration-role
     --assume-role-policy-document '{
   ```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "StringEquals": {
        "aws:SourceAccount": my_account_ID,
        "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:hostname"
      }
    }
  }
]'

For Windows:

```
aws iam create-role ^
  --role-name rds-s3-integration-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": my_account_ID,
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:hostname"
          }
        }
      }
    ]
  }'

For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

4. After the role is created, note the ARN of the role. You need the ARN for a subsequent step.
5. Attach the policy you created to the role you created.

The following AWS CLI command attaches the policy to the role named `rds-s3-integration-role`.

**Example**

For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
  --policy-arn your-policy-arn \
  --role-name rds-s3-integration-role
```

For Windows:

```
aws iam attach-role-policy ^
```
---policy-arn your-policy-arn ^
--role-name rds-s3-integration-role

Replace your-policy-arn with the policy ARN that you noted in a previous step.

6. Add the role to the Oracle DB instance.

The following AWS CLI command adds the role to an Oracle DB instance named mydbinstance.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance \\n   --db-instance-identifier mydbinstance \\n   --feature-name S3_INTEGRATION \\n   --role-arn your-role-arn
```

For Windows:

```bash
aws rds add-role-to-db-instance ^
   --db-instance-identifier mydbinstance ^
   --feature-name S3_INTEGRATION ^
   --role-arn your-role-arn
```

Replace your-role-arn with the role ARN that you noted in a previous step. S3_INTEGRATION must be specified for the --feature-name option.

### Adding the Amazon S3 integration option

To use Amazon RDS for Oracle Integration with Amazon S3, your Amazon RDS for Oracle DB instance must be associated with an option group that includes the S3_INTEGRATION option.

**Console**

**To configure an option group for Amazon S3 integration**

1. Create a new option group or identify an existing option group to which you can add the S3_INTEGRATION option.

   For information about creating an option group, see Creating an option group (p. 264).

2. Add the S3_INTEGRATION option to the option group.

   For information about adding an option to an option group, see Adding an option to an option group (p. 266).

3. Create a new Oracle DB instance and associate the option group with it, or modify an Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 175).

   For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance (p. 309).
AWS CLI

To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the S3_INTEGRATION option.

   For information about creating an option group, see Creating an option group (p. 264).

2. Add the S3_INTEGRATION option to the option group.

   For example, the following AWS CLI command adds the S3_INTEGRATION option to an option group named myoptiongroup.

   Example

   For Linux, macOS, or Unix:

   ```
   aws rds add-option-to-option-group
   --option-group-name myoptiongroup
   --options OptionName=S3_INTEGRATION,OptionVersion=1.0
   ```

   For Windows:

   ```
   aws rds add-option-to-option-group
   --option-group-name myoptiongroup
   --options OptionName=S3_INTEGRATION,OptionVersion=1.0
   ```

3. Create a new Oracle DB instance and associate the option group with it, or modify an Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 175).

   For information about modifying an Oracle DB instance, see Modifying an Amazon RDS DB instance (p. 309).

Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket

You can use Amazon RDS procedures to transfer files between an Oracle DB instance and an Amazon S3 bucket.

Note

These procedures upload or download the files in a single directory. You can't include subdirectories in these operations.

Topics

- Uploading files from an Oracle DB instance to an Amazon S3 bucket (p. 1459)
- Downloading files from an Amazon S3 bucket to an Oracle DB instance (p. 1461)
- Monitoring the status of a file transfer (p. 1463)

Uploading files from an Oracle DB instance to an Amazon S3 bucket

You can upload files from an Oracle DB instance to an Amazon S3 bucket. For example, you can upload Oracle Recovery Manager (RMAN) backup files. The maximum object size in an Amazon S3 bucket is 5 TB. For more information about working with objects, see Amazon Simple Storage Service User Guide. For
more information about performing RMAN backups, see Performing common RMAN tasks for Oracle DB instances (p. 1390).

You upload files using the `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure. This procedure has the following parameters.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_bucket_name</code></td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Amazon S3 bucket to upload files to.</td>
</tr>
<tr>
<td><code>p_directory_name</code></td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Oracle directory object to upload files from. The directory can be any user-created directory object or the Data Pump directory, such as <code>DATA_PUMP_DIR</code>. <strong>Note</strong> You can only upload files from the specified directory. You can't upload files in subdirectories in the specified directory.</td>
</tr>
<tr>
<td><code>p_s3_prefix</code></td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>An Amazon S3 file name prefix that files are uploaded to. An empty prefix uploads all files to the top level in the specified Amazon S3 bucket and doesn't add a prefix to the file names. For example, if the prefix is <code>folder_1/oradb</code>, files are uploaded to <code>folder_1</code>. In this case, the <code>oradb</code> prefix is added to each file.</td>
</tr>
<tr>
<td><code>p_prefix</code></td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>A file name prefix that file names must match to be uploaded. An empty prefix uploads all files in the specified directory.</td>
</tr>
</tbody>
</table>

The return value for the `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure is a task ID.

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
```
The following example uploads all of the files with the prefix `db` in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name => 'mys3bucket',
    p_prefix => 'db',
    p_s3_prefix => '',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files are uploaded to a `dbfiles` folder.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name => 'mys3bucket',
    p_prefix => '',
    p_s3_prefix => 'dbfiles/',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `mys3bucket`. The files are uploaded to a `dbfiles` folder and `ora` is added to the beginning of each file name.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name => 'mys3bucket',
    p_prefix => '',
    p_s3_prefix => 'dbfiles/ora',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure.

**Note**
Tasks are executed asynchronously.

### Downloading files from an Amazon S3 bucket to an Oracle DB instance

To download files from an Amazon S3 bucket to an Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`. The `rdsadmin.rdsadmin_s3_tasks.download_from_s3` procedure has the following parameters.
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Data type</th>
<th>Default</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_bucket_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Amazon S3 bucket to download files from.</td>
</tr>
<tr>
<td>p_directory_name</td>
<td>VARCHAR2</td>
<td>–</td>
<td>required</td>
<td>The name of the Oracle directory object to download files to. The directory can be any user-created directory object or the Data Pump directory, such as DATA_PUMP_DIR.</td>
</tr>
<tr>
<td>p_s3_prefix</td>
<td>VARCHAR2</td>
<td>&quot;</td>
<td>optional</td>
<td>A file name prefix that file names must match to be downloaded. An empty prefix downloads all of the top level files in the specified Amazon S3 bucket, but not the files in folders in the bucket. The procedure downloads Amazon S3 objects only from the first level folder that matches the prefix. Nested directory structures matching the specified prefix are not downloaded. For example, suppose that an Amazon S3 bucket has the folder structure folder_1/folder_2/ folder_3. Suppose also that you specify the 'folder_1/folder_2/' prefix. In this case, only the files in folder_2 are downloaded, not the files in folder_1 or folder_3. If, instead, you specify the 'folder_1/ folder_2' prefix, all files in folder_1 that match the 'folder_2' prefix are downloaded, and no files in folder_2 are downloaded.</td>
</tr>
</tbody>
</table>

The return value for the rdsadmin.rdsadmin_s3_tasks.download_from_s3 procedure is a task ID.

The following example downloads all of the files in the Amazon S3 bucket named mys3bucket to the DATA_PUMP_DIR directory.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
```
The following example downloads all of the files with the prefix `db` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'mys3bucket',
    p_s3_prefix => 'db',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example downloads all of the files in the folder `myfolder/` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory. Use the prefix parameter setting to specify the Amazon S3 folder.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'mys3bucket',
    p_s3_prefix => 'myfolder/',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example downloads the file `mydumpfile.dmp` in the Amazon S3 bucket named `mys3bucket` to the `DATA_PUMP_DIR` directory.

```sql
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'mys3bucket',
    p_s3_prefix => 'mydumpfile.dmp',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

In each example, the `SELECT` statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-<task-id>.log'));
```

Replace `task-id` with the task ID returned by the procedure.

**Note**
Tasks are executed asynchronously.
You can use the `UTL_FILE.FREMOVE` Oracle procedure to remove files from a directory. For more information, see `FREMOVE procedure` in the Oracle documentation.

**Monitoring the status of a file transfer**

File transfer tasks publish Amazon RDS events when they start and when they complete. For information about viewing events, see `Viewing Amazon RDS events` (p. 622).

You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsd/dbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-<task-id>.log
```
Replace `task-id` with the ID of the task that you want to monitor.

**Note**
Tasks are executed asynchronously.

You can use the `rdsadmin.rds_file_util.read_text_file` stored procedure to view the contents of bdump files. For example, the following query returns the contents of the `dbtask-154698886389-2444.log` bdump file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-154698886389-2444.log'));
```

## Removing the Amazon S3 integration option

You can remove Amazon S3 integration option from a DB instance.

To remove the Amazon S3 integration option from a DB instance, do one of the following:

- To remove the Amazon S3 integration option from multiple DB instances, remove the `S3_INTEGRATION` option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).

- To remove the Amazon S3 integration option from a single DB instance, modify the DB instance and specify a different option group that doesn't include the `S3_INTEGRATION` option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Oracle Application Express (APEX)

Amazon RDS supports Oracle Application Express (APEX) through the use of the APEX and APEX–DEV options. Oracle APEX can be deployed as a run-time environment or as a full development environment for web-based applications. Using Oracle APEX, developers can build applications entirely within the web browser. For more information, see Oracle application Express in the Oracle documentation.

Topics

• APEX components (p. 1465)
• APEX version requirements (p. 1465)
• Prerequisites for Oracle APEX and ORDS (p. 1466)
• Adding the Amazon RDS APEX options (p. 1466)
• Unlocking the public user account (p. 1467)
• Configuring RESTful services for Oracle APEX (p. 1468)
• Setting up ORDS for Oracle APEX (p. 1468)
• Setting up Oracle APEX listener (p. 1472)
• Upgrading the APEX version (p. 1474)
• Removing the APEX option (p. 1474)

APEX components

Oracle APEX consists of the following main components:

• A repository that stores the metadata for APEX applications and components. The repository consists of tables, indexes, and other objects that are installed in your Amazon RDS DB instance.
• A listener that manages HTTP communications with Oracle APEX clients. The listener accepts incoming connections from web browsers, forwards them to the Amazon RDS DB instance for processing, and then sends results from the repository back to the browsers. Amazon RDS for Oracle supports the following types of listeners:
  • For APEX version 5.0 and later, use Oracle Rest Data Services (ORDS) version 19.1 and higher. We recommend that you use the latest supported version of Oracle APEX and ORDS. This documentation describes older versions for backwards compatibility only.
  • For APEX version 4.1.1, you can use Oracle APEX Listener version 1.1.4.
  • You can use Oracle HTTP Server and mod_plsql listeners.

  Note
  Amazon RDS doesn't support the Oracle XML DB HTTP server with the embedded PL/SQL gateway; you can't use this as a listener for APEX. In general, Oracle recommends against using the embedded PL/SQL gateway for applications that run on the internet.

  For more information about these listener types, see About choosing a web listener in the Oracle documentation.

When you add the Amazon RDS APEX options to your DB instance, Amazon RDS installs the Oracle APEX repository only. Install your listener on a separate host, such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer.

APEX version requirements

The APEX option uses storage on the DB instance class for your DB instance. Following are the supported versions and approximate storage requirements for Oracle APEX.
<table>
<thead>
<tr>
<th>APEX version</th>
<th>Storage requirements</th>
<th>Supported Oracle Database versions</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle APEX version 21.1.v1</td>
<td>125 MiB</td>
<td>All</td>
<td>This version includes patch 32598392: PSE BUNDLE FOR APEX 21.1.</td>
</tr>
<tr>
<td>Oracle APEX version 20.2.v1</td>
<td>148 MiB</td>
<td>All except 21c</td>
<td>This version includes patch p32006852_2020_Generic. You can see the patch number and date by running the following query: SELECT PATCH_VERSION, PATCH_NUMBER FROM APEX_PATCHES;</td>
</tr>
<tr>
<td>Oracle APEX version 20.1.v1</td>
<td>173 MiB</td>
<td>All except 21c</td>
<td>This version includes patch 30990551.</td>
</tr>
<tr>
<td>Oracle APEX version 19.2.v1</td>
<td>149 MiB</td>
<td>All except 21c</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 19.1.v1</td>
<td>148 MiB</td>
<td>All except 21c</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 18.2.v1</td>
<td>146 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 18.1.v1</td>
<td>145 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 5.1.4.v1</td>
<td>220 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 5.1.2.v1</td>
<td>150 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 5.0.4.v1</td>
<td>140 MiB</td>
<td>12.1 and 12.2 only</td>
<td></td>
</tr>
<tr>
<td>Oracle APEX version 4.2.6.v1</td>
<td>160 MiB</td>
<td>12.1 only</td>
<td></td>
</tr>
</tbody>
</table>

**Prerequisites for Oracle APEX and ORDS**

To use Oracle APEX and ORDS, make sure you have the following:

- The Java Runtime Environment (JRE)
- An Oracle client installation that includes the following:
  - SQL*Plus or SQL Developer for administration tasks
  - Oracle Net Services for configuring connections to your Oracle instance

**Adding the Amazon RDS APEX options**

To add the Amazon RDS APEX options to a DB instance, do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the options to the option group.
3. Associate the option group with the DB instance.

When you add the Amazon RDS APEX options, a brief outage occurs while your DB instance is automatically restarted.

**To add the APEX options to a DB instance**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition that you want to use. The APEX options are supported on all editions.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).

2. Add the options to the option group. If you want to deploy only the Oracle APEX run-time environment, add only the **APEX** option. If you want to deploy the full development environment, add both the **APEX** and **APEX-DEV** options. For Oracle Database 12c, add the **APEX** and **APEX-DEV** options.

   For **Version**, choose the version of APEX that you want to use. If you don't choose a version, version 4.2.6.v1 is the default for Oracle Database 12c.

   **Important**
   If you add the APEX options to an existing option group that is already attached to one or more DB instances, a brief outage occurs. During this outage, all the DB instances are automatically restarted.

   For more information about adding options, see Adding an option to an option group (p. 266).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the APEX options to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**Unlocking the public user account**

After the Amazon RDS APEX options are installed, make sure to do the following:

1. Change the password for the APEX public user account.
2. Unlock the account.

You can do this by using the Oracle SQL*Plus command line utility. Connect to your DB instance as the master user, and issue the following commands. Replace `new_password` with a password of your choice.

```
ALTER USER APEX_PUBLIC_USER IDENTIFIED BY new_password;
ALTER USER APEX_PUBLIC_USER ACCOUNT UNLOCK;
```
Configuring RESTful services for Oracle APEX

To configure RESTful services in APEX (not needed for APEX 4.1.1.V1), use SQL*Plus to connect to your DB instance as the master user. After you do this, run the `rdsadmin.rdsadmin_run_apex_rest_config` stored procedure. When you run the stored procedure, you provide passwords for the following users:

- APEX_LISTENER
- APEX_REST_PUBLIC_USER

The stored procedure runs the `apex_rest_config.sql` script, which creates new database accounts for these users.

**Note**
Configuration isn't required for Oracle APEX version 4.1.1.v1. For this Oracle APEX version only, you don't need to run the stored procedure.

The following command runs the stored procedure.

```
EXEC rdsadmin.rdsadmin_run_apex_rest_config('apex_listener_password', 'apex_rest_public_user_password');
```

Setting up ORDS for Oracle APEX

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For APEX version 5.0 and later, use Oracle Rest Data Services (ORDS) version 19.1 and higher.

Install the listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. For the examples in this section, we assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

Preparing to install ORDS

Before you can install ORDS, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

**To prepare for ORDS installation**

1. Log in to `myapexhost.example.com` as `root`.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named `apexuser`.

   ```
   useradd -d /home/apexuser apexuser
   ```

   The following command assigns a password to the new user.

   ```
   passwd apexuser;
   ```

3. Log in to `myapexhost.example.com` as `apexuser`, and download the APEX installation file from Oracle to your `/home/apexuser` directory:

   - Oracle application Express prior release archives

4. Unzip the file in the `/home/apexuser` directory.
After you unzip the file, there is an apex directory in the /home/apexuser directory.

5. While you are still logged into myapexhost.example.com as apexuser, download the Oracle REST Data Services file from Oracle to your /home/apexuser directory: http://www.oracle.com/technetwork/developer-tools/apex-listener/downloads/index.html.

Installing and configuring ORDS

Before you can use APEX, you need to download the ords.war file, use Java to install ORDS, and then start the listener.

To install and configure ORDS for use with Oracle APEX

1. Create a new directory based on ORDS, and then unzip the listener file.

   ```
   mkdir /home/apexuser/ORDS
   cd /home/apexuser/ORDS
   ```

2. Download the file orbs.version.number.zip from Oracle REST data services.

3. Unzip the file into the /home/apexuser/ORDS directory.

4. If you're installing ORDS in a multitenant database, add the following line to the file /home/apexuser/ORDS/params/ords_params.properties:

   ```
   pdb.disable.lockdown=false
   ```

5. Grant the master user the required privileges to install ORDS.

   After the Amazon RDS APEX option is installed, give the master user the required privileges to install the ORDS schema. You can do this by connecting to the database and running the following commands. Replace MASTER_USER with the uppercase name of your master user.

   ```
   Important
   When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run CREATE USER myuser or CREATE USER MYUSER, the data dictionary stores MYUSER. However, if you use double quotes in CREATE USER "MyUser", the data dictionary stores MyUser. For more information, see Granting SELECT or EXECUTE privileges to SYS objects (p. 1357).
   ```

   ```
   exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('USER_PROCEDURES', 'MASTER_USER', 'SELECT', true);
   exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER', 'SELECT', true);
   ```
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER', 'EXECUTE', true);

**Note**
These commands apply to ORDS version 19.1 and later.

6. Install the ORDS schema using the downloaded ords.war file.

```
java -jar ords.war install advanced
```

The program prompts you for the following information. The default values are in brackets. For more information, see [Introduction to Oracle REST data services](https://docs.oracle.com/en-us/autotask/ords/index.html) in the Oracle documentation.

- Enter the location to store configuration data:
  
  Enter `/home/apexuser/ORDS`. This is the location of the ORDS configuration files.

  
  Choose the desired connection type.

- Enter the name of the database server [localhost]: `DB_instance_endpoint`
  
  Choose the default or enter the correct value.

- Enter the database listener port [1521]: `DB_instance_port`
  
  Choose the default or enter the correct value.

- Enter 1 to specify the database service name, or 2 to specify the database SID [1]:
  
  Choose 2 to specify the database SID.

- Database SID [xe]
  
  Choose the default or enter the correct value.

- Enter 1 if you want to verify/install Oracle REST Data Services schema or 2 to skip this step [1]:
  
  Choose 1. This step creates the Oracle REST Data Services proxy user named ORDS_PUBLIC_USER.

- Enter the database password for ORDS_PUBLIC_USER:
  
  Enter the password, and then confirm it.

- Requires to login with administrator privileges to verify Oracle REST Data Services schema.
  
  Enter the administrator user name: `master_user`

  Enter the database password for `master_user:master_user_password`

  Confirm the password: `master_user_password`

- Enter the default tablespace for ORDS_METADATA [SYSAUX].
  
  Enter the temporary tablespace for ORDS_METADATA [TEMP].

- Enter the default tablespace for ORDS_PUBLIC_USER [USERS].

- Enter the temporary tablespace for ORDS_PUBLIC_USER [TEMP].
• Enter 1 if you want to use PL/SQL Gateway or 2 to skip this step. If you're using Oracle Application Express or migrating from mod_plsql, you must enter 1 [1].
  Choose the default.
• Enter the PL/SQL Gateway database user name [APEX_PUBLIC_USER]
  Choose the default.
• Enter the database password for APEX_PUBLIC_USER:
  Enter the password, and then confirm it.
• Enter 1 to specify passwords for Application Express RESTful Services database users (APEX_LISTENER, APEX_REST_PUBLIC_USER) or 2 to skip this step [1]:
  Choose 2 for APEX 4.1.1.V1; choose 1 for all other APEX versions.
• [Not needed for APEX 4.1.1.v1] Database password for APEX_LISTENER
  Enter the password (if required), and then confirm it.
• [Not needed for APEX 4.1.1.v1] Database password for APEX_REST_PUBLIC_USER
  Enter the password (if required), and then confirm it.
• Enter a number to select a feature to enable:
  Enter 1 to enable all features: SQL Developer Web, REST Enabled SQL, and Database API.
• Enter 1 if you wish to start in standalone mode or 2 to exit [1]:
  Enter 1.
• Enter the APEX static resources location:
  If you unzipped APEX installation files into /home/apexuser, enter /home/apexuser/apex/images. Otherwise, enter unzip_path/apex/images, where unzip_path is the directory where you unzipped the file.
• Enter 1 if using HTTP or 2 if using HTTPS [1]:
  If you enter 1, specify the HTTP port. If you enter 2, specify the HTTPS port and the SSL host name. The HTTPS option prompts you to specify how you will provide the certificate:
    • Enter 1 to use the self-signed certificate.
    • Enter 2 to provide your own certificate. If you enter 2, specify the path for the SSL certificate and the path for the SSL certificate private key.

7. Set a password for the APEX admin user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```
Replace master with your master user name. When the apxchpwd.sql script prompts you, enter a new admin password.

8. Start the ORDS listener. Run the following code.

```
java -jar ords.war
```

The first time you start ORDS, you are prompted to provide the location of the APEX Static resources. This images folder is located in the /apex/images directory in the installation directory for APEX.
9. Return to the APEX administration window in your browser and choose Administration. Next, choose Application Express Internal Administration. When you are prompted for credentials, enter the following information:

- **User name** – admin
- **Password** – the password you set using the apxchpwd.sql script

Choose Login, and then set a new password for the admin user.

Your listener is now ready for use.

### Setting up Oracle APEX listener

**Note**

Oracle APEX Listener is deprecated.

Amazon RDS for Oracle continues to support APEX version 4.1.1 and Oracle APEX Listener version 1.1.4. We recommend that you use the latest supported versions of Oracle APEX and ORDS.

Install Oracle APEX Listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. We assume that the name of your host is myapexhost.example.com, and that your host is running Linux.

### Preparing to install Oracle APEX listener

Before you can install Oracle APEX Listener, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

**To prepare for Oracle APEX listener installation**

1. Log in to myapexhost.example.com as root.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named apexuser.

   ```bash
   useradd -d /home/apexuser apexuser
   ```

   The following command assigns a password to the new user.

   ```bash
   passwd apexuser;
   ```

3. Log in to myapexhost.example.com as apexuser, and download the APEX installation file from Oracle to your /home/apexuser directory:

   - [Oracle application Express prior release archives](#)

4. Unzip the file in the /home/apexuser directory.

   ```bash
   unzip apex_<version>.zip
   ```

   After you unzip the file, there is an apex directory in the /home/apexuser directory.

5. While you are still logged into myapexhost.example.com as apexuser, download the Oracle APEX Listener file from Oracle to your /home/apexuser directory.
Installing and configuring Oracle APEX listener

Before you can use APEX, you need to download the apex.war file, use Java to install Oracle APEX Listener, and then start the listener.

To install and configure Oracle APEX listener

1. Create a new directory based on Oracle APEX Listener and open the listener file.

   Run the following code:

   ```
   mkdir /home/apexuser/apexlistener
   cd /home/apexuser/apexlistener
   unzip ../apex_listener.version.zip
   ```

2. Run the following code.

   ```
   java -Dapex.home=./apex -Dapex.images=/home/apexuser/apex/images -Dapex.erase -jar ./apex.war
   ```

3. Enter information for the program prompts following:
   - The APEX Listener Administrator user name. The default is adminlistener.
   - A password for the APEX Listener Administrator.
   - The APEX Listener Manager user name. The default is managerlistener.
   - A password for the APEX Listener Administrator.

   The program prints a URL that you need to complete the configuration, as follows.

   ```
   INFO: Please complete configuration at: http://localhost:8080/apex/listenerConfigure
   Database is not yet configured
   ```

4. Leave Oracle APEX Listener running so that you can use Oracle Application Express. When you have finished this configuration procedure, you can run the listener in the background.

5. From your web browser, go to the URL provided by the APEX Listener program. The Oracle Application Express Listener administration window appears. Enter the following information:
   - **Username** – APEX_PUBLIC_USER
   - **Password** – the password for APEX_PUBLIC_USER. This password is the one that you specified earlier when you configured the APEX repository. For more information, see Unlocking the public user account (p. 1467).
   - **Connection type** – Basic
   - **Hostname** – the endpoint of your Amazon RDS DB instance, such as mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com.
   - **Port** – 1521
   - **SID** – the name of the database on your Amazon RDS DB instance, such as mydb.

6. Choose **Apply**. The APEX administration window appears.

7. Set a password for the APEX admin user. To do this, use SQL*Plus to connect to your DB instance as the master user, and then run the following commands.

   ```
   EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
   grant APEX_ADMINISTRATOR_ROLE to master;
   @/home/apexuser/apex/apxchpwd.sql
   ```
Replace `master` with your master user name. When the `apxchpwd.sql` script prompts you, enter a new `admin` password.

8. Return to the APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

- **User name** – `admin`
- **Password** – the password you set using the `apxchpwd.sql` script

Choose **Login**, and then set a new password for the `admin` user.

Your listener is now ready for use.

### Upgrading the APEX version

**Important**

Back up your DB instance before you upgrade APEX. For more information, see [Creating a DB snapshot](#) and [Testing an Oracle DB upgrade](#).

To upgrade APEX with your DB instance, do the following:

- Create a new option group for the upgraded version of your DB instance.
- Add the upgraded versions of APEX and APEX-DEV to the new option group. Be sure to include any other options that your DB instance uses. For more information, see [Option group considerations](#).
- When you upgrade your DB instance, specify the new option group for your upgraded DB instance.

After you upgrade your version of APEX, the APEX schema for the previous version might still exist in your database. If you don’t need it anymore, you can drop the old APEX schema from your database after you upgrade.

If you upgrade the APEX version and RESTful services were not configured in the previous APEX version, we recommend that you configure RESTful services. For more information, see [Configuring RESTful services for Oracle APEX](#).

In some cases when you plan to do a major version upgrade of your DB instance, you might find that you’re using an APEX version that isn’t compatible with your target database version. In these cases, you can upgrade your version of APEX before you upgrade your DB instance. Upgrading APEX first can reduce the amount of time that it takes to upgrade your DB instance.

**Note**

After upgrading APEX, install and configure a listener for use with the upgraded version. For instructions, see [Setting up Oracle APEX listener](#).

### Removing the APEX option

You can remove the Amazon RDS APEX options from a DB instance. To remove the APEX options from a DB instance, do one of the following:

- To remove the APEX options from multiple DB instances, remove the APEX options from the option group they belong to. This change affects all DB instances that use the option group. When you remove the APEX options from an option group that is attached to multiple DB instances, a brief outage occurs while all the DB instances are restarted.

For more information, see [Removing an option from an option group](#).
To remove the APEX options from a single DB instance, modify the DB instance and specify a different option group that doesn't include the APEX options. You can specify the default (empty) option group, or a different custom option group. When you remove the APEX options, a brief outage occurs while your DB instance is automatically restarted.

For more information, see Modifying an Amazon RDS DB instance (p. 309).

When you remove the APEX options from a DB instance, the APEX schema is removed from your database.
Oracle Java virtual machine

Amazon RDS supports Oracle Java Virtual Machine (JVM) through the use of the JVM option. Oracle Java provides a SQL schema and functions that facilitate Oracle Java features in an Oracle database. For more information, see Introduction to Java in Oracle database in the Oracle documentation.

You can use Oracle JVM with the following Oracle Database versions:

- Oracle Database 21c (21.0.0), all versions
- Oracle Database 19c (19.0.0), all versions
- Oracle Database 12c Release 2 (12.2), all versions
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 and higher

Java implementation in Amazon RDS has a limited set of permissions. The master user is granted the RDS_JAVA_ADMIN role, which grants a subset of the privileges granted by the JAVA_ADMIN role. To list the privileges granted to the RDS_JAVA_ADMIN role, run the following query on your DB instance:

```
SELECT * FROM dba_java_policy
WHERE grantee IN ('RDS_JAVA_ADMIN', 'PUBLIC')
AND enabled = 'ENABLED'
ORDER BY type_name, name, grantee;
```

Prerequisites for Oracle JVM

The following are prerequisites for using Oracle Java:

- Your DB instance must be inside a virtual private cloud (VPC). For more information, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869).
- Your DB instance must be of a large enough class. Oracle Java isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see DB instance classes (p. 9).
- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available. Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 309).

Best practices for Oracle JVM

The following are best practices for using Oracle Java:

- For maximum security, use the JVM option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1514).
- Configure your DB instance to restrict network access. For more information, see Scenarios for accessing a DB instance in a VPC (p. 1857) and Working with a DB instance in a VPC (p. 1849).
- Update the configuration of your HTTPS endpoints to support TLSv1.2 if you meet the following conditions:
  - You use Oracle Java Virtual Machine (JVM) to connect an HTTPS endpoint over TLSv1 or TLSv1.1 protocols.
  - Your endpoint doesn't support the TLSv1.2 protocol.
  - You haven't applied the April 2021 release update to your Oracle DB.

By updating your endpoint configuration, you ensure that the connectivity of the JVM to the HTTPS endpoint will continue to work. For more information about TLS changes in the Oracle JRE and JDK, see Oracle JRE and JDK Cryptographic Roadmap.
Adding the Oracle JVM option

The following is the general process for adding the JVM option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

There is a brief outage while the JVM option is added. After you add the option, you don’t need to restart your DB instance. As soon as the option group is active, Oracle Java is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the JVM option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   - For [Engine](https://example.com), choose the DB engine used by the DB instance (oracle-ee, oracle-se, oracle-se1, or oracle-se2).
   - For [Major engine version](https://example.com), choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).

2. Add the JVM option to the option group. For more information about adding options, see Adding an option to an option group (p. 266).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

4. Grant the required permissions to users.

   The Amazon RDS master user has the permissions to use the JVM option by default. If other users require these permissions, connect to the DB instance as the master user in a SQL client and grant the permissions to the users.

   The following example grants the permissions to use the JVM option to the test_proc user.

   ```sql
   create user test_proc identified by password;
   CALL dbms_java.grant_permission('TEST_PROC', 'oracle.aurora.security.JServerPermission', 'LoadClassInPackage.*', '');
   ```

   After the user is granted the permissions, the following query should return output.

   ```sql
   select * from dba_java_policy where grantee='TEST_PROC';
   ```

   **Note**
   The Oracle user name is case-sensitive, and it usually has all uppercase characters.
Removing the Oracle JVM option

You can remove the JVM option from a DB instance. There is a brief outage while the option is removed. After you remove the JVM option, you don’t need to restart your DB instance.

Warning
Removing the JVM option can result in data loss if the DB instance is using data types that were enabled as part of the option. Back up your data before proceeding. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 406).

To remove the JVM option from a DB instance, do one of the following:

- Remove the JVM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).
- Modify the DB instance and specify a different option group that doesn’t include the JVM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Oracle Enterprise Manager

Amazon RDS supports Oracle Enterprise Manager (OEM). OEM is the Oracle product line for integrated management of enterprise information technology.

Amazon RDS supports OEM through the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Option ID</th>
<th>Supported OEM releases</th>
<th>Supported Oracle Database releases</th>
</tr>
</thead>
<tbody>
<tr>
<td>OEM Database</td>
<td>OEM</td>
<td>OEM Database Express 12c</td>
<td>Oracle Database 19c (non-CDB only) and Oracle Database 12c</td>
</tr>
<tr>
<td>Express (p. 1480)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>OEM Management</td>
<td>OEM_AGENT</td>
<td>OEM Cloud Control for 13c</td>
<td>Oracle Database 19c (non-CDB only) and Oracle Database 12c</td>
</tr>
<tr>
<td>Agent (p. 1484)</td>
<td></td>
<td>OEM Cloud Control for 12c</td>
<td></td>
</tr>
</tbody>
</table>

**Note**
You can use OEM Database or OEM Management Agent, but not both.

**Note**
These options aren't supported for the single-tenant architecture.
Oracle Enterprise Manager Database Express

Amazon RDS supports Oracle Enterprise Manager (OEM) Database Express through the use of the OEM option. Amazon RDS supports Oracle Enterprise Manager Database Express for the following releases:

- Oracle Database 19c (non-CDB only)
- Oracle Database 12c

OEM Database Express and Database Control are similar tools that have a web-based interface for Oracle database administration. For more information about these tools, see Accessing Enterprise Manager database Express 18c and Accessing Enterprise Manager Database Express 12c in the Oracle documentation.

The following is a limitation for OEM Database Express:

- OEM Database Express isn't supported on the db.t3.micro or db.t3.small DB instance classes.

  For more information about DB instance classes, see RDS for Oracle instance classes (p. 1302).

OEM Database option settings

Amazon RDS supports the following settings for the OEM option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>An integer value</td>
<td>The port on the DB instance that listens for OEM Database. The default for OEM Database Express is 5500.</td>
</tr>
<tr>
<td>Security Groups</td>
<td>—</td>
<td>A security group that has access to Port.</td>
</tr>
</tbody>
</table>

Adding the OEM Database option

The general process for adding the OEM option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When you add the OEM option for an Oracle Database 12c or later DB instance, a brief outage occurs while your DB instance is automatically restarted.

To add the OEM option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine choose the oracle edition for your DB instance.
   b. For Major engine version choose the version of your DB instance.
2. Add the OEM option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 266). For more information about each setting, see OEM Database option settings (p. 1480).

Note
If you add the OEM option to an existing option group that is already attached to one or more Oracle Database 19c (non-CDB only) or Oracle Database 12c DB instances, a brief outage occurs while all the DB instances are automatically restarted.

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the OEM option for an Oracle Database 19c (non-CDB only) or Oracle Database 12c DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Note
You can also use the AWS CLI to add the OEM option. For examples, see Adding an option to an option group (p. 266).

Accessing OEM through your browser

After you enable the OEM option, you can begin using the OEM Database tool from your web browser. You can access either OEM Database Control or OEM Database Express from your web browser. For example, if the endpoint for your Amazon RDS DB instance is mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com, and your OEM port is 1158, then the URL to access the OEM Database Control is the following:

https://mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com:1158/em

When you access either tool from your web browser, a login window appears that prompts you for a user name and password. Type the master user name and master password for your DB instance. You are now ready to manage your Oracle databases.

Modifying OEM Database settings

After you enable OEM Database, you can modify the Security Groups setting for the option.

You can't modify the OEM port number after you have associated the option group with a DB instance. To change the OEM port number for a DB instance, do the following:

1. Create a new option group.
2. Add the OEM option with the new port number to the new option group.
3. Remove the existing option group from the DB instance.
4. Add the new option group to the DB instance.

For more information about how to modify option settings, see Modifying an option setting (p. 271). For more information about each setting, see OEM Database option settings (p. 1480).
Running OEM Database Express tasks

You can use Amazon RDS procedures to run certain OEM Database Express tasks. By running these procedures, you can do the tasks listed following.

**Note**

OEM Database Express tasks run asynchronously.

**Tasks**

- Switching the website front end for OEM Database Express to Adobe Flash (p. 1482)
- Switching the website front end for OEM Database Express to Oracle JET (p. 1483)

Switching the website front end for OEM Database Express to Adobe Flash

**Note**

This task is available only for Oracle Database 19c non-CDBs.

Starting with Oracle Database 19c, Oracle has deprecated the former OEM Database Express user interface, which was based on Adobe Flash. Instead, OEM Database Express now uses an interface built with Oracle JET. If you experience difficulties with the new interface, you can switch back to the deprecated Flash-based interface. Difficulties you might experience with the new interface include being stuck on a Loading screen after logging in to OEM Database Express. You might also miss certain features that were present in the Flash-based version of OEM Database Express.

To switch the OEM Database Express website front end to Adobe Flash, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash`. This procedure is equivalent to the `execemx emx` SQL command.

Security best practices discourage the use of Adobe Flash. Although you can revert to the Flash-based OEM Database Express, we recommend the use of the JET-based OEM Database Express websites if possible. If you revert to using Adobe Flash and want to switch back to using Oracle JET, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. After an Oracle database upgrade, a newer version of Oracle JET might resolve JET-related issues in OEM Database Express. For more information about switching to Oracle JET, see Switching the website front end for OEM Database Express to Oracle JET (p. 1483).

**Note**

Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Adobe Flash.

The following procedure invocation creates a task to switch the OEM Database Express website to Adobe Flash and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory (p. 1420)

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the **Logs & events** section for the `task-id`. 
Switching the website front end for OEM Database Express to Oracle JET

**Note**
This task is available only for Oracle Database 19c non-CDBs.

To switch the OEM Database Express website front end to Oracle JET, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet`. This procedure is equivalent to the `execemx omx` SQL command.

By default, the OEM Database Express websites for Oracle DB instances running 19c or later use Oracle JET. If you used the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash` procedure to switch the OEM Database Express website front end to Adobe Flash, you can switch back to Oracle JET. To do this, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. For more information about switching to Adobe Flash, see Switching the website front end for OEM Database Express to Adobe Flash (p. 1482).

**Note**
Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Oracle JET.

The following procedure invocation creates a task to switch the OEM Database Express website to Oracle JET and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-task-id.log'));
```

Replace `task-id` with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory (p. 1420)

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the **Logs & events** section for the `task-id`.

Removing the OEM Database option

You can remove the OEM option from a DB instance. When you remove the OEM option for an Oracle Database 12c or later DB instance, a brief outage occurs while your instance is automatically restarted. Therefore, after you remove the OEM option, you don't need to restart your DB instance.

To remove the OEM option from a DB instance, do one of the following:

- Remove the OEM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).
- Modify the DB instance and specify a different option group that doesn't include the OEM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Oracle Management Agent for Enterprise Manager Cloud Control

Oracle Enterprise Manager (OEM) Management Agent is a software component that monitors targets running on hosts and communicates that information to the middle-tier Oracle Management Service (OMS). For more information, see Summary of Oracle Enterprise Manager cloud control 12c and Summary of Oracle Enterprise Manager cloud control 13c in the Oracle documentation.

Amazon RDS supports Management Agent through the use of the OEM_AGENT option. Management Agent requires an Amazon RDS DB instance running any of the following releases:

- Oracle Database 19c (19.0.0.0) using the non-CDB architecture
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

Amazon RDS supports Management Agent for the following versions of OEM:

- Oracle Enterprise Manager Cloud Control for 13c
- Oracle Enterprise Manager Cloud Control for 12c

Topics

- Prerequisites for Management Agent (p. 1484)
- Limitations for Management Agent (p. 1486)
- Option settings for Management Agent (p. 1486)
- Adding the Management Agent option (p. 1488)
- Using the Management Agent (p. 1489)
- Modifying Management Agent settings (p. 1490)
- Performing database tasks with the Management Agent (p. 1490)
- Removing the Management Agent option (p. 1493)

Prerequisites for Management Agent

To use Management Agent, ensure that you meet the following prerequisites.

General prerequisites

Following are general prerequisites for using Management Agent:

- You need an Oracle Management Service (OMS) that is configured to connect to your Amazon RDS DB instance.
- In most cases, you must configure your VPC to allow connections from OMS to your DB instance. If you aren't familiar with Amazon Virtual Private Cloud (Amazon VPC), we recommend that you complete the steps in Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863) before continuing.
- Management Agent version 13.5.0.0.v1 requires OMS version 13.5.0.0 or later.
- Management Agent version 13.4.0.9.v1 requires OMS version 13.4.0.9 or later and patch 32198287.
- Ensure that you have sufficient storage space for your OEM release:
  - At least 8.5 GiB for OEM 13c Release 5
  - At least 8.5 GiB for OEM 13c Release 4
  - At least 8.5 GiB for OEM 13c Release 3
  - At least 5.5 GiB for OEM 13c Release 2
• At least 4.5 GiB OEM 13c Release 1
• At least 2.5 GiB for OEM 12c
• If you are using Management Agent versions OEM_AGENT 13.2.0.0.v3 and 13.3.0.0.v2, and if you want to use TCPS connectivity, follow the instructions in Configuring third party CA certificates for communication with target databases in the Oracle documentation. Also, update the JDK on your OMS by following the instructions in the Oracle document with the Oracle Doc ID 2241358.1. This step ensures that OMS supports all the cipher suites that the database supports.

**Note**
TCPS connectivity between the Management Agent and the DB instance is only supported for Management Agent versions OEM_AGENT 13.2.0.0.v3 and 13.3.0.0.v2.

**Oracle Database release prerequisites**

Following are the supported Oracle Database versions for each Management Agent version.

<table>
<thead>
<tr>
<th>Management Agent version</th>
<th>Oracle Database 19c using the non-CDB architecture</th>
<th>Oracle Database 12c Release 2 (12.2)</th>
<th>Oracle Database 12c Release 1 (12.1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>13.5.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.4.0.9.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.3.0.0.v2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.3.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v3</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v2</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.2.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>13.1.0.0.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>12.1.0.5.v1</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>12.1.0.4.v1</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

Following are prerequisites for different database versions:

• For an Amazon RDS DB instance running Oracle Database 19c (19.0.0.0), the minimum AGENT_VERSION is 13.1.0.0.v1.
• For an Amazon RDS DB instance running Oracle Database Release 2 (12.2.0.1) or lower, meet the following requirements:
  • For OMS 13c Release 2 with Oracle patch 25163555 applied, use OEM Agent 13.2.0.0.v2 or later.
    Use OMSPatcher to apply the patch.
  • For unpatched OMS 13c Release 2, use OEM Agent 13.2.0.0.v1.
    Use OMSPatcher to apply patches.

**OMS host communication prerequisites**

Make sure that your OMS host and your Amazon RDS DB instance can communicate. Do the following:
• To connect from the Management Agent to your OMS, if your OMS is behind a firewall, add the IP addresses of your DB instances to your OMS.

Make sure the firewall for the OMS allows traffic from both the DB listener port (default 1521) and the OEM Agent port (default 3872), originating from the IP address of the DB instance.

• To connect from your OMS to the Management Agent, if your OMS has a publicly resolvable host name, add the OMS address to a security group. Your security group must have inbound rules that allow access to the DB listener port and the Management Agent port. For an example of creating a security and adding inbound rules, see Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863).

• To connect from your OMS to the Management Agent, if your OMS doesn't have a publicly resolvable host name, use one of the following:
  • If your OMS is hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance in a private VPC, you can set up VPC peering to connect from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by an EC2 instance in a different VPC (p. 1859).
  • If your OMS is hosted on-premises, you can set up a VPN connection to allow access from OMS to Management Agent. For more information, see A DB instance in a VPC accessed by a client application through the internet (p. 1860) or VPN connections.

Limitations for Management Agent

Following are some limitations to using Management Agent:

• Administrative tasks such as job execution and database patching, that require host credentials, aren't supported.
• Host metrics and the process list aren't guaranteed to reflect the actual system state. Thus, you shouldn't use OEM to monitor the root file system or mount point file system. For more information about monitoring the operating system, see Monitoring OS metrics with Enhanced Monitoring (p. 582).
• Autodiscovery isn't supported. You must manually add database targets.
• OMS module availability depends on your database edition. For example, the database performance diagnosis and tuning module is only available for Oracle Database Enterprise Edition.
• Management Agent consumes additional memory and computing resources. If you experience performance problems after enabling the OEM_AGENT option, we recommend that you scale up to a larger DB instance class. For more information, see DB instance classes (p. 9) and Modifying an Amazon RDS DB instance (p. 309).
• The user running the OEM_AGENT on the Amazon RDS host doesn't have operating system access to the alert log. Thus, you can't collect metrics for DB Alert Log and DB Alert Log Error Status in OEM.

Option settings for Management Agent

Amazon RDS supports the following settings for the Management Agent option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Required</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version</strong> <em>(AGENT_VERSION)</em></td>
<td>Yes</td>
<td>13.5.0.0.v1</td>
<td>The version of the Management Agent software.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.4.0.9.v1</td>
<td>The AWS CLI option name is OptionVersion.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.3.0.0.v2</td>
<td><strong>Note</strong> In the AWS GovCloud (US) Regions, 12.1 and 13.1 versions aren't available.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.3.0.0.v1</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>13.2.0.0.v3</td>
<td></td>
</tr>
<tr>
<td>Option setting</td>
<td>Required</td>
<td>Valid values</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>----------</td>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>13.2.0.0.v2</strong></td>
<td>The port on the DB instance that listens for the OMS host. The default is 3872. Your OMS host must belong to a security group that has access to this port. The AWS CLI option name is Port.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>13.2.0.0.v1</strong></td>
<td></td>
</tr>
<tr>
<td>Port</td>
<td>Yes</td>
<td><strong>12.1.0.5.v1</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>12.1.0.4.v1</strong></td>
<td></td>
</tr>
<tr>
<td>Port (AGENT_PORT)</td>
<td>Yes</td>
<td><strong>13.1.0.0.v1</strong></td>
<td>The port on the DB instance that listens for the OMS host. The default is 3872. Your OMS host must belong to a security group that has access to this port. The AWS CLI option name is Port.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>12.1.0.5.v1</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>12.1.0.4.v1</strong></td>
<td></td>
</tr>
<tr>
<td>Security Groups</td>
<td>Yes</td>
<td>Existing security groups</td>
<td>A security group that has access to Port. Your OMS host must belong to this security group.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The AWS CLI option name is VpcSecurityGroupMemberships or DBSecurityGroupMemberships.</td>
</tr>
<tr>
<td>Security Groups</td>
<td>Yes</td>
<td><strong>my.example.oms</strong></td>
<td>The publicly accessible host name or IP address of the OMS.</td>
</tr>
<tr>
<td>OMS_HOST</td>
<td>Yes</td>
<td><strong>my.example.oms</strong></td>
<td>The publicly accessible host name or IP address of the OMS.</td>
</tr>
<tr>
<td>OMS_PORT</td>
<td>Yes</td>
<td><strong>my.example.oms</strong></td>
<td>The HTTPS upload port on the OMS Host that listens for the Management Agent.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>my.example.oms</strong></td>
<td>To determine the HTTPS upload port, connect to the OMS host, and run the following command (which requires the SYSMAN password): emctl status oms -details</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>my.example.oms</strong></td>
<td>The AWS CLI option name is OMS_PORT.</td>
</tr>
<tr>
<td>AGENT_REGISTRATION_PASSWORD</td>
<td>string</td>
<td><strong>true, false</strong></td>
<td>The password that the Management Agent uses to authenticate itself with the OMS. We recommend that you create a persistent password in your OMS before enabling the OEM_AGENT option. With a persistent password you can share a single Management Agent option group among multiple Amazon RDS databases.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>true, false</strong></td>
<td>The AWS CLI option name is AGENT_REGISTRATION_PASSWORD.</td>
</tr>
<tr>
<td>ALLOW_TLS_ONLY</td>
<td>true, false (default)</td>
<td><strong>true, false</strong></td>
<td>A value that configures the OEM Agent to support only the TLSv1 protocol while the agent listens as a server. This setting is only supported for 12.1 agent versions. Later agent versions only support Transport Layer Security (TLS) by default.</td>
</tr>
<tr>
<td>Option setting</td>
<td>Required</td>
<td>Valid values</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>----------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>MINIMUM_TLS_VERSION</td>
<td>No</td>
<td>TLSv1 (default), TLSv1.2</td>
<td>A value that specifies the minimum TLS version supported by the OEM Agent while the agent listens as a server. This setting is only supported for agent versions 13.1.0.0.v1 and higher. Earlier agent versions only support the TLSv1 setting.</td>
</tr>
<tr>
<td>TLS_CIPHER_SUITE</td>
<td>No</td>
<td>TLS_RSA_WITH_AES_128_CBC_SHA (Default supported by all agent versions) TLS_RSA_WITH_AES_128_CBC_SHA256 (Requires version 13.1.0.0.v1 or above) TLS_RSA_WITH_AES_256_CBC_SHA (Requires version 13.2.0.0.v3 or above) TLS_RSA_WITH_AES_256_CBC_SHA256 (Requires version 13.2.0.0.v3 or above)</td>
<td>A value that specifies the TLS cipher suite used by the OEM Agent while the agent listens as a server.</td>
</tr>
</tbody>
</table>

Adding the Management Agent option

The general process for adding the Management Agent option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If you encounter errors, check My Oracle Support documents for information about resolving specific problems.

After you add the Management Agent option, you don't need to restart your DB instance. As soon as the option group is active, the OEM Agent is active.

If your OMS host is using an untrusted third-party certificate, Amazon RDS returns the following error.

You successfully installed the OEM_AGENT option. Your OMS host is using an untrusted third party certificate. Configure your OMS host with the trusted certificates from your third party.

If this error is returned, the Management Agent option isn't enabled until the problem is corrected. For information about correcting the problem, see the My Oracle Support document 2202569.1.
To add the Management Agent option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).

2. Add the **OEM_AGENT** option to the option group, and configure the option settings. For more information about adding options, see Adding an option to an option group (p. 266). For more information about each setting, see Option settings for Management Agent (p. 1486).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**AWS CLI**

The following example uses the AWS CLI add-option-to-option-group command to add the **OEM_AGENT** option to an option group called **myoptiongroup**.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group
  --option-group-name "myoptiongroup" 
  --options
  OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-1234567890,OptionSettings=[
    {Name=OMS_HOST,Value=my.example.oms},
    {Name=OMS_PORT,Value=4903},
    {Name=AGENT_REGISTRATION_PASSWORD,Value=password}]
  --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --option-group-name "myoptiongroup" ^
  --options
  OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-1234567890,OptionSettings=[
    {Name=OMS_PORT,Value=4903},
    {Name=AGENT_REGISTRATION_PASSWORD,Value=password}] ^
  --apply-immediately
```

**Using the Management Agent**

After you enable the Management Agent option, take the following steps to begin using it.

**To use the Management Agent**

1. Unlock and reset the DBSNMP account credential. Do this by running the following code on your target database on your DB instance and using your master user account.

   ```sql
   ALTER USER dbsnmp IDENTIFIED BY new_password ACCOUNT UNLOCK;
   ```
2. Add your targets to the OMS console manually:
   a. In your OMS console, choose Setup, Add Target, Add Targets Manually.
   b. Choose Add Targets Declaratively by Specifying Target Monitoring Properties.
   c. For Target Type, choose Database Instance.
   d. For Monitoring Agent, choose the agent with the identifier that is the same as your RDS DB instance identifier.
   e. Choose Add Manually.
   f. Enter the endpoint for the Amazon RDS DB instance, or choose it from the host name list. Make sure that the specified host name matches the endpoint of the Amazon RDS DB instance.
      For information about finding the endpoint for your Amazon RDS DB instance, see Finding the endpoint of your Oracle DB instance (p. 1312).
   g. Specify the following database properties:
      • For Target name, enter a name.
      • For Database system name, enter a name.
      • For Monitor username, enter dbsnmp.
      • For Monitor password, enter the password from step 1.
      • For Role, enter normal.
      • For Oracle home path, enter /oracle.
      • For Listener Machine name, the agent identifier already appears.
      • For Port, enter the database port. The RDS default port is 1521.
      • For Database name, enter the name of your database.
   h. Choose Test Connection.
   i. Choose Next. The target database appears in your list of monitored resources.

Modifying Management Agent settings

After you enable the Management Agent, you can modify settings for the option. For more information about how to modify option settings, see Modifying an option setting (p. 271). For more information about each setting, see Option settings for Management Agent (p. 1486).

Performing database tasks with the Management Agent

You can use Amazon RDS procedures to run certain EMCTL commands on the Management Agent. By running these procedures, you can do the tasks listed following.

**Note**
Tasks are executed asynchronously.

**Tasks**
- Getting the status of the Management Agent (p. 1491)
- Restarting the Management Agent (p. 1491)
- Listing the targets monitored by the Management Agent (p. 1491)
- Listing the collection threads monitored by the Management Agent (p. 1491)
- Clearing the Management Agent state (p. 1492)
- Making the Management Agent upload its OMS (p. 1492)
- Pinging the OMS (p. 1492)
- Viewing the status of an ongoing task (p. 1492)
Getting the status of the Management Agent

To get the status of the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent`. This procedure is equivalent to the `emctl status agent` command.

The following procedure creates a task to get the Management Agent's status and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task’s output file, see Viewing the status of an ongoing task (p. 1492).

Restarting the Management Agent

To restart the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent`. This procedure is equivalent to running the `emctl stop agent` and `emctl start agent` commands.

The following procedure creates a task to restart the Management Agent and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task’s output file, see Viewing the status of an ongoing task (p. 1492).

Listing the targets monitored by the Management Agent

To list the targets monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent`. This procedure is equivalent to running the `emctl config agent listtargets` command.

The following procedure creates a task to list the targets monitored by the Management Agent and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task’s output file, see Viewing the status of an ongoing task (p. 1492).

Listing the collection threads monitored by the Management Agent

To list all of the running, ready, and scheduled collection threads monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent`. This procedure is equivalent to the `emctl status agent scheduler` command.

The following procedure creates a task to list the collection threads and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1492).
Clearing the Management Agent state

To clear the Management Agent's state, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent`. This procedure is equivalent to running the `emctl clearstate agent` command.

The following procedure creates a task that clears the Management Agent's state and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1492).

Making the Management Agent upload its OMS

To make the Management Agent upload the Oracle Management Server (OMS) associated with it, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent`. This procedure is equivalent to running the `emclt upload agent` command.

The following procedure creates a task that makes the Management Agent upload its associated OMS and return the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1492).

Pinging the OMS

To ping the Management Agent's OMS, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent`. This procedure is equivalent to running the `emctl pingOMS` command.

The following procedure creates a task that pings the Management Agent's OMS and returns the ID of the task.

```sql
SELECT rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see Viewing the status of an ongoing task (p. 1492).

Viewing the status of an ongoing task

You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

When you want to monitor a task, replace `task-id` with the ID of the task that you want to monitor.

To view the contents of bdump files, run the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The following query returns the contents of the bdump file.

```sql
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1546988886389-2444.log'));
```
For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see Reading files in a DB instance directory (p. 1420).

### Removing the Management Agent option

You can remove the OEM Agent from a DB instance. After you remove the OEM Agent, you don’t need to restart your DB instance.

To remove the OEM Agent from a DB instance, do one of the following:

- Remove the OEM Agent option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).
- Modify the DB instance and specify a different option group that doesn't include the OEM Agent option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Oracle Label Security

Amazon RDS supports Oracle Label Security for the Enterprise Edition of Oracle Database through the use of the OLS option.

Most database security controls access at the object level. Oracle Label Security provides fine-grained control of access to individual table rows. For example, you can use Label Security to enforce regulatory compliance with a policy-based administration model. You can use Label Security policies to control access to sensitive data, and restrict access to only users with the appropriate clearance level. For more information, see Introduction to Oracle Label Security in the Oracle documentation.

Topics

- Prerequisites for Oracle Label Security (p. 1494)
- Adding the Oracle Label Security option (p. 1494)
- Using Oracle Label Security (p. 1495)
- Removing the Oracle Label Security option (p. 1495)
- Troubleshooting (p. 1496)

Prerequisites for Oracle Label Security

Familiarize yourself with the following prerequisites for Oracle Label Security:

- Your DB instance must use the Bring Your Own License model. For more information, see Oracle licensing options (p. 1299).
- You must have a valid license for Oracle Enterprise Edition with Software Update License and Support.
- Your Oracle license must include the Label Security option.
- You must be using the non-multitenant database architecture rather than the single-tenant architecture. For more information, see RDS for Oracle architecture (p. 1305).

Adding the Oracle Label Security option

The general process for adding the Oracle Label Security option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

   **Important**
   
   Oracle Label Security is a permanent and persistent option.

4. After you add the Label Security option, as soon as the option group is active, Label Security is active.

   **To add the label security option to a DB instance**

   1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

      a. For **Engine**, choose oracle-ee.
      b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).
2. Add the **OLS** option to the option group. For more information about adding options, see *Adding an option to an option group* (p. 266).

   **Important**
   If you add Label Security to an existing option group that is already attached to one or more DB instances, all the DB instances are restarted.

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see *Creating an Amazon RDS DB instance* (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the Label Security option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see *Modifying an Amazon RDS DB instance* (p. 309).

### Using Oracle Label Security

To use Oracle Label Security, you create policies that control access to specific rows in your tables. For more information, see *Creating an Oracle Label Security policy* in the Oracle documentation.

When you work with Label Security, you perform all actions as the LBAC_DBA role. The master user for your DB instance is granted the LBAC_DBA role. You can grant the LBAC_DBA role to other users so that they can administer Label Security policies.

For the following releases, make sure to grant access to the **OLS_ENFORCEMENT** package to any new users who require access to Oracle Label Security:

- Oracle Database 19c using the non-CDB architecture
- Oracle Database 12c Release 2 (12.2)

To grant access to the **OLS_ENFORCEMENT** package, connect to the DB instance as the master user and run the following SQL statement:

```sql
GRANT ALL ON LBACSYS.OLS_ENFORCEMENT TO username;
```

You can configure Label Security through the Oracle Enterprise Manager (OEM) Cloud Control. Amazon RDS supports the OEM Cloud Control through the Management Agent option. For more information, see *Oracle Management Agent for Enterprise Manager Cloud Control* (p. 1484).

### Removing the Oracle Label Security option

You can remove Oracle Label Security from a DB instance.

To remove Label Security from a DB instance, do one of the following:

- To remove Label Security from multiple DB instances, remove the Label Security option from the option group they belong to. This change affects all DB instances that use the option group. When you remove Label Security from an option group that is attached to multiple DB instances, all the DB instances are restarted. For more information, see *Removing an option from an option group* (p. 274).

- To remove Label Security from a single DB instance, modify the DB instance and specify a different option group that doesn't include the Label Security option. You can specify the default (empty) option group, or a different custom option group. When you remove the Label Security option, a brief outage occurs while your DB instance is automatically restarted. For more information, see *Modifying an Amazon RDS DB instance* (p. 309).
# Troubleshooting

The following are issues you might encounter when you use Oracle Label Security.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Troubleshooting suggestions</th>
</tr>
</thead>
<tbody>
<tr>
<td>When you try to create a policy, you see an error message similar to the following: insufficient authorization for the SYSDBA package.</td>
<td>A known issue with Oracle's Label Security feature prevents users with usernames of 16 or 24 characters from running Label Security commands. You can create a new user with a different number of characters, grant LBAC_DBA to the new user, log in as the new user, and run the OLS commands as the new user. For additional information, please contact Oracle support.</td>
</tr>
</tbody>
</table>
Oracle Locator

Amazon RDS supports Oracle Locator through the use of the `LOCATOR` option. Oracle Locator provides capabilities that are typically required to support internet and wireless service-based applications and partner-based GIS solutions. Oracle Locator is a limited subset of Oracle Spatial. For more information, see Oracle Locator in the Oracle documentation.

**Important**

If you use Oracle Locator, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle Locator for the following releases of Oracle Database:

- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 or later

Oracle Locator isn't supported for Oracle Database 21c, but its functionality is available in the Oracle Spatial option. Formerly, the Spatial option required additional licenses. Oracle Locator represented a subset of Oracle Spatial features and didn't require additional licenses. In 2019, Oracle announced that all Oracle Spatial features were included in the Enterprise Edition and Standard Edition Two licenses without additional cost. Consequently, the Oracle Spatial option no longer required additional licensing.

Starting with Oracle Database 21c, the Oracle Locator option is no longer supported. To use the Oracle Locator features in Oracle Database 21c, install the Oracle Spatial option instead. For more information, see Machine Learning, Spatial and Graph - No License Required! in the Oracle Database Insider blog.

**Prerequisites for Oracle Locator**

The following are prerequisites for using Oracle Locator:

- Your DB instance must be inside a virtual private cloud (VPC). For more information, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869).
- Your DB instance must be of sufficient class. Oracle Locator is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1302).
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 309).

**Best practices for Oracle Locator**

The following are best practices for using Oracle Locator:

- For maximum security, use the `LOCATOR` option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1514).
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 1857) and Working with a DB instance in a VPC (p. 1849).

**Adding the Oracle Locator option**

The following is the general process for adding the `LOCATOR` option to a DB instance:
1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the LOCATOR option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Locator is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

**To add the LOCATOR option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the oracle edition for your DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).

2. Add the **LOCATOR** option to the option group. For more information about adding options, see Adding an option to an option group (p. 266).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**Using Oracle Locator**

After you enable the Oracle Locator option, you can begin using it. You should only use Oracle Locator features. Don't use any Oracle Spatial features unless you have a license for Oracle Spatial.

For a list of features that are supported for Oracle Locator, see Features Included with Locator in the Oracle documentation.

For a list of features that are not supported for Oracle Locator, see Features Not Included with Locator in the Oracle documentation.

**Removing the Oracle Locator option**

After you drop all objects that use data types provided by the LOCATOR option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the LOCATOR option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the LOCATOR option, you don't need to restart your DB instance.

**To drop the LOCATOR option**

1. Back up your data.
Warning
If the instance uses data types that were enabled as part of the option, and if you remove the LOCATOR option, you can lose data. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 406).

2. Check whether any existing objects reference data types or features of the LOCATOR option.

If LOCATOR options exist, the instance can get stuck when applying the new option group that doesn't have the LOCATOR option. You can identify the objects by using the following queries:

```sql
SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
FROM DBA_SEGMENTS
WHERE SEGMENT_TYPE LIKE '%TABLE%
AND (SELECT DISTINCT OWNER, TABLE_NAME
     FROM DBA_TAB_COLUMNS
     WHERE DATA_TYPE='SDO_GEOMETRY'
     AND OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM DBA_TAB_COLUMNS
WHERE DATA_TYPE = 'SDO_GEOMETRY'
AND OWNER <> 'MDSYS'
ORDER BY 1,2,3;
```

3. Drop any objects that reference data types or features of the LOCATOR option.
4. Do one of the following:

- Remove the LOCATOR option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).
- Modify the DB instance and specify a different option group that doesn't include the LOCATOR option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Oracle Multimedia

Amazon RDS supports Oracle Multimedia through the use of the MULTIMEDIA option. You can use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data. For more information, see Oracle Multimedia in the Oracle documentation.

Important
If you use Oracle Multimedia, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle Multimedia for all editions of the following versions:

• Oracle Database 12c Release 2 (12.2)
• Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v13 or higher

Note
Oracle desupported Oracle Multimedia in Oracle Database 19c. So, Oracle Multimedia isn't supported for Oracle Database 19c DB instances. For more information, see Desupport of Oracle Multimedia in the Oracle documentation.

Prerequisites for Oracle Multimedia

The following are prerequisites for using Oracle Multimedia:

• Your DB instance must be inside a virtual private cloud (VPC). For more information, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869).
• Your DB instance must be of sufficient class. Oracle Multimedia is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1302).
• Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 309).

Best practices for Oracle Multimedia

The following are best practices for using Oracle Multimedia:

• For maximum security, use the MULTIMEDIA option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1514).
• Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 1857) and Working with a DB instance in a VPC (p. 1849).

Adding the Oracle Multimedia option

The following is the general process for adding the MULTIMEDIA option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.
If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the MULTIMEDIA option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Multimedia is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

**To add the MULTIMEDIA option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the edition for your Oracle DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).

2. Add the MULTIMEDIA option to the option group. For more information about adding options, see Adding an option to an option group (p. 266).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**Removing the Oracle Multimedia option**

After you drop all objects that use data types provided by the MULTIMEDIA option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the MULTIMEDIA option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the MULTIMEDIA option, you don't need to restart your DB instance.

**To drop the MULTIMEDIA option**

1. Back up your data.
   - **Warning**
     If the instance uses data types that were enabled as part of the option, and if you remove the MULTIMEDIA option, you can lose data. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 406).

2. Check whether any existing objects reference data types or features of the MULTIMEDIA option.
3. Drop any objects that reference data types or features of the MULTIMEDIA option.
4. Do one of the following:
   - Remove the MULTIMEDIA option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).
   - Modify the DB instance and specify a different option group that doesn't include the MULTIMEDIA option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Oracle native network encryption

Amazon RDS supports Oracle native network encryption (NNE). With native network encryption, you can encrypt data as it moves to and from a DB instance. Amazon RDS supports NNE for all editions of Oracle Database.

A detailed discussion of Oracle native network encryption is beyond the scope of this guide, but you should understand the strengths and weaknesses of each algorithm and key before you decide on a solution for your deployment. For information about the algorithms and keys that are available through Oracle native network encryption, see Configuring network data encryption in the Oracle documentation. For more information about AWS security, see the AWS security center.

**Note**
You can use Native Network Encryption or Secure Sockets Layer, but not both. For more information, see Oracle Secure Sockets Layer (p. 1514).

NNE option settings

You can specify encryption requirements on both the server and the client. The DB instance can act as a client when, for example, it uses a database link to connect to another database. You might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the SQLNET.*CLIENT options.

Amazon RDS supports the following settings for the NNE option.

**Note**
When you use commas to separate values for an option setting, don't put a space after the comma.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.ALLOW_WEAK_CRYPTO_CLIENT</td>
<td>TRUE, FALSE</td>
<td>TRUE</td>
<td>The behavior of the server when a client using a non-secure cipher attempts to connect to the database. If TRUE, clients can connect even if they aren't patched with the July 2021 PSU.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>If the setting is FALSE, clients can connect to the database only when they are patched with the July 2021 PSU. Before you set SQLNET.ALLOW_WEAK_CRYPTO_CLIENT to FALSE, make sure that the following conditions are met:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.</td>
</tr>
<tr>
<td>Option setting</td>
<td>Valid values</td>
<td>Default values</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-----------------</td>
<td>----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SQLNET.ALLOW_WEAK_CRYPTO</td>

</tr>
</tbody>
</table>
### Native network encryption (NNE)

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.ENCRYPTION_TYPES_SERVER</td>
<td>RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40</td>
<td>RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40</td>
<td>A list of encryption algorithms used by the DB instance. The DB instance uses each algorithm, in order, to attempt to decrypt the client input until an algorithm succeeds or until the end of the list is reached.</td>
</tr>
</tbody>
</table>

Amazon RDS uses the following default list from Oracle. You can change the order or limit the algorithms that the client will accept.

1. RC4_256: RSA RC4 (256-bit key size)
2. AES256: AES (256-bit key size)
3. AES192: AES (192-bit key size)
4. 3DES168: 3-key Triple-DES (112-bit effective key size)
5. RC4_128: RSA RC4 (128-bit key size)
6. AES128: AES (128-bit key size)
7. 3DES112: 2-key Triple-DES (80-bit effective key size)
8. RC4_56: RSA RC4 (56-bit key size)
9. DES: Standard DES (56-bit key size)
10. RC4_40: RSA RC4 (40-bit key size)
11. DES40: DES40 (40-bit key size)

You can specify either one value or a comma-separated list of values. If you comma, don’t insert a space after the comma; otherwise, you receive an InvalidParameterValue error.

This parameter and SQLNET.SQLNET.ENCRYPTION_TYPES_SERVER must have a common cipher.

---

### Adding the NNE option

The general process for adding the NNE option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When the option group is active, NNE is active.

To add the NNE option to a DB instance using the AWS Management Console

1. For Engine, choose the Oracle edition that you want to use. NNE is supported on all editions.
2. For Major engine version, choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).
3. Add the **NNE** option to the option group. For more information about adding options, see **Adding an option to an option group** (p. 266).

   **Note**
   After you add the NNE option, you don’t need to restart your DB instances. As soon as the option group is active, NNE is active.

4. Apply the option group to a new or existing DB instance:

   - For a new DB instance, you apply the option group when you launch the instance. For more information, see **Creating an Amazon RDS DB instance** (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. After you add the NNE option, you don’t need to restart your DB instance. As soon as the option group is active, NNE is active. For more information, see **Modifying an Amazon RDS DB instance** (p. 309).

### Setting NNE values in the sqlnet.ora

With Oracle native network encryption, you can set network encryption on the server side and client side. The client is the computer used to connect to the DB instance. You can specify the following client settings in the sqlnet.ora:

- `SQLNET.ALLOW_WEAK_CRYPTO`
- `SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS`
- `SQLNET.CRYPTO_CHECKSUM_CLIENT`
- `SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT`
- `SQLNET.ENCRYPTION_CLIENT`
- `SQLNET.ENCRYPTION_TYPES_CLIENT`

For information, see **Configuring network data encryption and integrity for Oracle servers and clients** in the Oracle documentation.

Sometimes, the DB instance rejects a connection request from an application. For example, a rejection can occur when the encryption algorithms on the client and on the server don't match. To test Oracle native network encryption, add the following lines to the sqlnet.ora file on the client:

```
DIAG_ADR_ENABLED=off
TRACE_DIRECTORY_CLIENT=/tmp
TRACE_FILE_CLIENT=nettrace
TRACE_LEVEL_CLIENT=16
```

When a connection is attempted, the preceding lines generate a trace file on the client called `/tmp/nettrace*`. The trace file contains information about the connection. For more information about connection-related issues when you are using Oracle Native Network Encryption, see **About negotiating encryption and integrity** in the Oracle Database documentation.

### Modifying NNE option settings

After you enable NNE, you can modify settings for the option. For more information about how to modify option settings, see **Modifying an option setting** (p. 271). For more information about each setting, see **NNE option settings** (p. 1503).

**Topics**

- **Modifying CRYPTO_CHECKSUM_* values** (p. 1509)
- **Modifying ALLOW_WEAK_CRYPTO* settings** (p. 1509)
Modifying CRYPTO_CHECKSUM_* values

If you modify NNE option settings, make sure that the following option settings have at least one common cipher:

- SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
- SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT

The following example shows a scenario in which you modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER. The configuration is valid because the CRYPTO_CHECKSUM_TYPES_CLIENT and CRYPTO_CHECKSUM_TYPES_SERVER both use SHA256.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Values before modification</th>
<th>Values after modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT</td>
<td>SHA256, SHA384, SHA512</td>
<td>No change</td>
</tr>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER</td>
<td>SHA1, MD5, SHA256</td>
<td>SHA1, MD5, SHA256</td>
</tr>
</tbody>
</table>

For another example, assume that you want to modify SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER from its default setting to SHA1, MD5. In this case, make sure you set SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT to SHA1 or MD5. These algorithms aren't included in the default values for SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT.

Modifying ALLOW_WEAK_CRYPTO* settings

To set the SQLNET.ALLOW_WEAK_CRYPTO* options from the default value to FALSE, make sure that the following conditions are met:

- SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching secure encryption method. A method is considered secure if it's not DES, 3DES, or RC4 (all key lengths).
- SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method. A method is considered secure if it's not MD5.
- The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.

The following example shows sample NNE settings. Assume that you want to set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to FALSE, thereby blocking non-secure connections. The checksum option settings meet the prerequisites because they both have SHA256. However, SQLNET.ENCRYPTION_TYPES_CLIENT and SQLNET.ENCRYPTION_TYPES_SERVER use the DES, 3DES, and RC4 encryption methods, which are non-secure. Therefore, to set the SQLNET.ALLOW_WEAK_CRYPTO* options to FALSE, first set SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT to a secure encryption method such as AES256.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT</td>
<td>SHA256, SHA384, SHA512</td>
</tr>
<tr>
<td>SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER</td>
<td>SHA1, MD5, SHA256</td>
</tr>
<tr>
<td>SQLNET.ENCRYPTION_TYPES_CLIENT</td>
<td>RC4_256, 3DES168, DES40</td>
</tr>
<tr>
<td>Option setting</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>SQLNET.ENCRYPTION_TYPES_SERVER</td>
<td>RC4_256, 3DES168, DES40</td>
</tr>
</tbody>
</table>

**Removing the NNE option**

You can remove NNE from a DB instance.

To remove NNE from a DB instance, do one of the following:

- To remove NNE from multiple DB instances, remove the NNE option from the option group they belong to. This change affects all DB instances that use the option group. After you remove the NNE option, you don't need to restart your DB instances. For more information, see Removing an option from an option group (p. 274).

- To remove NNE from a single DB instance, modify the DB instance and specify a different option group that doesn't include the NNE option. You can specify the default (empty) option group, or a different custom option group. After you remove the NNE option, you don't need to restart your DB instance. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Oracle OLAP

Amazon RDS supports Oracle OLAP through the use of the OLAP option. This option provides On-line Analytical Processing (OLAP) for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see the Oracle documentation.

Important
If you use Oracle OLAP, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle OLAP for the following editions and versions of Oracle:

- Oracle Database 21c Enterprise Edition, all versions
- Oracle Database 19c Enterprise Edition, all versions
- Oracle Database 12c Release 2 (12.2.0.1) Enterprise Edition, all versions
- Oracle Database 12c Release 1 (12.1.0.2) Enterprise Edition, version 12.1.0.2.v13 or later

Prerequisites for Oracle OLAP

The following are prerequisites for using Oracle OLAP:

- You must have an Oracle OLAP license from Oracle. For more information, see Licensing Information in the Oracle documentation.
- Your DB instance must be inside a virtual private cloud (VPC). For more information, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869).
- Your DB instance must be of a sufficient instance class. Oracle OLAP isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1302).
- Your DB instance must have Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 309).
- Your DB instance must not have a user named OLAPSYS. If it does, the OLAP option installation fails.

Best practices for Oracle OLAP

The following are best practices for using Oracle OLAP:

- For maximum security, use the OLAP option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1514).
- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 1857) and Working with a DB instance in a VPC (p. 1849).

Adding the Oracle OLAP option

The following is the general process for adding the OLAP option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.
If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the \textit{OLAP} option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle OLAP is available.

**To add the OLAP option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   - For \textit{Engine}, choose the Oracle edition for your DB instance.
   - For \textit{Major engine version}, choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).

2. Add the \textit{OLAP} option to the option group. For more information about adding options, see Adding an option to an option group (p. 266).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**Using Oracle OLAP**

After you enable the Oracle OLAP option, you can begin using it. For a list of features that are supported for Oracle OLAP, see the Oracle documentation.

**Removing the Oracle OLAP option**

After you drop all objects that use data types provided by the \textit{OLAP} option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the \textit{OLAP} option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the \textit{OLAP} option, you don't need to restart your DB instance.

**To drop the \textit{OLAP} option**

1. Back up your data.
   
   \textbf{Warning}
   If the instance uses data types that were enabled as part of the option, and if you remove the \textit{OLAP} option, you can lose data. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 406).

2. Check whether any existing objects reference data types or features of the \textit{OLAP} option.

3. Drop any objects that reference data types or features of the \textit{OLAP} option.

4. Do one of the following:
   - Remove the \textit{OLAP} option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).
   - Modify the DB instance and specify a different option group that doesn't include the \textit{OLAP} option. This change affects a single DB instance. You can specify the default (empty) option group,
or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Secure Sockets Layer (SSL)

Oracle Secure Sockets Layer

You enable Secure Sockets Layer (SSL) encryption for an Oracle DB instance by adding the Oracle SSL option to the option group associated with an Oracle DB instance. You specify the port you want to communicate over using SSL. You must configure SQL*Plus as shown in this following section.

You enable SSL encryption for an Oracle DB instance by adding the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. This approach allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and SQL*Plus. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

Note
You can use Secure Sockets Layer or Native Network Encryption, but not both. For more information, see Oracle native network encryption (p. 1503).

You can use SSL encryption with all editions of the following Oracle database versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)
- Oracle Database 12c Release 2 (12.2)
- Oracle Database 12c Release 1 (12.1)

Note
You cannot use both SSL and Oracle native network encryption (NNE) on the same instance. If you use SSL encryption, you must disable any other connection encryption.

TLS versions for the Oracle SSL option

Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. To use the Oracle SSL option, use the SQLNET.SSL_VERSION option setting. The following values are allowed for this option setting:

- "1.0" – Clients can connect to the DB instance using TLS 1.0 only.
- "1.2" – Clients can connect to the DB instance using TLS 1.2 only.
- "1.2 or 1.0" – Clients can connect to the DB instance using either TLS 1.2 or 1.0.

To use the Oracle SSL option, the SQLNET.SSL_VERSION option setting is also required:

- For existing Oracle SSL options, SQLNET.SSL_VERSION is set to "1.0" automatically. You can change the setting if necessary.
- When you add a new Oracle SSL option, you must set SQLNET.SSL_VERSION explicitly to a valid value.

The following table shows the TLS option settings that are supported for different Oracle engine versions and editions.

<table>
<thead>
<tr>
<th>Oracle engine version</th>
<th>SQLNET.SSL_VERSION = &quot;1.0&quot;</th>
<th>SQLNET.SSL_VERSION = &quot;1.2&quot;</th>
<th>SQLNET.SSL_VERSION = &quot;1.2 or 1.0&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>21.0.0.0 (All editions)</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>19.0.0.0 (All editions)</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>
Cipher suites for the Oracle SSL option

Amazon RDS for Oracle supports multiple SSL cipher suites. By default, the Oracle SSL option is configured to use the `SSL_RSA_WITH_AES_256_CBC_SHA` cipher suite. To specify a different cipher suite to use over SSL connections, use the `SQLNET.CIPHER_SUITE` option setting. Following are the allowed values for this option setting:

- "SSL_RSA_WITH_AES_256_CBC_SHA" – The default setting, which is compatible with TLS 1.0 and TLS 1.2
- "SSL_RSA_WITH_AES_256_CBC_SHA256" – Only compatible with TLS 1.2
- "SSL_RSA_WITH_AES_256_GCM_SHA384" – Only compatible with TLS 1.2

For existing Oracle SSL options, `SQLNET.CIPHER_SUITE` is set to "SSL_RSA_WITH_AES_256_CBC_SHA" automatically. You can change the setting if necessary.

The following table shows the cipher suite option settings that are supported for different Oracle engine versions and editions.

<table>
<thead>
<tr>
<th>Oracle engine version</th>
<th>SQLNET.CIPHER_SUITE = &quot;SSL_RSA_WITH_AES_256_CBC_SHA&quot;</th>
<th>SQLNET.CIPHER_SUITE = &quot;SSL_RSA_WITH_AES_256_CBC_SHA256&quot;</th>
<th>SQLNET.CIPHER_SUITE = &quot;SSL_RSA_WITH_AES_256_GCM_SHA384&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td>19.0.0.0 (All editions)</td>

<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

FIPS support

Amazon RDS for Oracle enables you to use the Federal Information Processing Standard (FIPS) standard for 140-2. FIPS 140-2 is a United States government standard that defines cryptographic module security requirements. You enable the FIPS standard by setting the setting `FIPS.SSLFIPS_140` to `TRUE` for the Oracle SSL option. When FIPS 140-2 is configured for SSL, the cryptographic libraries are designed to encrypt data between the client and the Oracle DB instance.

You can enable the FIPS setting with the following Oracle database versions and editions:

- 19.0.0.0: All versions, all editions including Standard Edition Two
- 12.2.0.1: All versions, all editions including Standard Edition Two
- 12.1.0.2: Version 2 and later, all editions including Standard Edition Two

Clients must use the cipher suite that is FIPS-compliant. When establishing a connection, the client and Oracle DB instance negotiate which cipher suite to use when transmitting messages back and forth. The following table shows the FIPS-compliant SSL cipher suites for each TLS version.
Secure Sockets Layer (SSL)

**Supported cipher suites**

- 1.0  
  SSL_RSA_WITH_AES_256_CBC_SHA

- 1.2  
  SSL_RSA_WITH_AES_256_CBC_SHA
  SSL_RSA_WITH_AES_256_GCM_SHA384

For more information, see [Oracle database FIPS 140-2 settings](https://docs.oracle.com/en/database/oracle/database-121.2.0/securenet/securenet.pdf) in the Oracle documentation.

**Adding the SSL option**

To use SSL, your Amazon RDS for Oracle DB instance must be associated with an option group that includes the SSL option.

**Console**

**To add the SSL option to an option group**

1. Create a new option group or identify an existing option group to which you can add the SSL option.
   
2. Add the SSL option to the option group.
   
   If you want to use only FIPS-verified cipher suites for SSL connections, set the option FIPS.SSLFIPS_140 to TRUE. For information about the FIPS standard, see [FIPS support](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_OptGroup.html#USER_OptGroup.FIPS).  
   
   For information about adding an option to an option group, see [Adding an option to an option group](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_OptGroup.html#USER_OptGroup.Add).  
3. Create a new Oracle DB instance and associate the option group with it, or modify an Oracle DB instance to associate the option group with it.

   For information about creating a DB instance, see [Creating an Amazon RDS DB instance](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_CreateDBInstance.html).  
   
   For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_ModifyDBInstance.html).

**AWS CLI**

**To add the SSL option to an option group**

1. Create a new option group or identify an existing option group to which you can add the SSL option.
   
2. Add the SSL option to the option group.

   Specify the following option settings:

   - **Port** – The SSL port number
   - **VpcSecurityGroupMemberships** – The VPC security group for which the option is enabled
   - **SQLNET.SSL_VERSION** – The TLS version that client can use to connect to the DB instance

   For example, the following AWS CLI command adds the SSL option to an option group named `ora-option-group`.  

---

1516
Example

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group --option-group-name ora-option-group \
--options 'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=\[{Name=SQLNET.SSL_VERSION,Value=1.0}\]'
```

For Windows:

```bash
aws rds add-option-to-option-group --option-group-name ora-option-group ^ \
--options 'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings[\{Name=SQLNET.SSL_VERSION,Value=1.0\}]
```

3. Create a new Oracle DB instance and associate the option group with it, or modify an Oracle DB instance to associate the option group with it.

For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 175).

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

Configuring SQL*Plus to use SSL with an Oracle DB instance

You must configure SQL*Plus before connecting to an Oracle DB instance that uses the Oracle SSL option.

**Note**
To allow access to the DB instance from the appropriate clients, ensure that your security groups are configured correctly. For more information, see Controlling access with security groups (p. 1822). Also, these instructions are for SQL*Plus and other clients that directly use an Oracle home. For JDBC connections, see Setting up an SSL connection over JDBC (p. 1519).

To configure SQL*Plus to use SSL to connect to an Oracle DB instance

1. Set the `ORACLE_HOME` environment variable to the location of your Oracle home directory.

   The path to your Oracle home directory depends on your installation. The following example sets the `ORACLE_HOME` environment variable.

   ```bash
   prompt>export ORACLE_HOME=/home/user/app/user/product/12.1.0/dbhome_1
   ```

   For information about setting Oracle environment variables, see SQL*Plus environment variables in the Oracle documentation, and also see the Oracle installation guide for your operating system.

2. Append `$ORACLE_HOME/lib` to the `LD_LIBRARY_PATH` environment variable.

   The following is an example that sets the `LD_LIBRARY_PATH` environment variable.

   ```bash
   prompt>export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$ORACLE_HOME/lib
   ```

3. Create a directory for the Oracle wallet at `$ORACLE_HOME/ssl_wallet`.

   The following is an example that creates the Oracle wallet directory.

   ```bash
   ```
4. Download the root certificate that works for all AWS Regions and put the file in the ssl_wallet directory.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

5. In the $ORACLE_HOME/network/admin directory, modify or create the tnsnames.ora file and include the following entry.

```
<net_service_name> = (DESCRIPTION = (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCPS)
                     (HOST = <endpoint>) (PORT = <ssl port number>)))(CONNECT_DATA = (SID = <database name>))
                     (SECURITY = (SSL_SERVER_CERT_DN = "C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=<endpoint>")))
```

6. In the same directory, modify or create the sqlnet.ora file and include the following parameters.

```
WALLET_LOCATION = (SOURCE = (METHOD = FILE) (DIRECTORY = $ORACLE_HOME/ssl_wallet))
SSL_CLIENT_AUTHENTICATION = FALSE
SSL_VERSION = 1.0
SSL_CIPHER_SUITES = (SSL_RSA_WITH_AES_256_CBC_SHA)
SSL_SERVER_DN_MATCH = ON
```

**Note**

To communicate with entities over a TLS secured connection, Oracle requires a wallet with the necessary certificates for authentication. You can use Oracle's ORAPKI utility to create and maintain Oracle wallets, as shown in step 7. For more information, see Setting up Oracle wallet using ORAPKI in the Oracle documentation.

```
WALLET_LOCATION = (SOURCE = (METHOD = FILE) (DIRECTORY = $ORACLE_HOME/ssl_wallet))
SSL_CLIENT_AUTHENTICATION = FALSE
SSL_VERSION = 1.0
SSL_CIPHER_SUITES = (SSL_RSA_WITH_AES_256_CBC_SHA)
SSL_SERVER_DN_MATCH = ON
```

7. Run the following commands to create the Oracle wallet.

```
prompt>orapki wallet create -wallet $ORACLE_HOME/ssl_wallet -auto_login_only
prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert $ORACLE_HOME/ssl_wallet/rds-ca-2019-root.pem -auto_login_only
```

Replace the file name with the one you downloaded.

**Connecting to an Oracle DB instance using SSL**

After you configure SQL*Plus to use SSL as described previously, you can connect to the Oracle DB instance with the SSL option. Optionally, you can first export the TNS_ADMIN value that points to the directory that contains the tnsnames.ora and sqlnet.ora files. Doing so ensures that SQL*Plus can find these files consistently. The following example exports the TNS_ADMIN value.

```
export TNS_ADMIN = ${ORACLE_HOME}/network/admin
```

Connect to the DB instance. For example, you can connect using SQL*Plus and a `<net_service_name>` in a tnsnames.ora file.

```
sqlplus <mydbuser>@<net_service_name>
```
You can also connect to the DB instance using SQL*Plus without using a tnsnames.ora file by using the following command.

```sql
sqlplus 'user <mydbuser>@<endpoint>:<ssl port number> (DESCRIPTION = (ADDRESS = (PROTOCOL = TCPS)(HOST = <endpoint>)(PORT = <ssl port number>))(CONNECT_DATA = (SID = <database name>)))'
```

You can also connect to the Oracle DB instance without using SSL. For example, the following command connects to the DB instance through the clear text port without SSL encryption.

```sql
sqlplus 'user <mydbuser>@<endpoint>:<port number> (DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = <endpoint>)(PORT = <port number>))(CONNECT_DATA = (SID = <database name>)))'
```

If you want to close Transmission Control Protocol (TCP) port access, create a security group with no IP address ingresses and add it to the instance. This addition closes connections over the TCP port, while still allowing connections over the SSL port that are specified from IP addresses within the range permitted by the SSL option security group.

### Setting up an SSL connection over JDBC

To use an SSL connection over JDBC, you must create a keystore, trust the Amazon RDS root CA certificate, and use the code snippet specified following.

To create the keystore in JKS format, use the following command. For more information about creating the keystore, see the Oracle documentation.

```
keytool -keystore clientkeystore -genkey -alias client
```

Next, take the following steps to trust the Amazon RDS root CA certificate.

#### To trust the Amazon RDS root CA certificate

1. Download the root certificate that works for all AWS Regions and put the file in the ssl_wallet directory.
   
   For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance](#).

2. Convert the certificate to .der format using the following command. Replace the file name with the one you downloaded.

   ```bash
   ```

3. Import the certificate into the keystore using the following command.

   ```bash
   ```

4. Confirm that the key store was created successfully.

   ```bash
   keytool -list -v -keystore clientkeystore.jks
   ```

   Enter the keystore password when you are prompted for it.

The following code example shows how to set up the SSL connection using JDBC.
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
  private static final String DB_SERVER_NAME = "<dns-name-provided-by-amazon-rds>";
  private static final Integer SSL_PORT = "<ssl-option-port-configured-in-option-group>";
  private static final String DB_SID = "<oracle-sid>";
  private static final String DB_USER = "<user name>";
  private static final String DB_PASSWORD = "<password>";
  // This key store has only the prod root ca.
  private static final String KEY_STORE_FILE_PATH = "<file-path-to-keystore>";
  private static final String KEY_STORE_PASS = "<keystore-password>";

  public static void main(String[] args) throws SQLException {
    final Properties properties = new Properties();
    final String connectionString = String.format(
        "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))
           (CONNECT_DATA=(SID=%s)))",
        DB_SERVER_NAME, SSL_PORT, DB_SID);
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);
    properties.put("oracle.jdbc.J2EE13Compliant", "true");
    properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    properties.put("javax.net.ssl.trustStoreType", "JKS");
    properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
    final Connection connection = DriverManager.getConnection(connectionString, properties);
    // If no exception, that means handshake has passed, and an SSL connection can be opened
  }
}

Enforcing a DN match with an SSL connection

You can use the Oracle parameter SSL_SERVER_DN_MATCH to enforce that the distinguished name (DN) for the database server matches its service name. If you enforce the match verifications, then SSL ensures that the certificate is from the server. If you don’t enforce the match verification, then SSL performs the check but allows the connection, regardless if there is a match. If you do not enforce the match, you allow the server to potentially fake its identity.

To enforce DN matching, add the DN match property and use the connection string specified below.

Add the property to the client connection to enforce DN matching.

```
properties.put("oracle.net.ssl_server_dn_match", "TRUE");
```

Use the following connection string to enforce DN matching when using SSL.

```
final String connectionString = String.format(
    "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))
       (CONNECT_DATA=(SID=%s))") +
    "(SECURITY = (SSL_SERVER_CERT_DN = "C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=%s")", DB_SERVER_NAME, SSL_PORT, DB_SID, DB_SERVER_NAME);
```
Oracle Spatial

Amazon RDS supports Oracle Spatial through the use of the SPATIAL option. Oracle Spatial provides a SQL schema and functions that facilitate the storage, retrieval, update, and query of collections of spatial data in an Oracle database. For more information, see Spatial Concepts in the Oracle documentation.

Important
If you use Oracle Spatial, Amazon RDS automatically updates your DB instance to the latest Oracle PSU when any of the following exist:

- Security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+
- Other announced security vulnerabilities

Amazon RDS supports Oracle Spatial only in Oracle Enterprise Edition (EE) and Oracle Standard Edition 2 (SE2). The following table shows the versions of the DB engine that support EE and SE2.

<table>
<thead>
<tr>
<th>Oracle DB Version</th>
<th>EE</th>
<th>SE2</th>
</tr>
</thead>
<tbody>
<tr>
<td>21.0.0.0, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>19.0.0.0, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>12.2.0.1, all versions</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>12.1.0.2.v13 or later</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Prerequisites for Oracle Spatial

The following are prerequisites for using Oracle Spatial:

- Make sure that your DB instance is inside a virtual private cloud (VPC). For more information, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869).

- Make sure that your DB instance is of a sufficient instance class. Oracle Spatial isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see RDS for Oracle instance classes (p. 1302).

- Make sure that your DB instance has Auto Minor Version Upgrade enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see Modifying an Amazon RDS DB instance (p. 309).

Best practices for Oracle Spatial

The following are best practices for using Oracle Spatial:

- For maximum security, use the SPATIAL option with Secure Sockets Layer (SSL). For more information, see Oracle Secure Sockets Layer (p. 1514).

- Configure your DB instance to restrict access to your DB instance. For more information, see Scenarios for accessing a DB instance in a VPC (p. 1857) and Working with a DB instance in a VPC (p. 1849).
Adding the Oracle Spatial option

The following is the general process for adding the SPATIAL option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the SPATIAL option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Spatial is available.

**Note**
During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

To add the SPATIAL option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition for your DB instance.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).
2. Add the SPATIAL option to the option group. For more information about adding options, see Adding an option to an option group (p. 266).
3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Removing the Oracle Spatial option

After you drop all objects that use data types provided by the SPATIAL option, you can drop the option from a DB instance. If Oracle Java Virtual Machine (JVM) is not installed on the DB instance, there is a brief outage while the SPATIAL option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the SPATIAL option, you don't need to restart your DB instance.

To drop the SPATIAL option

1. Back up your data.

   **Warning**
   If the instance uses data types that were enabled as part of the option, and if you remove the SPATIAL option, you can lose data. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 406).
2. Check whether any existing objects reference data types or features of the SPATIAL option.
If **SPATIAL** options exist, the instance can get stuck when applying the new option group that doesn't have the **SPATIAL** option. You can identify the objects by using the following queries:

```sql
SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE '%TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
       (SELECT DISTINCT OWNER, TABLE_NAME
        FROM   DBA_TAB_COLUMNS
        WHERE  DATA_TYPE='SDO_GEOMETRY'
        AND    OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM   DBA_TAB_COLUMNS
WHERE  DATA_TYPE = 'SDO_GEOMETRY'
AND    OWNER <> 'MDSYS'
ORDER BY 1,2,3;
```

3. Drop any objects that reference data types or features of the **SPATIAL** option.

4. Do one of the following:

   - Remove the **SPATIAL** option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).
   - Modify the DB instance and specify a different option group that doesn't include the **SPATIAL** option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Oracle SQLT

Amazon RDS supports Oracle SQLT (SQLT) through the use of the SQLT option.

The Oracle EXPLAIN PLAN statement can determine the execution plan of a SQL statement. It can verify whether the Oracle optimizer chooses a certain execution plan, such as a nested loops join. It also helps you understand the optimizer's decisions, such as why it chose a nested loops join over a hash join. So EXPLAIN PLAN helps you understand the statement's performance.

SQLT is an Oracle utility that produces a report. The report includes object statistics, object metadata, optimizer-related initialization parameters, and other information that a database administrator can use to tune a SQL statement for optimal performance. SQLT produces an HTML report with hyperlinks to all of the sections in the report.

Unlike Automatic Workload Repository or Statspack reports, SQLT works on individual SQL statements. SQLT is a collection of SQL, PL/SQL, and SQL*Plus files that collect, store, and display performance data.

Following are the supported Oracle versions for each SQLT version.

<table>
<thead>
<tr>
<th>SQLT version</th>
<th>Oracle Database 21c</th>
<th>Oracle Database 19c</th>
<th>Oracle Database 12c Release 2 (12.2)</th>
<th>Oracle Database 12c Release 1 (12.1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-07-25.v1</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>2018-03-31.v1</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>2016-04-29.v1</td>
<td>Not supported</td>
<td>Not supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>

To download SQLT and access instructions for using it:

- Log in to your My Oracle Support account, and open the following documents:
  - To download SQLT: Document 215187.1
  - For SQLT usage instructions: Document 1614107.1
  - For frequently asked questions about SQLT: Document 1454160.1
  - For information about reading SQLT output: Document 1456176.1
  - For interpreting the Main report: Document 1922234.1

You can use SQLT with any edition of the following Oracle Database versions:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

Amazon RDS does not support the following SQLT methods:

- XPLORE
- XHUME

Prerequisites for SQLT

The following are prerequisites for using SQLT:

- Prerequisites for SQLT
• You must remove users and roles that are required by SQLT, if they exist.

The SQLT option creates the following users and roles on a DB instance:
• SQLTXPLAIN user
• SQLTXADMIN user
• SQLT_USER_ROLE role

If your DB instance has any of these users or roles, log in to the DB instance using a SQL client, and drop them using the following statements:

```
DROP USER SQLTXPLAIN CASCADE;
DROP USER SQLTXADMIN CASCADE;
DROP ROLE SQLT_USER_ROLE CASCADE;
```

• You must remove tablespaces that are required by SQLT, if they exist.

The SQLT option creates the following tablespaces on a DB instance:
• RDS_SQLT_TS
• RDS_TEMP_SQLT_TS

If your DB instance has these tablespaces, log in to the DB instance using a SQL client, and drop them.

### SQLT option settings

SQLT can work with licensed features that are provided by the Oracle Tuning Pack and the Oracle Diagnostics Pack. The Oracle Tuning Pack includes the SQL Tuning Advisor, and the Oracle Diagnostics Pack includes the Automatic Workload Repository. The SQLT settings enable or disable access to these features from SQLT.

Amazon RDS supports the following settings for the SQLT option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LICENSE_PACK</td>
<td>T, D, N</td>
<td>N</td>
<td>The Oracle Management Packs that you want to access with SQLT. Enter one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• T indicates that you have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, and you want to access the SQL Tuning Advisor and Automatic Workload Repository from SQLT.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• D indicates that you have a license for the Oracle Diagnostics Pack, and you want to access the Automatic Workload Repository from SQLT.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• N indicates that you don't have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, or that you have a license for one or both of them, but you don't want SQLT to access them.</td>
</tr>
</tbody>
</table>
### Option setting

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VERSION</td>
<td>2016-04-29.v1</td>
<td>2016-04-29.v1</td>
<td>The version of SQLT that you want to install. <strong>Note</strong> For Oracle Database 19c and 21c, the only supported version is 2018-07-25.v1. This version is the default for these releases.</td>
</tr>
<tr>
<td></td>
<td>2018-03-31.v1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>2018-07-25.v1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Adding the SQLT option

The following is the general process for adding the SQLT option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLT option to the option group.
3. Associate the option group with the DB instance.

After you add the SQLT option, as soon as the option group is active, SQLT is active.

**To add the SQLT option to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the Oracle edition that you want to use. The SQLT option is supported on all editions.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).
2. Add the SQLT option to the option group. For more information about adding options, see Adding an option to an option group (p. 266).
3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
• For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

4. (Optional) Verify the SQLT installation on each DB instance with the SQLT option.
   a. Use a SQL client to connect to the DB instance as the master user.
      For information about connecting to an Oracle DB instance using a SQL client, see Connecting to your Oracle DB instance (p. 1312).
   b. Run the following query:

```sql
SELECT sqltxplain.sqlt$a.get_param('tool_version') sqlt_version FROM DUAL;
```

The query returns the current version of the SQLT option on Amazon RDS. 12.1.160429 is an example of a version of SQLT that is available on Amazon RDS.

5. Change the passwords of the users that are created by the SQLT option.
   a. Use a SQL client to connect to the DB instance as the master user.
   b. Run the following SQL statement to change the password for the SQLTXADMIN user:

```sql
ALTER USER SQLTXADMIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

c. Run the following SQL statement to change the password for the SQLTXPLAIN user:

```sql
ALTER USER SQLTXPLAIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

**Note**
Upgrading SQLT requires uninstalling an older version of SQLT and then installing the new version. So, all SQLT metadata can be lost when you upgrade SQLT. A major version upgrade of a database also uninstalls and re-installs SQLT. An example of a major version upgrade is an upgrade from Oracle Database 12c Release 2 (12.2) to Oracle Database 19c.

**Using SQLT**

SQLT works with the Oracle SQL*Plus utility.

**To use SQLT**

1. Download the SQLT .zip file from Document 215187.1 on the My Oracle Support site.
   **Note**
   You can't download SQLT 12.1.160429 from the My Oracle Support site. Oracle has deprecated this older version.
2. Unzip the SQLT .zip file.
3. From a command prompt, change to the sqlt/run directory on your file system.
4. From the command prompt, open SQL*Plus, and connect to the DB instance as the master user.
For information about connecting to a DB instance using SQL*Plus, see Connecting to your Oracle DB instance (p. 1312).

5. Get the SQL ID of a SQL statement:

```
SELECT SQL_ID FROM V$SQL WHERE SQL_TEXT='sql_statement';
```

Your output is similar to the following:

```
SQL_ID
---------
chvsmttqjzjkn
```

6. Analyze a SQL statement with SQLT:

```
START sqltxtract.sql sql_id sqlxplain_user_password
```

For example, for the SQL ID chvsmttqjzjkn, enter the following:

```
START sqltxtract.sql chvsmttqjzjkn sqlxplain_user_password
```

SQLT generates the HTML report and related resources as a .zip file in the directory from which the SQLT command was run.

7. (Optional) To enable application users to diagnose SQL statements with SQLT, grant SQLT_USER_ROLE to each application user with the following statement:

```
GRANT SQLT_USER_ROLE TO application_user_name;
```

**Note**
Oracle does not recommend running SQLT with the SYS user or with users that have the DBA role. It is a best practice to run SQLT diagnostics using the application user's account, by granting SQLT_USER_ROLE to the application user.

### Upgrading the SQLT option

With Amazon RDS for Oracle, you can upgrade the SQLT option from your existing version to a higher version. To upgrade the SQLT option, complete steps 1–3 in Using SQLT (p. 1527) for the new version of SQLT. Also, if you granted privileges for the previous version of SQLT in step 7 of that section, grant the privileges again for the new SQLT version.

Upgrading the SQLT option results in the loss of the older SQLT version's metadata. The older SQLT version's schema and related objects are dropped, and the newer version of SQLT is installed. For more information about the changes in the latest SQLT version, see Document 1614201.1 on the My Oracle Support site.
Note
Version downgrades are not supported.

Modifying SQLT settings

After you enable SQLT, you can modify the LICENSE_PACK and VERSION settings for the option.

For more information about how to modify option settings, see Modifying an option setting (p. 271). For more information about each setting, see SQLT option settings (p. 1525).

Removing the SQLT option

You can remove SQLT from a DB instance.

To remove SQLT from a DB instance, do one of the following:

• To remove SQLT from multiple DB instances, remove the SQLT option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).

• To remove SQLT from a single DB instance, modify the DB instance and specify a different option group that doesn't include the SQLT option. You can specify the default (empty) option group or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).
Oracle Statspack

The Oracle Statspack option installs and enables the Oracle Statspack performance statistics feature. Oracle Statspack is a collection of SQL, PL/SQL, and SQL*Plus scripts that collect, store, and display performance data. For information about using Oracle Statspack, see Oracle Statspack in the Oracle documentation.

**Note**

Oracle Statspack is no longer supported by Oracle and has been replaced by the more advanced Automatic Workload Repository (AWR). AWR is available only for Oracle Enterprise Edition customers who have purchased the Diagnostics Pack. You can use Oracle Statspack with any Oracle DB engine on Amazon RDS. You can't run Oracle Statspack on Amazon RDS read replicas.

Setting up Oracle Statspack

To run Statspack scripts, you must add the Statspack option.

**To set up Oracle Statspack**

1. In a SQL client, log in to the Oracle DB with an administrative account.
2. Do either of the following actions, depending on whether Statspack is installed:
   - If Statspack is installed, and the `PERFSTAT` account is associated with Statspack, skip to Step 4.
   - If Statspack is not installed, and the `PERFSTAT` account exists, drop the account as follows:

     ```sql
     DROP USER PERFSTAT CASCADE;
     ```

     Otherwise, attempting to add the Statspack option generates an error and `RDS-Event-0058`.

3. Add the Statspack option to an option group. See Adding an option to an option group (p. 266).

   Amazon RDS automatically installs the Statspack scripts on the DB instance and then sets up the `PERFSTAT` account.

4. Reset the password using the following SQL statement, replacing `pwd` with your new password:

   ```sql
   ALTER USER PERFSTAT IDENTIFIED BY pwd ACCOUNT UNLOCK;
   ```

   You can log in using the `PERFSTAT` user account and run the Statspack scripts.

5. Do either of the following actions, depending on your DB engine version:
   - If you are using Oracle Database 12c Release 2 (12.2) or lower, skip this step.
   - If you are using Oracle Database 19c or higher, grant the `CREATE JOB` privilege to the `PERFSTAT` account using the following statement:

     ```sql
     GRANT CREATE JOB TO PERFSTAT;
     ```

6. Ensure that idle wait events in the `PERFSTAT.STATS$IDLE_EVENT` table are populated.

   Because of Oracle Bug 28523746, the idle wait events in `PERFSTAT.STATS$IDLE_EVENT` may not be populated. To ensure all idle events are available, run the following statement:

   ```sql
   INSERT INTO PERFSTAT.STATS$IDLE_EVENT (EVENT)
   SELECT NAME FROM V$EVENT_NAME WHERE WAIT_CLASS='Idle'
   MINUS
   SELECT EVENT FROM PERFSTAT.STATS$IDLE_EVENT;
   ```
Generating Statspack reports

A Statspack report compares two snapshots.

To generate Statspack reports

1. In a SQL client, log in to the Oracle DB with the PERFSTAT account.
2. Create a snapshot using either of the following techniques:
   
   - Create a Statspack snapshot manually.
   - Create a job that takes a Statspack snapshot after a given time interval. For example, the following job creates a Statspack snapshot every hour:

   ```sql
   VARIABLE jn NUMBER;
   exec dbms_job.submit(:jn, 'statspack.snap;', SYSDATE, 'TRUNC(SYSDATE+1/24,''HH24'')');
   COMMIT;
   ```

3. View the snapshots using the following query:

   ```sql
   SELECT SNAP_ID, SNAP_TIME FROM STATS$SNAPSHOT ORDER BY 1;
   ```

4. Run the Amazon RDS procedure `rdsadmin.rds_run_spreport`, replacing `begin_snap` and `end_snap` with the snapshot IDs:

   ```sql
   exec rdsadmin.rds_run_spreport(begin_snap, end_snap);
   ```

   For example, the following command creates a report based on the interval between Statspack snapshots 1 and 2:

   ```sql
   exec rdsadmin.rds_run_spreport(1,2);
   ```

   The file name of the Statspack report includes the number of the two snapshots. For example, a report file created using Statspack snapshots 1 and 2 would be named `ORCL_spreport_1_2.lst`.

5. Monitor the output for errors.

   Oracle Statspack performs checks before running the report. Therefore, you could also see error messages in the command output. For example, you might try to generate a report based on an invalid range, where the beginning Statspack snapshot value is larger than the ending value. In this case, the output shows the error message, but the DB engine does not generate an error file.

   ```sql
   exec rdsadmin.rds_run_spreport(2,1);
   * ERROR at line 1:
   ORA-20000: Invalid snapshot IDs. Find valid ones in perfstat.stats$snapshot.
   ```

   If you use an invalid number a Statspack snapshot, the output shows an error. For example, if you try to generate a report for snapshots 1 and 50, but snapshot 50 doesn't exist, the output shows an error.

   ```sql
   exec rdsadmin.rds_run_spreport(1,50);
   * ERROR at line 1:
   ```
ORA-20000: Could not find both snapshot IDs

6. (Optional)

To retrieve the report, call the trace file procedures, as explained in Working with Oracle trace files (p. 673).

Alternatively, download the Statspack report from the RDS console. Go to the Log section of the DB instance details and choose Download:

If an error occurs while generating a report, the DB engine uses the same naming conventions as for a report but with an extension of .err. For example, if an error occurred while creating a report using Statspack snapshots 1 and 7, the report file would be named ORCL_spreport_1_7.err. You can download the error report using the same techniques as for a standard Snapshot report.

Removing Statspack files

To remove Oracle Statspack files, use the following command:

```sql
exec statspack.purge(begin snap, end snap);
```
Oracle time zone

To change the system time zone used by your Oracle DB instance, use the time zone option. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Changing the time zone impacts all date columns and values, including SYSDATE and SYSTIMESTAMP.

The time zone option differs from the rdsadmin_util.alter_db_time_zone command. The alter_db_time_zone command changes the time zone only for certain data types. The time zone option changes the time zone for all date columns and values. For more information about alter_db_time_zone, see Setting the database time zone (p. 1369). For more information about upgrade considerations, see Time zone considerations (p. 1553).

Considerations for setting the time zone

The time zone option is a permanent and persistent option. Therefore, you can't do the following:

- Remove the option from an option group after you add the option.
- Remove the option group from a DB instance after you add the group.
- Modify the time zone setting of the option to a different time zone.

If you accidentally set the time zone incorrectly, you need to recover the DB instance to its previous time zone setting. We strongly urge you to use one of the following strategies, depending on your situation:

- Your DB instance currently uses the default option group.
  Take a snapshot of your DB instance, and then add the time zone option to your DB instance. For more information, see Creating a DB snapshot (p. 428).
- Your DB instance currently uses a nondefault option group.
  Take a snapshot of your DB instance, create a new option group with the time zone option, and then add the option group to your instance.

We strongly urge you to test the time zone option on a test DB instance before you add it to a production DB instance. Adding the time zone option can cause problems with tables that use system date to add dates or times. We recommend that you analyze your data and applications to determine the impact of changing the time zone.

Time zone option settings

Amazon RDS supports the following settings for the time zone option.

<table>
<thead>
<tr>
<th>Option setting</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME_ZONE</td>
<td>One of the available time zones. For the full list, see Available time zones (p. 1535).</td>
<td>The new time zone for your DB instance.</td>
</tr>
</tbody>
</table>

Adding the time zone option

The general process for adding the time zone option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When you add the time zone option, a brief outage occurs while your DB instance is automatically restarted.

**Console**

**To add the time zone option to a DB instance**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine** choose the oracle edition for your DB instance.
   b. For **Major engine version** choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).

2. Add the **Timezone** option to the option group, and configure the option settings.

   **Important**
   If you add the time zone option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

   For more information about adding options, see Adding an option to an option group (p. 266). For more information about each setting, see Time zone option settings (p. 1533).

3. Apply the option group to a new or existing DB instance:

   • For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the time zone option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**AWS CLI**

The following example uses the AWS CLI add-option-to-option-group command to add the Timezone option and the TIME_ZONE option setting to an option group called myoptiongroup. The time zone is set to Africa/Cairo.

For Linux, macOS, or Unix:

```bash
aws rds add-option-to-option-group \
  --option-group-name "myoptiongroup" \
  --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/Cairo}]" \
  --apply-immediately
```

For Windows:

```bash
aws rds add-option-to-option-group ^
  --option-group-name "myoptiongroup" ^
  --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/Cairo}]" ^
  --apply-immediately
```
Modifying time zone settings

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. You can't modify the time zone setting of the option to a different time zone. If you set the time zone incorrectly, restore a snapshot of your DB instance from before you added the time zone option.

Removing the time zone option

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. To remove the time zone option, restore a snapshot of your DB instance from before you added the time zone option.

Available time zones

You can use the following values for the time zone option.

<table>
<thead>
<tr>
<th>Zone</th>
<th>Time zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Africa</td>
<td>Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek</td>
</tr>
<tr>
<td>America</td>
<td>America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima, America/Los_Angeles, America/Manaus, America/Matamoros, America/Mexico_City, America/Monterrey, America/Montevideo, America/New_York, America/Phoenix, America/Santiago, America/Sao_Paulo, America/Tijuana, America/Toronto</td>
</tr>
<tr>
<td>Asia</td>
<td>Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Hong_Kong, Asia/Irkutsk, Asia/Jakarta, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Kolkata, Asia/Krasnoyarsk, Asia/Magadan, Asia/Manila, Asia/Muscat, Asia/Novosibirsk, Asia/Rangoon, Asia/Riyadh, Asia/Seoul, Asia/Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan</td>
</tr>
<tr>

</tbody>
</table>
Oracle time zone file autoupgrade

With the TIMEZONE_FILE_AUTOUPGRADE option, you can upgrade the current time zone file to the latest version on your DB instance.

Topics

- Purpose of time zone files (p. 1537)
- Considerations for updating your time zone file (p. 1537)
- Strategies for updating your time zone file (p. 1538)
- Preparing to update the time zone file (p. 1539)
- Adding the time zone file autoupgrade option (p. 1540)
- Checking your data after the update of the time zone file (p. 1541)

Purpose of time zone files

In Oracle Database, the TIMESTAMP WITH TIME ZONE data type stores time stamp and time zone data. This data type is useful for preserving local time zone information.

Oracle Database stores transition rules and UTC offsets in time zone files. The offset is the difference between local time and UTC. When you create an Oracle database in an on-premises environment, you choose the time zone file version. Data with the TIMESTAMP WITH TIME ZONE data type uses the rules in the associated time zone file version. The time zone files reside in $ORACLE_HOME/oracore/zoneinfo/.

If a government changes the rules for Daylight Savings Time (DST), Oracle publishes new time zone files. Oracle releases time zone files separately from PSUs and RUs. The time zone file names use the format DSTvversion, as in DSTv35. When you add the TIMEZONE_FILE_AUTOUPGRADE option in Amazon RDS for Oracle, you can update your time zone files.

The TIMEZONE_FILE_AUTOUPGRADE option is useful when you move data between different environments. If you try to import data from a source database with a higher time zone file version than the target database, you receive the ORA-39405 error. Previously, you had to work around the error by using either of the following techniques:

- Create an RDS for Oracle instance with the desired time zone file, export data from your source database, and then import it into the new database.
- Use AWS DMS or logical replication to migrate your data.

With the TIMEZONE_FILE_AUTOUPGRADE option, you can upgrade the time zone file on the source database without using the preceding cumbersome techniques.

Considerations for updating your time zone file

When you update your time zone file, data that uses TIMESTAMP WITH TIME ZONE might change. Your primary consideration is downtime.

Warning

If you add the TIMEZONE_FILE_AUTOUPGRADE, your engine upgrade might have prolonged downtime. Updating time zone data for a large database might take hours or even days.

The length of the update depends on factors such as the following:

- The amount of TIMESTAMP WITH TIME ZONE data in your database
Additional downtime can occur when you do the following:

- Add the option to the option group when the instance uses an outdated time zone file
- Upgrade the Oracle database engine when the new engine version contains a new version of the time zone file

**Note**

During the time zone file update, RDS for Oracle calls `PURGE DBA_RECYCLEBIN`.

### Strategies for updating your time zone file

You can upgrade your engine and update your time zone file independently. Thus, you must choose among different update strategies.

The examples in this section assume that your instance uses database version 19.0.0.0.ru-2019-07.rur-2019-07.r1 and time zone file DSTv33. Your DB instance file system includes file DSTv34. Also assume that release update 19.0.0.0.ru-2021-01.rur-2021-01.r1 includes DSTv35. To update your time zone file, you can use the following strategies:

- **Update the time zone file used by your database without upgrading the DB engine version.**
  
  Update the time zone file used by your instance from DSTv33 to DSTv34. In your modify instance operation, do the following:
  
  - Add `TIMEZONE_FILE_AUTOPURGE` to the option group used by your instance.
  - Don’t change your engine version.

- **Upgrade your DB engine version and the time zone file in the same operation.**
  
  Upgrade your engine to version 19.0.0.0.ru-2021-01.rur-2021-01.r1 and update your time zone file to DSTv35 in the same operation. In your modify instance operation, do the following:
  
  - Add `TIMEZONE_FILE_AUTOPURGE` to the option group used by your instance.
  - Change your engine version.

- **Upgrade your DB engine version without updating the time zone file.**
  
  Upgrade your database to version 19.0.0.0.ru-2021-01.rur-2021-01.r1 but retain time zone file DSTv33. In this case, the possibilities are as follows:
  
  - Your instance isn’t associated with an option group that includes `TIMEZONE_FILE_AUTOPURGE`. Leave the option group as it is.
  - Your instance is associated with an option group that includes `TIMEZONE_FILE_AUTOPURGE`. Associate your instance with an option group that doesn’t have `TIMEZONE_FILE_AUTOPURGE`. Then modify the engine version.

You might choose this strategy for the following reasons:

- Your data doesn’t use the `TIMESTAMP WITH TIME ZONE` data type.
- Your data uses the `TIMESTAMP WITH TIME ZONE` data type, but your data is not affected by the time zone changes.
- You want to postpone updating the time zone file because you can’t tolerate the extra downtime.
Preparing to update the time zone file

A time zone file upgrade has two separate phases: prepare and upgrade. While not required, we strongly recommend that you perform the prepare step. In this step, you find out which data will be affected by running the PL/SQL procedure `DBMS_DST.FIND_AFFECTED_TABLES`. For more information about the prepare window, see Upgrading the Time Zone File and Timestamp with Time Zone Data in the Oracle Database documentation.

To prepare to update the time zone file

1. Connect to your Oracle database using a SQL client.
2. Determine the current time zone file version used.

```sql
SELECT * FROM V$TIMEZONE_FILE;
```

3. Determine the latest time zone file version available on your DB instance. This step is only applicable if you use Oracle Database 12c Release 2 (12.2) or higher.

```sql
SELECT DBMS_DST.GET_LATEST_TIMEZONE_VERSION FROM DUAL;
```

4. Determine the total size of tables that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

```sql
SELECT SUM(BYTES)/1024/1024/1024 "Total_size_w_TSTZ_columns_GB"
FROM DBA_SEGMENTS
WHERE SEGMENT_TYPE LIKE 'TABLE%'
AND (OWNER, SEGMENT_NAME) IN
  (SELECT OWNER, TABLE_NAME
   FROM DBA_TAB_COLUMNS
   WHERE DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE');
```

5. Determine the names and sizes of segments that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

```sql
SELECT OWNER, SEGMENT_NAME, SUM(BYTES)/1024/1024/1024 "SEGMENT_SIZE_W_TSTZ_COLUMNS_GB"
FROM DBA_SEGMENTS
WHERE SEGMENT_TYPE LIKE 'TABLE%'
AND (OWNER, SEGMENT_NAME) IN
  (SELECT OWNER, TABLE_NAME
   FROM DBA_TAB_COLUMNS
   WHERE DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE')
GROUP BY OWNER, SEGMENT_NAME;
```

6. Run the prepare step.
   - The procedure `DBMS_DST.CREATE_AFFECTED_TABLE` creates a table to store any affected data. You pass the name of this table to the `DBMS_DST.FIND_AFFECTED_TABLES` procedure. For more information, see CREATE_AFFECTED_TABLE Procedure in the Oracle Database documentation.
   - This procedure `CREATE_ERROR_TABLE` creates a table to log errors. For more information, see CREATE_ERROR_TABLE Procedure in the Oracle Database documentation.

The following example creates the affected data and error tables, and finds all affected tables.

```sql
EXEC DBMS_DST.CREATE_ERROR_TABLE('my_error_table')
EXEC DBMS_DST.CREATE_AFFECTED_TABLE('my_affected_table')
EXEC DBMS_DST.BEGIN_PREPARE('new_version');
EXEC DBMS_DST.FIND_AFFECTED_TABLES('my_affected_table', TRUE, 'my_error_table');
```
EXEC DBMS_DST.END_PREPARE;

SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;

7. Query the affected and error tables.

SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;

Adding the time zone file autoupgrade option

The procedure for adding the time zone autoupgrade option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When you add the option, a brief outage occurs while your DB instance is automatically restarted.

Console

To add the time zone file autoupgrade option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For Engine choose the oracle edition for your DB instance.
   b. For Major engine version choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).

2. Add the TIMEZONE_FILE_AUTOUPLGRADE option to the option group.

   Important
   If you add the option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

3. Apply the option group to a new or existing DB instance:
   • For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   • For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the time zone option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see Modifying an Amazon RDS DB instance (p. 309).

AWS CLI

The following example uses the AWS CLI add-option-to-option-group command to add the TIMEZONE_FILE_AUTOUPLGRADE option to an option group called myoptiongroup.

For Linux, macOS, or Unix:

aws rds add-option-to-option-group \
Time zone file autoupgrade

```
--option-group-name "myoptiongroup" \
--options "OptionName=TIMEZONE_FILE_AUTOPGRADE" \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
   --option-group-name "myoptiongroup" ^
   --options "OptionName=TIMEZONE_FILE_AUTOPGRADE" ^
   --apply-immediately
```

Checking your data after the update of the time zone file

We recommend that you check your data after you update the time zone file. During the prepare step, RDS for Oracle automatically creates the following tables:

- `rdsadmin.rds_dst_affected_tables` – Lists the tables that contain data affected by the update
- `rdsadmin.rds_dst_error_table` – Lists the errors generated during the update

These tables are independent of any tables that you create in the prepare window. To see the results of the update, query the tables as follows.

```
SELECT * FROM rdsadmin.rds_dst_affected_tables;
SELECT * FROM rdsadmin.rds_dst_error_table;
```

For more information about the schema for the affected data and error tables, see `FIND_AFFECTED_TABLES Procedure` in the Oracle documentation.
Oracle Transparent Data Encryption

Amazon RDS supports Oracle Transparent Data Encryption (TDE), a feature of the Oracle Advanced Security option available in Oracle Enterprise Edition. This feature automatically encrypts data before it is written to storage and automatically decrypts data when the data is read from storage.

Oracle Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data in case data files and backups are obtained by a third party or when you need to address security-related regulatory compliance issues.

The TDE option is a permanent option that can't be removed from an option group. You can't disable TDE from a DB instance once that instance is associated with an option group with the Oracle TDE option. You can change the option group of a DB instance that is using the TDE option, but the option group associated with the DB instance must include the TDE option. You can also modify an option group that includes the TDE option by adding or removing other options.

A detailed explanation about Oracle Transparent Data Encryption is beyond the scope of this guide. For information about using Oracle Transparent Data Encryption, see Securing stored data using Transparent Data Encryption. For more information about Oracle Advanced Security, see Oracle advanced security in the Oracle documentation. For more information on AWS security, see the AWS security center.

Note
You can't share a DB snapshot that uses this option. For more information about sharing DB snapshots, see Sharing a DB snapshot (p. 452).

TDE encryption modes

Oracle Transparent Data Encryption supports two encryption modes: TDE tablespace encryption and TDE column encryption. TDE tablespace encryption is used to encrypt entire application tables. TDE column encryption is used to encrypt individual data elements that contain sensitive data. You can also apply a hybrid encryption solution that uses both TDE tablespace and column encryption.

Note
Amazon RDS manages the Oracle Wallet and TDE master key for the DB instance. You do not need to set the encryption key using the command ALTER SYSTEM set encryption key.

For information about TDE best practices, see Oracle advanced security Transparent Data Encryption best practices.

Once the option is enabled, you can check the status of the Oracle Wallet by using the following command:

```
SELECT * FROM v$encryption_wallet;
```

To create an encrypted tablespace, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION DEFAULT STORAGE (ENCRYPT);
```

To specify the encryption algorithm, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION USING 'AES256' DEFAULT STORAGE (ENCRYPT);
```

Note that the previous commands for encrypting a tablespace are the same as the commands you would use with an Oracle installation not on Amazon RDS, and the ALTER TABLE syntax to encrypt a column is also the same as the commands you would use for an Oracle installation not on Amazon RDS.
You should determine if your DB instance is associated with an option group that has the **TDE** option. To view the option group that a DB instance is associated with, you can use the RDS console, the `describe-db-instance` AWS CLI command, or the API operation `DescribeDBInstances`.

To comply with several security standards, Amazon RDS is working to implement automatic periodic master key rotation.

**Adding the TDE option**

The process for using Oracle Transparent Data Encryption (TDE) with Amazon RDS is as follows:

1. If the DB instance is not associated with an option group that has the **TDE** option enabled, you must either create an option group and add the **TDE** option or modify the associated option group to add the **TDE** option. For information about creating or modifying an option group, see Working with option groups (p. 262). For information about adding an option to an option group, see Adding an option to an option group (p. 266).
2. Associate the DB instance with the option group with the **TDE** option. For information about associating a DB instance with an option group, see Modifying an Amazon RDS DB instance (p. 309).

**Removing the TDE option**

To remove the **TDE** option with a DB instance, complete the following steps:

1. Decrypt all your data on the DB instance.
2. Copy the data to a new DB instance that is not associated with an option group with **TDE** enabled.
3. Delete the original instance.

You can name the new instance the same name as the previous DB instance.

**Using TDE with Oracle Data Pump**

You can use Oracle Data Pump to import or export encrypted dump files. Amazon RDS supports the password encryption mode (ENCRYPTION_MODE=PASSWORD) for Oracle Data Pump. Amazon RDS does not support transparent encryption mode (ENCRYPTION_MODE=TRANSPARENT) for Oracle Data Pump. For more information about using Oracle Data Pump with Amazon RDS, see Importing using Oracle Data Pump (p. 1430).
Oracle UTL_MAIL

Amazon RDS supports Oracle UTL_MAIL through the use of the UTL_MAIL option and SMTP servers. You can send email directly from your database by using the UTL_MAIL package. Amazon RDS supports UTL_MAIL for the following versions of Oracle:

- Oracle Database 21c (21.0.0.0), all versions
- Oracle Database 19c (19.0.0.0), all versions
- Oracle Database 12c Release 2 (12.2), all versions
- Oracle Database 12c Release 1 (12.1), version 12.1.0.2.v5 and later

The following are some limitations to using UTL_MAIL:

- UTL_MAIL does not support Transport Layer Security (TLS) and therefore emails are not encrypted.
- To connect securely to remote SSL/TLS resources by creating and uploading custom Oracle wallets, follow the instructions in Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1336).
  The specific certificates that are required for your wallet vary by service. For AWS services, these can typically be found in the Amazon trust services repository.
- UTL_MAIL does not support authentication with SMTP servers.
- You can only send a single attachment in an email.
- You can't send attachments larger than 32 K.
- You can only use ASCII and Extended Binary Coded Decimal Interchange Code (EBCDIC) character encodings.
- SMTP port (25) is throttled based on the elastic network interface owner's policies.

When you enable UTL_MAIL, only the master user for your DB instance is granted the execute privilege. If necessary, the master user can grant the execute privilege to other users so that they can use UTL_MAIL.

**Important**

We recommend that you enable Oracle's built-in auditing feature to track the use of UTL_MAIL procedures.

Prerequisites for Oracle UTL_MAIL

The following are prerequisites for using Oracle UTL_MAIL:

- One or more SMTP servers, and the corresponding IP addresses or public or private Domain Name Server (DNS) names. For more information about private DNS names resolved through a custom DNS server, see Setting up a custom DNS server (p. 1363).
- For Oracle versions prior to 12c, your DB instance must also use the XML DB option. For more information, see Oracle XML DB (p. 1547).

Adding the Oracle UTL_MAIL option

The general process for adding the Oracle UTL_MAIL option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the UTL_MAIL option, as soon as the option group is active, UTL_MAIL is active.

**To add the UTL_MAIL option to a DB instance**

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
   a. For **Engine**, choose the edition of Oracle you want to use.
   b. For **Major engine version**, choose the version of your DB instance.

   For more information, see Creating an option group (p. 264).

2. Add the **UTL_MAIL** option to the option group. For more information about adding options, see Adding an option to an option group (p. 266).

3. Apply the option group to a new or existing DB instance:
   - For a new DB instance, you apply the option group when you launch the instance. For more information, see Creating an Amazon RDS DB instance (p. 175).
   - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

**Using Oracle UTL_MAIL**

After you enable the UTL_MAIL option, you must configure the SMTP server before you can begin using it.

You configure the SMTP server by setting the SMTP_OUT_SERVER parameter to a valid IP address or public DNS name. For the SMTP_OUT_SERVER parameter, you can specify a comma-separated list of the addresses of multiple servers. If the first server is unavailable, UTL_MAIL tries the next server, and so on.

You can set the default SMTP_OUT_SERVER for a DB instance by using a DB parameter group. You can set the SMTP_OUT_SERVER parameter for a session by running the following code on your database on your DB instance.

```
ALTER SESSION SET smtp_out_server = mailserver.domain.com:25;
```

After the UTL_MAIL option is enabled, and your SMTP_OUT_SERVER is configured, you can send mail by using the **SEND** procedure. For more information, see **UTL_MAIL** in the Oracle documentation.

**Removing the Oracle UTL_MAIL option**

You can remove Oracle UTL_MAIL from a DB instance.

To remove UTL_MAIL from a DB instance, do one of the following:

- To remove UTL_MAIL from multiple DB instances, remove the UTL_MAIL option from the option group they belong to. This change affects all DB instances that use the option group. For more information, see Removing an option from an option group (p. 274).
- To remove UTL_MAIL from a single DB instance, modify the DB instance and specify a different option group that doesn't include the UTL_MAIL option. You can specify the default (empty) option group.
group, or a different custom option group. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Troubleshooting

The following are issues you might encounter when you use UTL_MAIL with Amazon RDS.

- Throttling. SMTP port (25) is throttled based on the elastic network interface owner's policies. If you can successfully send email by using UTL_MAIL, and you see the error ORA-29278: SMTP transient error: 421 Service not available, you are possibly being throttled. If you experience throttling with email delivery, we recommend that you implement a backoff algorithm. For more information about backoff algorithms, see Error retries and exponential backoff in AWS and How to handle a “throttling – Maximum sending rate exceeded” error.

You can request that this throttle be removed. For more information, see How do I remove the throttle on port 25 from my EC2 instance?
Oracle XML DB

Oracle XML DB adds native XML support to your DB instance. With XML DB, you can store and retrieve structured or unstructured XML, in addition to relational data. XML DB is preinstalled on Oracle version 12c and later.
Upgrading the Oracle DB engine

When Amazon RDS supports a new version of Oracle, you can upgrade your DB instances to the new version. For information about which Oracle versions are available on Amazon RDS, see Amazon RDS for Oracle Release Notes.

**Important**
RDS for Oracle Database 11g is deprecated. If you maintain Oracle Database 11g snapshots, you can upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot (p. 1556).

**Topics**
- Overview of Oracle DB engine upgrades (p. 1548)
- Oracle major version upgrades (p. 1550)
- Oracle minor version upgrades (p. 1551)
- Oracle SE2 upgrade paths (p. 1551)
- Considerations for Oracle DB upgrades (p. 1552)
- Preparing for the automatic upgrade of Oracle Database 12c (p. 1554)
- Testing an Oracle DB upgrade (p. 1555)
- Upgrading an Oracle DB instance (p. 1556)
- Upgrading an Oracle DB snapshot (p. 1556)

Overview of Oracle DB engine upgrades

Before upgrading your Oracle DB instance, familiarize yourself with the following concepts.

**Topics**
- Major and minor version upgrades (p. 1548)
- Oracle engine version management (p. 1549)
- Automatic snapshots during engine upgrades (p. 1549)
- Oracle upgrades in a Multi-AZ deployment (p. 1549)
- Oracle upgrades of read replicas (p. 1549)
- Oracle upgrades of micro DB instances (p. 1550)

Major and minor version upgrades

Amazon RDS supports the following upgrades to an Oracle DB instance:

- **Major version upgrades**

  In general, a major version upgrade for a database engine can introduce changes that aren't compatible with existing applications. To upgrade your DB instance to a major version, you must perform the action manually.

- **Minor version upgrades**

  A minor version upgrade includes only changes that are backward-compatible with existing applications. If you enable auto minor version upgrades on your DB instance, minor version upgrades occur automatically. In all other cases, you upgrade the DB instance manually.
When you upgrade the DB engine, an outage occurs. The duration of the outage depends on your engine version and instance size.

**Oracle engine version management**

With DB engine version management, you control when and how the database engine is patched and upgraded. You get the flexibility to maintain compatibility with database engine patch versions. You can also test new patch versions to ensure they work with your application before deploying them in production. In addition, you upgrade the versions on your own terms and timelines.

*Note*

Amazon RDS periodically aggregates official Oracle database patches using an Amazon RDS-specific DB engine version. To see a list of which Oracle patches are contained in an Amazon RDS Oracle-specific engine version, go to [Amazon RDS for Oracle Release Notes](#).

**Automatic snapshots during engine upgrades**

During upgrades of an Oracle DB instance, snapshots offer protection against upgrade issues. If the backup retention period for your DB instance is greater than 0, Amazon RDS takes the following DB snapshots during the upgrade:

1. A snapshot of the DB instance before any upgrade changes have been made. If the upgrade fails, you can restore this snapshot to create a DB instance running the old version.
2. A snapshot of the DB instance after the upgrade completes.

*Note*

To change your backup retention period, see [Modifying an Amazon RDS DB instance](p. 309).

After an upgrade, you can't revert to the previous engine version. However, you can create a new Oracle DB instance by restoring the pre-upgrade snapshot.

**Oracle upgrades in a Multi-AZ deployment**

If your DB instance is in a Multi-AZ deployment, Amazon RDS upgrades both the primary and standby replicas. If no operating system updates are required, the primary and standby upgrades occur simultaneously. The instances are not available until the upgrade completes.

If operating system updates are required in a Multi-AZ deployment, Amazon RDS applies the updates when you request the DB upgrade. Amazon RDS performs the following steps:

1. Updates the operating system on the standby DB instance.
2. Upgrades the standby DB instance.
3. Fails over the primary instance to the standby DB instance.
4. Upgrades the operating system on the new standby DB instance, which was formerly the primary instance.
5. Upgrades the new standby DB instance.

**Oracle upgrades of read replicas**

The Oracle DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS performs the upgrade in the following stages:

1. Upgrades the source DB instance. The read replicas are available during this stage.
2. Upgrades the read replicas in parallel, regardless of the replica maintenance windows. The source DB is available during this stage.

For major version upgrades of cross-Region read replicas, Amazon RDS performs additional actions:

- Generates an option group for the target version automatically
- Copies all options and option settings from the original option group to the new option group
- Associates the upgraded cross-Region read replica with the new option group

**Oracle upgrades of micro DB instances**

We don't recommend upgrading databases running on micro DB instances. Because these instances have limited CPU, the upgrade can take hours to complete.

You can upgrade micro DB instances with small amounts of storage (10–20 GiB) by copying your data using Data Pump. Before you migrate your production DB instances, we recommend that you test by copying data using Data Pump.

**Oracle major version upgrades**

To perform a major version upgrade, modify the DB instance manually. Major version upgrades don't occur automatically.

**Supported versions for major upgrades**

Amazon RDS supports the following major version upgrades.

<table>
<thead>
<tr>
<th>Current version</th>
<th>Upgrade supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>19.0.0.0 using the CDB architecture</td>
<td>21.0.0.0</td>
</tr>
<tr>
<td>12.2.0.1</td>
<td>19.0.0.0 using the non-CDB architecture</td>
</tr>
<tr>
<td>12.1.0.2</td>
<td>19.0.0.0 using the non-CDB architecture</td>
</tr>
<tr>
<td></td>
<td>12.2.0.1</td>
</tr>
</tbody>
</table>

A major version upgrade of Oracle Database must upgrade to a Release Update (RU) that was released in the same month or later. Major version downgrades aren't supported for any Oracle Database versions.

**Supported instance classes for major upgrades**

Your current Oracle DB instance might run on a DB instance class that isn't supported for the version to which you are upgrading. In this case, before you upgrade, migrate the DB instance to a supported DB instance class. For more information about the supported DB instance classes for each version and edition of Amazon RDS for Oracle, see DB instance classes (p. 9).

**Gathering statistics before major upgrades**

Before you perform a major version upgrade, Oracle recommends that you gather optimizer statistics on the DB instance that you are upgrading. This action can reduce DB instance downtime during the upgrade.
To gather optimizer statistics, connect to the DB instance as the master user, and run the `DBMS_STATS.GATHER_DICTIONARY_STATS` procedure, as in the following example.

```sql
EXEC DBMS_STATS.GATHER_DICTIONARY_STATS;
```

For more information, see Gathering optimizer statistics to decrease Oracle database downtime in the Oracle documentation.

**Allowing major upgrades**

A major engine version upgrade might be incompatible with your application. The upgrade is irreversible. If you specify a major version for the `EngineVersion` parameter that is different from the current major version, you must allow major version upgrades.

If you upgrade a major version using the CLI command `modify-db-instance`, specify `--allow-major-version-upgrade`. This setting isn't persistent, so you must specify `--allow-major-version-upgrade` whenever you perform a major upgrade. This parameter has no impact on upgrades of minor engine versions. For more information, see Upgrading a DB instance engine version (p. 344).

If you upgrade a major version using the console, you don’t need to choose an option to allow the upgrade. Instead, the console displays a warning that major upgrades are irreversible.

**Oracle minor version upgrades**

A minor version upgrade applies an Oracle Database Patch Set Update (PSU) or Release Update (RU) in a major version.

An Amazon RDS for Oracle DB instance is scheduled to be upgraded automatically during its next maintenance window when it meets the following conditions:

- The DB instance has the **Auto minor version upgrade** option enabled.
- The DB instance is not running the latest minor DB engine version.

The DB instance is upgraded to the latest quarterly PSU or RU four to six weeks after it is made available by Amazon RDS for Oracle. For more information about PSUs and RUs, see Amazon RDS for Oracle Release Notes.

The following minor version upgrades aren't supported.

<table>
<thead>
<tr>
<th>Current version</th>
<th>Upgrade not supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.1.0.2.v6</td>
<td>12.1.0.2.v7</td>
</tr>
<tr>
<td>12.1.0.2.v5</td>
<td>12.1.0.2.v7</td>
</tr>
<tr>
<td>12.1.0.2.v5</td>
<td>12.1.0.2.v6</td>
</tr>
</tbody>
</table>

**Note**

Minor version downgrades aren't supported.

**Oracle SE2 upgrade paths**

The following table shows supported upgrade paths to Standard Edition Two (SE2). For more information about the License Included and Bring Your Own License (BYOL) models, see Oracle licensing options (p. 1299).
Amazon Relational Database Service User Guide
Upgrade considerations

Your existing configuration | Supported SE2 configuration
--- | ---
12.2.0.1 SE2, BYOL | 12.2.0.1 SE2, BYOL or License Included
12.1.0.2 SE2, BYOL | 12.2.0.1 SE2, BYOL or License Included
12.1.0.2 SE2, BYOL or License | Included

To upgrade from your existing configuration to a supported SE2 configuration, use a supported upgrade path. For more information, see Oracle major version upgrades (p. 1550).

Considerations for Oracle DB upgrades

Before you upgrade your Oracle instance, review the following information.

Topics
- Oracle Multitenant considerations (p. 1552)
- Option group considerations (p. 1553)
- Parameter group considerations (p. 1553)
- Time zone considerations (p. 1553)

Oracle Multitenant considerations

The following table describes the architectures supported in different releases.

<table>
<thead>
<tr>
<th>Oracle Database release</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Database 21c</td>
<td>CDB only</td>
</tr>
<tr>
<td>Oracle Database 19c</td>
<td>CDB or non-CDB</td>
</tr>
<tr>
<td>Oracle Database 12c Release 2 (12.2)</td>
<td>Non-CDB only</td>
</tr>
<tr>
<td>Oracle Database 12c Release 1 (12.1)</td>
<td>Non-CDB only</td>
</tr>
</tbody>
</table>

The following table describes supported and unsupported upgrade paths.

<table>
<thead>
<tr>
<th>Upgrade path</th>
<th>Supported?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-CDB to non-CDB</td>
<td>Yes</td>
</tr>
<tr>
<td>CDB to CDB</td>
<td>Yes</td>
</tr>
<tr>
<td>Non-CDB to CDB</td>
<td>No</td>
</tr>
<tr>
<td>CDB to non-CDB</td>
<td>No</td>
</tr>
</tbody>
</table>

For more information about Oracle Multitenant in RDS for Oracle, see RDS for Oracle architecture (p. 1305).
Option group considerations

If your DB instance uses a custom option group, sometimes Amazon RDS can't automatically assign a new option group. For example, this situation occurs when you upgrade to a new major version. In such cases, specify a new option group when you upgrade. We recommend that you create a new option group, and add the same options to it as in your existing custom option group.

For more information, see Creating an option group (p. 264) or Copying an option group (p. 265).

If your DB instance uses a custom option group that contains the APEX option, you can sometimes reduce the upgrade time. To do this, upgrade your version of APEX at the same time as your DB instance. For more information, see Upgrading the APEX version (p. 1474).

Parameter group considerations

If your DB instance uses a custom parameter group, sometimes Amazon RDS can't automatically assign your DB instance a new parameter group. For example, this situation occurs when you upgrade to a new major version. In such cases, make sure to specify a new parameter group when you upgrade. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see Creating a DB parameter group (p. 280) or Copying a DB parameter group (p. 287).

Time zone considerations

You can use the time zone option to change the system time zone used by your Oracle DB instance. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Amazon RDS for Oracle updates the system time zone automatically throughout the year. For more information about the system time zone, see Oracle time zone (p. 1533).

When you create an Oracle DB instance, the database automatically sets the database time zone. The database time zone is also known as the Daylight Saving Time (DST) time zone. The database time zone is distinct from the system time zone.

Between Oracle Database releases, patch sets or individual patches may include new DST versions. These patches reflect the changes in transition rules for various time zone regions. For example, a government might change when DST takes effect. Changes to DST rules may affect existing data of the TIMESTAMP WITH TIME ZONE data type.

If you upgrade an RDS for Oracle DB instance, Amazon RDS doesn't upgrade the database time zone file automatically. To upgrade the time zone file automatically, you can include the TIMEZONE_FILE_AUTOUPGRADE option in the option group associated with your DB instance during or after the engine version upgrade. For more information, see Oracle time zone file autoupgrade (p. 1537).

Alternatively, to upgrade the database time zone file manually, create a new Oracle DB instance that has the desired DST patch. However, we recommend that you upgrade the database time zone file using the TIMEZONE_FILE_AUTOUPGRADE option.

After upgrading the time zone file, migrate the data from your current instance to the new instance. You can migrate data using several techniques, including the following:

- AWS Database Migration Service
- Oracle GoldenGate
- Oracle Data Pump
• Original Export/Import (desupported for general use)

**Note**
When you migrate data using Oracle Data Pump, the utility raises the error ORA-39405 when the target time zone version is lower than the source time zone version.

For more information, see **TIMESTAMP WITH TIMEZONE restrictions** in the Oracle documentation.

### Preparing for the automatic upgrade of Oracle Database 12c

*** REVIEWERS 3/15/22: 12c deprecation***

Oracle Database 12c is on a deprecation path. As explained in Oracle Database 12c with Amazon RDS (p. 1298), Amazon RDS plans to begin automatically upgrading Oracle Database 12c DB instances to Oracle Database 19c. The automatic upgrades are scheduled to begin on the following dates:

- April 1, 2022 for Oracle Database 12c Release 2 (12.2.0.1)
- August 1, 2022 for Oracle Database 12c Release 1 (12.1.0.2)

The automatic upgrades are not guaranteed to occur in your maintenance window. All Oracle Database 12c DB instances, including reserved instances, will move to the latest available Release Update (RU).

Before the automatic upgrades begin, we highly recommend that you upgrade your existing Oracle Database 12c DB instances to Oracle Database 19c manually. In this way, you can validate that your applications work correctly. To avoid the automatic upgrade, use one of the following strategies before the beginning of the automatic upgrades.

**Topics**
- Upgrade your Oracle Database 12c Release 2 (12.2) DB instance (p. 1554)
- Upgrade your Oracle Database 12c DB snapshots (p. 1554)
- Downgrade your Oracle Database 12c Release 2 (12.2) DB instance (p. 1555)

### Upgrade your Oracle Database 12c Release 2 (12.2) DB instance

Before you upgrade your Oracle Database 12c DB instance to Oracle Database 19c, consider the following:

- Your SQL statements might perform differently after the upgrade. If so, you can use the `OPTIMIZER_FEATURES_ENABLE` parameter to retain the behavior of the Oracle Database 12c optimizer. For more information, see **Influencing the Optimizer** in the Oracle Database documentation.
- If you have Extended Support for Oracle Database 12c on the BYOL model, consider the implications. In this case, you must have Extended Support agreements from Oracle Support for Oracle Database 19c. For details on licensing and support requirements for BYOL, see **Amazon RDS for Oracle FAQs**.

### Upgrade your Oracle Database 12c DB snapshots

You can upgrade your existing snapshots to Oracle Database 19c, and then restore them. For more information, see **Upgrading an Oracle DB snapshot** (p. 1556).

If you plan to upgrade Oracle Database 12c using snapshots, the planned deadlines to avoid the automatic upgrade are listed in **Oracle Database 12c with Amazon RDS** (p. 1298).
Downgrade your Oracle Database 12c Release 2 (12.2) DB instance

You might decide not to upgrade your Oracle Database 12c Release 2 (12.2) DB instances to Oracle Database 19c. In this case, you can downgrade your instance to Oracle Database Release 1 (12.1.0.2). Use any of the following techniques:

- Oracle Data Pump
- AWS Database Migration Service (DMS)
- Any supported logical replication tool

For more information about import options, see Importing data into Oracle on Amazon RDS (p. 1429).

Testing an Oracle DB upgrade

Before you upgrade your DB instance to a major version, thoroughly test your database and all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review the Oracle upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications. For more information, see Database Upgrade Guide in the Oracle documentation.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see Option group considerations (p. 1553).
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see Parameter group considerations (p. 1553).
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see Creating a DB snapshot (p. 428).
5. Restore the DB snapshot to create a new test DB instance. For more information, see Restoring from a DB snapshot (p. 432).
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
   - Console (p. 344)
   - AWS CLI (p. 345)
   - RDS API (p. 345)
7. Perform testing:
   - Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version.
   - Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1.
   - Test all stored procedures, functions, and triggers.
   - Direct test versions of your applications to the upgraded DB instance. Verify that the applications work correctly with the new version.
   - Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage. You might need to choose a larger instance class to support the new version in production. For more information, see DB instance classes (p. 9).
8. If all tests pass, upgrade your production DB instance. We recommend that you confirm that the DB instance working correctly before allowing write operations to the DB instance.

Upgrading an Oracle DB instance

To learn how to upgrade an Oracle DB instance, see Upgrading a DB instance engine version (p. 344).

Upgrading an Oracle DB snapshot

If you have existing manual DB snapshots, you can upgrade them to a later version of the Oracle database engine.

When Oracle stops providing patches for a version, and Amazon RDS deprecates the version, you can upgrade your snapshots that correspond to the deprecated version. For more information, see Oracle engine version management (p. 1549).

The following snapshot upgrades are currently supported. You can't upgrade a snapshot and downgrade the minor version. For example, you can't upgrade a snapshot from the 12.2.0.1 October 2021 PSU to the 19.0 July 2020 PSU.

<table>
<thead>
<tr>
<th>Current snapshot version</th>
<th>Supported snapshot upgrade</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2.0.1</td>
<td>19.0.0.0.ru-2021-10.rur-2021-10.r1</td>
</tr>
<tr>
<td>12.1.0.1</td>
<td>12.1.0.2.v8</td>
</tr>
<tr>
<td>11.2.0.4</td>
<td>19.0.0.0.ru-2020-07.rur-2020-07.r1</td>
</tr>
<tr>
<td></td>
<td>19.0.0.0.ru-2020-10.rur-2020-10.r1</td>
</tr>
<tr>
<td></td>
<td>12.2.0.1.ru-2020-10.rur-2020-10.r1</td>
</tr>
<tr>
<td></td>
<td>12.2.0.1.ru-2020-07.rur-2020-07.r1</td>
</tr>
<tr>
<td></td>
<td>12.1.0.2.v22</td>
</tr>
<tr>
<td></td>
<td>12.1.0.2.v21</td>
</tr>
<tr>
<td>18.0.0.0</td>
<td>19.0.0.0.ru-2021-04.rur-2021-04.r1</td>
</tr>
<tr>
<td>11.2.0.3</td>
<td>11.2.0.4.v11</td>
</tr>
<tr>
<td>11.2.0.2</td>
<td>11.2.0.4.v12</td>
</tr>
</tbody>
</table>

Amazon RDS supports upgrading snapshots in all AWS Regions.

Console

To upgrade an Oracle DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots, and then select the DB snapshot that you want to upgrade.
3. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.
4. Choose the New engine version to upgrade the snapshot to.
5. (Optional) For Option group, choose the option group for the upgraded DB snapshot. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see Option group considerations (p. 1553).
6. Choose **Save changes** to save your changes.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **available** to **upgrading**, and then changes to **active** upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **unavailable**. You can't recover the snapshot from this state.

**Note**
If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

**AWS CLI**

To upgrade an Oracle DB snapshot by using the AWS CLI, call the `modify-db-snapshot` command with the following parameters:

- `--db-snapshot-identifier` – The name of the DB snapshot.
- `--engine-version` – The version to upgrade the snapshot to.

You might also need to include the following parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see *Option group considerations (p. 1553).*

- `--option-group-name` – The option group for the upgraded DB snapshot.

**Example**

The following example upgrades a DB snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
  --db-snapshot-identifier mydbsnapshot \
  --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 \
  --option-group-name default:oracle-se2-19
```

For Windows:

```
aws rds modify-db-snapshot ^
  --db-snapshot-identifier mydbsnapshot ^
  --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 ^
  --option-group-name default:oracle-se2-19
```

**RDS API**

To upgrade an Oracle DB snapshot by using the Amazon RDS API, call the `ModifyDBSnapshot` operation with the following parameters:

- `DBSnapshotIdentifier` – The name of the DB snapshot.
- `EngineVersion` – The version to upgrade the snapshot to.

You might also need to include the `OptionGroupName` parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see *Option group considerations (p. 1553).*
Using third-party software with your RDS for Oracle DB instance

To use tools and third-party software with RDS for Oracle DB instances, review the information in the following sections.

**Topics**

- Setting up Amazon RDS to host tools and third-party software for Oracle (p. 1559)
- Using Oracle GoldenGate with Amazon RDS (p. 1565)
- Using the Oracle Repository Creation Utility on Amazon RDS for Oracle (p. 1578)
- Configuring Oracle Connection Manager on an Amazon EC2 instance (p. 1583)
- Installing a Siebel database on Oracle on Amazon RDS (p. 1585)
Setting up Amazon RDS to host tools and third-party software for Oracle

You can use Amazon RDS to host an Oracle DB instance that supports software and components such as the following:

- Siebel Customer Relationship Management (CRM)
- Oracle Fusion Middleware Metadata — installed by the Repository Creation Utility (RCU)

The following procedures help you create an Oracle DB instance on Amazon RDS that you can use to host additional software and components for Oracle.

Topics
- Creating a VPC for use with an Oracle database (p. 1559)
- Creating an Oracle DB instance (p. 1564)
- Additional Amazon RDS interfaces (p. 1564)

Creating a VPC for use with an Oracle database

In the following procedure, you create a virtual private cloud (VPC) based on the Amazon VPC service, a private subnet, and a security group. Your Amazon RDS DB instance needs to be available only to your middle-tier components, and not to the public internet. Thus, your Amazon RDS DB instance is hosted in a private subnet, providing greater security.

To create a VPC based on Amazon VPC

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region for your VPC. This example uses the US West (Oregon) region.
3. In the upper-left corner, choose VPC Dashboard, and then choose Start VPC Wizard.
4. On the page Step 1: Select a VPC Configuration, choose VPC with Public and Private Subnets, and then choose Select.
5. On the page Step 2: VPC with Public and Private Subnets, shown following, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4 CIDR block</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td></td>
<td>For more information about selecting CIDR blocks for your VPC, see VPC sizing.</td>
</tr>
<tr>
<td>IPv6 CIDR block</td>
<td>No IPv6 CIDR Block</td>
</tr>
<tr>
<td>VPC name</td>
<td>The name for your VPC, for example vpc-1.</td>
</tr>
<tr>
<td>Public subnet's IPv4 CIDR</td>
<td>10.0.0.0/24</td>
</tr>
<tr>
<td></td>
<td>For more information about subnet sizing, see Subnet sizing.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
<tr>
<td>Option</td>
<td>Value</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Public subnet name</td>
<td>The name for your public subnet, for example <code>subnet-public-1</code>.</td>
</tr>
<tr>
<td>Private subnet's IPv4 CIDR</td>
<td>10.0.1.0/24</td>
</tr>
<tr>
<td></td>
<td>For more information about subnet sizing, see <a href="#">Subnet sizing</a>.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>An Availability Zone for your AWS Region.</td>
</tr>
<tr>
<td>Private subnet name</td>
<td>The name for your private subnet, for example <code>subnet-private-1</code>.</td>
</tr>
<tr>
<td>Instance type</td>
<td>An instance type for your NAT instance, for example <code>t2.small</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>&lt;br&gt;If you don't see <strong>Instance type</strong> in the console, choose <strong>Use a NAT instance instead</strong>.</td>
</tr>
<tr>
<td>Key pair name</td>
<td>No key pair</td>
</tr>
<tr>
<td>Service endpoints</td>
<td>None</td>
</tr>
<tr>
<td>Enable DNS hostnames</td>
<td>Yes</td>
</tr>
<tr>
<td>Hardware tenancy</td>
<td>Default</td>
</tr>
</tbody>
</table>
6. Choose **Create VPC**.

An Amazon RDS DB instance in a VPC requires at least two private subnets or at least two public subnets, to support Multi-AZ deployment. For more information about working with multiple Availability Zones, see *Regions, Availability Zones, and Local Zones (p. 60)*. Because your database is private, add a second private subnet to your VPC.

**To create an additional subnet**

1. Sign in to the AWS Management Console and open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose **VPC Dashboard**, choose **Subnets**, and then choose **Create Subnet**.
4. On the **Create Subnet** page, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name tag</strong></td>
<td>The name for your second private subnet, for example <code>subnet-private-2</code>.</td>
</tr>
<tr>
<td><strong>VPC</strong></td>
<td>Your VPC, for example <code>vpc-1</code>.</td>
</tr>
<tr>
<td><strong>Availability Zone</strong></td>
<td>An Availability Zone for your AWS Region. Note</td>
</tr>
<tr>
<td></td>
<td>Choose an Availability Zone different from the one that you chose for the first private subnet.</td>
</tr>
<tr>
<td><strong>CIDR block</strong></td>
<td>10.0.2.0/24</td>
</tr>
</tbody>
</table>

5. Choose **Yes, Create**.

Both private subnets must use the same route table. In the following procedure, you check to make sure the route tables match, and if not you edit one of them.

**To ensure the subnets use the same route table.**

1. Sign in to the AWS Management Console and open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose **VPC Dashboard**, choose **Subnets**, and then choose your first private subnet, for example `subnet-private-1`.
4. At the bottom of the console, choose the **Route Table** tab, shown following.

5. Make a note of the route table, for example `rtb-0d9fc668`.
6. In the list of subnets, choose the second private subnet, for example `subnet-private-2`.
7. At the bottom of the console, choose the **Route Table** tab.
8. If the route table for the second subnet is not the same as the route table for the first subnet, edit it to match:
   a. Choose **Edit**.
   b. For **Change to**, choose the route table that matches your first subnet.
   c. Choose **Save**.
A security group acts as a virtual firewall for your DB instance to control inbound and outbound traffic. In the following procedure, you create a security group for your DB instance. For more information about security groups, see Security groups for your VPC.

**To create a VPC security group for a private Amazon RDS DB instance**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Security Groups, and then choose Create Security Group.
4. On the page Create Security Group, set the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name tag</td>
<td>The name for your security group, for example <code>sgdb-1</code>.</td>
</tr>
<tr>
<td>Group name</td>
<td>The name for your security group, for example <code>sgdb-1</code>.</td>
</tr>
<tr>
<td>Description</td>
<td>A description for your security group.</td>
</tr>
<tr>
<td>VPC</td>
<td>Your VPC, for example <code>vpc-1</code>.</td>
</tr>
</tbody>
</table>

5. Choose Yes, Create.

In the following procedure, you add rules to your security group to control inbound traffic to your DB instance. For more information about inbound rules, see Security group rules.

**To add inbound rules to the security group**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the upper-right corner of the AWS Management Console, confirm that you are in the correct AWS Region for your VPC.
3. In the upper-left corner, choose VPC Dashboard, choose Security Groups, and then choose your security group, for example `sgdb-1`.
4. At the bottom of the console, choose the Inbound Rules tab, and then choose Edit.
5. Set these values, as shown following.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Oracle (1521)</td>
</tr>
<tr>
<td>Protocol</td>
<td>TCP (6)</td>
</tr>
<tr>
<td>Port Range</td>
<td>1521</td>
</tr>
<tr>
<td>Source</td>
<td>The identifier of your security group. When you choose the box, you see the name of your security group, for example <code>sgdb-1</code>.</td>
</tr>
</tbody>
</table>
6. Choose **Save**.

### Creating an Oracle DB instance

You can use Amazon RDS to host an Oracle DB instance. When you create the new DB instance, specify the VPC and security group you created previously using the instructions in Creating a VPC for use with an Oracle database (p. 1559). Also, choose **No** for **Publicly accessible**.

For information about creating a DB instance, see Creating an Amazon RDS DB instance (p. 175).

### Additional Amazon RDS interfaces

In the preceding tasks, you use the AWS Management Console to perform tasks. Amazon Web Services also provides the AWS Command Line Interface (AWS CLI), and an application programming interface (API). You can use the AWS CLI or the API to automate many of the tasks for managing Amazon RDS, including tasks to manage an Oracle DB instance with Amazon RDS.

For more information, see AWS Command Line Interface reference for Amazon RDS and Amazon RDS API Reference.
Using Oracle GoldenGate with Amazon RDS

Oracle GoldenGate (GoldenGate) collects, replicates, and manages transactional data between databases. It is a log-based change data capture (CDC) and replication software package used with Oracle databases for online transaction processing (OLTP) systems. GoldenGate creates trail files that contain the most recent changed data from the source database and then pushes these files to the target database.

You can use GoldenGate with Amazon RDS to do the following:

- Active-Active database replication
- Disaster recovery
- Data protection
- In-Region and cross-Region replication
- Zero-downtime migration and upgrades

**Note**
You can use GoldenGate using Amazon RDS to upgrade to major versions of Oracle Database. For example, you can use GoldenGate with Amazon RDS to upgrade from an Oracle Database 11g on-premises database to Oracle Database 19c on an Amazon RDS DB instance.

**Supported versions and licensing options for Oracle GoldenGate**

Amazon RDS supports the following editions and versions with Oracle GoldenGate:

- Oracle Database Standard Edition Two (SE2)
- Oracle Database Enterprise Edition (EE)
- Oracle GoldenGate version 11.2.1 and later
- Oracle GoldenGate DDL is supported with Oracle GoldenGate version 12.1 and later when using Integrated capture mode

You are responsible for managing GoldenGate licensing (BYOL) for use with Amazon RDS in all AWS Regions. For more information, see Oracle licensing options (p. 1299).

**Requirements and limitations for Oracle GoldenGate**

When working with GoldenGate on Amazon RDS, consider the following requirements and limitations:

- You are responsible for setting up and managing GoldenGate for use with Amazon RDS.
- Amazon RDS supports migration and replication across Oracle databases using GoldenGate. We do not support nor prevent customers from migrating or replicating across heterogeneous databases.
- You can use GoldenGate on Amazon RDS for Oracle DB instances that use Oracle Transparent Data Encryption (TDE). To maintain the integrity of replicated data, configure encryption on the Oracle GoldenGate hub using Amazon EBS encrypted volumes or trail file encryption. Also configure
encryption for data sent between the Oracle GoldenGate hub and the source and target database instances. Amazon RDS for Oracle DB instances support encryption with Oracle Secure Sockets Layer (p. 1514) or Oracle native network encryption (p. 1503).

**Oracle GoldenGate architecture**

The Oracle GoldenGate architecture for use with Amazon RDS consists of the following decoupled modules:

**Source database**

Your source database can be either an on-premises Oracle database, an Oracle database on an Amazon EC2 instance, or an Oracle database on an Amazon RDS DB instance.

**Oracle GoldenGate hub**

An Oracle GoldenGate hub moves transaction information from the source database to the target database. Your hub can be either of the following:

- An Amazon EC2 instance with Oracle Database and GoldenGate installed
- An on-premises Oracle installation

You can have more than one Amazon EC2 hub. We recommend that you use two hubs if you use GoldenGate for cross-Region replication.

**Target database**

Your target database can be on either an Amazon RDS DB instance, an Amazon EC2 instance, or an on-premises location.

The following sections describe common scenarios for GoldenGate on Amazon RDS.

**Topics**

- On-premises source database and Oracle GoldenGate hub (p. 1566)
- On-premises source database and Amazon EC2 hub (p. 1567)
- Amazon RDS source database and Amazon EC2 hub (p. 1567)
- Amazon EC2 source database and Amazon EC2 hub (p. 1567)
- Amazon EC2 hubs in different AWS Regions (p. 1568)

**On-premises source database and Oracle GoldenGate hub**

In this scenario, an on-premises Oracle source database and on-premises Oracle GoldenGate hub provides data to a target Amazon RDS DB instance.
On-premises source database and Amazon EC2 hub

In this scenario, an on-premises Oracle database acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

Amazon RDS source database and Amazon EC2 hub

In this scenario, an RDS for Oracle DB instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

Amazon EC2 source database and Amazon EC2 hub

In this scenario, an Oracle database on an Amazon EC2 instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.
Amazon EC2 hubs in different AWS Regions

In this scenario, an Oracle database on an Amazon RDS DB instance is connected to an Amazon EC2 instance hub in the same AWS Region. The hub is connected to an Amazon EC2 instance hub in a different AWS Region. This second hub provides data to the target RDS for Oracle DB instance in the same AWS Region as the second Amazon EC2 instance hub.

**Note**

Any issues that affect running GoldenGate on an on-premises environment also affect running GoldenGate on AWS. We strongly recommend that you monitor the Oracle GoldenGate hub to ensure that `EXTRACT` and `REPLICAT` are resumed if a failover occurs. Because the Oracle GoldenGate hub is run on an Amazon EC2 instance, Amazon RDS does not manage the Oracle GoldenGate hub and cannot ensure that it is running.
Setting up Oracle GoldenGate

To set up GoldenGate using Amazon RDS, you configure the hub on the Amazon EC2 instance, and then configure the source and target databases. The following sections show how to set up GoldenGate for use with Amazon RDS.

Topics

- Setting up a GoldenGate hub on Amazon EC2 (p. 1569)
- Setting up a source database for use with GoldenGate on Amazon RDS (p. 1570)
- Setting up a target database for use with GoldenGate on Amazon RDS (p. 1572)

Setting up a GoldenGate hub on Amazon EC2

To create a GoldenGate hub on an Amazon EC2 instance, you complete several steps. First, you create an Amazon EC2 instance with a full client installation of Oracle RDBMS. The Amazon EC2 instance must also have Oracle GoldenGate software installed. The exact software versions depend on the source and target database versions. For more information about installing GoldenGate, see the Oracle documentation.

The Amazon EC2 instance that serves as the Oracle GoldenGate hub stores and processes the transaction information from the source database into trail files. To support this process, make sure that you meet the following conditions:

- You have allocated enough storage for the trail files
- The Amazon EC2 instance has enough processing power to manage the amount of data.
- The EC2 instance has enough memory to store the transaction information before it's written to the trail file.

The following tasks set up a GoldenGate hub on an Amazon EC2 instance; each task is explained in detail in this section:

1. Create the Oracle GoldenGate subdirectories.
2. Update the GLOBALS parameter file.
3. Configure the mgr.prm file and start the manager.

Create subdirectories in the Oracle GoldenGate directory using the Amazon EC2 command line shell and `ggsci`, the Oracle GoldenGate command interpreter. The subdirectories are created under the gg directory and include directories for parameter, report, and checkpoint files.

```
prompt$ cd /gg
prompt$ ./ggsci
GGSCI> CREATE SUBDIRS
```

Create a GLOBALS parameter file using the Amazon EC2 command line shell. Parameters that affect all GoldenGate processes are defined in the GLOBALS parameter file. The following example creates the necessary file:

```
$ cd $GGHOME
$ vi GLOBALS
CheckpointTable oggadm1.oggchkpt
```

The last step in setting up and configuring the Oracle GoldenGate hub is to configure the manager. Add the following lines to the `mgr.prm` file, then start the manager using `ggsci`:

```
```
PORT 8199
PurgeOldExtracts ./dirdat/*, UseCheckpoints, MINKEEPDAYS 5

GGSCI> start mgr

Once you have completed these steps, the Oracle GoldenGate hub is ready for use. Next, you set up the source and target databases.

### Setting up a source database for use with GoldenGate on Amazon RDS

When your source database is running Oracle Database 12c or later, complete the following tasks to set up a source database for use with GoldenGate:

1. Set the `ENABLE_GOLDENGATE_REPLICATION` parameter to `True`. This parameter turns on supplemental logging for the source database. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the `ENABLE_GOLDENGATE_REPLICATION` parameter set to `true`. For more information about the `ENABLE_GOLDENGATE_REPLICATION` parameter, see the Oracle documentation.
2. Set the retention period for archived redo logs for the Oracle GoldenGate source database.
3. Create a GoldenGate user account on the source database.
4. Grant the necessary privileges to the Oracle GoldenGate user.
5. Add a TNS alias for the source database to the `tnsnames.ora` file on the Oracle GoldenGate hub.

### Enable supplemental logging on the source DB

The `ENABLE_GOLDENGATE_REPLICATION` parameter, when set to `True`, turns on supplemental logging for the source database and configures the required GoldenGate permissions. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with `ENABLE_GOLDENGATE_REPLICATION` set to `true`. For more information about `ENABLE_GOLDENGATE_REPLICATION`, see the Oracle documentation.

### Set the log retention period on the source DB

The source database must also retain archived redo logs. For example, set the retention period for archived redo logs to 24 hours.

```sql
exec rdsadmin.rdsadmin_util.set_configuration('archivelog retention hours',24);
```

Specify the duration for log retention in hours. The duration should exceed any potential downtime of the source instance, any potential period of communication, and any potential period of networking issues for the source instance. Such a duration lets Oracle GoldenGate recover logs from the source instance as needed.

The absolute minimum value required is one hour of logs retained. If you don't have log retention enabled, or if the retention value is too small, you receive the following message.

```
2014-03-06 06:17:27  ERROR   OGG-00446  error 2 (No such file or directory) opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bpln6_.log for sequence 1306Not able to establish initial position for begin time 2014-03-06 06:16:55.
```

The logs are retained on your DB instance. Ensure that you have sufficient storage on your instance for the files. To see how much space you have used in the last X hours, use the following query, replacing X with the number of hours.
Create a user account on the source

GoldenGate runs as a database user and requires the appropriate database privileges to access the redo and archive logs for the source database. To provide these, create a GoldenGate user account on the source database. For more information about the permissions for a GoldenGate user account, see the sections 4, section 4.4, and table 4.1 in the Oracle documentation.

The following statements create a user account named oggadm1.

```sql
CREATE TABLESPACE administrator;
CREATE USER oggadm1 IDENTIFIED BY "password"
    DEFAULT TABLESPACE ADMINISTRATOR TEMPORARY TABLESPACE TEMP;
```

Grant account privileges on the source DB

Grant the necessary privileges to the Oracle GoldenGate user account using the SQL command `grant` and the `rdsadmin.rdsadmin_util` procedure `grant_sys_object`. The following statements grant privileges to a user named oggadm1.

```sql
GRANT CREATE SESSION, ALTER SESSION TO oggadm1;
GRANT RESOURCE TO oggadm1;
GRANT SELECT ANY DICTIONARY TO oggadm1;
GRANT FLASHBACK ANY TABLE TO oggadm1;
GRANT SELECT ANY TABLE TO oggadm1;
GRANT SELECT_CATALOG_ROLE TO rds_master_user_name WITH ADMIN OPTION;
exec rdsadmin.rdsadmin_util.grant_sys_object ('DBA_CLUSTERS', 'OGGADM1');
GRANT EXECUTE ON DBMS_FLASHBACK TO oggadm1;
GRANT SELECT ON SYS.V_$DATABASE TO oggadm1;
GRANT ALTER ANY TABLE TO oggadm1;
```

Finally, grant the privileges needed by a user account to be a GoldenGate administrator. The package that you use to perform the grant, `dbms_goldengate_auth` or `rdsadmin_dbms_goldengate_auth`, depends on the Oracle DB engine version.

- For Oracle DB versions that are earlier than Oracle Database 12c Release 2 (12.2), run the following PL/SQL program.

  ```sql
  exec dbms_goldengate_auth.grant_admin_privilege (grantee=>'OGGADM1',
    privilege_type=>'capture',
    grant_select_privileges=>true,
    do_grants=>TRUE);
  ```

- For Oracle DB versions that are later than or equal to Oracle Database 12c Release 2 (12.2), which requires patch level 12.2.0.1.ru-2019-04.rur-2019-04.r1 or later, run the following PL/SQL program.

  ```sql
  exec rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (grantee=>'OGGADM1',
    privilege_type=>'capture',
    grant_select_privileges=>true,
    do_grants=>TRUE);
  ```

To revoke privileges, use the procedure `revoke_admin_privilege` in the same package.
Add a TNS alias for the source DB

Add the following entry to $ORACLE_HOME/network/admin/tnsnames.ora in the Oracle Home to be used by the EXTRACT process. For more information on the tnsnames.ora file, see the Oracle documentation.

```
OGGSOURCE=
  (DESCRIPTION=
    (ENABLE=BROKEN)
    (ADDRESS_LIST=
      (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-source.abcdef12345.us-west-2.rds.amazonaws.com)(PORT=8200))
      (CONNECT_DATA=(SID=ORCL))
    )
  )
```

Setting up a target database for use with GoldenGate on Amazon RDS

The following tasks set up a target DB instance for use with GoldenGate:

1. Set the `ENABLE_GOLDENGATE_REPLICATION` parameter to TRUE. If your target database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the `ENABLE_GOLDENGATE_REPLICATION` parameter set to TRUE. For more information about the `ENABLE_GOLDENGATE_REPLICATION` parameter, see the Oracle documentation.
2. Create and manage a GoldenGate user account on the target database
3. Grant the necessary privileges to the Oracle GoldenGate user
4. Add a TNS alias for the target database to tnsnames.ora on the Oracle GoldenGate hub.

Create a user account on the target DB

GoldenGate runs as a database user and requires the appropriate database privileges. To make sure it has these, create a GoldenGate user account on the target database.

The following statements create a user named `oggadm1`:

```
CREATE TABLESPACE administrator;
CREATE TABLESPACE administrator_idx;
CREATE USER oggadm1 IDENTIFIED BY "password"
    DEFAULT TABLESPACE administrator
    TEMPORARY TABLESPACE temp;
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator_idx;
```

Grant account privileges on the target DB

Grant necessary privileges to the Oracle GoldenGate user account on the target DB. In the following example, you grant privileges to `oggadm1`.

```
GRANT CREATE SESSION TO oggadm1;
GRANT ALTER SESSION TO oggadm1;
GRANT CREATE CLUSTER TO oggadm1;
GRANT CREATE INDEXTYPE TO oggadm1;
GRANT CREATE OPERATOR TO oggadm1;
GRANT CREATE PROCEDURE TO oggadm1;
GRANT CREATE SEQUENCE TO oggadm1;
GRANT CREATE TABLE TO oggadm1;
```
Finally, grant the privileges needed by a user account to be a GoldenGate administrator. The package that you use to perform the grant, dbms_goldengate_auth or rdsadmin_dbms_goldengate_auth, depends on the Oracle DB engine version.

- For Oracle DB versions that are **earlier than** Oracle Database 12c Release 2 (12.2), run the following PL/SQL program.

  exec dbms_goldengate_auth.grant_admin_privilege (grantee=>'OGGADM1', privilege_type=>'capture', grant_select_privileges=>true, do_grants=>TRUE);

- For Oracle DB versions that are **later than or equal to** Oracle Database 12c Release 2 (12.2), which requires patch level 12.2.0.1.ru-2019-04.rur-2019-04.r1 or later, run the following PL/SQL program.

  exec rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (grantee=>'OGGADM1', privilege_type=>'capture', grant_select_privileges=>true, do_grants=>TRUE);

To revoke privileges, use the procedure revoke_admin_privilege in the same package.

---

Add a TNS alias for the target DB

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle Home to be used by the REPLICAT process. For more information on the tnsname.ora file, see the Oracle documentation.

```plaintext
OGGTARGET=
  (DESCRIPTION=
    (ENABLE=BROKEN)
    (ADDRESS_LIST=
      (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-target.abc12345.us-west-2.rds.amazonaws.com)(PORT=8200)))
    (CONNECT_DATA=(SID=ORCL))
  )
```

---

Working with the EXTRACT and REPLICAT utilities of GoldenGate

The GoldenGate utilities EXTRACT and REPLICAT work together to keep the source and target databases in sync via incremental transaction replication using trail files. All changes that occur on the source database are automatically detected by EXTRACT, then formatted and transferred to trail files on the Oracle GoldenGate on-premises or EC2-instance hub. After initial load is completed, the data is read from these files and replicated to the target database by the REPLICAT utility.
Running the Oracle GoldenGate EXTRACT utility

The EXTRACT utility retrieves, converts, and outputs data from the source database to trail files. EXTRACT queues transaction details to memory or to temporary disk storage. When the transaction is committed to the source database, EXTRACT flushes all of the transaction details to a trail file. The trail file routes these details to the Oracle GoldenGate on-premises or the EC2 instance hub and then to the target database.

The following tasks enable and start the EXTRACT utility:

1. Configure the EXTRACT parameter file on the Oracle GoldenGate hub (on-premises or EC2 instance). The following listing shows an example EXTRACT parameter file.

```
EXTRACT EABC
SETENV (ORACLE_SID=ORCL)
SETENV (NLSLANG=AL32UTF8)
USERID oggadm1@OGGSOURCE, PASSWORD XXXXXX
EXTTRAIL /path/to/goldengate/dirdat/ab
IGNOREREPLICATES
GETAPPLOPS
TRANLOGOPTIONS EXCLUDEUSER OGGADM1
TABLE EXAMPLE.TABLE;
```

2. On the Oracle GoldenGate hub, launch the Oracle GoldenGate command line interface (ggsci). Log into the source database. The following example shows the format for logging in:

```
dblogin userid <user>@<db tnsname>
```

3. Add a checkpoint table for the database:

```
add checkpointtable
```

4. Add transdata to turn on supplemental logging for the database table:

```
add trandata <user>.<table>
```

Alternatively, you can add transdata to turn on supplemental logging for all tables in the database:

```
add trandata <user>.*
```

5. Using the ggsci command line, enable the EXTRACT utility using the following commands:

```
add extract <extract name> tranlog, INTEGRATED tranlog, begin now
add extrail <path-to-trail-from-the param-file>
    extract <extractname-from-paramfile>,
    MEGABYTES Xm
```

6. Register the EXTRACT utility with the database so that the archive logs are not deleted. This allows you to recover old, uncommitted transactions if necessary. To register the EXTRACT utility with the database, use the following command:

```
register EXTRACT <extract process name>, DATABASE
```

7. To start the EXTRACT utility, use the following command:
Running the Oracle GoldenGate REPLICAT utility

The REPLICAT utility is used to "push" transaction information in the trail files to the target database.

The following tasks enable and start the REPLICAT utility:

1. Configure the REPLICAT parameter file on the Oracle GoldenGate hub (on-premises or EC2 instance).
   The following listing shows an example REPLICAT parameter file.

   ```
   REPLICAT RABC
   SETENV (ORACLE_SID=ORCL)
   SETENV (NLSLANG=AL32UTF8)
   USERID oggadm1@OGGTARGET, password XXXXXX
   ASSUMETARGETDEFS
   MAP EXAMPLE.TABLE, TARGET EXAMPLE.TABLE;
   ```

2. Launch the Oracle GoldenGate command line interface (ggsci). Log into the target database. The following example shows the format for logging in.

   ```
   dblogin userid <user>@<db tnsname>
   ```

3. Using the ggsci command line, add a checkpoint table. The user indicated should be the Oracle GoldenGate user account, not the target table schema owner. The following example creates a checkpoint table named `gg_checkpoint`.

   ```
   add checkpointtable <user>.gg_checkpoint
   ```

4. To enable the REPLICAT utility, use the following command.

   ```
   add replicat <replicat name> EXTTRAIL <extract trail file> CHECKPOINTTABLE <user>.gg_checkpoint
   ```

5. To start the REPLICAT utility, use the following command.

   ```
   start <replicat name>
   ```

Troubleshooting Oracle GoldenGate

This section explains the most common issues when using Oracle GoldenGate with Amazon RDS.

**Topics**

- Log retention (p. 1575)
- Oracle GoldenGate appears to be properly configured but replication is not working (p. 1576)
- Integrated REPLICAT slow due to query on sys."_DBA.Apply_CDR_INFO" (p. 1576)

**Log retention**

To work with Oracle GoldenGate and Amazon RDS, make sure that you have log retention enabled.
Specify the duration for log retention in hours. The duration should exceed any potential downtime of the source instance, any potential period of communication, and any potential period of networking issues for the source instance. Such a duration lets Oracle GoldenGate recover logs from the source instance as needed.

The absolute minimum value required is one hour of logs retained. If you don’t have log retention enabled, or if the retention value is too small, you receive the following message.

```
2014-03-06 06:17:27   ERROR   OGG-00446  error 2 (No such file or directory)
opening redo log /rdsdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log
for sequence 1306Not able to establish initial position for begin time 2014-03-06
06:16:55.
```

**Oracle GoldenGate appears to be properly configured but replication is not working**

For pre-existing tables, Oracle GoldenGate must be told which SCN it should work from. Take the following steps to fix this issue:

1. Launch the Oracle GoldenGate command line interface (ggsci). Log into the source database. The following example shows the format for logging.

   ```sql
   dblogin userid <user>@<db tnsname>
   ```

2. Using the ggsci command line, set up the start SCN for the EXTRACT process. The following example sets the SCN to 223274 for the extract.

   ```sql
   ALTER EXTRACT <extract process name> SCN 223274
   start <extract process name>
   ```

3. Log in to the target database. The following example shows the format for logging in.

   ```sql
   dblogin userid <user>@<db tnsname>
   ```

4. Using the ggsci command line, set up the start SCN for the REPLICAT process. The following example sets the SCN to 223274 for the REPLICAT.

   ```sql
   start <replicat process name> atcsn 223274
   ```

**Integrated REPLICAT slow due to query on sys."_DBA_APPLY_CDR_INFO"**

Oracle GoldenGate Conflict Detection and Resolution (CDR) provides basic conflict resolution routines. For example, CDR can resolve a unique conflict for an INSERT statement.

When CDR resolves a collision, it can insert records into the exception table `_DBA_APPLY_CDR_INFO` temporarily. Integrated REPLICAT deletes these records later. In a rare scenario, the integrated REPLICAT can process a large number of collisions, but a new integrated REPLICAT does not replace it. Instead of being removed, the existing rows in `_DBA_APPLY_CDR_INFO` are orphaned. Any new integrated REPLICAT processes slow down because they are querying orphaned rows in `_DBA_APPLY_CDR_INFO`.

To remove all rows from `_DBA_APPLY_CDR_INFO`, use the Amazon RDS procedure `rdsadmin_util.truncate_apply$_cdr_info`. This procedure is released as part of the October 2020 release and patch update. The procedure is available in the following database versions:

- Version 19.0.0.0.ru-2020-10.rur-2020-10.r1
The following example truncates the table `_DBA_APPLY_CDR_INFO`.

```sql
SET SERVEROUTPUT ON SIZE 2000
EXEC rdsadmin.rdsadmin_util.truncate_apply$_cdr_info;
```
Using the Oracle Repository Creation Utility on Amazon RDS for Oracle

You can use Amazon RDS to host an Oracle DB instance that holds the schemas to support your Oracle Fusion Middleware components. Before you can use Fusion Middleware components, create and populate schemas for them in your database. You create and populate the schemas by using the Oracle Repository Creation Utility (RCU).

Supported versions and licensing options for RCU

Amazon RDS supports Oracle Repository Creation Utility (RCU) version 12c only. You can use the RCU in the following configurations:

- RCU 12c with Oracle database 12.2.0.1
- RCU 12c with Oracle database 12.1.0.2.v4 or later

Before you can use RCU, you need a license for Oracle Fusion Middleware. You also need to follow the Oracle licensing guidelines for the Oracle database that hosts the repository. For more information, see Oracle fusion middleware licensing information user manual in the Oracle documentation.

Fusion MiddleWare supports repositories on Oracle Database Enterprise Edition and Standard Editions (SE, SE One, or SE Two). Oracle recommends Enterprise Edition for production installations that require partitioning and installations that require online index rebuild.

Before you create your Oracle DB instance, confirm the Oracle database version that you need to support the components that you want to deploy. You can use the Certification Matrix to find the requirements for the Fusion Middleware components and versions you want to deploy. For more information, see Oracle fusion middleware supported system configurations in the Oracle documentation.

Amazon RDS supports Oracle database version upgrades as needed. For more information, see Upgrading a DB instance engine version (p. 344).

Requirements and limitations for RCU

To use RCU, you need an Amazon VPC. Your Amazon RDS DB instance must be available only to your Fusion Middleware components, and not to the public Internet. Thus, host your Amazon RDS DB instance in a private subnet, which provides greater security. For information about how to create an Amazon VPC for use with an Oracle DB instance, see Creating a VPC for use with an Oracle database (p. 1559).

You also need an Oracle DB instance. For information about how to create an Oracle DB instance for use with Fusion Middleware metadata, see Creating an Oracle DB instance (p. 1564).

You can store the schemas for any Fusion Middleware components in your Amazon RDS DB instance. The following schemas have been verified to install correctly:

- Analytics (ACTIVITIES)
- Audit Services (IAU)
- Audit Services Append (IAU_APPEND)
- Audit Services Viewer (IAU_VIEWER)
- Discussions (DISCUSSIONS)
- Metadata Services (MDS)
- Oracle Business Intelligence (BIPLATFORM)
- Oracle Platform Security Services (OPSS)
Guidelines for using RCU

The following are some recommendations for working with your DB instance in this scenario:

- We recommend that you use Multi-AZ for production workloads. For more information about working with multiple Availability Zones, see Regions, Availability Zones, and Local Zones (p. 60).
- For additional security, Oracle recommends that you use Transparent Data Encryption (TDE) to encrypt your data at rest. If you have an Enterprise Edition license that includes the Advanced Security Option, you can enable encryption at rest by using the TDE option. For more information, see Oracle Transparent Data Encryption (p. 1542).

Amazon RDS also provides an encryption at rest option for all database editions. For more information, see Encrypting Amazon RDS resources (p. 1750).
- Configure your VPC Security Groups to allow communication between your application servers and your Amazon RDS DB instance. The application servers that host the Fusion Middleware components can be on Amazon EC2 or on-premises.

Running RCU

To create and populate the schemas to support your Fusion Middleware components, use the Oracle Repository Creation Utility (RCU). You can run RCU in different ways.

Topics
- Running RCU using the command line in one step (p. 1579)
- Running RCU using the command line in multiple steps (p. 1580)
- Running RCU in interactive mode (p. 1581)

Running RCU using the command line in one step

If you don’t need to edit any of your schemas before populating them, you can run RCU in a single step. Otherwise, see the following section for running RCU in multiple steps.

You can run the RCU in silent mode by using the command-line parameter `-silent`. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for `dbUser` on the first line, and the password for each component on subsequent lines. You specify the name of the password file as the last parameter to the RCU command.

Example

The following example creates and populates schemas for the SOA Infrastructure component (and its dependencies) in a single step.

For Linux, macOS, or Unix:

```bash
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
```
export JAVA_HOME=/usr/java/jdk1.8.0_65
#(ORACLE_HOME)/oracle_common/bin/rcu \
-silent \ 
-createRepository \ 
-connectString ${dbhost}:${dbport}:${dbname} \ 
-dbUser ${dbuser} \ 
-dbRole Normal \ 
-honorOMF \ 
-schemaPrefix ${SCHEMA_PREFIX} \ 
-component MDS \ 
-component STB \ 
-component OPSS \ 
-component IAU \ 
-component IAU_APPEND \ 
-component IAU_VIEWER \ 
-component UCSUMS \ 
-component WLS \ 
-component SOAINFRA \ 
-f < /tmp/passwordfile.txt

For more information, see Running Repository Creation Utility from the command line in the Oracle documentation.

Running RCU using the command line in multiple steps

To manually edit your schema scripts, run RCU in multiple steps:

1. Run RCU in Prepare Scripts for System Load mode by using the -generateScript command-line parameter to create the scripts for your schemas.
2. Manually edit and run the generated script script_systemLoad.sql.
3. Run RCU again in Perform Product Load mode by using the -dataLoad command-line parameter to populate the schemas.
4. Run the generated cleanup script script_postDataLoad.sql.

To run RCU in silent mode, specify the command-line parameter -silent. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for dbUser on the first line, and the password for each component on subsequent lines. Specify the name of the password file as the last parameter to the RCU command.

Example

The following example creates schema scripts for the SOA Infrastructure component and its dependencies.

For Linux, macOS, or Unix:

export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
#(ORACLE_HOME)/oracle_common/bin/rcu \
-silent \ 
-generateScript \ 
-connectString ${dbhost}:${dbport}:${dbname} \ 
-dbUser ${dbuser} \ 
-dbRole Normal \ 
-honorOMF \ 
[-encryptTablespace true] \ 
-schemaPrefix ${SCHEMA_PREFIX} \ 
-component MDS \ 
-component STB \ 
-component IAU 

1580
Now you can edit the generated script, connect to your Oracle DB instance, and run the script. The generated script is named `script_systemLoad.sql`. For information about connecting to your Oracle DB instance, see "Connecting to your sample Oracle DB instance (p. 128)."

The following example populates the schemas for the SOA Infrastructure component (and its dependencies).

For Linux, macOS, or Unix:

```bash
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu -silent -dataLoad -connectString ${dbhost}:${dbport}:${dbname} -dbUser ${dbuser} -dbRole Normal -honorOMF -schemaPrefix ${SCHEMA_PREFIX} -component MDS -component STB -component OPSS -component IAU -component IAU_APPEND -component IAU_VIEWER -component UCSUMS -component WLS -component SOAINFRA -f < /tmp/passwordfile.txt
```

To finish, you connect to your Oracle DB instance, and run the clean-up script. The script is named `script_postDataLoad.sql`.

For more information, see "Running Repository Creation Utility from the command line" in the Oracle documentation.

**Running RCU in interactive mode**

To use the RCU graphical user interface, run RCU in interactive mode. Include the `-interactive` parameter and omit the `-silent` parameter. For more information, see "Understanding Repository Creation Utility screens" in the Oracle documentation.

**Example**

The following example starts RCU in interactive mode and pre-populates the connection information.

For Linux, macOS, or Unix:

```bash
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu -interactive
```
Troubleshooting RCU

The following are some known issues for working with RCU, with some troubleshooting suggestions:

- **Oracle Managed Files (OMF)** — Amazon RDS uses OMF data files to simplify storage management. You can customize tablespace attributes, such as size and extent management. However, specifying a data file name when you run RCU causes tablespace code to fail with ORA-20900. The RCU can be used with OMF in the following ways:
  - In RCU 12.2.1.0 and later, use the `-honorOMF` command-line parameter.
  - In RCU 12.1.0.3 and later, use multiple steps and edit the generated script. For more information, see Running RCU using the command line in multiple steps (p. 1580).
- **SYSDBA** — Because Amazon RDS is a managed service, you don’t have full SYSDBA access to your Oracle DB instance. However, RCU 12c supports users with lower privileges. In most cases, the master user privilege is sufficient to create repositories. In some cases, the RCU might fail with ORA-01031 when attempting to grant SYS object privileges. You can retry and run the RDSADMIN_UTIL.GRANT_SYS_OBJECT() stored procedure, or contact AWS Support.
- **Dropping Enterprise Scheduler Service** — When you use the RCU to drop an Enterprise Scheduler Service repository, the RCU might fail with Error: Component drop check failed.
Configuring Oracle Connection Manager on an Amazon EC2 instance

Oracle Connection Manager (CMAN) is a proxy server that forwards connection requests to database servers or other proxy servers. You can use CMAN to configure the following:

Access control

- You can create rules that filter out user-specified client requests and accept others.

Session multiplexing

- You can funnel multiple client sessions through a network connection to a shared server destination.

Typically, CMAN resides on a host separate from the database server and client hosts. For more information, see Configuring Oracle Connection Manager in the Oracle Database documentation.

Topics

- Supported versions and licensing options for CMAN (p. 1583)
- Requirements and limitations for CMAN (p. 1583)
- Configuring CMAN (p. 1583)

Supported versions and licensing options for CMAN

CMAN supports the Enterprise Edition of all versions of Oracle Database that Amazon RDS supports. For more information, see Oracle versions on Amazon RDS (p. 1295).

You can install Oracle Connection Manager on a separate host from the host where Oracle Database is installed. You don't need a separate license for the host that runs CMAN.

Requirements and limitations for CMAN

To provide a fully managed experience, Amazon RDS restricts access to the operating system. You can't modify database parameters that require operating system access. Thus, Amazon RDS doesn't support features of CMAN that require you to log in to the operating system.

Configuring CMAN

When you configure CMAN, you perform most of the work outside of your RDS for Oracle database.

Topics

- Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance (p. 1583)
- Step 2: Configure database parameters for CMAN (p. 1584)
- Step 3: Associate your DB instance with the parameter group (p. 1584)

Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance

To learn how to set up CMAN, follow the detailed instructions in the blog post Configuring and using Oracle Connection Manager on Amazon EC2 for Amazon RDS for Oracle.
Step 2: Configure database parameters for CMAN

For CMAN features such as Traffic Director Mode and session multiplexing, set `REMOTE_LISTENER` parameter to the address of CMAN instance in a DB parameter group. Consider the following scenario:

- The CMAN instance resides on a host with IP address `10.0.159.100` and uses port `1521`.
- The databases `orcla`, `orclb`, and `orclc` reside on separate RDS for Oracle DB instances.

The following table shows how to set the `REMOTE_LISTENER` value. The `LOCAL_LISTENER` value is set automatically by Amazon RDS.

<table>
<thead>
<tr>
<th>DB instance name</th>
<th>DB instance IP</th>
<th>Local listener value (set automatically)</th>
<th>Remote listener value (set by user)</th>
</tr>
</thead>
<tbody>
<tr>
<td>orcla</td>
<td>10.0.159.200</td>
<td>( address=(protocol=tcp) (host=10.0.159.200) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
<tr>
<td>orclb</td>
<td>10.0.159.300</td>
<td>( address=(protocol=tcp) (host=10.0.159.300) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
<tr>
<td>orclc</td>
<td>10.0.159.400</td>
<td>( address=(protocol=tcp) (host=10.0.159.400) (port=1521) )</td>
<td>10.0.159.100:1521</td>
</tr>
</tbody>
</table>

Step 3: Associate your DB instance with the parameter group

Create or modify your DB instance to use the parameter group that you configured in Step 2: Configure database parameters for CMAN (p. 1584). For more information, see Associations a DB parameter group with a DB instance (p. 281).
Installing a Siebel database on Oracle on Amazon RDS

You can use Amazon RDS to host a Siebel Database on an Oracle DB instance. The Siebel Database is part of the Siebel Customer Relationship Management (CRM) application architecture. For an illustration, see Generic architecture of Siebel business application.

Use the following topic to help set up a Siebel Database on an Oracle DB instance on Amazon RDS. You can also find out how to use Amazon Web Services to support the other components required by the Siebel CRM application architecture.

Note
To install a Siebel Database on Oracle on Amazon RDS, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges (p. 1835).

Licensing and versions

To install a Siebel Database on Amazon RDS, you must use your own Oracle Database license, and your own Siebel license. You must have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition. For more information, see Oracle licensing options (p. 1299).

Oracle Database Enterprise Edition is the only edition certified by Siebel for this scenario. Amazon RDS supports Siebel CRM version 15.0 or 16.0. Use Oracle Database 12c Release 1 (12.1.0.2.0) or Oracle Database Release 2 (12.2.0.1). For more information, see Oracle Database 12c with Amazon RDS (p. 1298).

Amazon RDS supports database version upgrades. For more information, see Upgrading a DB instance engine version (p. 344).

Before you begin

Before you begin, you need an Amazon VPC. Because your Amazon RDS DB instance needs to be available only to your Siebel Enterprise Server, and not to the public Internet, your Amazon RDS DB instance is hosted in a private subnet, providing greater security. For information about how to create an Amazon VPC for use with Siebel CRM, see Creating a VPC for use with an Oracle database (p. 1559).

Before you begin, you also need an Oracle DB instance. For information about how to create an Oracle DB instance for use with Siebel CRM, see Creating an Oracle DB instance (p. 1564).

Installing and configuring a Siebel database

After you create your Oracle DB instance, you can install your Siebel Database. You install the database by creating table owner and administrator accounts, installing stored procedures and functions, and then running the Siebel Database Configuration Wizard. For more information, see Installing the Siebel database on the RDBMS.

To run the Siebel Database Configuration Wizard, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see Master user account privileges (p. 1835).

Using other Amazon RDS features with a Siebel database

After you create your Oracle DB instance, you can use additional Amazon RDS features to help you customize your Siebel Database.
Collecting statistics with the Oracle Statspack option

You can add features to your DB instance through the use of options in DB option groups. When you created your Oracle DB instance, you used the default DB option group. If you want to add features to your database, you can create a new option group for your DB instance.

If you want to collect performance statistics on your Siebel Database, you can add the Oracle Statspack feature. For more information, see Oracle Statspack (p. 1530).

Some option changes are applied immediately, and some option changes are applied during the next maintenance window for the DB instance. For more information, see Working with option groups (p. 262). After you create a customized option group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance (p. 309).

Performance tuning with parameters

You manage your DB engine configuration through the use of parameters in a DB parameter group. When you created your Oracle DB instance, you used the default DB parameter group. If you want to customize your database configuration, you can create a new parameter group for your DB instance.

When you change a parameter, depending on the type of the parameter, the changes are applied either immediately or after you manually reboot the DB instance. For more information, see Working with parameter groups (p. 278). After you create a customized parameter group, modify your DB instance to attach it. For more information, see Modifying an Amazon RDS DB instance (p. 309).

To optimize your Oracle DB instance for Siebel CRM, you can customize certain parameters. The following table shows some recommended parameter settings. For more information about performance tuning Siebel CRM, see Siebel CRM Performance Tuning Guide.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Default value</th>
<th>Guidance for optimal Siebel CRM performance</th>
</tr>
</thead>
<tbody>
<tr>
<td>_always_semi_join</td>
<td>CHOOSE</td>
<td>OFF</td>
</tr>
<tr>
<td>_b_tree_bitmap_plans</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>_like_with_bind</td>
<td>FALSE</td>
<td>TRUE</td>
</tr>
<tr>
<td>_no_or_expansion</td>
<td>FALSE</td>
<td>FALSE</td>
</tr>
<tr>
<td>_optimizer_join</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>_optimizer_max_permutations</td>
<td>2000</td>
<td>100</td>
</tr>
<tr>
<td>_optimizer_sortmerge_join</td>
<td>TRUE</td>
<td>TRUE</td>
</tr>
<tr>
<td>_partition_view</td>
<td>TRUE</td>
<td>FALSE</td>
</tr>
<tr>
<td>open_cursors</td>
<td>300</td>
<td>At least 2000.</td>
</tr>
</tbody>
</table>

Creating snapshots

After you create your Siebel Database, you can copy the database by using the snapshot features of Amazon RDS. For more information, see Creating a DB snapshot (p. 428) and Restoring from a DB snapshot (p. 432).
### Support for other Siebel CRM components

In addition to your Siebel Database, you can also use Amazon Web Services to support the other components of your Siebel CRM application architecture. You can find more information about the support provided by Amazon AWS for additional Siebel CRM components in the following table.

<table>
<thead>
<tr>
<th>Siebel CRM component</th>
<th>Amazon AWS Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Siebel Enterprise (with one or more Siebel Servers)</td>
<td>You can host your Siebel Servers on Amazon Elastic Compute Cloud (Amazon EC2) instances. You can use Amazon EC2 to launch as many or as few virtual servers as you need. Using Amazon EC2, you can scale up or down easily to handle changes in requirements. For more information, see <a href="#">What is Amazon EC2?</a>. You can put your servers in the same VPC with your DB instance and use the VPC security group to access the database. For more information, see <a href="#">Working with a DB instance in a VPC</a> (p. 1849).</td>
</tr>
<tr>
<td>Web Servers (with Siebel Web Server Extensions)</td>
<td>You can install multiple Web Servers on multiple EC2 instances. You can then use Elastic Load Balancing to distribute incoming traffic among the instances. For more information, see <a href="#">What is Elastic Load Balancing?</a>.</td>
</tr>
<tr>
<td>Siebel Gateway Name Server</td>
<td>You can host your Siebel Gateway Name Server on an EC2 instance. You can then put your server in the same VPC with the DB instance and use the VPC security group to access the database. For more information, see <a href="#">Working with a DB instance in a VPC</a> (p. 1849).</td>
</tr>
</tbody>
</table>
Oracle database engine releases

Updates to your Amazon RDS for Oracle DB instances keep them current. If you apply updates, you can be confident that your DB instance is running a version of the database software that has been tested by both Oracle and Amazon. We don't support applying one-off patches to individual DB instances.

You can specify any currently supported Oracle Database version when creating a new DB instance. You can specify the major version, such as Oracle Database 12c Release 1 (12.1), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version that you have specified. To see a list of supported versions and defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command.

For details about the Oracle Database versions that are supported by Amazon RDS, see the Amazon RDS for Oracle Release Notes.
Amazon RDS supports DB instances running several versions of PostgreSQL. For a list of available versions, see Available PostgreSQL database versions (p. 1595).

**Note**
Deprecation of PostgreSQL 9.6 is scheduled for April 26, 2022. For more information, see Deprecation of PostgreSQL version 9.6 (p. 1595).

You can create DB instances and DB snapshots, point-in-time restores and backups. DB instances running PostgreSQL support Multi-AZ deployments, read replicas, Provisioned IOPS, and can be created inside a virtual private cloud (VPC). You can also use Secure Socket Layer (SSL) to connect to a DB instance running PostgreSQL.

Before creating a DB instance, make sure to complete the steps in Setting up for Amazon RDS (p. 93).

You can use any standard SQL client application to run commands for the instance from your client computer. Such applications include pgAdmin, a popular Open Source administration and development tool for PostgreSQL, or psql, a command line utility that is part of a PostgreSQL installation. To deliver a managed service experience, Amazon RDS doesn’t provide host access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn’t allow direct host access to a DB instance by using Telnet or Secure Shell (SSH).

Amazon RDS for PostgreSQL is compliant with many industry standards. For example, you can use Amazon RDS for PostgreSQL databases to build HIPAA-compliant applications and to store healthcare-related information. This includes storage for protected health information (PHI) under a completed Business Associate Agreement (BAA) with AWS. Amazon RDS for PostgreSQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. Amazon RDS for PostgreSQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see AWS cloud compliance.

To import PostgreSQL data into a DB instance, follow the information in the Importing data into PostgreSQL on Amazon RDS (p. 1645) section.

Following is a list of other sections in this guide that can help you understand and use important features of RDS for PostgreSQL:

- Understanding the rds_superuser role (p. 1713)
- Controlling user access to the PostgreSQL database (p. 1702)
- Working with parameters on your RDS for PostgreSQL DB instance (p. 1704)
- Understanding logging mechanisms supported by RDS for PostgreSQL (p. 1703)
- Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 1694)
- Using a custom DNS server for outbound network access (p. 1624)
Working with the database preview environment

When you create a DB instance in Amazon RDS, you know that the PostgreSQL version it's based on has been tested and is fully supported by Amazon. The PostgreSQL community releases new versions and new extensions continuously. You can try out new PostgreSQL versions and extensions before they are fully supported. To do that, you can create a new DB instance in the Database Preview Environment.

DB instances in the Database Preview Environment are similar to DB instances in a production environment. However, keep in mind several important factors:

- All DB instances are deleted 60 days after you create them, along with any backups and snapshots.
- You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
- You can only create M6g, M5, T3, R6g, and R5 instance types. For more information about RDS instance classes, see DB instance classes (p. 9).
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. You can post your questions in the RDS database preview environment forum.
- You can't copy a snapshot of a DB instance to a production environment.
- You can use both single-AZ and multi-AZ deployments.
- You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.

Topics

- Features not supported in the preview environment (p. 1593)
- Creating a new DB instance in the preview environment (p. 1593)

Features not supported in the preview environment

The following features are not available in the preview environment:

- Cross-Region snapshot copy
- Cross-Region read replicas

Creating a new DB instance in the preview environment

Use the following procedure to create a DB instance in the preview environment.

To create a DB instance in the preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Dashboard from the navigation pane.
3. Choose Switch to database preview environment.
You also can navigate directly to the Database preview environment.

**Note**
If you want to create an instance in the Database Preview Environment with the API or CLI, the endpoint is rds-preview.us-east-2.amazonaws.com.

4. Continue with the procedure as described in Console (p. 175).

**Limitations for PostgreSQL DB instances**

The following is a list of limitations for RDS for PostgreSQL:

- You can have up to 40 PostgreSQL DB instances.
- For storage limits, see Amazon RDS DB instance storage (p. 53).
- Amazon RDS reserves up to 3 connections for system maintenance. If you specify a value for the user connections parameter, add 3 to the number of connections that you expect to use.
Available PostgreSQL database versions

Amazon RDS supports DB instances running several editions of PostgreSQL. You can specify any currently available PostgreSQL version when creating a new DB instance. You can specify the major version (such as PostgreSQL 10), and any available minor version for the specified major version. If no version is specified, Amazon RDS defaults to an available version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

To see a list of available versions, as well as defaults for newly created DB instances, use the `describe-db-engine-versions` AWS CLI command. For example, to display the default PostgreSQL engine version, use the following command:

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

For details about the PostgreSQL versions that are supported on Amazon RDS, see the Amazon RDS for PostgreSQL Release Notes.

Deprecation of PostgreSQL version 9.6

On March 31, 2022, Amazon RDS plans to deprecate PostgreSQL 9.6 using the following schedule. This extends the previously announced date of January 18, 2022 to April 26, 2022. You should upgrade all your PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. We recommend that you first upgrade to minor version 9.6.20 or higher and then upgrade directly to PostgreSQL 12 rather than upgrading to an intermediate major version. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 1626).

<table>
<thead>
<tr>
<th>Action or recommendation</th>
<th>Dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>The PostgreSQL community discontinued support for PostgreSQL 9.6, and will no longer provide bug fixes or security patches for this version.</td>
<td>November 11, 2021</td>
</tr>
<tr>
<td>Start upgrading RDS for PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. Although you can continue to restore PostgreSQL 9.6 snapshots and create read replicas with version 9.6, be aware of the other critical dates in this deprecation schedule and their impact.</td>
<td>Now – March 31, 2022</td>
</tr>
<tr>
<td>After this date, you can't create new Amazon RDS instances with PostgreSQL major version 9.6 from either the AWS Management Console or the AWS CLI.</td>
<td>March 31, 2022</td>
</tr>
<tr>
<td>Amazon RDS automatically upgrades PostgreSQL 9.6 instances to version 12. If you restore a PostgreSQL 9.6 database snapshot, Amazon RDS automatically upgrades the restored database to PostgreSQL 12.</td>
<td>April 26, 2022</td>
</tr>
</tbody>
</table>

For more information about RDS for PostgreSQL 9.6 deprecation, see Announcement: Extending end-of-life process for Amazon RDS for PostgreSQL 9.6.
Deprecation for Amazon RDS for PostgreSQL

RDS for PostgreSQL 9.5 is deprecated as of March, 2021. For more information about RDS for PostgreSQL 9.5 deprecation, see Upgrading from Amazon RDS for PostgreSQL version 9.5.

To learn more about deprecation policy for RDS for PostgreSQL, see Amazon RDS FAQs. For more information about PostgreSQL versions, see Versioning Policy in the PostgreSQL documentation.
Supported PostgreSQL extension versions

RDS for PostgreSQL supports many PostgreSQL extensions. The PostgreSQL community sometimes refers to these as modules. Extensions expand on the functionality provided by the PostgreSQL engine. You can find a list of extensions supported by Amazon RDS in the default DB parameter group for that PostgreSQL version. You can also see the current extensions list using `psql` by showing the `rds.extensions` parameter as in the following example.

```
SHOW rds.extensions;
```

**Note**
Parameters added in a minor version release might display inaccurately when using the `rds.extensions` parameter in `psql`.

For details about the PostgreSQL extensions that are supported on Amazon RDS, see PostgreSQL extensions supported on Amazon RDS in Amazon RDS for PostgreSQL Release Notes.

Contents
- Restricting installation of PostgreSQL extensions (p. 1597)
- PostgreSQL trusted extensions (p. 1598)

Restricting installation of PostgreSQL extensions

You can restrict which extensions can be installed on a PostgreSQL DB instance. To do so, set the `rds.allowed_extensions` parameter to a string of comma-separated extension names. Only these extensions can then be installed in the PostgreSQL DB instance.

The default string for the `rds.allowed_extensions` parameter is `*`, which means that any extension available for the engine version can be installed. Changing the `rds.allowed_extensions` parameter does not require a database restart because it's a dynamic parameter.

The PostgreSQL DB instance engine must be one of the following versions for you to use the `rds.allowed_extensions` parameter:
- PostgreSQL 14.1 or a higher minor version
- PostgreSQL 13.2 or a higher minor version
- PostgreSQL 12.6 or a higher minor version

To see which extension installations are allowed, use the following `psql` command.

```
postgres=> SHOW rds.allowed_extensions;
  rds.allowed_extensions
  ------------------------
  *
```

If an extension was installed prior to it being left out of the list in the `rds.allowed_extensions` parameter, the extension can still be used normally, and commands such as `ALTER EXTENSION` and `DROP EXTENSION` will continue to work. However, after an extension is restricted, `CREATE EXTENSION` commands for the restricted extension will fail.

Installation of extension dependencies with `CREATE EXTENSION CASCADE` are also restricted. The extension and its dependencies must be specified in `rds.allowed_extensions`. If an extension dependency installation fails, the entire `CREATE EXTENSION CASCADE` statement will fail.
If an extension is not included with the `rds.allowed_extensions` parameter, you will see an error such as the following if you try to install it.

```
ERROR: permission denied to create extension "extension-name"
HINT: This extension is not specified in "rds.allowed_extensions".
```

### PostgreSQL trusted extensions

To install most PostgreSQL extensions requires `rds_superuser` privileges. PostgreSQL 13 introduced trusted extensions, which reduce the need to grant `rds_superuser` privileges to regular users. With this feature, users can install many extensions if they have the `CREATE` privilege on the current database instead of requiring the `rds_superuser` role. For more information, see the SQL `CREATE EXTENSION` command in the PostgreSQL documentation.

The following lists the extensions that can be installed by a user who has the `CREATE` privilege on the current database and do not require the `rds_superuser` role:

- `bool_plperl`
- `btree_gin`
- `btree_gist`
- `citext`
- `cube`
- `dict_int`
- `fuzzystrmatch`
- `hstore`
- `intarray`
- `isn`
- `jsonb_plperl`
- `ltree`
- `pg_trgm`
- `pgcrypto`
- `plperl`
- `plpgsql`
- `pltcl`
- `tablefunc`
- `tsm_system_rows`
- `tsm_system_time`
- `unaccent`
- `uuid-ossp`
Connecting to a DB instance running the PostgreSQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. Before you can connect, the DB instance must be available and accessible. Whether you can connect to the instance from outside the VPC depends on how you created the Amazon RDS DB instance:

- If you created your DB instance as public, devices and Amazon EC2 instances outside the VPC can connect to your database.
- If you created your DB instance as private, only Amazon EC2 instances and devices inside the Amazon VPC can connect to your database.

To check whether your DB instance is public or private, use the AWS Management Console to view the Connectivity & security tab for your instance. Under Security, you can find the "Publicly accessible" value, with No for private, Yes for public.

To learn more about different Amazon RDS and Amazon VPC configurations and how they affect accessibility, see Scenarios for accessing a DB instance in a VPC (p. 1857).

If the DB instance is available and accessible, you can connect by providing the following information to the SQL client application:

- The DB instance endpoint, which serves as the host name (DNS name) for the instance.
- The port on which the DB instance is listening. For PostgreSQL, the default port is 5432.
- The user name and password for the DB instance. The default 'master username' for PostgreSQL is postgres.
- The name and password of the database (DB name).

You can obtain these details by using the AWS Management Console, the AWS CLI describe-db-instances command, or the Amazon RDS API DescribeDBInstances operation.

To find the endpoint, port number, and DB name using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Open the RDS console and then choose Databases to display a list of your DB instances.
3. Choose the PostgreSQL DB instance name to display its details.
4. On the Connectivity & security tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.
5. On the **Configuration** tab, note the DB name. If you created a database when you created the RDS for PostgreSQL instance, you see the name listed under DB name. If you didn't create a database, the DB name displays a dash (-).
Using pgAdmin to connect to a RDS for PostgreSQL DB instance

Following are two ways to connect to a PostgreSQL DB instance. The first example uses pgAdmin, a popular open-source administration and development tool for PostgreSQL. The second example uses psql, a command line utility that is part of a PostgreSQL installation.

**Topics**

- Using pgAdmin to connect to a RDS for PostgreSQL DB instance (p. 1601)
- Using psql to connect to your RDS for PostgreSQL DB instance (p. 1603)
- Troubleshooting connections to your RDS for PostgreSQL instance (p. 1603)

**Using pgAdmin to connect to a RDS for PostgreSQL DB instance**

You can use the open-source tool pgAdmin to connect to your RDS for PostgreSQL DB instance. You can download and install pgAdmin from [http://www.pgadmin.org/](http://www.pgadmin.org/) without having a local instance of PostgreSQL on your client computer.

**To connect to your RDS for PostgreSQL DB instance using pgAdmin**

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, type a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, type the following information from your DB instance:
   - For **Host**, type the endpoint, for example `mypostgresql.c6c8dntfzzhgv0.us-east-2.rds.amazonaws.com`.
   - For **Port**, type the assigned port.
   - For **Username**, type the user name that you entered when you created the DB instance (if you changed the 'master username' from the default, `postgres`).
   - For **Password**, type the password that you entered when you created the DB instance.
5. Choose Save.

If you have any problems connecting, see Troubleshooting connections to your RDS for PostgreSQL instance (p. 1603).

6. To access a database in the pgAdmin browser, expand Servers, the DB instance, and Databases. Choose the DB instance's database name.

7. To open a panel where you can enter SQL commands, choose Tools, Query Tool.
Using psql to connect to your RDS for PostgreSQL DB instance

You can use a local instance of the psql command line utility to connect to a RDS for PostgreSQL DB instance. You need either PostgreSQL or the psql client installed on your client computer.

To connect to your RDS for PostgreSQL DB instance using psql, you need to provide host (DNS) information, access credentials, and the name of the database.

Use one of the following formats to connect to your RDS for PostgreSQL DB instance. When you connect, you're prompted for a password. For batch jobs or scripts, use the --no-password option. This option is set for the entire session.

**Note**
A connection attempt with --no-password fails when the server requires password authentication and a password is not available from other sources. For more information, see the psql documentation.

If this is the first time you are connecting to this DB instance, or if you didn't yet create a database for this RDS for PostgreSQL instance, you can connect to the postgres database using the 'master username' and password.

For Unix, use the following format.

```bash
psql
   --host=<DB instance endpoint> \ 
   --port=<port> \ 
   --username=<master username> \ 
   --password \ 
   --dbname=<database name>
```

For Windows, use the following format.

```bash
psql ^
   --host=<DB instance endpoint> ^
   --port=<port> ^
   --username=<master username> ^
   --password ^
   --dbname=<database name>
```

For example, the following command connects to a database called mypgdb on a PostgreSQL DB instance called mypostgresql using fictitious credentials.

```bash
psql --host=mypostgresql.c6c8mwvdqv0.us-west-2.rds.amazonaws.com --port=5432 --username=awsuser --password --dbname=mypgdb
```

Troubleshooting connections to your RDS for PostgreSQL instance

**Topics**
- Error – FATAL: database name does not exist (p. 1604)
- Error – Could not connect to server: Connection timed out (p. 1604)
- Errors with security group access rules (p. 1604)
Error – FATAL: database name does not exist

If when trying to connect you receive an error like FATAL: database name does not exist, try using the default database name postgres for the --dbname option.

Error – Could not connect to server: Connection timed out

If you can't connect to the DB instance, the most common error is Could not connect to server: Connection timed out. If you receive this error, check the following:

- Check that the host name used is the DB instance endpoint and that the port number used is correct.
- Make sure that the DB instance's public accessibility is set to Yes to allow external connections. To modify the Public access setting, see Modifying an Amazon RDS DB instance (p. 309).
- Check that the security group assigned to the DB instance has rules to allow access through any firewall your connection might go through. For example, if the DB instance was created using the default port of 5432, your company might have firewall rules blocking connections to that port from external company devices.

To fix this, modify the DB instance to use a different port. Also, make sure that the security group applied to the DB instance allows connections to the new port. To modify the Database port setting, see Modifying an Amazon RDS DB instance (p. 309).
- See also Errors with security group access rules (p. 1604).

Errors with security group access rules

By far the most common connection problem is with the security group's access rules assigned to the DB instance. If you used the default DB security group when you created the DB instance, the security group likely didn't have access rules that allow you to access the instance.

For the connection to work, the security group you assigned to the DB instance at its creation must allow access to the DB instance. For example, if the DB instance was created in a VPC, it must have a VPC security group that authorizes connections. Check if the DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the application is running.

You can add or edit an inbound rule in the security group. For Source, choosing My IP allows access to the DB instance from the IP address detected in your browser. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

Alternatively, if the DB instance was created outside of a VPC, it must have a database security group that authorizes those connections.

For more information about Amazon RDS security groups, see Controlling access with security groups (p. 1822).
Securing connections to RDS for PostgreSQL with SSL/TLS

RDS for PostgreSQL supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. You can also force all connections to your PostgreSQL DB instance to use SSL. RDS for PostgreSQL also supports Transport Layer Security (TLS), the successor protocol to SSL.

To learn more about Amazon RDS and data protection, including encrypting connections using SSL/TLS, see Data protection in Amazon RDS (p. 1749).

Topics
- Using SSL with a PostgreSQL DB instance (p. 1605)
- Updating applications to use new SSL/TLS certificates (p. 1608)

Using SSL with a PostgreSQL DB instance

Amazon RDS supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. You can also force all connections to your PostgreSQL DB instance to use SSL. RDS for PostgreSQL supports Transport Layer Security (TLS) versions 1.1 and 1.2.

For general information about SSL support and PostgreSQL databases, see SSL support in the PostgreSQL documentation. For information about using an SSL connection over JDBC, see Configuring the client in the PostgreSQL documentation.

SSL support is available in all AWS Regions for PostgreSQL. Amazon RDS creates an SSL certificate for your PostgreSQL DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

Topics
- Connecting to a PostgreSQL DB instance over SSL (p. 1605)
- Requiring an SSL connection to a PostgreSQL DB instance (p. 1606)
- Determining the SSL connection status (p. 1606)
- SSL cipher suites in RDS for PostgreSQL (p. 1607)

Connecting to a PostgreSQL DB instance over SSL

To connect to a PostgreSQL DB instance over SSL

1. Download the certificate.
   
   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

2. Import the certificate into your operating system.
   
   For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 1764).

3. Connect to your PostgreSQL DB instance over SSL.
When you connect using SSL, your client can choose whether to verify the certificate chain. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, and JDBC clients default to `verify-full`.

Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ca-2019-root.pem`.

The following is an example of using psql to connect to a PostgreSQL DB instance.

```bash
$ psql -h testpg.555555555555.us-east-1.rds.amazonaws.com -p 5432 "dbname=testpg user=testuser sslrootcert=rds-ca-2019-root.pem sslmode=verify-full"
```

### Requiring an SSL connection to a PostgreSQL DB instance

You can require that connections to your PostgreSQL DB instance use SSL by using the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL for connections to your DB instance. Updating the `rds.force_ssl` parameter also sets the PostgreSQL `ssl` parameter to 1 (on) and modifies your DB instance's `pg_hba.conf` file to support the new SSL configuration.

You can set the `rds.force_ssl` parameter value by updating the parameter group for your DB instance. If the parameter group for your DB instance isn't the default one, and the `ssl` parameter is already set to 1 when you set `rds.force_ssl` to 1, you don't need to reboot your DB instance. Otherwise, you must reboot your DB instance for the change to take effect. For more information on parameter groups, see Working with parameter groups (p. 278).

When the `rds.force_ssl` parameter is set to 1 for a DB instance, you see output similar to the following when you connect, indicating that SSL is now required:

```bash
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
.
.
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```

### Determining the SSL connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB instance:

```
Password for user master:
psql (10.3)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL is being used. The function returns `t` if the connection is using SSL, otherwise it returns `f`. 

---

**Amazon Relational Database Service User Guide**

**Using SSL with a PostgreSQL DB instance**

When you connect using SSL, your client can choose whether to verify the certificate chain. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, and JDBC clients default to `verify-full`.

Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ca-2019-root.pem`.

The following is an example of using psql to connect to a PostgreSQL DB instance.

```bash
$ psql -h testpg.555555555555.us-east-1.rds.amazonaws.com -p 5432 "dbname=testpg user=testuser sslrootcert=rds-ca-2019-root.pem sslmode=verify-full"
```

### Requiring an SSL connection to a PostgreSQL DB instance

You can require that connections to your PostgreSQL DB instance use SSL by using the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL for connections to your DB instance. Updating the `rds.force_ssl` parameter also sets the PostgreSQL `ssl` parameter to 1 (on) and modifies your DB instance's `pg_hba.conf` file to support the new SSL configuration.

You can set the `rds.force_ssl` parameter value by updating the parameter group for your DB instance. If the parameter group for your DB instance isn't the default one, and the `ssl` parameter is already set to 1 when you set `rds.force_ssl` to 1, you don't need to reboot your DB instance. Otherwise, you must reboot your DB instance for the change to take effect. For more information on parameter groups, see Working with parameter groups (p. 278).

When the `rds.force_ssl` parameter is set to 1 for a DB instance, you see output similar to the following when you connect, indicating that SSL is now required:

```bash
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
.
.
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```

### Determining the SSL connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB instance:

```
Password for user master:
psql (10.3)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL is being used. The function returns `t` if the connection is using SSL, otherwise it returns `f`.
Using SSL with a PostgreSQL DB instance

postgres=> create extension sslinfo;
CREATE EXTENSION

postgres=> select ssl_is_used();
ssl_is_used
---------
t
(1 row)

You can use the `select ssl_cipher()` command to determine the SSL cipher:

postgres=> select ssl_cipher();
ssl_cipher
-------------------
DHE-RSA-AES256-SHA
(1 row)

If you enable `set rds.force_ssl` and restart your instance, non-SSL connections are refused with the following message:

# export PGSSLMODE=disable
# psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
psql: FATAL: no pg_hba.conf entry for host "host.ip", user "someuser", database "postgres", SSL off
#

For information about the `sslmode` option, see Database connection control functions in the PostgreSQL documentation.

### SSL cipher suites in RDS for PostgreSQL

The PostgreSQL configuration parameter `ssl_ciphers` specifies the categories of cipher suites that are allowed for SSL connections. The following table lists the default cipher suites used in RDS for PostgreSQL:

<table>
<thead>
<tr>
<th>PostgreSQL engine version</th>
<th>Cipher suites</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>HIGH:!aNULL:!3DES</td>
</tr>
<tr>
<td>12</td>
<td>HIGH:!aNULL:!3DES</td>
</tr>
<tr>
<td>11.4 and higher minor versions</td>
<td>HIGH:MEDIUM:+3DES:!aNULL:!RC4</td>
</tr>
<tr>
<td>11.1, 11.2</td>
<td>HIGH:MEDIUM:+3DES:!aNULL</td>
</tr>
<tr>
<td>10.9 and higher minor versions</td>
<td>HIGH:MEDIUM:+3DES:!aNULL:!RC4</td>
</tr>
<tr>

Updating applications to use new SSL/TLS certificates

Certificates used for Secure Socket Layer or Transport Layer Security (SSL/TLS) typically have a set lifetime. When service providers update their Certificate Authority (CA) certificates, clients must update their applications to use the new certificates. Following, you can find information about how to determine if your client applications use SSL/TLS to connect to your Amazon RDS for PostgreSQL DB instance. You also find information about how to check if those applications verify the server certificate when they connect.

**Note**
A client application that's configured to verify the server certificate before SSL/TLS connection must have a valid CA certificate in the client's trust store. Update the client trust store when necessary for new certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a nonproduction environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate (p. 1757). For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755). For information about using SSL/TLS with PostgreSQL DB instances, see Using SSL with a PostgreSQL DB instance (p. 1605).

**Topics**

- Determining whether applications are connecting to PostgreSQL DB instances using SSL (p. 1608)
- Determining whether a client requires certificate verification in order to connect (p. 1609)
- Updating your application trust store (p. 1609)
- Using SSL/TLS connections for different types of applications (p. 1610)

Determining whether applications are connecting to PostgreSQL DB instances using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Working with parameter groups (p. 278).

If you are using RDS PostgreSQL version 9.5 or later major version and `rds.force_ssl` is not set to 1 (on), query the `pg_stat_ssl` view to check connections using SSL. For example, the following query returns only SSL/TLS connections and information about the clients using SSL.

```sql
select datname, usename, ssl, client_addr from pg_stat_ssl inner join pg_stat_activity on pg_stat_ssl.pid = pg_stat_activity.pid where ssl is true and usename<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

<table>
<thead>
<tr>
<th>datname</th>
<th>usename</th>
<th>ssl</th>
<th>client_addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>benchdb</td>
<td>pgadmin</td>
<td>t</td>
<td>53.95.6.13</td>
</tr>
</tbody>
</table>
This query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

**Determining whether a client requires certificate verification in order to connect**

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as psql) and JDBC. The libpq-based clients default to `prefer`, where JDBC clients default to `verify-full`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `require`, `verify-ca`, or `verify-full`. An error is thrown if the certificate is invalid.

Use `PGSSLROOTCERT` to verify the certificate with the `PGSSLMODE` environment variable, with `PGSSLMODE` set to `require`, `verify-ca`, or `verify-full`.

```
```

Use the `sslrootcert` argument to verify the certificate with `sslmode` in connection string format, with `sslmode` set to `require`, `verify-ca`, or `verify-full` to verify the certificate.

```
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=require sslrootcert=/full/path/rds-ca-2019-root.pem user=masteruser dbname=postgres"
```

For example, in the preceding case, if you are using an invalid root certificate, then you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

**Updating your application trust store**

For information about updating the trust store for PostgreSQL applications, see Secure TCP/IP connections with SSL in the PostgreSQL documentation.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

For sample scripts that import certificates, see Sample script for importing certificates into your trust store (p. 1764).

**Note**

When you update the trust store, you can retain older certificates in addition to adding the new certificates.
Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**
  The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).
  
  For the complete list of options, see Parameter key words in the PostgreSQL documentation. For the complete list of environment variables, see Environment variables in the PostgreSQL documentation.

- **pgAdmin**
  This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.
  
  For information about configuring connections, see the pgAdmin documentation.

- **JDBC**
  JDBC enables database connections with Java applications.
  
  For general information about connecting to a PostgreSQL database with JDBC, see Connecting to the database in the PostgreSQL documentation. For information about connecting with SSL/TLS, see Configuring the client in the PostgreSQL documentation.

- **Python**
  A popular Python library for connecting to PostgreSQL databases is `psycopg2`.
  
  For information about using `psycopg2`, see the `psycopg2 documentation`. For a short tutorial on how to connect to a PostgreSQL database, see Psycopg2 tutorial. You can find information about the options the `connect` command accepts in The psycopg2 module content.

**Important**

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance (p. 1757).
Using Kerberos authentication with Amazon RDS for PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB instance running PostgreSQL. In this case, your DB instance works with AWS Directory Service for Microsoft Active Directory to enable Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD.

You create an AWS Managed Microsoft AD directory to store user credentials. You then provide to your PostgreSQL DB instance the Active Directory’s domain and other information. When users authenticate with the PostgreSQL DB instance, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

You can also access credentials from your own on-premises Microsoft Active Directory. To do so you create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL instances with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

Availability of Kerberos authentication

Amazon RDS supports Kerberos authentication for PostgreSQL DB instances in the following AWS Regions:

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
</tr>
<tr>
<td>Asia Pacific (Mumbai)</td>
<td>ap-south-1</td>
</tr>
<tr>
<td>Asia Pacific (Seoul)</td>
<td>ap-northeast-2</td>
</tr>
<tr>
<td>Asia Pacific (Singapore)</td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td>Asia Pacific (Sydney)</td>
<td>ap-southeast-2</td>
</tr>
<tr>
<td>Asia Pacific (Tokyo)</td>
<td>ap-northeast-1</td>
</tr>
</tbody>
</table>
Overview of Kerberos authentication

region name | region
---|---
Canada (Central) | ca-central-1
China (Beijing) | cn-north-1
China (Ningxia) | cn-northwest-1
Europe (Frankfurt) | eu-central-1
Europe (Ireland) | eu-west-1
Europe (London) | eu-west-2
Europe (Paris) | eu-west-3
Europe (Stockholm) | eu-north-1
South America (São Paulo) | sa-east-1

Overview of Kerberos authentication for PostgreSQL DB instances

To set up Kerberos authentication for a PostgreSQL DB instance, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the instance.

2. Create a role that provides Amazon RDS access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see What is VPC peering? in the Amazon VPC Peering Guide.

5. Create or modify a PostgreSQL DB instance either from the console, CLI, or RDS API using one of the following methods:
   - Creating an Amazon RDS DB instance (p. 175)
   - Modifying an Amazon RDS DB instance (p. 309)
   - Restoring from a DB snapshot (p. 432)
   - Restoring a DB instance to a specified time (p. 480)

You can locate the instance in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB instance, do the following:
• Provide the domain identifier (d-*) identifier) that was generated when you created your directory.
• Provide the name of the IAM role that you created.
• Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB instance. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for PostgreSQL DB instances

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB instance. To set up Kerberos authentication, take the following steps.

Topics
• Step 1: Create a directory using AWS Managed Microsoft AD (p. 1613)
• Step 2: (Optional) create a trust for an on-premises Active Directory (p. 1616)
• Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service (p. 1617)
• Step 4: Create and configure users (p. 1618)
• Step 5: Enable cross-VPC traffic between the directory and the DB instance (p. 1618)
• Step 6: Create or modify a PostgreSQL DB instance (p. 1619)
• Step 7: Create Kerberos authentication PostgreSQL logins (p. 1620)
• Step 8: Configure a PostgreSQL client (p. 1620)

Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

Important
Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.
The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

**To create a directory with AWS Managed Microsoft AD**

1. In the AWS Directory Service console navigation pane, choose **Directories**, and then choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option currently supported for use with Amazon RDS.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

   **Edition**
   
   Choose the edition that meets your requirements.

   **Directory DNS name**
   
   The fully qualified name for the directory, such as **corp.example.com**.

   **Directory NetBIOS name**
   
   An optional short name for the directory, such as **CORP**.

   **Directory description**
   
   An optional description for the directory.

   **Admin password**
   
   The password for the directory administrator. The directory creation process creates an administrator account with the user name **Admin** and this password.
   
   The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:
   - Lowercase letters (a–z)
   - Uppercase letters (A–Z)
   - Numbers (0–9)
   - Nonalphanumeric characters (~!#$%^&*_-+=`\|{}[]:;"'<>,.?/)
Confirm password

Retype the administrator password.

**Important**

Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose **Next**.

6. On the **Choose VPC and subnets** page, provide the following information:

**VPC**

Choose the VPC for the directory. You can create the PostgreSQL DB instance in this same VPC or in a different VPC.

**Subnets**

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.

8. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.
To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.

**Step 2: (Optional) create a trust for an on-premises Active Directory**

If you don't plan to use your own on-premises Microsoft Active Directory, skip to Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service (p. 1617).

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in Step 1: Create a directory using AWS Managed Microsoft AD (p. 1613)). The trust can be one-way, where the AWS Managed Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

**Note**
If you use an on-premises Microsoft Active Directory, DB instance endpoints can't be used by Windows clients.
Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service

For Amazon RDS to call AWS Directory Service for you, an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess is required. This role allows Amazon RDS to make calls to AWS Directory Service.

When a DB instance is created using the AWS Management Console and the console user has the iam:CreateRole permission, the console creates this role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, create the IAM role manually. Choose RDS and then RDS - Directory Service. Attach the AWS managed policy AmazonRDSDirectoryServiceAccess to this role.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

Note
The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon RDS for PostgreSQL.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy AmazonRDSDirectoryServiceAccess. In this case, the IAM role must have the following IAM trust policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": [
```
"directoryservice.rds.amazonaws.com",
"rds.amazonaws.com"
]
},
"Action": "sts:AssumeRole"
}
]
}

The role must also have the following IAM role policy.

```json
{
"Version": "2012-10-17",
"Statement": [
{
"Action": [
"ds:DescribeDirectories",
"ds:AuthorizeApplication",
"ds:UnauthorizeApplication",
"ds:GetAuthorizedApplicationDetails"
],
"Effect": "Allow",
"Resource": "*"
}
]
}
```

**Step 4: Create and configure users**

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, users are individual people or entities who have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance. Also, this EC2 instance must be a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see Create a user in the AWS Directory Service Administration Guide.

**Step 5: Enable cross-VPC traffic between the directory and the DB instance**

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to Step 6: Create or modify a PostgreSQL DB instance (p. 1619).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

**To enable cross-VPC traffic using VPC peering**

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.
To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.

Step 6: Create or modify a PostgreSQL DB instance

Create or modify a PostgreSQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB instance using the console, the create-db-instance CLI command, or the CreateDBInstance RDS API operation. For instructions, see Creating an Amazon RDS DB instance (p. 175).
- Modify an existing PostgreSQL DB instance using the console, the modify-db-instance CLI command, or the ModifyDBInstance RDS API operation. For instructions, see Modifying an Amazon RDS DB instance (p. 309).
- Restore a PostgreSQL DB instance from a DB snapshot using the console, the restore-db-instance-from-db-snapshot CLI command, or the RestoreDBInstanceFromDBSnapshot RDS API operation. For instructions, see Restoring a DB instance from a specified time (p. 480).
- Restore a PostgreSQL DB instance to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBInstanceToPointInTime RDS API operation. For instructions, see Restoring from a DB snapshot (p. 432).

Kerberos authentication is only supported for PostgreSQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows ingress and egress within the directory's VPC so the DB instance can communicate with the directory.

Console

When you use the console to create, modify, or restore a DB instance, choose Password and Kerberos authentication in the Database authentication section. Then choose Browse Directory. Select the directory or choose Create a new directory to use the Directory Service.

AWS CLI

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the --domain parameter, use the domain identifier (“d-*” identifier) generated when you created the directory.
- For the --domain-iam-role-name parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB instance to use a directory.

```
aws rds modify-db-instance --db-instance-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```
**Important**
If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

### Step 7: Create Kerberos authentication PostgreSQL logins

Use the RDS master user credentials to connect to the PostgreSQL DB instance as you do with any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision PostgreSQL logins and users from the Microsoft Active Directory users and groups in your domain. To manage database permissions, you grant and revoke standard PostgreSQL permissions to these logins.

To allow an Active Directory user to authenticate with PostgreSQL, use the RDS master user credentials. You use these credentials to connect to the PostgreSQL DB instance as you do with any other DB instance. After you're logged in, create an externally authenticated user in PostgreSQL and grant the `rds_ad` role to this user.

```
CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
```

Replace `username` with the user name and include the domain name in uppercase. Users (both humans and applications) from your domain can now connect to the RDS PostgreSQL instance from a domain-joined client machine using Kerberos authentication.

Note that a database user can use either Kerberos or IAM authentication but not both, so this user can't also have the `rds_iam` role. This also applies to nested memberships. For more information, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786).

### Step 8: Configure a PostgreSQL client

To configure a PostgreSQL client, take the following steps:

- Create a krb5.conf file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
- Verify that traffic can flow between the client host and the DB instance over the database port. For example, use psql to connect and access the database.

The following is sample krb5.conf content for AWS Managed Microsoft AD.

```ini
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
kdc = example.com
admin_server = example.com
}
[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
```

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```
```
Managing a DB instance in a Domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-instance` CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the `modify-db-instance` CLI command. Specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the `modify-db-instance` CLI command. Specify the domain identifier of the new domain for the `--domain` option.

Understanding Domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
• disabling-kerberos – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB instance. If so, make sure that you are using the correct IAM role, then modify the DB instance to join the domain.

**Note**
Only Kerberos authentication with RDS for PostgreSQL sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running PostgreSQL. For more information about outbound network access with RDS for PostgreSQL, see Using a custom DNS server for outbound network access (p. 1624).

**Connecting to PostgreSQL with Kerberos authentication**

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command line interface such as psql. For more information about connecting, see Connecting to a DB instance running the PostgreSQL database engine (p. 1599).

**pgAdmin**

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, enter a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, enter the following information from your RDS for PostgreSQL database:
   - For **Host**, enter the endpoint. Use a format such as `PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com`.
     
     If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.

     For example, suppose that the domain name for the AWS Managed Active Directory is `corp.example.com`. Then for **Host**, use the format `PostgreSQL-endpoint.AWS-Region.corp.example.com`.
   - For **Port**, enter the assigned port.
   - For **Maintenance database**, enter the name of the initial database to which the client will connect.
   - For **Username**, enter the user name that you entered for Kerberos authentication in Step 7: Create Kerberos authentication PostgreSQL logins (p. 1620).
5. Choose **Save**.

**Psql**

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

```
kinit username
```
Replace *username* with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB instance is using a publicly accessible VPC, put a private IP address for your DB instance endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the private IP address and then put it in the `/etc/hosts` file.

```bash
% dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
;; Truncated, retrying in TCP mode.
ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
34.210.197.118
% echo " 34.210.197.118 PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/hosts
```

If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.

For example, suppose that the domain name for your AWS Managed Active Directory is `corp.example.com`. Then use the format `PostgreSQL-endpoint.AWS-Region.corp.example.com` for the endpoint and put it in the `/etc/hosts` file.

```bash
% echo " 34.210.197.118 PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/hosts
```

3. Use the following `psql` command to log in to a PostgreSQL DB instance that is integrated with Active Directory.

```bash
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com postgres
```

To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following `psql` command with the domain name from the previous step (`corp.example.com`):

```bash
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.corp.example.com postgres
```
Using a custom DNS server for outbound network access

RDS for PostgreSQL supports outbound network access on your DB instances and allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your RDS for PostgreSQL DB instance through your custom DNS server.

Topics

- Turning on custom DNS resolution (p. 1624)
- Turning off custom DNS resolution (p. 1624)
- Setting up a custom DNS server (p. 1624)

Turning on custom DNS resolution

To turn on DNS resolution in your customer VPC, first associate a custom DB parameter group to your RDS for PostgreSQL instance. Then turn on the `rds.custom_dns_resolution` parameter by setting it to 1, and then restart the DB instance for the changes to take place.

Turning off custom DNS resolution

To turn off DNS resolution in your customer VPC, first turn off the `rds.custom_dns_resolution` parameter of your custom DB parameter group by setting it to 0. Then restart the DB instance for the changes to take place.

Setting up a custom DNS server

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

Note

If you don't set up a custom DNS server and `rds.custom_dns_resolution` is set to 1, hosts are resolved using an Amazon Route 53 private zone. For more information, see Working with private hosted zones.

To set up a custom DNS server for your RDS for PostgreSQL DB instance

1. From the Dynamic Host Configuration Protocol (DHCP) options set attached to your VPC, set the `domain-name-servers` option to the IP address of your DNS name server. For more information, see DHCP options sets.

   Note

   The `domain-name-servers` option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

2. Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.

3. Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.

4. Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1,024 bytes or less.
5. Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that allow UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall settings to allow UDP and TCP inbound traffic on port 53. For more information, see Security groups for your VPC and Adding and removing rules.

6. Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

For more information, see Security groups for your VPC and Adding and removing rules in the Amazon VPC User Guide.

7. Make sure that the routing path between the Amazon RDS DB instance and the DNS server is configured correctly to allow DNS traffic.

Also, if the Amazon RDS DB instance and the DNS server are not in the same VPC, make sure that a peering connection is set up between them. For more information, see What is VPC peering? in Amazon VPC Peering Guide.
Upgrading the PostgreSQL DB engine for Amazon RDS

There are two types of upgrades you can manage for your PostgreSQL DB instance:

- **Operating system updates** – Occasionally, Amazon RDS might need to update the underlying operating system of your DB instance to apply security fixes or OS changes. You can decide when Amazon RDS applies OS updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API. For more information about OS updates, see Applying updates for a DB instance (p. 335).
- **Database engine upgrades** – When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version.

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for PostgreSQL DB instances: major version upgrades and minor version upgrades.

**Major version upgrades**

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the steps described in Choosing a major version upgrade for PostgreSQL (p. 1628). During a major version upgrade, Amazon RDS also upgrades all of your in-Region read replicas along with the primary DB instance.

**Minor version upgrades**

In contrast, minor version upgrades include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the Auto minor version upgrade option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. If your PostgreSQL DB instance is using read replicas, you must first upgrade all of the read replicas before upgrading the primary instance. If your DB instance is in a Multi-AZ deployment, then the writer and any standby replicas are upgraded simultaneously. Therefore, your DB instance might not be available until the upgrade is complete. For more details, see Automatic minor version upgrades for PostgreSQL (p. 1634). For information about manually performing a minor version upgrade, see Manually upgrading the engine version (p. 344).

For more information about database engine versions, and the policy for deprecating database engine versions, see Database Engine Versions in the Amazon RDS FAQs.

**Topics**

- Overview of upgrading PostgreSQL (p. 1627)
- PostgreSQL version numbers (p. 1628)
- Choosing a major version upgrade for PostgreSQL (p. 1628)
- How to perform a major version upgrade (p. 1630)
- Automatic minor version upgrades for PostgreSQL (p. 1634)
- Upgrading PostgreSQL extensions (p. 1636)
Overview of upgrading PostgreSQL

To safely upgrade your DB instances, Amazon RDS uses the `pg_upgrade` utility described in the PostgreSQL documentation.

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine postgres \
  --engine-version version-number \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine postgres ^
  --engine-version version-number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For example, to identify the valid upgrade targets for a PostgreSQL version 10.11 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine postgres \
  --engine-version 10.11 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
  --engine postgres ^
  --engine-version 10.11 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

If your backup retention period is greater than 0, Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases, you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken after the upgrade completes.

**Note**
Amazon RDS takes DB snapshots during the upgrade process only if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 309).

When you perform a major version upgrade of the primary DB instance, all the in-Region read replicas are also automatically upgraded. After the upgrade workflow starts, the read replicas wait for the `pg_upgrade` to complete successfully on the primary DB instance. Then the primary DB instance
upgrade waits for the read replica upgrades to complete. You experience an outage until the upgrade is complete.

If your DB instance is in a Multi-AZ deployment, both the primary writer DB instance and standby DB instances are upgraded. The writer and standby DB instances are upgraded at the same time.

After an upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the DB snapshot that was taken before the upgrade to create a new DB instance.

**PostgreSQL version numbers**

The version numbering sequence for the PostgreSQL database engine is as follows:

- For PostgreSQL versions 10 and later, the engine version number is in the form `major.minor`. The major version number is the integer part of the version number. The minor version number is the fractional part of the version number.

  A major version upgrade increases the integer part of the version number, such as upgrading from `10.minor` to `11.minor`.

- For PostgreSQL versions earlier than 10, the engine version number is in the form `major.major.minor`. The major engine version number is both the integer and the first fractional part of the version number. For example, 9.6 is a major version. The minor version number is the third part of the version number. For example, for version 9.6.12, the 12 is the minor version number.

  A major version upgrade increases the major part of the version number. For example, an upgrade from `9.6.12` to `10.11` is a major version upgrade, where 9.6 and 10 are the major version numbers.

**Choosing a major version upgrade for PostgreSQL**

Major version upgrades can contain changes that are not backward-compatible with previous versions of the database. New functionality can cause your existing applications to stop working correctly. For this reason, Amazon RDS doesn't apply major version upgrades automatically. To perform a major version upgrade, you modify your DB instance manually. Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production DB instances. When you do a PostgreSQL major version upgrade, we recommend that you follow the steps described in *How to perform a major version upgrade* (p. 1630).

When you upgrade a PostgreSQL DB instance to its next major version, any read replicas associated with the DB instance are also upgraded to that next major version. In some cases, you can skip to a higher major version when upgrading. If your upgrade skips a major version, the read replicas are also upgraded to that target major version. Upgrades to version 11 that skip other major versions have certain limitations. You can find the details in the steps described in *How to perform a major version upgrade* (p. 1630).

Most PostgreSQL extensions aren't upgraded during a PostgreSQL engine upgrade. These must be upgraded separately. For more information, see *Upgrading PostgreSQL extensions* (p. 1636).

You can find out which major versions are available for your RDS for PostgreSQL DB instance by running the following AWS CLI query:

```bash
aws rds describe-db-engine-versions --engine postgres --engine-version your-version --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --output text
```

The following table summarizes the results of this query for all available versions. An asterisk (*) on the version number means that version is deprecated. If your current version is deprecated, we
recommend that you upgrade to the newest minor version upgrade target or to one of the other available upgrade targets for that version. For more information about RDS for PostgreSQL 9.6 deprecation, see Deprecation of PostgreSQL version 9.6 (p. 1595).

</tbody>
</table>
How to perform a major version upgrade

We recommend the following process when upgrading an Amazon RDS PostgreSQL DB instance:

1. **Have a version-compatible parameter group ready** – If you are using a custom parameter group, you have two options. You can specify a default parameter group for the new DB engine version. Or you can create your own custom parameter group for the new DB engine version. For more information, see [Working with parameter groups](#)

<table>
<thead>
<tr>
<th>Current source version (deprecated)</th>
<th>Newest minor version upgrade target</th>
<th>Newest major version upgrade target</th>
<th>Other available upgrade targets</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.18</td>
<td>13.4</td>
<td>12.8</td>
<td>11.15 11.14 11.13 10.20 10.19</td>
</tr>
<tr>
<td>9.6.24</td>
<td>14.1</td>
<td>13.5</td>
<td>12.9 11.14 10.20 10.19</td>
</tr>
</tbody>
</table>
2. **Check for unsupported DB instance classes** – Check that your database's instance class is compatible with the PostgreSQL version you are upgrading to. For more information, see Supported DB engines for DB instance classes (p. 11).

3. **Check for unsupported usage:**
   - **Prepared transactions** – Commit or roll back all open prepared transactions before attempting an upgrade.

   You can use the following query to verify that there are no open prepared transactions on your instance.

   ```sql
   SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
   ```

   - **Reg* data types** – Remove all uses of the reg* data types before attempting an upgrade. Except for regtype and regclass, you can't upgrade the reg* data types. The pg_upgrade utility can't persist this data type, which is used by Amazon RDS to do the upgrade.

   To verify that there are no uses of unsupported reg* data types, use the following query for each database.

   ```sql
   SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n, pg_catalog.pg_attribute a
   WHERE c.oid = a.attrelid
   AND NOT a.attisdropped
   AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
   'pg_catalog.regprocedure'::pg_catalog.regtype,
   'pg_catalog.regoper'::pg_catalog.regtype,
   'pg_catalog.regoperator'::pg_catalog.regtype,
   'pg_catalog.regconfig'::pg_catalog.regtype,
   'pg_catalog.regdictionary'::pg_catalog.regtype)
   AND c.relnamespace = n.oid
   AND n.nspname NOT IN ('pg_catalog', 'information_schema');
   ```

4. **Handle logical replication slots** – An upgrade can't occur if the instance has any logical replication slots. Logical replication slots are typically used for AWS DMS migration and for replicating tables from the database to data lakes, BI tools, and other targets. Before upgrading, make sure you know the purpose of any logical replication slots that are in use, and confirm that it's okay to delete them. If the logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade.

   If the logical replication slots aren't needed, you can delete them using the following SQL:

   ```sql
   SELECT * FROM pg_replication_slots;
   SELECT pg_drop_replication_slot(slot_name);
   ```

5. **Handle read replicas** – An upgrade also upgrades the in-Region read replicas along with the primary DB instance.

   You can't upgrade read replicas separately. If you could, it could lead to situations where the primary and replica DB instances have different PostgreSQL major versions. However, read replica upgrades might increase downtime on the primary DB instance. To prevent a read replica upgrade, promote the replica to a standalone instance or delete it before starting the upgrade process.

   The upgrade process recreates the read replica's parameter group based on the read replica's current parameter group. You can apply a custom parameter group to a read replica only after the upgrade completes by modifying the read replica.
Read replicas on the virtual private cloud (VPC) platform are upgraded but replicas on the EC2-Classic platform aren't upgraded. Any EC2-Classic replicas are left in the replication terminated state after the upgrade process completes. To move a DB instance from the EC2-Classic platform into a VPC, see Moving a DB instance not in a VPC into a VPC (p. 1873). For more information about read replicas, see Working with PostgreSQL read replicas in Amazon RDS (p. 1640).

6. **Perform a backup** – We recommend that you perform a backup before performing the major version upgrade so that you have a known restore point for your database. If your backup retention period is greater than 0, the upgrade process creates DB snapshots of your DB instance before and after upgrading. To change your backup retention period, see Modifying an Amazon RDS DB instance (p. 309). To perform a backup manually, see Creating a DB snapshot (p. 428).

7. **Upgrade certain extensions before a major version upgrade** – If you plan to skip a major version with the upgrade, you need to update certain extensions before performing the major version upgrade. Upgrading from versions 9.5.x or 9.6.x to version 11.x skips a major version. The extensions to update include:
   - address_standardizer
   - address_standardizer_data_us
   - postGIS
   - postgis_tiger_geocoder
   - postgis_topology

   Run the following command for each extension you are using.

   ```sql
   ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version'
   ```

   For more information, see Upgrading PostgreSQL extensions (p. 1636).

8. **Drop certain extensions before the major version upgrade** – An upgrade that skips a major version to version 11.x doesn't support updating the pgRouting extension. Upgrading from versions 9.4.x, 9.5.x, or 9.6.x to versions 11.x skip a major version. It's safe to drop the pgRouting extension and then reinstall it to a compatible version after the upgrade. For the extension versions you can update to, see Supported PostgreSQL extension versions (p. 1597).

   The tsearch2 and chkpass extensions are no longer supported for PostgreSQL versions 11 or later. If you are upgrading to version 11.x, drop the tsearch2, and chkpass extensions before the upgrade.

9. **Drop unknown data types** – Drop unknown data types depending on the target version.

   PostgreSQL version 10 stopped supporting the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to a version 10 shows an error message such as the following:

   ```sql
   Database instance is in a state that cannot be upgraded: PreUpgrade checks failed: The instance could not be upgraded because the 'unknown' data type is used in user tables. Please remove all usages of the 'unknown' data type and try again."
   ```

   To find the unknown data type in your database so you can remove the offending column or change it to a supported data type, use the following SQL:

   ```sql
   SELECT DISTINCT data_type FROM information_schema.columns WHERE data_type ILIKE 'unknown';
   ```

10. **Perform an upgrade dry run** – We highly recommend testing a major version upgrade on a duplicate of your production database before attempting the upgrade on your production database. To create a duplicate test instance, you can either restore your database from a recent snapshot or do a point-in-time restore of your database to its latest restorable time. For more information, see Restoring from a
snapshot (p. 434) or Restoring a DB instance to a specified time (p. 480). For details on performing the upgrade, see Manually upgrading the engine version (p. 344).

In upgrading a version 9.6 DB instance to version 10, be aware that PostgreSQL 10 enables parallel queries by default. You can test the impact of parallelism before the upgrade by changing the `max_parallel_workers_per_gather` parameter on your test DB instance to 2.

**Note**
The default value for `max_parallel_workers_per_gather` parameter in the `default.postgresql10` DB parameter group is 2.

For more information, see Parallel Query in the PostgreSQL documentation. To disable parallelism on version 10, set the `max_parallel_workers_per_gather` parameter to 0.

During the major version upgrade, the `public` and `template1` databases and the `public` schema in every database on the instance are temporarily renamed. These objects appear in the logs with their original name and a random string appended. The string is appended so that custom settings such as `locale` and `owner` are preserved during the major version upgrade. After the upgrade completes, the objects are renamed back to their original names.

**Note**
During the major version upgrade process, you can't do a point-in-time restore of your instance. After Amazon RDS performs the upgrade, it takes an automatic backup of the instance. You can perform a point-in-time restore to times before the upgrade began and after the automatic backup of your instance has completed.

11. If an upgrade fails with precheck procedure errors, resolve the issues – During the major version upgrade process, Amazon RDS for PostgreSQL first runs a precheck procedure to identify any issues that might cause the upgrade to fail. The precheck procedure checks all potential incompatible conditions across all databases in the instance.

If the precheck encounters an issue, it creates a log event indicating the upgrade precheck failed. The precheck process details are in an upgrade log named `pg_upgrade_precheck.log` for all the databases of a DB instance. Amazon RDS appends a timestamp to the file name. For more information about viewing logs, see Monitoring Amazon RDS log files (p. 646).

If a read replica upgrade fails at precheck, replication on the failed read replica is broken and the read replica is put in the terminated state. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

Resolve all of the issues identified in the precheck log and then retry the major version upgrade. The following is an example of a precheck log.

```
Upgrade could not be run on Wed Apr 4 18:30:52 2018

The instance could not be upgraded from 9.6.11 to 10.6 for the following reasons.
Please take appropriate action on databases that have usage incompatible with the requested major engine version upgrade and try the upgrade again.

* There are uncommitted prepared transactions. Please commit or rollback all prepared transactions.* One or more role names start with 'pg_'. Rename all role names that start with 'pg_'.

* The following issues in the database 'my"million"db' need to be corrected before upgrading:** The ['"line","reg*"'] data types are used in user tables. Remove all usage of these data types.
** The database name contains characters that are not supported by RDS for PostgreSQL. Rename the database.
** The database has extensions installed that are not supported on the target PostgreSQL version. Drop the following extensions from your database: ['"tsearch2"'].
```
* The following issues in the database 'mydb' need to be corrected before upgrading:**

The database has views or materialized views that depend on 'pg_stat_activity'. Drop the views.

12 If a read replica upgrade fails while upgrading the database, resolve the issue – A failed read replica is placed in the incompatible-restore state and replication is terminated on the DB instance. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

A read replica upgrade might fail for the following reasons:

- It was unable to catch up with the primary DB instance even after a wait time.
- It was in a terminal or incompatible lifecycle state such as storage-full, incompatible-restore, and so on.
- When the primary DB instance upgrade started, there was a separate minor version upgrade running on the read replica.
- The read replica used incompatible parameters.
- The read replica was unable to communicate with the primary DB instance to synchronize the data folder.

13 Upgrade your production instance – When the dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see Manually upgrading the engine version (p. 344).

14 Run the ANALYZE operation to refresh the pg_statistic table. You should do this for every database on all your PostgreSQL DB instances. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run the command without any parameters to generate statistics for all regular tables in the current database, as follows:

```
ANALYZE VERBOSE
```

The VERBOSE flag is optional, but using it shows you the progress. For more information, see ANALYZE in the PostgreSQL documentation.

**Note**

Run ANALYZE on your system after the upgrade to avoid performance issues.

After the major version upgrade is complete, we recommend the following:

- A PostgreSQL upgrade doesn't upgrade any PostgreSQL extensions. To upgrade extensions, see Upgrading PostgreSQL extensions (p. 1636).
- Optionally, use Amazon RDS to view two logs that the pg_upgrade utility produces. These are pg_upgrade_internal.log and pg_upgrade_server.log. Amazon RDS appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see Monitoring Amazon RDS log files (p. 646).

You can also upload the upgrade logs to Amazon CloudWatch Logs. For more information, see Publishing PostgreSQL logs to Amazon CloudWatch Logs (p. 683).

- To verify that everything works as expected, test your application on the upgraded database with a similar workload. After the upgrade is verified, you can delete this test instance.

**Automatic minor version upgrades for PostgreSQL**

If you enable the Auto minor version upgrade option when creating or modifying a DB instance, you can have your DB instance automatically upgraded.
For each RDS for PostgreSQL major version, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn’t automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the PostgreSQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified PostgreSQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
--engine postgres
--engine-version minor-version
--region region
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output text
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
--engine postgres ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for PostgreSQL minor version 10.11 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```bash
aws rds describe-db-engine-versions
--engine postgres
--engine-version 10.11
--region us-east-2
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```bash
aws rds describe-db-engine-versions ^
--engine postgres ^
--engine-version 10.11 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.
In this example, the `AutoUpgrade` value is `True` for PostgreSQL version 10.17. So, the automatic minor upgrade target is PostgreSQL version 10.17, which is highlighted in the output.

A PostgreSQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The DB instance has the **Auto minor version upgrade** option enabled.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version](p. 346).

**Note**
A PostgreSQL upgrade doesn't upgrade PostgreSQL extensions. To upgrade extensions, see [Upgrading PostgreSQL extensions](p. 1636).

### Upgrading PostgreSQL extensions

A PostgreSQL engine upgrade doesn't upgrade most PostgreSQL extensions. To update an extension after a version upgrade, use the `ALTER EXTENSION UPDATE` command.

**Note**
For the `PostGIS` extension, be sure to follow the [PostGIS upgrade instructions](PostGIS documentation) in the PostGIS documentation before you update the extension. For the `pg_repack` extension, drop the extension and then create the new version in the upgraded DB instance. For more information, see [pg_repack installation](pg_repack documentation).

To upgrade an extension, use the following command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version'
```

For the list of supported versions of PostgreSQL extensions, see [Supported PostgreSQL extension versions](p. 1597).

To list your currently installed extensions, use the PostgreSQL `pg_extension` catalog in the following command.
To view a list of the specific extension versions that are available for your installation, use the PostgreSQL `pg_available_extension_versions` view in the following command.

```sql
SELECT * FROM pg_available_extension_versions;
```
Upgrading a PostgreSQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your PostgreSQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your Amazon RDS instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 1626). To learn how to restore a DB snapshot, see Restoring from a DB snapshot (p. 432).

You can upgrade manual DB snapshots that are either encrypted or not encrypted.

For the list of engine versions that are available for upgrading a DB snapshot, see Upgrading the PostgreSQL DB engine for Amazon RDS.

Note
You can’t upgrade automated DB snapshots that are created during the automated backup process.

Console

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Snapshots.
3. Choose the snapshot that you want to upgrade.
4. For Actions, choose Upgrade snapshot. The Upgrade snapshot page appears.
5. Choose the New engine version to upgrade to.
6. Choose Save changes to upgrade the snapshot.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from available to upgrading, and then changes to active upon completion. If the DB snapshot can’t be upgraded because of snapshot corruption issues, the status changes to unavailable. You can’t recover the snapshot from this state.

Note
If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI modify-db-snapshot command.

Parameters

- --db-snapshot-identifier – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385).
- --engine-version – The engine version to upgrade the DB snapshot to.
Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-snapshot
   --db-snapshot-identifier my_db_snapshot
   --engine-version new_version
```

For Windows:

```bash
aws rds modify-db-snapshot
   --db-snapshot-identifier my_db_snapshot
   --engine-version new_version
```

RDS API

To upgrade a DB snapshot to a new database engine version, call the Amazon RDS API `ModifyDBSnapshot` operation.

- **DBSnapshotIdentifier** – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385).
- **EngineVersion** – The engine version to upgrade the DB snapshot to.
Working with PostgreSQL read replicas in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see Working with read replicas (p. 354).

Following, you can find information specific to working with read replicas on PostgreSQL.

Topics

• Read replica configuration with PostgreSQL (p. 1640)
• Monitoring PostgreSQL read replicas (p. 1641)
• Read replica limitations with PostgreSQL (p. 1641)
• Replication interruptions with PostgreSQL read replicas (p. 1641)
• Troubleshooting PostgreSQL read replica problems (p. 1642)

Read replica configuration with PostgreSQL

Amazon RDS PostgreSQL uses PostgreSQL native streaming replication to create a read-only copy of a source DB instance. This read replica (a "standby" in PostgreSQL terms) DB instance is an asynchronously created physical replication of the source DB instance. It’s created by a special connection that transmits write ahead log (WAL) data between the source DB instance and the read replica. PostgreSQL asynchronously streams database changes to this connection as they are made.

PostgreSQL uses a "replication" role to perform streaming replication. The role is privileged, but can’t be used to modify any data. PostgreSQL uses a single process for handling replication.

So that your DB instance can serve as a source DB instance, make sure to set up automatic backups on that DB instance. To do this, set the backup retention period to a value other than 0.

You can create a PostgreSQL read replica without affecting the source DB instance and users of the source. Amazon RDS sets the necessary parameters and permissions for the source DB instance and the read replica without interrupting the service. A snapshot is taken of the source DB instance, and this snapshot becomes the read replica. No outage occurs when you delete a read replica.

You can create up to five read replicas from one source DB instance. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

Amazon RDS overrides any incompatible parameters on a read replica if it prevents the read replica from starting. For example, suppose that the max_connections parameter value is higher on the source DB instance than on the read replica. In that case, Amazon RDS updates the parameter on the read replica to be the same value as that on the source DB instance.

PostgreSQL DB instances use a secure connection that you can encrypt by setting the ssl parameter to 1 for both the source and the read replica instances.

You can create a read replica from a single-AZ or Multi-AZ DB instance. You can use Multi-AZ deployments to improve the durability and availability of critical data, but you can’t use the Multi-AZ standby replica to serve read traffic. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries.

If the source DB instance of a Multi-AZ deployment fails over to the standby, any associated read replicas switch to using the standby (now primary) as their replication source. The new primary has a different IP address than its predecessor. As a result, in some cases the read replicas reboot after a failover so that
they can get back into sync with the new primary. This is the case for all PostgreSQL versions prior to PostgreSQL 13. For PostgreSQL 13 and higher releases, rebooting isn't needed.

**Note**
Changing a DB instance class or changing a DB instance name also changes the IP address for the instance. Prior to PostgreSQL 13, such changes required that the DB instance be rebooted.

To learn more about Multi-AZ deployments, see Multi-AZ DB instance deployments (p. 66). For information about the failover mechanism, see Failover process for Amazon RDS (p. 67). To learn more about how read replicas work in a Multi-AZ deployment, see Working with read replicas (p. 354).

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone (AZ) for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

If you use the `postgres_fdw` extension to access data from a remote server, the read replica also has access to the remote server. For more information about using `postgres_fdw`, see Using the `postgres_fdw` extension to access external data (p. 1738).

### Monitoring PostgreSQL read replicas

For your RDS for PostgreSQL read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. `Replica lag` is the amount of time, in milliseconds, that a read replica lags behind the source DB instance. The `ReplicaLag` metric reports the value of `SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS replica_lag`.

To learn more about `ReplicaLag` and other metrics for Amazon RDS, see Amazon CloudWatch metrics for Amazon RDS (p. 591).

### Read replica limitations with PostgreSQL

The following are limitations for PostgreSQL read replicas:

- Each PostgreSQL read replica is read-only. You can't make a writable read replica.
- You can't create a read replica from another read replica. Thus, you can't create cascading read replicas.
- You can promote a PostgreSQL read replica to be a new source DB instance. However, the read replica doesn't become the new source DB instance automatically. The read replica, when promoted, stops receiving write-head log (WAL) communications and is no longer a read-only instance. Make sure to set up any replication that you intend to have in the future, because the promoted read replica is now a new source DB instance.
- If no user transactions are occurring on the source DB instance, a PostgreSQL read replica reports a replication lag of up to five minutes.
- You can't turn on automated backups for PostgreSQL read replicas.

### Replication interruptions with PostgreSQL read replicas

Several PostgreSQL parameters control the replication process. They can unintentionally break replication with a read replica in some situations. Following are some examples:

- The `max_wal_senders` parameter is set too low to provide enough data to the number of read replicas. If this happens, replication stops.
- The `wal_keep_segments` parameter specifies the number of write-head log (WAL) files (logs) to keep to provide data to the read replicas. If you set the parameter value too low, you can cause a
read replica to fall so far behind that streaming replication stops. In this case, Amazon RDS reports a replication error. RDS then begins recovery on the read replica by replaying the source DB instance's archived WAL logs from Amazon S3. This recovery process continues until the read replica has caught up enough to continue streaming replication. For more information, see Troubleshooting PostgreSQL read replica problems (p. 1642).

- The max_slot_wal_keep_size parameter dictates the maximum size of WAL files that replication slots are allowed to keep in the pg_wal directory at checkpoint time. If max_slot_wal_keep_size is -1 (the default), replication slots might retain an unlimited number of WAL files. Otherwise, the restart_lsn value of a replication slot might fall behind the current log sequence number (LSN) by more than the given size. If so, the standby using the slot might no longer be able to continue replication due to removal of required WAL files. You can see the WAL availability of replication slots in pg_replication_slots.

When the WAL stream that provides data to a read replica is broken, PostgreSQL switches into recovery mode. It restores the read replica by using archived WAL files from Amazon S3. When this process is complete, PostgreSQL attempts to re-establish streaming replication.

Troubleshooting PostgreSQL read replica problems

How to troubleshoot PostgreSQL read replica problems differs based on a couple of factors. These are the version of RDS for PostgreSQL that you are running and whether replication is across AWS Regions or within the same Region:

- Starting with PostgreSQL version 9.5.2, RDS for PostgreSQL uses physical replication slots to manage write ahead log (WAL) retention on each source DB instance across AWS Regions.
- As of RDS for PostgreSQL version 14.1 and higher, physical replication slots are used for replicas across Regions and also within the same Region.

To troubleshoot replication issues when physical replication slots are used, see Read replicas and physical replication slots (p. 1643). The information in that section applies to in-Region read replicas for RDS for PostgreSQL 14.1 and higher. It also applies to cross-Region read replicas for RDS for PostgreSQL 9.5.2 and higher (but before PostgreSQL 14.1).

To troubleshoot replication issues that might be caused by your PostgreSQL parameter settings, see Read replicas and WAL parameter settings (p. 1642).

Read replicas and WAL parameter settings

As mentioned in Replication interruptions with PostgreSQL read replicas (p. 1641), the PostgreSQL parameter wal_keep_segments parameter value can interrupt replication if it's set too low. The value that you set for this parameter specifies the number of logs to keep. If the value is too low, a read replica can fall so far behind that streaming replication stops. If that happens, Amazon RDS reports a replication error and begins recovery on the read replica by replaying the source DB instance's archived WAL logs. This recovery process continues until the read replica has caught up enough to continue streaming replication.

The read replica's PostgreSQL log captures the process, as shown in this example. The bold line shows that Amazon RDS recovered a read replica that fell behind and lost contact with the primary, by replaying an archived WAL file.

```
2014-11-07 19:01:10 UTC::@:[23180]:DEBUG: switched WAL source from archive to stream after failure
2014-11-07 19:01:10 UTC::@:[11575]:LOG: started streaming WAL from primary at 1A/D3000000
on timeline 1
2014-11-07 19:01:10 UTC::@:[11575]:FATAL: could not receive data from WAL stream:
```
When Amazon RDS replays enough archived WAL files on the replica to catch up, streaming to the read replica can begin again. When PostgreSQL resumes streaming, it writes an entry to the log file, similar to the following.

```
2014-11-07 19:41:36 UTC::@::[24714]:LOG: started streaming WAL from primary at 1B/B6000000 on timeline 1
```

The PostgreSQL log captures other important information that you can use to help you troubleshoot read replica issues. For example, at every checkpoint, the PostgreSQL log captures the number of recycled transaction log files, as shown in the following example.

```
2014-11-07 19:59:35 UTC::@::[26820]:LOG: checkpoint complete: wrote 376 buffers (0.2%); 0 transaction log file(s) added, 0 removed, 1 recycled; write=35.681 s, sync=0.013 s, total=35.703 s; sync files=10, longest=0.013 s, average=0.001 s
```

You can use this information to figure out how many transaction files will be recycled in a given time period, and tune the `wal_keep_segments` parameter as needed. For example, suppose that the PostgreSQL log at `checkpoint complete` shows 35 recycled for a 5-minute interval. In this case, the `wal_keep_segments` default value of 32 isn’t sufficient to keep pace with the streaming activity, and we recommend that you increase the value of this parameter.

Also, if the workload on your DB instance generates a large amount of WAL data, you might need to change the DB instance class of your source DB instance and read replica. Changing it to an instance class with high (10 Gbps) network performance helps the replica keep up with the source. To learn more about the rate at which your workload is generating WAL data, check the Amazon CloudWatch `TransactionLogsGeneration` metric.

**Read replicas and physical replication slots**

Physical replication slots have been used since RDS for PostgreSQL 9.5.2 to manage write ahead log (WAL) retention on the source DB instance for cross-Region read replicas. As of RDS for PostgreSQL 14.1, physical replication slots are also used within an AWS Region to manage WAL retention. For each read replica, Amazon RDS creates and associates a physical replication slot that holds onto WAL data. Physical replication slots provide faster recovery than using the archived log files from Amazon S3, so the goal is to ensure that your RDS for PostgreSQL DB instance uses them when possible to provide fast recovery.

You can use two Amazon CloudWatch metrics to help you manage the physical slots:

- `OldestReplicationSlotLag` – Lists the replica that has the most lag, that is, it’s furthest behind the primary
- `TransactionLogsDiskUsage` – Shows how much storage is being used for WAL data. When a read replica lags significantly, the value of this metric can increase substantially.

To learn more about using Amazon CloudWatch and its metrics for RDS for PostgreSQL, see [Monitoring Amazon RDS metrics with Amazon CloudWatch](p. 508).

To check the status of a physical replication slot for a read replica, you can query `pg_replication_slots` on the source instance, as in the following example.
As noted in Replication interruptions with PostgreSQL read replicas (p. 1641), the value of max_slot_wal_keep_size parameter has an effect on the replication process. By default, this parameter has a value of -1, which allows replication slots to retain an unlimited number of WAL files. You can change this to a specific value, but be aware that after your DB instance reaches that value, its slots can hold no more WAL logs. The resulting behavior of your Amazon RDS DB instance if the max_slot_wal_keep_size parameter reaches a limit depends on whether replication is for in-Region or cross-Region read replicas:

- For in-Region replicas, if the max_slot_wal_keep_size limit is reached, Amazon RDS uses the archive logs from Amazon S3 until it catches up to the source. It can then start streaming again. To avoid this, you can monitor your physical replication slots and adjust the max_slot_wal_keep_size to minimize the need for the archive log files.
- For cross-Region replicas, if the max_slot_wal_keep_size limit is reached, replication stops. Archive logs aren't used, so be careful if you adjust the max_slot_wal_keep_size parameter for cross-Region read replicas.
Importing data into PostgreSQL on Amazon RDS

Suppose that you have an existing PostgreSQL deployment that you want to move to Amazon RDS. The complexity of your task depends on the size of your database and the types of database objects that you’re transferring. For example, consider a database that contains datasets on the order of gigabytes, along with stored procedures and triggers. Such a database is going to be more complicated than a simple database with only a few megabytes of test data and no triggers or stored procedures.

We recommend that you use native PostgreSQL database migration tools under the following conditions:

- You have a homogeneous migration, where you are migrating from a database with the same database engine as the target database.
- You are migrating an entire database.
- The native tools allow you to migrate your system with minimal downtime.

In most other cases, performing a database migration using AWS Database Migration Service (AWS DMS) is the best approach. AWS DMS can migrate databases without downtime and, for many database engines, continue ongoing replication until you are ready to switch over to the target database. You can migrate to either the same database engine or a different database engine using AWS DMS. If you are migrating to a different database engine than your source database, you can use the AWS Schema Conversion Tool (AWS SCT). You use AWS SCT to migrate schema objects that are not migrated by AWS DMS. For more information about AWS DMS, see What is AWS Database Migration Service?

Modify your DB parameter group to include the following settings for your import only. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Modify your DB instance settings to the following:

- Disable DB instance backups (set backup_retention to 0).
- Disable Multi-AZ.

Modify your DB parameter group to include the following settings. You should only use these settings when importing data. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Recommended value when importing</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maintenance_work_mem</td>
<td>524288, 1048576, 2097152, or 4194304 (in KB)</td>
<td>The value for this setting depends on the size of your host. This parameter is used during CREATE INDEX statements and each parallel command can use this much memory. Calculate the best value so that you don't set this value so high that you run out of memory.</td>
</tr>
<tr>
<td>max_wal_size</td>
<td>256 (for version 9.6), 4096 (for versions 10 and higher)</td>
<td>Maximum size to let the WAL grow during automatic checkpoints. Increasing this parameter can increase the amount of time needed for crash recovery. This parameter replaces checkpoint_segments for PostgreSQL 9.6 and later.</td>
</tr>
</tbody>
</table>
Importing a PostgreSQL database from an Amazon EC2 instance

If you have data in a PostgreSQL server on an Amazon EC2 instance and want to move it to a PostgreSQL DB instance, you can use the following process. The following list shows the steps to take. Each step is discussed in more detail in the following sections.

1. Create a file using pg_dump that contains the data to be loaded
2. Create the target DB instance
3. Use psql to create the database on the DB instance and load the data
4. Create a DB snapshot of the DB instance

Parameter | Recommended value when importing | Description
--- | --- | ---
checkpoint_timeout | 1800 | The value for this setting allows for less frequent WAL rotation.
synchronous_commit | Off | Disable this setting to speed up writes. Turning this parameter off can increase the risk of data loss in the event of a server crash (do not turn off FSYNC).
wal_buffers | 8192 | This is value is in 8 KB units. This again helps your WAL generation speed
autovacuum | Off | Disable the PostgreSQL auto vacuum parameter while you are loading data so that it doesn't use resources

Use the pg_dump -Fc (compressed) or pg_restore -j (parallel) commands with these settings.

**Note**
The PostgreSQL command pg_dumpall requires super_user permissions that are not granted when you create a DB instance, so it cannot be used for importing data.

**Topics**
- Importing a PostgreSQL database from an Amazon EC2 instance (p. 1646)
- Using the \copy command to import data to a table on a PostgreSQL DB instance (p. 1648)
- Importing Amazon S3 data into an RDS for PostgreSQL DB instance (p. 1649)
- Transporting PostgreSQL databases between DB instances (p. 1661)
Step 1: Create a file using `pg_dump` that contains the data to load

The `pg_dump` utility uses the COPY command to create a schema and data dump of a PostgreSQL database. The dump script generated by `pg_dump` loads data into a database with the same name and recreates the tables, indexes, and foreign keys. You can use the `pg_restore` command and the `-d` parameter to restore the data to a database with a different name.

Before you create the data dump, you should query the tables to be dumped to get a row count so you can confirm the count on the target DB instance.

The following command creates a dump file called `mydb2dump.sql` for a database called `mydb2`.

```
prompt>pg_dump dbname=mydb2 -f mydb2dump.sql
```

Step 2: Create the target DB instance

Create the target PostgreSQL DB instance using either the Amazon RDS console, AWS CLI, or API. Create the instance with the backup retention setting set to 0 and disable Multi-AZ. Doing so allows faster data import. You must create a database on the instance before you can dump the data. The database can have the same name as the database that is contained the dumped data. Alternatively, you can create a database with a different name. In this case, you use the `pg_restore` command and the `-d` parameter to restore the data into the newly named database.

For example, the following commands can be used to dump, restore, and rename a database.

```
pg_dump -Fc -v -h [endpoint of instance] -U [master username] [database] > [database].dump
createdb [new database name]
pg_restore -v -h [endpoint of instance] -U [master username] -d [new database name] [database].dump
```

Step 3: Use `psql` to create the database on the DB instance and load data

You can use the same connection you used to run the `pg_dump` command to connect to the target DB instance and recreate the database. Using `psql`, you can use the master user name and master password to create the database on the DB instance.

The following example uses `psql` and a dump file named `mydb2dump.sql` to create a database called `mydb2` on a PostgreSQL DB instance called `mypginstance`:

For Linux, macOS, or Unix:

```
psql \
- f mydb2dump.sql \n--host mypginstance.55555555555.aws-region.rds.amazonaws.com \n--port 8199 \n--username myawsuser \n--password password \n--dbname mydb2
```

For Windows:

```
psql ^
```
Using the \copy command to import data to a table on a PostgreSQL DB instance

The PostgreSQL \copy command is a meta-command available from the psql interactive client tool. You can use \copy to import data into a table on your RDS for PostgreSQL DB instance. To use the \copy command, you need to first create the table structure on the target DB instance so that \copy has a destination for the data being copied.

You can use \copy to load data from a comma-separated values (CSV) file, such as one that’s been exported and saved to your client workstation.

To import the CSV data to the target RDS for PostgreSQL DB instance, first connect to the target DB instance using psql.

```
psql --host=host=myinstance.55555555555.aws-region.rds.amazonaws.com --port=8199 --username=myawsuser --password --dbname=mydb
```

You then run \copy command with the following parameters to identify the target for the data and its format.

- \target_table - The name of the table that should receive the data being copied from the CSV file.
- \column_list - Column specifications for the table.
- 'filename' - The complete path to the CSV file on your local workstation.

```
\copy target_table from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV;
```

If your CSV file has column heading information, you can use this version of the command and parameters.

```
\copy target_table (column-1, column-2, column-3, ...) from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV HEADER;
```

If the \copy command fails, PostgreSQL outputs error messages.

You can also combine the psql command with the \copy meta-command as shown in the following examples. This example uses source-table as the source table name, source-table.csv as the .csv file, and target-db as the target database:

```
psql --host=host=myinstance.55555555555.aws-region.rds.amazonaws.com --port=8199 --username=myawsuser --password --dbname=target-db
```

```
\copy source-table from '/path/to/local/source-table.csv' WITH DELIMITER ',' CSV;
```

Step 4: Create a DB snapshot of the DB instance

Once you have verified that the data was loaded into your DB instance, we recommend that you create a DB snapshot of the target PostgreSQL DB instance. DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap. You can also use such a snapshot to seed new DB instances. For information about creating a DB snapshot, see Creating a DB snapshot (p. 428).
For Linux, macOS, or Unix:

```
$psql target-db \
   -U <admin user> \
   -p <port> \
   -h <DB instance name> \
   -c "\copy source-table from 'source-table.csv' with DELIMITER ','"
```

For Windows:

```
$psql target-db ^
   -U <admin user> ^
   -p <port> ^
   -h <DB instance name> ^
   -c "\copy source-table from 'source-table.csv' with DELIMITER ','"
```

For complete details about the \copy command, see the psql page in the PostgreSQL documentation, in the Meta-Commands section.

Importing Amazon S3 data into an RDS for PostgreSQL DB instance

You can import data from Amazon S3 into a table belonging to an RDS for PostgreSQL DB instance. To do this, you use the aws_s3 PostgreSQL extension that Amazon RDS provides. Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into RDS for PostgreSQL. You can import into a provisioned DB instance only. That is, these steps aren't supported for Aurora Serverless v1.

For more information on storing data with Amazon S3, see Create a bucket in the Amazon Simple Storage Service User Guide. For instructions on how to upload a file to an Amazon S3 bucket, see Add an object to a bucket in the Amazon Simple Storage Service User Guide.

Topics
- Overview of importing Amazon S3 data (p. 1649)
- Setting up access to an Amazon S3 bucket (p. 1650)
- Using the aws_s3.table_import_from_s3 function to import Amazon S3 data (p. 1655)
- Function reference (p. 1657)

Overview of importing Amazon S3 data

To import data stored in an Amazon S3 bucket to a PostgreSQL database table, follow these steps.

To import S3 data into Amazon RDS

1. Install the required PostgreSQL extensions. These include the aws_s3 and aws_commons extensions. To do so, start psql and use the following command.

   ```
   psql=> CREATE EXTENSION aws_s3 CASCADE;
   NOTICE: installing required extension "aws_commons"
   ```

   The aws_s3 extension provides the aws_s3.table_import_from_s3 function that you use to import Amazon S3 data. The aws_commons extension provides additional helper functions.

2. Identify the database table and Amazon S3 file to use.
The `aws_s3.table_import_from_s3 (p. 1658)` function requires the name of the PostgreSQL database table that you want to import data into. The function also requires that you identify the Amazon S3 file to import. To provide this information, take the following steps.

a. Identify the PostgreSQL database table to put the data in. For example, the following is a sample `t1` database table used in the examples for this topic.

```sql
psql=> CREATE TABLE t1 (col1 varchar(80), col2 varchar(80), col3 varchar(80));
```

b. Get the following information to identify the Amazon S3 file that you want to import:

- **Bucket name** – A *bucket* is a container for Amazon S3 objects or files.
- **File path** – The file path locates the file in the Amazon S3 bucket.
- **AWS Region** – The AWS Region is the location of the Amazon S3 bucket. For example, if the S3 bucket is in the US East (N. Virginia) Region, use `us-east-1`. For a listing of AWS Region names and associated values, see *Regions, Availability Zones, and Local Zones (p. 60)*.

To find how to get this information, see *View an object in the Amazon Simple Storage Service User Guide*. You can confirm the information by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

```bash
aws s3 cp s3://sample_s3_bucket/sample_file_path ./
```

c. Use the `aws_commons.create_s3_uri (p. 1660)` function to create an `aws_commons._s3_uri_1` structure to hold the Amazon S3 file information. You provide this `aws_commons._s3_uri_1` structure as a parameter in the call to the `aws_s3.table_import_from_s3 (p. 1658)` function.

For a `psql` example, see the following.

```sql
psql=> SELECT aws_commons.create_s3_uri('sample_s3_bucket', 'sample.csv', 'us-east-1') AS s3_uri \gset
```

3. Provide permission to access the Amazon S3 file.

To import data from an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket the file is in. To do this, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see *Setting up access to an Amazon S3 bucket (p. 1650)*.

4. Import the Amazon S3 data by calling the `aws_s3.table_import_from_s3` function.

After you complete the previous preparation tasks, use the `aws_s3.table_import_from_s3 (p. 1658)` function to import the Amazon S3 data. For more information, see *Using the aws_s3.table_import_from_s3 function to import Amazon S3 data (p. 1655)*.

**Setting up access to an Amazon S3 bucket**

To import data from an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

**Topics**
Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the `aws_s3.table_import_from_s3` function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB instance.

**Note**
You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.

To give an RDS for PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your RDS for PostgreSQL DB instance to access Amazon S3.

   Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Amazon RDS:
   - `s3:GetObject`
   - `s3:ListBucket`

   Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.
   - `arn:aws:s3:::your-s3-bucket`
   - `arn:aws:s3:::your-s3-bucket/*`

   For more information on creating an IAM policy for Amazon RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access. See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named `your-s3-bucket`.

   **Note**
   Note the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN when you attach the policy to an IAM role, in a subsequent step.

   **Example**

   For Linux, macOS, or Unix:

   ```bash
   aws iam create-policy \
   --policy-name rds-s3-import-policy \
   --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   ```

   1651
For Windows:

```bash
aws iam create-policy
   --policy-name rds-s3-import-policy
   --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "s3import",
   "Action": ["s3:GetObject", "s3:ListBucket"],
   "Effect": "Allow",
   "Resource": [
   "arn:aws:s3:::your-s3-bucket",
   "arn:aws:s3:::your-s3-bucket/*"
   ]
   }
   ]
}

2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

**Example**

For Linux, macOS, or Unix:
aws iam create-role
--role-name rds-s3-import-role
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
        }
      }
    }
  ]
}
'}

For Windows:

aws iam create-role ^
--role-name rds-s3-import-role ^
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
        }
      }
    }
  ]
}
'}

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created in the previous step to the role named rds-s3-import-role Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

**Example**

For Linux, macOS, or Unix:

aws iam attach-role-policy
--policy-arn `your-policy-arn`
--role-name rds-s3-import-role

For Windows:
aws iam attach-role-policy ^
--policy-arn your-policy-arn ^
--role-name rds-s3-import-role

4. Add the IAM role to the DB instance.

You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

**To add an IAM role for a PostgreSQL DB instance using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Import**.
5. Choose **Add role**.

**AWS CLI**

**To add an IAM role for a PostgreSQL DB instance using the CLI**

- Use the following command to add the role to the PostgreSQL DB instance named `my-db-instance`. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `s3Import` for the value of the `--feature-name` option.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance \\n--db-instance-identifier my-db-instance \\n--feature-name s3Import \\n--role-arn your-role-arn \\n--region your-region
```

For Windows:

```bash
aws rds add-role-to-db-instance ^
--db-instance-identifier my-db-instance ^
--feature-name s3Import ^
--role-arn your-role-arn ^
--region your-region
```

**RDS API**

To add an IAM role for a PostgreSQL DB instance using the Amazon RDS API, call the `AddRoleToDBInstance` operation.
Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. To do this, use the credentials parameter in the `aws_s3.table_import_from_s3` function call.

The credentials parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the `aws_commons.create_aws_credentials` function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```sql
psql=> SELECT aws_commons.create_aws_credentials(
    'sample_access_key',
    'sample_secret_key',
    ''
)
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the `aws_s3.table_import_from_s3` function with the credentials parameter to import the data, as shown following.

```sql
psql=> SELECT aws_s3.table_import_from_s3(
    't',
    '',
    '(format csv)',
    's3_uri',
    'creds'
);
```

Or you can include the `aws_commons.create_aws_credentials` function call inline within the `aws_s3.table_import_from_s3` function call.

```sql
psql=> SELECT aws_s3.table_import_from_s3(
    't',
    '',
    '(format csv)',
    's3_uri',
    aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
);
```

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import Amazon S3 file data, see the following for recommendations:

- Troubleshooting Amazon RDS identity and access (p. 1812)
- Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide
- Troubleshooting Amazon S3 and IAM in the IAM User Guide

Using the `aws_s3.table_import_from_s3` function to import Amazon S3 data

Import your Amazon S3 data by calling the `aws_s3.table_import_from_s3` function.

**Note**

The following examples use the IAM role method for providing access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don’t include credential parameters.

The following shows a typical PostgreSQL example using `psql`.

```sql
psql=> SELECT aws_s3.table_import_from_s3(
    't1',
```
The parameters are the following:

- \( t1 \) – The name for the table in the PostgreSQL DB instance to copy the data into.
- \( \text{''} \) – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see Importing an Amazon S3 file that uses a custom delimiter (p. 1656).
- \( \text{\texttt{(format csv)}} \) – PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command. In the preceding example, the \texttt{COPY} command uses the comma-separated value (CSV) file format to copy the data.
- \( \text{s3\_uri} \) – A structure that contains the information identifying the Amazon S3 file. For an example of using the \	exttt{aws_commons.create\_s3\_uri} (p. 1660) function to create an \texttt{s3\_uri} structure, see Overview of importing Amazon S3 data (p. 1649).

For more information about this function, see \texttt{aws\_s3.table\_import\_from\_s3} (p. 1658).

The \texttt{aws\_s3.table\_import\_from\_s3} function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

**Topics**

- Importing an Amazon S3 file that uses a custom delimiter (p. 1656)
- Importing an Amazon S3 compressed (gzip) file (p. 1657)
- Importing an encoded Amazon S3 file (p. 1657)

**Importing an Amazon S3 file that uses a custom delimiter**

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the \texttt{column\_list} parameter of the \texttt{aws\_s3.table\_import\_from\_s3} (p. 1658) function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

<table>
<thead>
<tr>
<th>1</th>
<th>foo1</th>
<th>bar1</th>
<th>elephant1</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>foo2</td>
<td>bar2</td>
<td>elephant2</td>
</tr>
<tr>
<td>3</td>
<td>foo3</td>
<td>bar3</td>
<td>elephant3</td>
</tr>
<tr>
<td>4</td>
<td>foo4</td>
<td>bar4</td>
<td>elephant4</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**To import a file that uses a custom delimiter**

1. Create a table in the database for the imported data.

   \[
   \text{psql}=> \text{CREATE TABLE test (a text, b text, c text, d text, e text);}
   \]

2. Use the following form of the \texttt{aws\_s3.table\_import\_from\_s3} (p. 1658) function to import data from the Amazon S3 file.

   You can include the \texttt{aws_commons.create\_s3\_uri} (p. 1660) function call inline within the \texttt{aws\_s3.table\_import\_from\_s3} function call to specify the file.
Importing S3 data into RDS for PostgreSQL

```sql
psql=> SELECT aws_s3.table_import_from_s3(
    'test',
    'a,b,c,d,e',
    'DELIMITER '|'','
    aws_commons.create_s3_uri('sampleBucket', 'pipeDelimitedSampleFile', 'us-east-2')
);
```

The data is now in the table in the following columns.

```sql
psql=> SELECT * FROM test;
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
<th>e</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>foo1</td>
<td></td>
<td>bar1</td>
<td>elephant1</td>
</tr>
<tr>
<td>2</td>
<td>foo2</td>
<td></td>
<td>bar2</td>
<td>elephant2</td>
</tr>
<tr>
<td>3</td>
<td>foo3</td>
<td></td>
<td>bar3</td>
<td>elephant3</td>
</tr>
<tr>
<td>4</td>
<td>foo4</td>
<td></td>
<td>bar4</td>
<td>elephant4</td>
</tr>
</tbody>
</table>
```

Importing an Amazon S3 compressed (gzip) file

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- Key: Content-Encoding
  - Value: gzip

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see Uploading objects in the Amazon Simple Storage Service User Guide.

For more information about Amazon S3 metadata and details about system-provided metadata, see Editing object metadata in the Amazon S3 console in the Amazon Simple Storage Service User Guide.

Import the gzip file into your RDS for PostgreSQL DB instance as shown following.

```sql
psql=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
psql=> SELECT aws_s3.table_import_from_s3(
    'test_gzip', '', '(format csv)',
    'myS3Bucket', 'test-data.gz', 'us-east-2' );
```

Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```sql
psql=> SELECT aws_s3.table_import_from_s3(
    'test_table', '', 'encoding 'WIN1252'' ,
    aws_commons.create_s3_uri('sampleBucket', 'SampleFile', 'us-east-2')
);
```

Function reference

Functions
- `aws_s3.table_import_from_s3` (p. 1658)
- `aws_commons.create_s3_uri` (p. 1660)
• **aws_commons.create_aws_credentials** (p. 1660)

### aws_s3.table_import_from_s3

Imports Amazon S3 data into an Amazon RDS table. The **aws_s3** extension provides the `aws_s3.table_import_from_s3` function. The return value is text.

#### Syntax

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB instance.

  ```python
  aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    s3_info aws_commons._s3_uri_1  
  )
  ```

- The `credentials` parameter specifies the credentials to access Amazon S3. When you use this parameter, you don’t use an IAM role.

  ```python
  aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    s3_info aws_commons._s3_uri_1,  
    credentials aws_commons._aws_credentials_1  
  )
  ```

#### Parameters

**table_name**

A required text string containing the name of the PostgreSQL database table to import the data into.

**column_list**

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see Importing an Amazon S3 file that uses a custom delimiter (p. 1656).

**options**

A required text string containing arguments for the PostgreSQL **COPY** command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the PostgreSQL **COPY** documentation.

**s3_info**

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket containing the file.
• file_path – The Amazon S3 file name including the path of the file.
• region – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 60).

credentials

An aws_commons._aws_credentials_1 composite type containing the following credentials to use for the import operation:
• Access key
• Secret key
• Session token

For information about creating an aws_commons._aws_credentials_1 composite structure, see aws_commons.create_aws_credentials (p. 1660).

Alternate syntax

To help with testing, you can use an expanded set of parameters instead of the s3_info and credentials parameters. Following are additional syntax variations for the aws_s3.table_import_from_s3 function:

• Instead of using the s3_info parameter to identify an Amazon S3 file, use the combination of the bucket, file_path, and region parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```sql
aws_s3.table_import_from_s3 (    table_name text,    column_list text,    options text,    bucket text,    file_path text,    region text)
```

• Instead of using the credentials parameter to specify Amazon S3 access, use the combination of the access_key, session_key, and session_token parameters.

```sql
aws_s3.table_import_from_s3 (    table_name text,    column_list text,    options text,    bucket text,    file_path text,    region text,    access_key text,    secret_key text,    session_token text)
```

Alternate parameters

bucket

A text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A text string containing the Amazon S3 file name including the path of the file.
**region**

A text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 60).

**access_key**

A text string containing the access key to use for the import operation. The default is NULL.

**secret_key**

A text string containing the secret key to use for the import operation. The default is NULL.

**session_token**

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

**aws_commons.create_s3_uri**

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. Use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the `aws_s3.table_import_from_s3 (p. 1658)` function.

**Syntax**

```
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

**Parameters**

**bucket**

A required text string containing the Amazon S3 bucket name for the file.

**file_path**

A required text string containing the Amazon S3 file name including the path of the file.

**region**

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 60).

**aws_commons.create_aws_credentials**

Sets an access key and secret key in an `aws_commons._aws_credentials_1` structure. Use the results of the `aws_commons.create_aws_credentials` function in the `credentials` parameter of the `aws_s3.table_import_from_s3 (p. 1658)` function.

**Syntax**

```
aws_commons.create_aws_credentials(
    access_key text,
    secret_key text,
    session_token text
)
```
Parameters

`access_key`

A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

`secret_key`

A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.

`session_token`

An optional text string containing the session token to use for importing an Amazon S3 file. The default is NULL. If you provide an optional `session_token`, you can use temporary credentials.

Transporting PostgreSQL databases between DB instances

By using PostgreSQL transportable databases for Amazon RDS, you can move a PostgreSQL database between two DB instances. This is a very fast way to migrate large databases between different DB instances. To use this approach, your DB instances must both run the same major version of PostgreSQL.

This capability requires that you install the `pg_transport` extension on both the source and the destination DB instance. The `pg_transport` extension provides a physical transport mechanism that moves the database files with minimal processing. This mechanism moves data much faster than traditional dump and load processes, with less downtime.

**Note**

PostgreSQL transportable databases are available in RDS for PostgreSQL 11.5 and higher, and RDS for PostgreSQL version 10.10 and higher.

To transport a PostgreSQL DB instance from one RDS for PostgreSQL DB instance to another, you first set up the source and destination instances as detailed in Setting up a DB instance for transport (p. 1662). You can then transport the database by using the function described in Transporting a PostgreSQL database (p. 1663).

Topics

- Limitations for using PostgreSQL transportable databases (p. 1661)
- Setting up to transport a PostgreSQL database (p. 1662)
- Transporting a PostgreSQL database to the destination from the source (p. 1663)
- What happens during database transport (p. 1664)
- Transportable databases function reference (p. 1665)
- Transportable databases parameter reference (p. 1666)

Limitations for using PostgreSQL transportable databases

Transportable databases have the following limitations:

- **Read replicas** – You can’t use transportable databases on read replicas or parent instances of read replicas.
- **Unsupported column types** – You can’t use the `reg` data types in any database tables that you plan to transport with this method. These types depend on system catalog object IDs (OIDs), which often change during transport.
• **Tablespaces** – All source database objects must be in the default `pg_default` tablespace.

• **Compatibility** – Both the source and destination DB instances must run the same major version of PostgreSQL.

• **Extensions** – The source DB instance can have only the `pg_transport` installed.

• **Roles and ACLs** – The source database's access privileges and ownership information aren't carried over to the destination database. All database objects are created and owned by the local destination user of the transport.

• **Concurrent transports** – A single DB instance can support up to 32 concurrent transports, including both imports and exports, if worker processes have been configured properly.

• **RDS for PostgreSQL DB instances only** – PostgreSQL transportable databases are supported on RDS for PostgreSQL DB instances only. You can't use it with on-premises databases or databases running on Amazon EC2.

### Setting up to transport a PostgreSQL database

Before you begin, make sure that your RDS for PostgreSQL DB instances meet the following requirements:

• The RDS for PostgreSQL DB instances for source and destination must run the same version of PostgreSQL.

• The destination DB can't have a database of the same name as the source DB that you want to transport.

• The account you use to run the transport needs `rds_superuser` privileges on both the source DB and the destination DB.

• The security group for the source DB instance must allow inbound access from the destination DB instance. This might already be the case if your source and destination DB instances are located in the VPC. For more information about security groups, see Controlling access with security groups (p. 1822).

Transporting databases from a source DB instance to a destination DB instance requires several changes to the DB parameter group associated with each instance. That means that you must create a custom DB parameter group for the source DB instance and create a custom DB parameter group for the destination DB instance.

**Note**

If your DB instances are already configured using custom DB parameter groups, you can start with step 2 in the following procedure.

### To configure the custom DB group parameters for transporting databases

For the following steps, use an account that has `rds_superuser` privileges.

1. If the source and destination DB instances use a default DB parameter group, you need to create a custom DB parameter using the appropriate version for your instances. You do this so you can change values for several parameters. For more information, see Working with parameter groups (p. 278).

2. In the custom DB parameter group, change values for the following parameters:

   • `shared_preload_libraries` – Add `pg_transport` to the list of libraries.

   • `pg_transport.num_workers` – The default value is 3. Increase or reduce this value as needed for your database. For a 200 GB database, we recommend no larger than 8. Keep in mind that if you increase the default value for this parameter, you should also increase the value of `max_worker_processes`.  

• **pg_transport.work_mem** – The default value is either 128 MB or 256 MB, depending on the PostgreSQL version. The default setting can typically be left unchanged.

• **max_worker_processes** – We recommend that you set this parameter to at least three times the pg_transport.num_workers parameter (3x pg_transport.num_workers) to handle the many background worker processes used by the transport process, plus other non-transport background processes. To learn more about max_worker_processes and other parameters, see Resource Consumption in the PostgreSQL documentation.

For more information about these parameters, see Transportable databases parameter reference (p. 1666).

3. Reboot the source RDS for PostgreSQL DB instance and the destination instance so that the settings for the parameters take effect.
4. Connect to your RDS for PostgreSQL source DB instance.

```
psql --host=source-instance.1112223333.ows-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

5. Remove extraneous extensions from the public schema of the DB instance. Only the pg_transport extension is allowed during the actual transport operation.
6. Install the pg_transport extension as follows:

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

7. Connect to your RDS for PostgreSQL destination DB instance. Remove any extraneous extensions, and then install the pg_transport extension.

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

### Transporting a PostgreSQL database to the destination from the source

After you complete the process described in Setting up to transport a PostgreSQL database (p. 1662), you can start the transport. To do so, run the transport.import_from_server function on the destination DB instance. In the syntax following you can find the function parameters.

```
SELECT transport.import_from_server(
    'source-db-instance-endpoint',
    'source-db-instance-port',
    'source-db-instance-user',
    'source-user-password',
    'source-database-name',
    'destination-user-password',
false);
```

The false value shown in the example tells the function that this is not a dry run. To test your transport setup, you can specify true for the dry_run option when you call the function, as shown following:

```
postgres=> SELECT transport.import_from_server(
    'docs-lab-source-db.666666666666.ows-region.rds.amazonaws.com', 5432,
    'postgres', '********', 'labdb', '******', true);
INFO:  Starting dry-run of import of database "labdb".
INFO:  Created connections to remote database        (took 0.03 seconds).
```

1663
INFO:  Checked remote cluster compatibility          (took 0.05 seconds).
INFO:  Dry-run complete                         (took 0.08 seconds total).
import_from_server
--------------------
(1 row)

The INFO lines are output because the `pg_transport.timing` parameter is set to its default value, `true`. Set the `dry_run` to `false` when you run the command and the source database is imported to the destination, as shown following:

INFO:  Starting import of database "labdb".
INFO:  Created connections to remote database        (took 0.02 seconds).
INFO:  Marked remote database as read only           (took 0.13 seconds).
INFO:  Checked remote cluster compatibility          (took 0.03 seconds).
INFO:  Signaled creation of PITR blackout window     (took 2.01 seconds).
INFO:  Applied remote database schema pre-data       (took 0.50 seconds).
INFO:  Created connections to local cluster          (took 0.01 seconds).
INFO:  Locked down destination database              (took 0.00 seconds).
INFO:  Completed transfer of database files          (took 0.24 seconds).
INFO:  Completed clean up                            (took 1.02 seconds).
INFO:  Physical transport complete              (took 3.97 seconds total).
import_from_server
--------------------
(1 row)

This function requires that you provide database user passwords. Thus, we recommend that you change the passwords of the user roles you used after transport is complete. Or, you can use SQL bind variables to create temporary user roles. Use these temporary roles for the transport and then discard the roles afterwards.

If your transport isn't successful, you might see an error message similar to the following:

```
pg_transport.num_workers=8 25% of files transported failed to download file data
```

The "failed to download file data" error message indicates that the number of worker processes isn't set correctly for the size of the database. You might need to increase or decrease the value set for `pg_transport.num_workers`. Each failure reports the percentage of completion, so you can see the impact of your changes. For example, changing the setting from 8 to 4 in one case resulted in the following:

```
pg_transport.num_workers=4 75% of files transported failed to download file data
```

Keep in mind that the `max_worker_processes` parameter is also taken into account during the transport process. In other words, you might need to modify both `pg_transport.num_workers` and `max_worker_processes` to successfully transport the database. The example shown finally worked when the `pg_transport.num_workers` was set to 2:

```
pg_transport.num_workers=2 100% of files transported
```

For more information about the `transport.import_from_server` function and its parameters, see Transportable databases function reference (p. 1665).

**What happens during database transport**

The PostgreSQL transportable databases feature uses a pull model to import the database from the source DB instance to the destination. The `transport.import_from_server` function creates the in-
transit database on the destination DB instance. The in-transit database is inaccessible on the destination DB instance for the duration of the transport.

When transport begins, all current sessions on the source database are ended. Any databases other than the source database on the source DB instance aren't affected by the transport.

The source database is put into a special read-only mode. While it's in this mode, you can connect to the source database and run read-only queries. However, write-enabled queries and some other types of commands are blocked. Only the specific source database that is being transported is affected by these restrictions.

During transport, you can't restore the destination DB instance to a point in time. This is because the transport isn't transactional and doesn't use the PostgreSQL write-ahead log to record changes. If the destination DB instance has automatic backups enabled, a backup is automatically taken after transport completes. Point-in-time restores are available for times after the backup finishes.

If the transport fails, the `pg_transport` extension attempts to undo all changes to the source and destination DB instances. This includes removing the destination's partially transported database. Depending on the type of failure, the source database might continue to reject write-enabled queries. If this happens, use the following command to allow write-enabled queries.

```
ALTER DATABASE db-name SET default_transaction_read_only = false;
```

### Transportable databases function reference

The `transport.import_from_server` function transports a PostgreSQL database by importing it from a source DB instance to a destination DB instance. It does this by using a physical database connection transport mechanism.

Before starting the transport, this function verifies that the source and the destination DB instances are the same version and are compatible for the migration. It also confirms that the destination DB instance has enough space for the source.

#### Syntax

```sql
transport.import_from_server(
    host text,
    port int,
    username text,
    password text,
    database text,
    local_password text,
    dry_run bool
)
```

#### Return Value

None.

#### Parameters

You can find descriptions of the `transport.import_from_server` function parameters in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>The endpoint of the source DB instance.</td>
</tr>
</tbody>
</table>
### Transporting PostgreSQL databases between DB instances

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>port</strong></td>
<td>An integer representing the port of the source DB instance. PostgreSQL DB instances often use port 5432.</td>
</tr>
<tr>
<td><strong>username</strong></td>
<td>The user of the source DB instance. This user must be a member of the <code>rds_superuser</code> role.</td>
</tr>
<tr>
<td><strong>password</strong></td>
<td>The user password of the source DB instance.</td>
</tr>
<tr>
<td><strong>database</strong></td>
<td>The name of the database in the source DB instance to transport.</td>
</tr>
<tr>
<td><strong>local_password</strong></td>
<td>The local password of the current user for the destination DB instance. This user must be a member of the <code>rds_superuser</code> role.</td>
</tr>
<tr>
<td><strong>dry_run</strong></td>
<td>An optional Boolean value specifying whether to perform a dry run. The default is <code>false</code>, which means the transport proceeds. To confirm compatibility between the source and destination DB instances without performing the actual transport, set <code>dry_run</code> to <code>true</code>.</td>
</tr>
</tbody>
</table>

### Example

For an example, see [Transporting a PostgreSQL database to the destination from the source (p. 1663)](Transporting%20a%20PostgreSQL%20database%20to%20the%20destination%20from%20the%20source%20(p.%201663)).

### Transportable databases parameter reference

Several parameters control the behavior of the `pg_transport` extension. Following, you can find descriptions of these parameters.

**pg_transport.num_workers**

The number of workers to use for the transport process. The default is 3. Valid values are 1–32. Even the largest database transports typically require fewer than 8 workers. The value of this setting on the destination DB instance is used by both destination and source during transport.

**pg_transport.timing**

Specifies whether to report timing information during the transport. The default is `true`, meaning that timing information is reported. We recommend that you leave this parameter set to `true` so you can monitor progress. For example output, see [Transporting a PostgreSQL database to the destination from the source (p. 1663)](Transporting%20a%20PostgreSQL%20database%20to%20the%20destination%20from%20the%20source%20(p.%201663)).

**pg_transport.work_mem**

The maximum amount of memory to allocate for each worker. The default is 131072 kilobytes (KB) or 262144 KB (256 MB), depending on the PostgreSQL version. The minimum value is 64 megabytes (65536 KB). Valid values are in kilobytes (KBs) as binary base-2 units, where 1 KB = 1024 bytes.

The transport might use less memory than is specified in this parameter. Even large database transports typically require less than 256 MB (262144 KB) of memory per worker.
Exporting data from an RDS for PostgreSQL DB instance to Amazon S3

You can query data from an RDS for PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. To do this, you use the `aws_s3` PostgreSQL extension that Amazon RDS provides.

For more information on storing data with Amazon S3, see Create a bucket in the Amazon Simple Storage Service User Guide.

The upload to Amazon S3 uses server-side encryption by default. If you are using encryption, the Amazon S3 bucket must be encrypted with an AWS managed key. Currently, you can’t export data to a bucket that is encrypted with a customer managed key.

**Note**

You can save DB snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB snapshot data to Amazon S3 (p. 461).

Topics

- Overview of exporting data to Amazon S3 (p. 1667)
- Verify that your RDS for PostgreSQL version supports exports (p. 1668)
- Specifying the Amazon S3 file path to export to (p. 1668)
- Setting up access to an Amazon S3 bucket (p. 1669)
- Exporting query data using the `aws_s3.query_export_to_s3` function (p. 1672)
- Troubleshooting access to Amazon S3 (p. 1674)
- Function reference (p. 1674)

Overview of exporting data to Amazon S3

To export data stored in an RDS for PostgreSQL database to an Amazon S3 bucket, use the following procedure.

**To export RDS for PostgreSQL data to S3**

1. Install the required PostgreSQL extensions. These include the `aws_s3` and `aws_commons` extensions. To do so, start psql and use the following commands.

   ```sql
   CREATE EXTENSION IF NOT EXISTS aws_s3 CASCADE;
   ```

   The `aws_s3` extension provides the `aws_s3.query_export_to_s3` (p. 1675) function that you use to export data to Amazon S3. The `aws_commons` extension is included to provide additional helper functions.

2. Identify an Amazon S3 file path to use for exporting data. For details about this process, see Specifying the Amazon S3 file path to export to (p. 1668).

3. Provide permission to access the Amazon S3 bucket.

   To export data to an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

   1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
   2. Create an IAM role.
   3. Attach the policy you created to the role you created.
4. Add this IAM role to your DB instance.

For details about this process, see Setting up access to an Amazon S3 bucket (p. 1669).

4. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

After you complete the preceding preparation tasks, use the `aws_s3.query_export_to_s3` function to export query results to Amazon S3. For details about this process, see Exporting query data using the `aws_s3.query_export_to_s3` function (p. 1672).

**Verify that your RDS for PostgreSQL version supports exports**

Currently, Amazon S3 exports are supported for the following versions of RDS for PostgreSQL:

- 14.1 and higher 14 versions
- 13.1 and higher 13 versions
- 12.4 and higher 12 versions
- 11.9 and higher 11 versions
- 10.14 and higher 10 versions

You can also verify support by using the `describe-db-engine-versions` command. The following example verify support for version 10.14.

```
aws rds describe-db-engine-versions --region us-east-1 --engine postgres --engine-version 10.14 | grep s3Export
```

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

**Specifying the Amazon S3 file path to export to**

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- **Bucket name** – A *bucket* is a container for Amazon S3 objects or files.
  
  For more information on storing data with Amazon S3, see [Create a bucket](#) and [View an object](#) in the Amazon Simple Storage Service User Guide.

- **File path** – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on.

For example, a file path with an exports folder and a query-1-export file prefix is `/exports/query-1-export`.

- **AWS Region (optional)** – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Amazon RDS saves your files into Amazon S3 in the same AWS Region as the exporting DB instance.
Note
Currently, the AWS Region must be the same as the region of the exporting DB instance.

For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 60).

To hold the Amazon S3 file information about where the export is to be stored, you can use the aws_commons.create_s3_uri (p. 1677) function to create an aws_commons._s3_uri_1 composite structure as follows.

```sql
psql=> SELECT aws_commons.create_s3_uri(
   'sample-bucket',
   'sample-filepath',
   'us-west-2'
) AS s3_uri_1 \\
gset
```

You later provide this s3_uri_1 value as a parameter in the call to the aws_s3.query_export_to_s3 (p. 1675) function. For examples, see Exporting query data using the aws_s3.query_export_to_s3 function (p. 1672).

Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB instance permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

To give a PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your PostgreSQL DB instance to access Amazon S3.

   As part of creating this policy, take the following steps:

   a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB instance to an Amazon S3 bucket:

   ```
   • s3:PutObject
   • s3:AbortMultipartUpload
   ```

   b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: arn:aws:s3:::

   ```
   your-s3-bucket/*
   ```

   For more information on creating an IAM policy for Amazon RDS for PostgreSQL, see Creating and using an IAM policy for IAM database access (p. 1789). See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.

   The following AWS CLI command creates an IAM policy named rds-s3-export-policy with these options. It grants access to a bucket named your-s3-bucket.

   Warning
   We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see Using endpoint policies for Amazon S3 in the Amazon VPC User Guide.

   We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives S3:PutObject access
Setting up access to an Amazon S3 bucket

After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy  --policy-name rds-s3-export-policy  --policy-document '{
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "s3export",
    "Action": [
      "S3:PutObject"
    ],
    "Effect": "Allow",
    "Resource": [
      "arn:aws:s3:::your-s3-bucket/*"
    ]
  }
]
}
'
```

2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

**Example**

For Linux, macOS, or Unix:

```
aws iam create-role  \
  --role-name rds-s3-export-role  \
  --assume-role-policy-document '{
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
  }
]'
```

Setting up access to an Amazon S3 bucket

```
"Condition": {
    "StringEquals": {
        "aws:SourceAccount": "111122223333",
    }
}
```

For Windows:

```
aws iam create-role  
--role-name rds-s3-export-role  
--assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333",
                }
            }
        }
    ]
}'
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

4. Add the IAM role to the DB instance. You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

**To add an IAM role for a PostgreSQL DB instance using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Export**.
5. Choose **Add role**.
AWS CLI

To add an IAM role for a PostgreSQL DB instance using the CLI

- Use the following command to add the role to the PostgreSQL DB instance named `my-db-instance`. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `s3Export` for the value of the `--feature-name` option.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds add-role-to-db-instance \
  --db-instance-identifier my-db-instance \
  --feature-name s3Export \ 
  --role-arn your-role-arn \ 
  --region your-region
```

For Windows:

```bash
aws rds add-role-to-db-instance ^ \
  --db-instance-identifier my-db-instance ^ \
  --feature-name s3Export ^ \
  --role-arn your-role-arn ^ \
  --region your-region
```

Exporting query data using the aws_s3.query_export_to_s3 function

Export your PostgreSQL data to Amazon S3 by calling the `aws_s3.query_export_to_s3` function.

**Topics**

- Prerequisites (p. 1672)
- Calling `aws_s3.query_export_to_s3` (p. 1673)
- Exporting to a CSV file that uses a custom delimiter (p. 1674)
- Exporting to a binary file with encoding (p. 1674)

**Prerequisites**

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in Overview of exporting data to Amazon S3 (p. 1667).
- Determine where to export your data to Amazon S3 as described in Specifying the Amazon S3 file path to export to (p. 1668).
- Make sure that the DB instance has export access to Amazon S3 as described in Setting up access to an Amazon S3 bucket (p. 1669).
The examples following use a database table called `sample_table`. These examples export the data into a bucket called `sample-bucket`. The example table and data are created with the following SQL statements in `psql`.

```
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid,name) VALUES (1, 'Monday'), (2,'Tuesday'), (3,'Wednesday');
```

### Calling `aws_s3.query_export_to_s3`

The following shows the basic ways of calling the `aws_s3.query_export_to_s3` function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the `aws_commons.create_s3_uri` function to create the structure.

```
psql=> SELECT aws_commons.create_s3_uri('sample-bucket', 'sample filepath', 'us-west-2') AS s3_uri_1 \gset

```

Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called `sample-bucket`.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1', options :='format text');
```

The parameters are described as follows:

- `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
- `'s3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

```
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',
   aws_commons.create_s3_uri('sample-bucket', 'sample filepath', 'us-west-2'))
```

- `options :='format text'` – The `options` parameter is an optional text string containing PostgreSQL `COPY` arguments. The copy process uses the arguments and format of the `PostgreSQL COPY` command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region://bucket-name[/path-prefix]/file-prefix
```
Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with _partXX appended. The XX represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```plaintext
s3-us-west-2://my-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```plaintext
s3-us-west-2://my-bucket/my-prefix
s3-us-west-2://my-bucket/my-prefix_part2
s3-us-west-2://my-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see `aws_s3.query_export_to_s3 (p. 1675)`. For more about accessing files in Amazon S3, see View an object in the Amazon Simple Storage Service User Guide.

### Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the `aws_s3.query_export_to_s3 (p. 1675)` function to export data to a file that uses a custom delimiter. The example uses arguments of the PostgreSQL COPY command to specify the comma-separated value (CSV) format and a colon (:) delimiter.

```sql
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
options :='format csv, delimiter $$:$$');
```

### Exporting to a binary file with encoding

The following example shows how to call the `aws_s3.query_export_to_s3 (p. 1675)` function to export data to a binary file that has Windows-1253 encoding.

```sql
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :'s3_uri_1',
options :='format binary, encoding WIN1253');
```

### Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, they must allow access to port 443 for SSL connections. For more information, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

See also the following for recommendations:

- Troubleshooting Amazon RDS identity and access (p. 1812)
- Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide
- Troubleshooting Amazon S3 and IAM in the IAM User Guide

### Function reference

**Functions**
- `aws_s3.query_export_to_s3 (p. 1675)`
- `aws_commons.create_s3_uri (p. 1677)`
**aws_s3.query_export_to_s3**

Exports a PostgreSQL query result to an Amazon S3 bucket. The aws_s3 extension provides the aws_s3.query_export_to_s3 function.

The two required parameters are query and s3_info. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called options provides for defining various export parameters. For examples of using the aws_s3.query_export_to_s3 function, see Exporting query data using the aws_s3.query_export_to_s3 function (p. 1672).

**Syntax**

```python
aws_s3.query_export_to_s3(
    query text,
    s3_info aws_commons._s3_uri_1,
    options text
)
```

**Input parameters**

**query**

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the s3_info parameter.

**s3_info**

An aws_commons._s3_uri_1 composite type containing the following information about the S3 object:

- **bucket** – The name of the Amazon S3 bucket to contain the file.
- **file_path** – The Amazon S3 file name and path.
- **region** – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 60).

Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

To create an aws_commons._s3_uri_1 composite structure, see the aws_commons.create_s3_uri (p. 1677) function.

**options**

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

**Alternate input parameters**

To help with testing, you can use an expanded set of parameters instead of the s3_info parameter. Following are additional syntax variations for the aws_s3.query_export_to_s3 function.

Instead of using the s3_info parameter to identify an Amazon S3 file, use the combination of the bucket, file_path, and region parameters.

```python
aws_s3.query_export_to_s3(
    query text,
    bucket text,
    file_path text,
)`
query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the s3_info parameter.

bucket

A required text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 60).

Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

options

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

Output parameters

```
aws_s3.query_export_to_s3(
    OUT rows_uploaded bigint,
    OUT files_uploaded bigint,
    OUT bytesUploaded bigint
)
```

rows_uploaded

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

files_uploaded

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has _partXX appended to the name. The XX represents 2, then 3, and so on as needed.

bytes_uploaded

The total number of bytes uploaded to Amazon S3.

Examples

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', 'sample-bucket', 'sample-filepath');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', 'sample-bucket', 'sample-filepath', 'us-west-2');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', 'sample-bucket', 'sample-filepath', 'us-west-2', 'format text');
```
**aws_commons.create_s3_uri**

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. You use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the `aws_s3.query_export_to_s3` function. For an example of using the `aws_commons.create_s3_uri` function, see Specifying the Amazon S3 file path to export to (p. 1668).

**Syntax**

```python
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

**Input parameters**

- **bucket**
  
  A required text string containing the Amazon S3 bucket name for the file.

- **file_path**

  A required text string containing the Amazon S3 file name including the path of the file.

- **region**

  A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions, Availability Zones, and Local Zones (p. 60).
Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many AWS services, including RDS for PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see What is AWS Lambda? in the AWS Lambda Developer Guide.

**Note**
Invoking an AWS Lambda function is supported in these RDS for PostgreSQL versions:

- 14.1 and higher minor versions
- 13.2 and higher minor versions
- 12.6 and higher minor versions

Setting up RDS for PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your RDS for PostgreSQL DB instance. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see Getting started with Lambda and AWS Lambda foundations in the AWS Lambda Developer Guide.

**Topics**
- **Step 1**: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda (p. 1678)
- **Step 2**: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda (p. 1679)
- **Step 3**: Install the aws_lambda extension for an RDS for PostgreSQL DB instance (p. 1680)
- **Step 4**: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) (p. 1681)
- **Step 5**: Invoke a Lambda function from your RDS for PostgreSQL DB instance (p. 1681)
- Lambda function error messages (p. 1684)
- AWS Lambda function reference (p. 1685)

**Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda**

Lambda functions always run inside an Amazon VPC owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your RDS for PostgreSQL DB instance needs to send network traffic to the Lambda service's VPC. How you configure this depends on whether your DB instance is public or private.

- If your RDS for PostgreSQL DB instance is public, you need only configure your security group to allow outbound traffic from your VPC. Your DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is true.

To find the value of this property, you can use the describe-db-instances AWS CLI command. Or, you can use the AWS Management Console to open the Connectivity & security tab and check that Publicly accessible is Yes. You can also use the AWS Management Console and the AWS CLI to check that the instance is in a public subnet in your VPC.
• If your RDS for PostgreSQL DB instance is private, you have a couple of choices. You can use a Network Address Translation) NAT gateway or you can use a VPC endpoint. For information about NAT gateways, see NAT gateways. The summary of steps for using a VPC endpoint follow.

**To configure connectivity to AWS Lambda for a public DB instance**

• Configure the VPC in which your RDS for PostgreSQL DB instance is running to allow outbound connections. You do so by creating an outbound rule on your VPC's security group that allows TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0).

**To configure connectivity to AWS Lambda for a private DB instance**

1. Configure your VPC with a VPC endpoint for AWS Lambda. For details, see VPC endpoints in the Amazon VPC User Guide. The endpoint returns responses to calls made by your RDS for PostgreSQL DB instance to your Lambda functions.
2. Add the endpoint to your VPC's route table. For more information, see Work with route tables in the Amazon VPC User Guide.
3. The VPC endpoint uses its own private DNS resolution. RDS for PostgreSQL can't use the Lambda VPC endpoint until you change the value of the rds.custom_dns_resolution from its default value of 0 (not enabled) to 1.
   a. Create a custom DB parameter group.
   b. Change the value of the rds.custom_dns_resolution parameter from its default of 0 to 1.
   c. Modify your DB instance to use your custom DB parameter group.
   d. Reboot the instance to have the modified parameter take effect.

Your VPC can now interact with the AWS Lambda VPC at the network level. However, you still need to configure the permissions using IAM.

**Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda**

Invoking Lambda functions from your RDS for PostgreSQL DB instance requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB instance. This approach gives the DB instance privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

**To configure IAM permissions for using your Amazon RDS instance with Lambda**

1. Use the create-policy AWS CLI command to create an IAM policy that allows your RDS for PostgreSQL DB instance to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your DB instance the minimum permissions needed to invoke the specified Lambda function.

```bash
aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToExampleFunction",
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
    }
  ]
}'
```
Alternatively, you can use the predefined AWSLambdaRole policy that allows you to invoke any of your Lambda functions. For more information, see Identity-based IAM policies for Lambda

2. Use the create-role AWS CLI command to create an IAM role that the policy can assume at runtime.

```bash
aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}"
```

3. Apply the policy to the role by using the attach-role-policy AWS CLI command.

```bash
aws iam attach-role-policy
--policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy
--role-name rds-lambda-role --region aws-region
```

4. Apply the role to your RDS for PostgreSQL DB instance by using the add-role-to-db-instance AWS CLI command. This last step allows your DB instance's database users to invoke Lambda functions.

```bash
aws rds add-role-to-db-instance
--db-cluster-identifier my-cluster-name
--feature-name Lambda
--role-arn arn:aws:iam::444455556666:role/rds-lambda-role
--region aws-region
```

With the VPC and the IAM configurations complete, you can now install the aws_lambda extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the aws_lambda extension adds nothing to your RDS for PostgreSQL DB instance's capabilities.)

### Step 3: Install the aws_lambda extension for an RDS for PostgreSQL DB instance

To use AWS Lambda with your RDS for PostgreSQL DB instance, the aws_lambda PostgreSQL extension to your RDS for PostgreSQL. This extension provides your RDS for PostgreSQL DB instance with the ability to call Lambda functions from PostgreSQL.

#### To install the aws_lambda extension in your RDS for PostgreSQL DB instance

Use the PostgreSQL psql command-line or the pgAdmin tool to connect to your RDS for PostgreSQL DB instance.

1. Connect to your RDS for PostgreSQL DB instance as a user with rds_superuser privileges. The default postgres user is shown in the example.

```bash
psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```
2. Install the `aws_lambda` extension. The `aws_commons` extension is also required. It provides helper functions to `aws_lambda` and many other Aurora extensions for PostgreSQL. If it's not already on your RDS for PostgreSQLDB instance, it's installed with `aws_lambda` as shown following.

```sql
CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;
NOTICE: installing required extension "aws_commons"
CREATE EXTENSION
```

The `aws_lambda` extension is installed in your DB instance. You can now create convenience structures for invoking your Lambda functions.

## Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional)

You can use the helper functions in the `aws_commons` extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in Step 2: Configure IAM for your instance and Lambda (p. 1679) requires the ARN, so we recommend that you use your function's ARN.
- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it's not in the same Region as your RDS for PostgreSQL DB instance.

To hold the Lambda function name information, you use the `aws_commons.create_lambda_function_arn` (p. 1687) function. This helper function creates an `aws_commons._lambda_function_arn_1` composite structure with the details needed by the invoke function. Following, you can find three alternative approaches to setting up this composite structure.

```sql
SELECT aws_commons.create_lambda_function_arn('my-function', 'aws-region') AS aws_lambda_arn_1 \gset
SELECT aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-region:111122223333:function:my-function' ) AS lambda_arn_1 \gset
```

Any of these values can be used in calls to the `aws_lambda.invoke` (p. 1685) function. For examples, see Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance (p. 1681).

## Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance

The `aws_lambda.invoke` function behaves synchronously or asynchronously, depending on the `invocation_type`. The two alternatives for this parameter are `RequestResponse` (the default) and `Event`, as follows.

---

1681
• **RequestResponse** – This invocation type is *synchronous*. It’s the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the `aws_lambda.invoke` function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.

• **Event** – This invocation type is *asynchronous*. The response doesn’t include a payload containing results. Use this invocation type when your workflow doesn’t need a result from the Lambda function to continue processing.

As a simple test of your setup, you can connect to your DB instance using `psql` and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.

To invoke an example function

1. Connect to your DB instance using `psql` or pgAdmin.

   ```shell
   psql -h instance.4444555666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Invoke the function using its ARN.

   ```sql
   SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-region:4444555666:function:simple', 'us-west-1'), '{"body": "Hello from Postgres!"}');
   ```

   The response looks as follows.

   ```plaintext
   status_code | payload | executed_version
   -----------|---------|------------------
               | log_result
   +-----------------+------------+------------------+
   | 200 | {"statusCode": 200, "body": "Hello from Lambda!"} | $LATEST
   | (1 row)
   ```

   If your invocation attempt doesn’t succeed, see Lambda function error messages (p. 1684).

   Following, you can find several examples of calling the `aws_lambda.invoke` (p. 1685) function. Most all the examples use the composite structure `aws_lambda_arn_1` that you create in Step 4: Use Lambda.
helper functions with your RDS for PostgreSQL DB instance (Optional) (p. 1681) to simplify passing the function details. For an example of asynchronous invocation, see Example: Asynchronous (Event) invocation of Lambda functions (p. 1683). All the other examples listed use synchronous invocation.

To learn more about Lambda invocation types, see Invoking Lambda functions in the AWS Lambda Developer Guide. For more information about aws_lambda_arn_1, see aws_commons.create_lambda_function_arn (p. 1687).

Examples list
- Example: Synchronous (RequestResponse) invocation of Lambda functions (p. 1683)
- Example: Asynchronous (Event) invocation of Lambda functions (p. 1683)
- Example: Capturing the Lambda execution log in a function response (p. 1684)
- Example: Including client context in a Lambda function (p. 1684)
- Example: Invoking a specific version of a Lambda function (p. 1684)

Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these aws_lambda.invoke function calls are the same.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}::json);
```

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}::json, 'RequestResponse');
```

The parameters are described as follows:

- 'aws_lambda_arn_1' – This parameter identifies the composite structure created in Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional) (p. 1681), with the aws_commons.create_lambda_function_arn helper function. You can also create this structure inline within your aws_lambda.invoke call as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'aws-region'), '{"body": "Hello from Postgres!"}::json);
```

- '{"body": "Hello from PostgreSQL!"}::json' – The JSON payload to pass to the Lambda function.
- 'RequestResponse' – The Lambda invocation type.

Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The Event invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the Event invocation type in certain workflows that don't depend on the results of the Lambda function.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}::json, 'Event');
```
Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the log_type parameter in your aws_lambda.invoke function call. By default, this parameter is set to None, but you can specify Tail to capture the results of the Lambda execution log in the response, as shown following.

```
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'Tail');
```

Set the aws_lambda.invoke function's log_type parameter to Tail to include the execution log in the response. The default value for the log_type parameter is None.

The log_result that's returned is a base64 encoded string. You can decode the contents using a combination of the decode and convert_from PostgreSQL functions.

For more information about log_type, see aws_lambda.invoke (p. 1685).

Example: Including client context in a Lambda function

The aws_lambda.invoke function has a context parameter that you can use to pass information separate from the payload, as shown following.

```
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the aws_lambda.invoke function's context parameter.

For more information about the context parameter, see the aws_lambda.invoke (p. 1685) reference.

Example: Invoking a specific version of a Lambda function

You can specify a particular version of a Lambda function by including the qualifier parameter with the aws_lambda.invoke call. Following, you can find an example that does this using 'custom_version' as an alias for the version.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse', 'None', NULL, 'custom_version');
```

You can also supply a Lambda function qualifier with the function name details instead, as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function:custom_version', 'us-west-2'), '{"body": "Hello from Postgres!"}':json);
```

For more information about qualifier and other parameters, see the aws_lambda.invoke (p. 1685) reference.

Lambda function error messages

Incorrect VPC configuration can result in error messages, such as the following.

```
ERROR:  invoke API failed
```

1684
DETAIL: AWS Lambda client returned 'Unable to connect to endpoint'.
CONTEXT: SQL function "invoke" statement 1

The first thing to check is your VPC security group. Make sure you have an outbound rule for TCP open on port 443 so that your VPC can connect to the Lambda VPC.

If your DB instance is private, check the private DNS setup for your VPC. Make sure that you set the rds.custom_dns_resolution parameter to 1 and setup AWS PrivateLink as outlined in Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda (p. 1678). For more information, see Interface VPC endpoints (AWS PrivateLink).

If a Lambda function throws an exception during request processing, aws_lambda.invoke fails with a PostgreSQL error such as the following.

```
SELECT * FROM aws_lambda.invoke(':aws_lambda_arn_1', '{"body": "Hello from Postgres!"}');
```
ERROR: lambda invocation failed

Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

AWS Lambda function reference

Following is the reference for the functions to use for invoking Lambda functions with RDS for PostgreSQL.

Functions

- aws_lambda.invoke (p. 1685)
- aws_commons.create_lambda_function_arn (p. 1687)

**aws_lambda.invoke**

Runs a Lambda function for an RDS for PostgreSQL DB instance.

For more details about invoking Lambda functions, see also Invoke in the AWS Lambda Developer Guide.

**Syntax**

JSON

```
aws_lambda.invoke(
    IN function_name TEXT,
    IN payload JSON,
    IN region TEXT DEFAULT NULL,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSON DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSON,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```

```
aws_lambda.invoke(
    IN function_name aws_commons._lambda_function_arn_1,
    IN payload JSON,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
```
IN log_type TEXT DEFAULT 'None',
IN context JSON DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSON,
OUT executed_version TEXT,
OUT log_result TEXT)

JSONB

aws_lambda.invoke(
  IN function_name TEXT,
  IN payload JSONB,
  IN region TEXT DEFAULT NULL,
  IN invocation_type TEXT DEFAULT 'RequestResponse',
  IN log_type TEXT DEFAULT 'None',
  IN context JSONB DEFAULT NULL,
  IN qualifier VARCHAR(128) DEFAULT NULL,
  OUT status_code INT,
  OUT payload JSONB,
  OUT executed_version TEXT,
  OUT log_result TEXT)

aws_lambda.invoke(
  IN function_name aws_commons._lambda_function_arn_1,
  IN payload JSONB,
  IN invocation_type TEXT DEFAULT 'RequestResponse',
  IN log_type TEXT DEFAULT 'None',
  IN context JSONB DEFAULT NULL,
  IN qualifier VARCHAR(128) DEFAULT NULL,
  OUT status_code INT,
  OUT payload JSONB,
  OUT executed_version TEXT,
  OUT log_result TEXT)

**Input parameters**

**function_name**

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see [Lambda function name formats](https://docs.aws.amazon.com/lambda/latest/dg/lambda-name-arn-structure.html) in the AWS Lambda Developer Guide.

**payload**

The input for the Lambda function. The format can be JSON or JSONB. For more information, see [JSON Types](https://www.postgresql.org/docs/current/datatype-json.html) in the PostgreSQL documentation.

**region**

(Optional) The Lambda Region for the function. By default, RDS resolves the AWS Region from the full ARN in the function_name or it uses the RDS for PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the function_name ARN, an error is raised.

**invocation_type**

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- **RequestResponse** – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the RequestResponse invocation type when your workflow depends on receiving the Lambda function result immediately.
• Event – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the Event invocation type when you don’t need results of the Lambda function before your workflow moves on.

• DryRun – This type of invocation tests access without running the Lambda function.

`log_type`

The type of Lambda log to return in the `log_result` output parameter. The value is case-sensitive. Possible values include the following:

• Tail – The returned `log_result` output parameter will include the last 4 KB of the execution log.

• None – No Lambda log information is returned.

`context`

Client context in JSON or JSONB format. Fields to use include `custom` and `env`.

`qualifier`

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the `function_name` ARN, an error is raised.

**Output parameters**

`status_code`

An HTTP status response code. For more information, see Lambda Invoke response elements in the AWS Lambda Developer Guide.

`payload`

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

`executed_version`

The version of the Lambda function that ran.

`log_result`

The execution log information returned if the `log_type` value is Tail when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

**aws_commons.create_lambda_function_arn**

Creates an `aws_commons._lambda_function_arn_1` structure to hold Lambda function name information. You can use the results of the `aws_commons.create_lambda_function_arn` function in the `function_name` parameter of the `aws_lambda.invoke` function.

**Syntax**

```python
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
) RETURNS aws_commons._lambda_function_arn_1
```

**Input parameters**

`function_name`

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.
Working with PostgreSQL features supported by Amazon RDS for PostgreSQL

Amazon RDS for PostgreSQL supports many of the most common PostgreSQL features and much common functionality. For example, PostgreSQL has an autovacuum feature that performs routine maintenance on the database. This feature is active by default. Although you can turn off this feature, we highly recommend that you keep it on. Understanding this feature and what you can do to make sure it works as it should is a basic task of any DBA. For more information about the autovacuum, see Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 1694). To learn more about other common DBA tasks, Common DBA tasks for Amazon RDS for PostgreSQL (p. 1694).

RDS for PostgreSQL also supports extensions that add important functionality to the DB instance. For example, you can use the PostGIS extension to work with spatial data, or use the pg_cron extension to schedule maintenance from within the instance. For more information about PostgreSQL extensions, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL (p. 1715).

Foreign data wrappers are a specific type of extension designed to let your RDS for PostgreSQL DB instance work with other commercial databases or data types. For more information about foreign data wrappers supported by RDS for PostgreSQL, see Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL (p. 1737).

Following, you can find information about some PostgreSQL features supported by RDS for PostgreSQL.

Topics
- Custom data types and enumerations with RDS for PostgreSQL (p. 1688)
- Event triggers for RDS for PostgreSQL (p. 1689)
- Huge pages for RDS for PostgreSQL (p. 1689)
- Performing logical replication for Amazon RDS for PostgreSQL (p. 1690)
- RAM disk for the stats_temp_directory (p. 1692)
- Tablespaces for RDS for PostgreSQL (p. 1692)

Custom data types and enumerations with RDS for PostgreSQL

PostgreSQL supports creating custom data types and working with enumerations. For more information about creating and working with enumerations and other data types, see Enumerated types in the PostgreSQL documentation.

The following is an example of creating a type as an enumeration and then inserting values into a table.

```sql
CREATE TYPE rainbow AS ENUM ('red', 'orange', 'yellow', 'green', 'blue', 'purple');
CREATE TABLE t1 (colors rainbow);
INSERT INTO t1 VALUES ('red'), ('orange');
```

1688
Event triggers for RDS for PostgreSQL

All current PostgreSQL versions support event triggers, and so do all available versions of RDS for PostgreSQL. You can use the main user account (default, postgres) to create, modify, rename, and delete event triggers. Event triggers are at the DB instance level, so they can apply to all databases on an instance.

For example, the following code creates an event trigger that prints the current user at the end of every data definition language (DDL) command.

```
CREATE OR REPLACE FUNCTION raise_notice_func()
RETURNS event_trigger
LANGUAGE plpgsql AS
$$
BEGIN
  RAISE NOTICE 'In trigger function: %', current_user;
END;
$$;
CREATE EVENT TRIGGER event_trigger_1
ON ddl_command_end
EXECUTE PROCEDURE raise_notice_func();
```

For more information about PostgreSQL event triggers, see Event triggers in the PostgreSQL documentation.

There are several limitations to using PostgreSQL event triggers on Amazon RDS. These include the following:

- You can't create event triggers on read replicas. You can, however, create event triggers on a read replica source. The event triggers are then copied to the read replica. The event triggers on the read replica don't fire on the read replica when changes are pushed from the source. However, if the read replica is promoted, the existing event triggers fire when database operations occur.
- To perform a major version upgrade to a PostgreSQL DB instance that uses event triggers, make sure to delete the event triggers before you upgrade the instance.

Huge pages for RDS for PostgreSQL

Huge pages are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available RDS for PostgreSQL versions. You allocate huge pages for your application by using calls to \texttt{mmap} or \texttt{SYSV} shared memory. RDS for PostgreSQL supports both 4-KB and 2-MB page sizes.
You can turn huge pages on or off by changing the value of the `huge_pages` parameter. The feature is turned on by default for all DB instance classes other than micro, small, and medium DB instance classes.

**Note**
Huge pages aren't supported for db.m1, db.m2, and db.m3 DB instance classes.

RDS for PostgreSQL uses huge pages based on the available shared memory. If the DB instance can't use huge pages due to shared memory constraints, Amazon RDS prevents the DB instance from starting. In this case, Amazon RDS sets the status of the DB instance to an incompatible parameters state. If this occurs, you can set the `huge_pages` parameter to `off` to allow Amazon RDS to start the DB instance.

The `shared_buffers` parameter is key to setting the shared memory pool that is required for using huge pages. The default value for the `shared_buffers` parameter uses a database parameters macro. This macro sets a percentage of the total 8 KB pages available for the DB instance's memory. When you use huge pages, those pages are located with the huge pages. Amazon RDS puts a DB instance into an incompatible parameters state if the shared memory parameters are set to require more than 90 percent of the DB instance memory.

To learn more about PostgreSQL memory management, see Resource Consumption in the PostgreSQL documentation.

### Performing logical replication for Amazon RDS for PostgreSQL

Starting with version 10.4, Amazon RDS for PostgreSQL supports the publication and subscription SQL syntax that was first introduced in PostgreSQL 10. To learn more, see Logical replication in the PostgreSQL documentation.

Following, you can find information about setting up logical replication for an RDS for PostgreSQL DB instance.

**Topics**
- Understanding logical replication and logical decoding (p. 1690)
- Working with logical replication slots (p. 1691)

### Understanding logical replication and logical decoding

RDS for PostgreSQL supports the streaming of write-ahead log (WAL) changes using PostgreSQL's logical replication slots. It also supports using logical decoding. You can set up logical replication slots on your instance and stream database changes through these slots to a client such as `pg_receivolog`. You create logical replication slots at the database level, and they support replication connections to a single database.

The most common clients for PostgreSQL logical replication are AWS Database Migration Service or a custom-managed host on an Amazon EC2 instance. The logical replication slot has no information about the receiver of the stream. Also, there's no requirement that the target be a replica database. If you set up a logical replication slot and don't read from the slot, data can be written and quickly fill up your DB instance's storage.

You turn on PostgreSQL logical replication and logical decoding for Amazon RDS with a parameter, a replication connection type, and a security role. The client for logical decoding can be any client that can establish a replication connection to a database on a PostgreSQL DB instance.

### To turn on logical decoding for an RDS for PostgreSQL DB instance

1. Make sure that the user account that you're using has these roles:
• The `rds_superuser` role so you can turn on logical replication
• The `rds_replication` role to grant permissions to manage logical slots and to stream data using logical slots

2. Set the `rds.logical_replication` static parameter to 1. As part of applying this parameter, also set the parameters `wal_level`, `max_wal_senders`, `max_replication_slots`, and `max_connections`. These parameter changes can increase WAL generation, so set the `rds.logical_replication` parameter only when you are using logical slots.

3. Reboot the DB instance for the static `rds.logical_replication` parameter to take effect.

4. Create a logical replication slot as explained in the next section. This process requires that you specify a decoding plugin. Currently, RDS for PostgreSQL supports the `test_decoding` and `wal2json` output plugins that ship with PostgreSQL.

For more information on PostgreSQL logical decoding, see the PostgreSQL documentation.

**Working with logical replication slots**

You can use SQL commands to work with logical slots. For example, the following command creates a logical slot named `test_slot` using the default PostgreSQL output plugin `test_decoding`.

```sql
SELECT * FROM pg_create_logical_replication_slot('test_slot', 'test_decoding');
```

```
slot_name    | xlog_position
-----------------+---------------
regression_slot | 0/16B1970
(1 row)
```

To list logical slots, use the following command.

```sql
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the following command.

```sql
SELECT pg_drop_replication_slot('test_slot');
```

```
pg_drop_replication_slot
-----------------------
(1 row)
```

For more examples on working with logical replication slots, see Logical decoding examples in the PostgreSQL documentation.

After you create the logical replication slot, you can start streaming. The following example shows how logical decoding is controlled over the streaming replication protocol. This example uses the program `pg_recvlogical`, which is included in the PostgreSQL distribution. Doing this requires that client authentication is set up to allow replication connections.

```bash
pg_recvlogical -d postgres --slot test_slot -U postgres
--host -instance-name.111122223333.aws-region.rds.amazonaws.com
-f - --start
```

To see the contents of the `pg_replication_origin_status` view, query the `pg_show_replication_origin_status` function.

```sql
SELECT * FROM pg_show_replication_origin_status();
```

```
local_id | external_id | remote_lsn | local_lsn
---------|-------------|------------|------------
1691
```
RAM disk for the stats_temp_directory

You can use the RDS for PostgreSQL parameter `rds.pg_stat_ramdisk_size` to specify the system memory allocated to a RAM disk for storing the PostgreSQL `stats_temp_directory`. The RAM disk parameter is available for all PostgreSQL versions on Amazon RDS.

Under certain workloads, setting this parameter can improve performance and decrease I/O requirements. For more information about the `stats_temp_directory`, see the PostgreSQL documentation.

To set up a RAM disk for your `stats_temp_directory`, set the `rds.pg_stat_ramdisk_size` parameter to a nonzero value in the parameter group used by your DB instance. The parameter value is in MB. You must reboot the DB instance before the change takes effect. For information about setting parameters, see Working with parameter groups (p. 278).

For example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```
aws rds modify-db-parameter-group
  --db-parameter-group-name pg-95-ramdisk-testing
  --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256,
  ApplyMethod=pending-reboot"
```

After you reboot, run the following command to see the status of the `stats_temp_directory`.

```
postgres=> SHOW stats_temp_directory;
```

The command should return the following.

```
stats_temp_directory
---------------------------
/rdsdbramdisk/pg_stat_tmp
(1 row)
```

Tablespaces for RDS for PostgreSQL

RDS for PostgreSQL supports tablespaces for compatibility. Because all storage is on a single logical volume, you can’t use tablespaces for I/O splitting or isolation. Our benchmarks and experience indicate that a single logical volume is the best setup for most use cases.

To create and use tablespaces with your RDS for PostgreSQL DB instance requires the `rds_superuser` role. Your RDS for PostgreSQL DB instance’s main user account (default name, `postgres`) is a member of this role. For more information, see Understanding the rds_superuser role (p. 1713).

If you specify a file name when you create a tablespace, the path prefix is `/rdsdbdata/db/base/tablespace`. The following example places tablespace files in `/rdsdbdata/db/base/tablespace/data`. This example assumes that a `dbadmin` user (role) exists and that it’s been granted the `rds_superuser` role needed to work with tablespaces.

```
postgres=> CREATE TABLESPACE act_data
  OWNER dbadmin
  LOCATION '/data';
CREATE TABLESPACE
```
To learn more about PostgreSQL tablespaces, see Tables in the PostgreSQL documentation.
Common DBA tasks for Amazon RDS for PostgreSQL

Database administrators (DBAs) perform a variety of tasks when administering an Amazon RDS for PostgreSQL DB instance. It helps to understand some of the basic capabilities of PostgreSQL and how to use them in an RDS for PostgreSQL DB instance. For example, if you're a DBA already familiar with PostgreSQL, be aware that Amazon RDS doesn't allow shell access to DB instances. That means that you can't access log files in the same way that you do when you run PostgreSQL on your server hardware. To learn more about working with RDS for PostgreSQL log files, see PostgreSQL database log files (p. 680).

Amazon RDS limits access to certain system procedures and tables that require advanced privileges to the `rds_superuser` role. This is the most privileged identity on an RDS for PostgreSQL DB instance. For more information, see Understanding the rds_superuser role (p. 1713).

Following are some common DBA tasks for RDS for PostgreSQL.

Topics
- Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 1694)
- Controlling user access to the PostgreSQL database (p. 1702)
- Working with logging mechanisms supported by RDS for PostgreSQL (p. 1703)
- Using pgBadger for log analysis with PostgreSQL (p. 1703)
- Limiting control of user passwords to a specific role (p. 1703)
- Working with parameters on your RDS for PostgreSQL DB instance (p. 1704)
- Understanding the rds_superuser role (p. 1713)

Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL

We strongly recommend that you use the autovacuum feature to maintain the health of your PostgreSQL DB instance. Autovacuum automates the start of the VACUUM and the ANALYZE commands. It checks for tables with a large number of inserted, updated, or deleted tuples. After this check, it reclaims storage by removing obsolete data or tuples from the PostgreSQL database.

By default, autovacuum is turned on for the Amazon RDS for PostgreSQL DB instances that you create using any of the default PostgreSQL DB parameter groups. These include `default.postgres10`, `default.postgres11`, and so on. All default PostgreSQL DB parameter groups have an `rds.adaptive_autovacuum` parameter that's set to 1, thus activating the feature. Other configuration parameters associated with the autovacuum feature are also set by default. Because these defaults are somewhat generic, you can benefit from tuning some of the parameters associated with the autovacuum feature for your specific workload.

Following, you can find more information about the autovacuum and how to tune some of its parameters on your RDS for PostgreSQL DB instance. For high-level information, see Best practices for working with PostgreSQL (p. 169).

Topics
- Allocating memory for autovacuum (p. 1695)
- Reducing the likelihood of transaction ID wraparound (p. 1695)
- Determining if the tables in your database need vacuuming (p. 1696)
- Determining which tables are currently eligible for autovacuum (p. 1697)
- Determining if autovacuum is currently running and for how long (p. 1698)
Allocating memory for autovacuum

One of the most important parameters influencing autovacuum performance is the `maintenance_work_mem` parameter. This parameter determines how much memory that you allocate for autovacuum to use to scan a database table and to hold all the row IDs that are going to be vacuumed. If you set the value of the `maintenance_work_mem` parameter too low, the vacuum process might have to scan the table multiple times to complete its work. Such multiple scans can have a negative impact on performance.

When doing calculations to determine the `maintenance_work_mem` parameter value, keep in mind two things:

- The default unit is kilobytes (KB) for this parameter.
- The `maintenance_work_mem` parameter works in conjunction with the `autovacuum_max_workers` parameter. If you have many small tables, allocate more `autovacuum_max_workers` and less `maintenance_work_mem`. If you have large tables (say, larger than 100 GB), allocate more memory and fewer worker processes. You need to have enough memory allocated to succeed on your biggest table. Each `autovacuum_max_workers` can use the memory that you allocate. Thus, make sure that the combination of worker processes and memory equal the total memory that you want to allocate.

In general terms, for large hosts set the `maintenance_work_mem` parameter to a value between one and two gigabytes (between 1,048,576 and 2,097,152 KB). For extremely large hosts, set the parameter to a value between two and four gigabytes (between 2,097,152 and 4,194,304 KB). The value that you set for this parameter depends on the workload. Amazon RDS has updated its default for this parameter to be kilobytes calculated as follows.

\[
\text{GREATEST}([\text{DBInstanceClassMemory}/63963136*1024], 65536).
\]

Reducing the likelihood of transaction ID wraparound

In some cases, parameter group settings related to autovacuum might not be aggressive enough to prevent transaction ID wraparound. To address this, RDS for PostgreSQL provides a mechanism that adapts the autovacuum parameter values automatically. Adaptive autovacuum parameter tuning is a feature for RDS for PostgreSQL. A detailed explanation of TransactionID wraparound is found in the PostgreSQL documentation.

Adaptive autovacuum parameter tuning is turned on by default for RDS for PostgreSQL instances with the dynamic parameter `rds.adaptive_autovacuum` set to ON. We strongly recommend that you keep this turned on. However, to turn off adaptive autovacuum parameter tuning, set the `rds.adaptive_autovacuum` parameter to 0 or OFF.

Transaction ID wraparound is still possible even when Amazon RDS tunes the autovacuum parameters. We encourage you to implement an Amazon CloudWatch alarm for transaction ID wraparound. For more information, see the post Implement an early warning system for transaction ID wraparound in RDS for PostgreSQL on the AWS Database Blog.

With adaptive autovacuum parameter tuning turned on, Amazon RDS begins adjusting autovacuum parameters when the CloudWatch metric `MaximumUsedTransactionIDs` reaches the value of the `autovacuum_freeze_max_age` parameter or 500,000,000, whichever is greater.
Amazon RDS continues to adjust parameters for autovacuum if a table continues to trend toward transaction ID wraparound. Each of these adjustments dedicate more resources to autovacuum to avoid wraparound. Amazon RDS updates the following autovacuum-related parameters:

- `autovacuum_vacuum_cost_delay`
- `autovacuum_vacuum_cost_limit`
- `autovacuum_work_mem`
- `autovacuum_naptime`

RDS modifies these parameters only if the new value makes autovacuum more aggressive. The parameters are modified in memory on the DB instance. The values in the parameter group aren't changed. To view the current in-memory settings, use the PostgreSQL `SHOW` SQL command.

When Amazon RDS modifies any of these autovacuum parameters, it generates an event for the affected DB instance. This event is visible on the AWS Management Console and through the Amazon RDS API. After the `MaximumUsedTransactionIDs` CloudWatch metric returns below the threshold, Amazon RDS resets the autovacuum-related parameters in memory back to the values specified in the parameter group. It then generates another event corresponding to this change.

**Determining if the tables in your database need vacuuming**

You can use the following query to show the number of unvacuumed transactions in a database. The `datfrozenxid` column of a database's `pg_database` row is a lower bound on the normal transaction IDs appearing in that database. This column is the minimum of the per-table `relfrozenxid` values within the database.

```
SELECT datname, age(datfrozenxid) FROM pg_database ORDER BY age(datfrozenxid) desc limit 20;
```

For example, the results of running the preceding query might be the following.

<table>
<thead>
<tr>
<th>datname</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydb</td>
<td>1771757888</td>
</tr>
<tr>
<td>template0</td>
<td>1721757888</td>
</tr>
<tr>
<td>template1</td>
<td>1721757888</td>
</tr>
<tr>
<td>rdsadmin</td>
<td>1694008527</td>
</tr>
<tr>
<td>postgres</td>
<td>1693881061</td>
</tr>
</tbody>
</table>

(5 rows)

When the age of a database reaches 2 billion transaction IDs, transaction ID (XID) wraparound occurs and the database becomes read-only. You can use this query to produce a metric and run a few times a day. By default, autovacuum is set to keep the age of transactions to no more than 200,000,000 (\texttt{autovacuum_freeze_max_age}).

A sample monitoring strategy might look like this:

- Set the `autovacuum_freeze_max_age` value to 200 million transactions.
- If a table reaches 500 million unvacuumed transactions, that triggers a low-severity alarm. This isn't an unreasonable value, but it can indicate that autovacuum isn't keeping up.
- If a table ages to 1 billion, this should be treated as an alarm to take action on. In general, you want to keep ages closer to `autovacuum_freeze_max_age` for performance reasons. We recommend that you investigate using the recommendations that follow.
- If a table reaches 1.5 billion unvacuumed transactions, that triggers a high-severity alarm. Depending on how quickly your database uses transaction IDs, this alarm can indicate that the system is running out of time to run autovacuum. In this case, we recommend that you resolve this immediately.
If a table is constantly breaching these thresholds, modify your autovacuum parameters further. By default, using VACUUM manually (which has cost-based delays disabled) is more aggressive than using the default autovacuum, but it is also more intrusive to the system as a whole.

We recommend the following:

- Be aware and turn on a monitoring mechanism so that you are aware of the age of your oldest transactions.

  For information on creating a process that warns you about transaction ID wraparound, see the AWS Database Blog post Implement an early warning system for transaction ID wraparound in Amazon RDS for PostgreSQL.

- For busier tables, perform a manual vacuum freeze regularly during a maintenance window, in addition to relying on autovacuum. For information on performing a manual vacuum freeze, see Performing a manual vacuum freeze (p. 1699).

### Determining which tables are currently eligible for autovacuum

Often, it is one or two tables in need of vacuuming. Tables whose `relfrozenxid` value is greater than the number of transactions in `autovacuum_freeze_max_age` are always targeted by autovacuum. Otherwise, if the number of tuples made obsolete since the last VACUUM exceeds the vacuum threshold, the table is vacuumed.

The **autovacuum threshold** is defined as:

\[
\text{Vacuum-threshold} = \text{vacuum-base-threshold} + \text{vacuum-scale-factor} \times \text{number-of-tuples}
\]

While you are connected to your database, run the following query to see a list of tables that autovacuum sees as eligible for vacuuming.

```sql
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold FROM pg_settings WHERE name = 'autovacuum_vacuum_threshold'),
    vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor FROM pg_settings WHERE name = 'autovacuum_vacuum_scale_factor'),
    fma AS (SELECT setting AS autovacuum_freeze_max_age FROM pg_settings WHERE name = 'autovacuum_freeze_max_age'),
    sto AS (select opt_oid, split_part(setting, '=', 1) as param, split_part(setting, ' = ', 2) as value from (select oid opt_oid, unnest(reloptions) setting from pg_class) opt)
    SELECT '"'||ns.nspname||'"."'||c.relname||'"' as relation,
            pg_size_pretty(pg_table_size(c.oid)) as table_size,
            age(relfrozenxid) as xid_age,
            coalesce(cfma.value::float, autovacuum_freeze_max_age::float) as autovacuum_freeze_max_age,
            (coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
            coalesce(cvsf.value::float, autovacuum_vacuum_scale_factor::float) * c.reltuples) AS autovacuum_vacuum_tuples, n_dead_tup as dead_tuples
    FROM pg_class c join pg_namespace ns on ns.oid = c.oid
    join pg_stat_all_tables stat on stat.relid = c.oid
    join vbt on (1=1)
    join vsf on (1=1)
    join fma on (1=1)
    left join sto cvbt on cvbt.param = 'autovacuum_vacuum_threshold' and c.oid = cvbt.opt_oid
    left join sto cvsfd on cvsfd.param = 'autovacuum_vacuum_scale_factor' and c.oid = cvsfd.opt_oid
    left join sto cfma on cfma.param = 'autovacuum_freeze_max_age' and c.oid = cfma.opt_oid
    WHERE c.relkind = 'r' and ns.nspname <> 'pg_catalog'
    AND (age(relfrozenxid) >= coalesce(cfma.value::float, autovacuum_freeze_max_age::float))
    OR (coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) + coalesce(cvsf.value::float, autovacuum_vacuum_scale_factor::float) * c.reltuples <= n_dead_tup -- or 1 = 1)
ORDER BY age(relfrozenxid) DESC LIMIT 50;
```
Determining if autovacuum is currently running and for how long

If you need to manually vacuum a table, make sure to determine if autovacuum is currently running. If it is, you might need to adjust parameters to make it run more efficiently, or turn off autovacuum temporarily so that you can manually run VACUUM.

Use the following query to determine if autovacuum is running, how long it has been running, and if it is waiting on another session.

```sql
SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS xact_runtime, query
FROM pg_stat_activity
WHERE upper(query) LIKE 'VACUUM'
ORDER BY xact_start;
```

After running the query, you should see output similar to the following.

```
<table>
<thead>
<tr>
<th>datname</th>
<th>usename</th>
<th>pid</th>
<th>state</th>
<th>wait_event</th>
<th>xact_runtime</th>
<th>query</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydb</td>
<td>rdsadmin</td>
<td>16473</td>
<td>active</td>
<td></td>
<td>33 days 16:32:11.600656</td>
<td>autovacuum: VACUUM ANALYZE public.mytable1 (to prevent wraparound)</td>
</tr>
<tr>
<td>mydb</td>
<td>rdsadmin</td>
<td>22553</td>
<td>active</td>
<td></td>
<td>14 days 09:15:34.073141</td>
<td>autovacuum: VACUUM ANALYZE public.mytable2 (to prevent wraparound)</td>
</tr>
<tr>
<td>mydb</td>
<td>rdsadmin</td>
<td>41909</td>
<td>active</td>
<td></td>
<td>3 days 02:43:54.203349</td>
<td>autovacuum: VACUUM ANALYZE public.mytable3</td>
</tr>
<tr>
<td>mydb</td>
<td>rdsadmin</td>
<td>618</td>
<td>active</td>
<td></td>
<td>00:00:00</td>
<td>SELECT datname, usename, pid, state, wait_event, current_timestamp - xact_start AS xact_runtime, query WHERE query like 'VACUUM' ORDER BY xact_start;</td>
</tr>
<tr>
<td>pg_stat_activity</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>FROM pg_stat_activity WHERE query like 'VACUUM' ORDER BY xact_start;</td>
</tr>
</tbody>
</table>
```

Several issues can cause a long-running autovacuum session (that is, multiple days long). The most common issue is that your `maintenance_work_mem` parameter value is set too low for the size of the table or rate of updates.

We recommend that you use the following formula to set the `maintenance_work_mem` parameter value.

```
GREATEST({DBInstanceClassMemory/63963136*1024},65536)
```

Short running autovacuum sessions can also indicate problems:

- It can indicate that there aren't enough `autovacuum_max_workers` for your workload. In this case, you need to indicate the number of workers.
- It can indicate that there is an index corruption (autovacuum crashes and restarts on the same relation but makes no progress). In this case, run a manual `vacuum freeze verbose table` to see the exact cause.
Performing a manual vacuum freeze

You might want to perform a manual vacuum on a table that has a vacuum process already running. This is useful if you have identified a table with an age approaching 2 billion transactions (or above any threshold you are monitoring).

The following steps are guidelines, with several variations to the process. For example, during testing, suppose that you find that the `maintenance_work_mem` parameter value is set too small and that you need to take immediate action on a table. However, perhaps you don't want to bounce the instance at the moment. Using the queries in previous sections, you determine which table is the problem and notice a long running autovacuum session. You know that you need to change the `maintenance_work_mem` parameter setting, but you also need to take immediate action and vacuum the table in question. The following procedure shows what to do in this situation.

To manually perform a vacuum freeze

1. Open two sessions to the database containing the table you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the process ID (PID) of the autovacuum session running on the table.
   
   Run the following query to get the PID of the autovacuum session.

   ```sql
   SELECT datname, usename, pid, current_timestamp - xact_start AS xact_runtime, query
   FROM pg_stat_activity WHERE upper(query) LIKE '%VACUUM%' ORDER BY xact_start;
   ```

3. In session two, calculate the amount of memory that you need for this operation. In this example, we determine that we can afford to use up to 2 GB of memory for this operation, so we set `maintenance_work_mem` for the current session to 2 GB.

   ```sql
   SET maintenance_work_mem='2 GB';
   SET
   ```

4. In session two, issue a vacuum freeze verbose command for the table. The verbose setting is useful because, although there is no progress report for this in PostgreSQL currently, you can see activity.

   ```sql
   \timing on
   vacuum freeze verbose pgbench_branches;
   ```
5. In session one, if autovacuum was blocking the vacuum session, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you need to end the autovacuum process as follows.

   ```sql
   SELECT pg_terminate_backend('the_pid');
   ```

   At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

6. Initiate your `vacuum freeze verbose` command in session two, and then end the autovacuum process in session one.

## Reindexing a table when autovacuum is running

If an index has become corrupt, autovacuum continues to process the table and fails. If you attempt a manual vacuum in this situation, you receive an error message like the following.

```
postgres=> vacuum freeze pgbench_branches;
ERROR: index "pgbench_branches_test_index" contains unexpected zero page at block 30521
HINT: Please REINDEX it.
```

When the index is corrupted and autovacuum is attempting to run on the table, you contend with an already running autovacuum session. When you issue a `REINDEX` command, you take out an exclusive lock on the table. Write operations are blocked, and also read operations that use that specific index.

### To reindex a table when autovacuum is running on the table

1. Open two sessions to the database containing the table that you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.

2. In session one, get the PID of the autovacuum session running on the table.

   Run the following query to get the PID of the autovacuum session.

   ```sql
   SELECT datname, usename, pid, current_timestamp - xact_start
   AS xact_runtime, query
   FROM pg_stat_activity
   WHERE upper(query) like '%VACUUM%'
   ORDER BY xact_start;
   ```

3. In session two, issue the reindex command.

   ```sql
   \timing on
   Timing is on.
   reindex index pgbench_branches_test_index;
   REINDEX
   Time: 9.966 ms
   ```

4. In session one, if autovacuum was blocking the process, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you end the autovacuum process.

   ```sql
   SELECT pg_terminate_backend('the_pid');
   ```

   At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.
5. Initiate your command in session two, and then end the autovacuum process in session 1.

Other parameters that affect autovacuum

The following query shows the values of some of the parameters that directly affect autovacuum and its behavior. The autovacuum parameters are described fully in the PostgreSQL documentation.

```sql
SELECT name, setting, unit, short_desc
FROM pg_settings
WHERE name IN (
    'autovacuum_max_workers',
    'autovacuum_analyze_scale_factor',
    'autovacuum_naptime',
    'autovacuum_analyze_threshold',
    'autovacuum_analyze_scale_factor',
    'autovacuum_vacuum_threshold',
    'autovacuum_vacuum_scale_factor',
    'autovacuum_vacuum_threshold',
    'autovacuum_vacuum_cost_delay',
    'autovacuum_vacuum_cost_limit',
    'vacuum_cost_limit',
    'autovacuum_freeze_max_age',
    'maintenance_work_mem',
    'vacuum_freeze_min_age'
);
```

While these all affect autovacuum, some of the most important ones are:

- `maintenance_work_mem`
- `autovacuum_freeze_max_age`
- `autovacuum_max_workers`
- `autovacuum_vacuum_cost_delay`
- `autovacuum_vacuum_cost_limit`

Setting table-level autovacuum parameters

You can set autovacuum-related storage parameters at a table level, which can be better than altering the behavior of the entire database. For large tables, you might need to set aggressive settings and you might not want to make autovacuum behave that way for all tables.

The following query shows which tables currently have table-level options in place.

```sql
SELECT relname, reloptions
FROM pg_class
WHERE reloptions IS NOT null;
```

An example where this might be useful is on tables that are much larger than the rest of your tables. Suppose that you have one 300-GB table and 30 other tables less than 1 GB. In this case, you might set some specific parameters for your large table so you don't alter the behavior of your entire system.

```sql
ALTER TABLE mytable set (autovacuum_vacuum_cost_delay=0);
```

Doing this turns off the cost-based autovacuum delay for this table at the expense of more resource usage on your system. Normally, autovacuum pauses for autovacuum_vacuum_cost_delay each time autovacuum_cost_limit is reached. For more details, see the PostgreSQL documentation about cost-based vacuuming.
Logging autovacuum and vacuum activities

Information about autovacuum activities is sent to the `postgresql.log` based on the level specified in the `rds.force_autovacuum_logging_level` parameter. Following are the values allowed for this parameter and the PostgreSQL versions for which that value is the default setting:

- disabled (PostgreSQL 10, PostgreSQL 9.6)
- debug5, debug4, debug3, debug2, debug1
- info (PostgreSQL 12, PostgreSQL 11)
- notice
- warning (PostgreSQL 14, PostgreSQL 13)
- error, log, fatal, panic

The `rds.force_autovacuum_logging_level` works with the `log_autovacuum_min_duration` parameter. The `log_autovacuum_min_duration` parameter's value is the threshold (in milliseconds) above which autovacuum actions get logged. A setting of -1 logs nothing, while a setting of 0 logs all actions. As with `rds.force_autovacuum_logging_level`, default values for `log_autovacuum_min_duration` are version dependent, as follows:

- 10000 ms – PostgreSQL 14, PostgreSQL 13, PostgreSQL 12, and PostgreSQL 11
- (empty) – No default value for PostgreSQL 10 and PostgreSQL 9.6

We recommend that you set `rds.force_autovacuum_logging_level` to LOG. We also recommend that you set `log_autovacuum_min_duration` to a value from 1000 to 5000. A setting of 5000 logs activity that takes longer than 5,000 milliseconds. Any setting other than -1 also logs messages if the autovacuum action is skipped because of a conflicting lock or concurrently dropped relations. For more information, see Automatic Vacuuming in the PostgreSQL documentation.

To troubleshoot issues, you can change the `rds.force_autovacuum_logging_level` parameter to one of the debug levels, from debug1 up to debug5 for the most verbose information. We recommend that you use debug settings for short periods of time and for troubleshooting purposes only. To learn more, see When to log in the PostgreSQL documentation.

Note

PostgreSQL allows the `rds_superuser` account to view autovacuum sessions in `pg_stat_activity`. For example, you can identify and end an autovacuum session that is blocking a command from running, or running slower than a manually issued vacuum command.

Controlling user access to the PostgreSQL database

In RDS for PostgreSQL, you can manage which users have privileges to connect to which databases. In PostgreSQL environments, you sometimes perform this kind of management by modifying the `pg_hba.conf` file. In Amazon RDS, you can use database grants instead.

New databases in PostgreSQL are always created with a default set of privileges. The default privileges allow PUBLIC (all users) to connect to the database and to create temporary tables while connected.

To control which users are allowed to connect to a given database in Amazon RDS, first revoke the default PUBLIC privileges. Then grant back the privileges on a more granular basis. The following example shows how.

```
postgres=> REVOKE ALL on database db-name from public;
postgres=> GRANT CONNECT, TEMPORARY on database db-name to user/role;
```
For more information about privileges in PostgreSQL databases, see the GRANT command in the PostgreSQL documentation.

**Working with logging mechanisms supported by RDS for PostgreSQL**

There are several parameters, extensions, and other configurable items that you can set to log activities that occur on your PostgreSQL DB instance. These include the following:

- The `log_statement` parameter can be used to log user activity in your PostgreSQL database. To learn more about RDS for PostgreSQL logging and how to monitor the logs, see PostgreSQL database log files (p. 680).
- The `rds.force_admin_logging_level` parameter logs actions by the Amazon RDS internal user (rdsadmin) in the databases on the DB instance. It writes the output to the PostgreSQL error log. Allowed values are disabled, debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, and panic. The default value is disabled.
- The `rds.force_autovacuum_logging_level` parameter can be set to capture various autovacuum operations in the PostgreSQL error log. For more information, see Logging autovacuum and vacuum activities (p. 1702).
- The `pgaudit` extension can be installed and configured to capture activities at the session level or at the object level. For more information, see Logging at the session and object level with the pgaudit extension (p. 1721).
- The `log_fdw` extension makes it possible for you to access the database engine log using SQL. For more information, see Using the log_fdw extension to access the DB log using SQL (p. 1737).
- The `pg_stat_statements` library is specified as the default for the `shared_preload_libraries` parameter in RDS for PostgreSQL version 10 and higher. It's this library that you can use to analyze running queries. Be sure that `pg_stat_statements` is set in your DB parameter group. For more information about monitoring your RDS for PostgreSQL DB instance using the information that this library provides, see Analyzing running queries in PostgreSQL (p. 556).

In general terms, the point of logging is so that the DBA can monitor, tune performance, and troubleshoot. Many of the logs are uploaded automatically to Amazon CloudWatch or Performance Insights. Here, they're sorted and grouped to provide complete metrics for your DB instance. To learn more about Amazon RDS monitoring and metrics, see Monitoring metrics in an Amazon RDS instance (p. 491).

**Using pgBadger for log analysis with PostgreSQL**

You can use a log analyzer such as pgBadger to analyze PostgreSQL logs. The pgBadger documentation states that the `%l` pattern (the log line for the session or process) should be a part of the prefix. However, if you provide the current RDS `log_line_prefix` as a parameter to pgBadger it should still produce a report.

For example, the following command correctly formats an Amazon RDS for PostgreSQL log file dated 2014-02-04 using pgBadger.

```
./pgbadger -f stderr -p '%t:%r:%u@%d:[%p]:' postgresql.log.2014-02-04-00
```

**Limiting control of user passwords to a specific role**

You can restrict who can manage database user passwords to a special role. By doing this, you can have more control over password management on the client side.
You turn on restricted password management with the static parameter `rds.restrict_password_commands` and use a role called `rds_password`. When the parameter `rds.restrict_password_commands` is set to 1, only users that are members of the `rds_password` role can run certain SQL commands. The restricted SQL commands are commands that modify database user passwords and password expiration time.

To use restricted password management, make sure that your DB instance is running RDS for PostgreSQL 10.6 or higher. Because the `rds.restrict_password_commands` parameter is static, changing this parameter requires a database restart.

When a database has restricted password management turned on, if you try to run restricted SQL commands you get the following error: `ERROR: must be a member of rds_password to alter passwords`.

Following are some examples of SQL commands that are restricted when restricted password management is turned on.

```
postgres=> CREATE ROLE myrole WITH PASSWORD 'mypassword';
postgres=> CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2020-01-01';
postgres=> ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2020-01-01';
postgres=> ALTER ROLE myrole WITH PASSWORD 'mypassword';
postgres=> ALTER ROLE myrole VALID UNTIL '2020-01-01';
postgres=> ALTER ROLE myrole RENAME TO myrole2;
```

Some `ALTER ROLE` commands that include `RENAME TO` might also be restricted. They might be restricted because renaming a PostgreSQL role that has an MD5 password clears the password.

The `rds_superuser` role has membership for the `rds_password` role by default, and you can’t change this. You can give other roles membership for the `rds_password` role by using the `GRANT` SQL command. We recommend that you give membership to `rds_password` to only a few roles that you use solely for password management. These roles require the `CREATEROLE` attribute to modify other roles.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. We recommend that you restrict password-related changes by using your own client-side utility. This utility should have a role that is a member of `rds_password` and has the `CREATEROLE` role attribute.

### Working with parameters on your RDS for PostgreSQL DB instance

In some cases, you might create an RDS for PostgreSQL DB instance without specifying a custom parameter group. If so, your DB instance is created using the default parameter group for the version of PostgreSQL that you choose. For example, suppose that you create an RDS for PostgreSQL DB instance using PostgreSQL 13.3. In this case, the DB instance is created using the values in the parameter group for PostgreSQL 13 releases, `default.postgres13`.

You can also create your own custom DB parameter group. You need to do this if you want to modify any settings for the RDS for PostgreSQL DB instance from their default values. To learn how, see Working with parameter groups (p. 278).

You can track the settings on your RDS for PostgreSQL DB instance in several different ways. You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also query the values from the PostgreSQL `pg_settings` table of your instance, as shown following.

```
SELECT name, setting, boot_val, reset_val, unit
FROM pg_settings
ORDER BY name;
```
To learn more about the values returned from this query, see `pg_settings` in the PostgreSQL documentation.

Be especially careful when changing the settings for `max_connections` and `shared_buffers` on your RDS for PostgreSQL DB instance. For example, suppose that you modify settings for `max_connections` or `shared_buffers` and you use values that are too high for your actual workload. In this case, your RDS for PostgreSQL DB instance won't start. If this happens, you see an error such as the following in the `postgres.log`.

```
2018-09-18 21:13:15 UTC::@::@[8097]:FATAL:  could not map anonymous shared memory: Cannot allocate memory
2018-09-18 21:13:15 UTC::@::@[8097]:HINT:  This error usually means that PostgreSQL's request for a shared memory segment exceeded available memory or swap space. To reduce the request size (currently 351413274048 bytes), reduce PostgreSQL's shared memory usage, perhaps by reducing shared_buffers or max_connections.
```

However, you can't change any values of the settings contained in the default RDS for PostgreSQL DB parameter groups. To change settings for any parameters, first create a custom DB parameter group. Then change the settings in that custom group, and then apply the custom parameter group to your RDS for PostgreSQL DB instance. To learn more, see Working with parameter groups (p. 278).

There are two types of RDS for PostgreSQL DB parameters.

- **Static parameters** – Static parameters require that the RDS for PostgreSQL DB instance be rebooted after a change so that the new value can take effect.
- **Dynamic parameters** – Dynamic parameters don't require a reboot after changing their settings.

**Note**

If your RDS for PostgreSQL DB instance is using your own custom DB parameter group, you can change the values of dynamic parameters on the running DB instance. You can do this by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have privileges to do so, you can also change parameter values by using the `ALTER DATABASE`, `ALTER ROLE`, and `SET` commands.
# RDS for PostgreSQL DB instance parameter list

The following table lists some of the parameters available in an RDS for PostgreSQL DB instance.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Apply_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>application_name</td>
<td>Dynamic</td>
<td>Sets the application name to be reported in statistics and logs.</td>
</tr>
<tr>
<td>array_nulls</td>
<td>Dynamic</td>
<td>Enables input of NULL elements in arrays.</td>
</tr>
<tr>
<td>authentication_timeout</td>
<td>Dynamic</td>
<td>Sets the maximum allowed time to complete client authentication.</td>
</tr>
<tr>
<td>autovacuum</td>
<td>Dynamic</td>
<td>Starts the autovacuum subprocess.</td>
</tr>
<tr>
<td>autovacuum_analyze_scale_factor</td>
<td>Dynamic</td>
<td>Number of tuple inserts, updates, or deletes before analyze as a fraction of reltuples.</td>
</tr>
<tr>
<td>autovacuum_analyze_threshold</td>
<td>Dynamic</td>
<td>Minimum number of tuple inserts, updates, or deletes before analyze.</td>
</tr>
<tr>
<td>autovacuum_freeze_max_age</td>
<td>Static</td>
<td>Age at which to autovacuum a table to prevent transaction ID wraparound.</td>
</tr>
<tr>
<td>autovacuum_naptime</td>
<td>Dynamic</td>
<td>Time to sleep between autovacuum runs.</td>
</tr>
<tr>
<td>autovacuum_max_workers</td>
<td>Static</td>
<td>Sets the maximum number of simultaneously running autovacuum worker processes.</td>
</tr>
<tr>
<td>autovacuum_vacuum_cost_delay</td>
<td>Dynamic</td>
<td>Vacuum cost delay, in milliseconds, for autovacuum.</td>
</tr>
<tr>
<td>autovacuum_vacuum_cost_limit</td>
<td>Dynamic</td>
<td>Vacuum cost amount available before napping, for autovacuum.</td>
</tr>
<tr>
<td>autovacuum_vacuum_scale_factor</td>
<td>Dynamic</td>
<td>Number of tuple updates or deletes before vacuum as a fraction of reltuples.</td>
</tr>
<tr>
<td>autovacuum_vacuum_threshold</td>
<td>Dynamic</td>
<td>Minimum number of tuple updates or deletes before vacuum.</td>
</tr>
<tr>
<td>backslash_quote</td>
<td>Dynamic</td>
<td>Sets whether a backslash () is allowed in string literals.</td>
</tr>
<tr>
<td>bgwriter_delay</td>
<td>Dynamic</td>
<td>Background writer sleep time between rounds.</td>
</tr>
<tr>
<td>bgwriter_lru_maxpages</td>
<td>Dynamic</td>
<td>Background writer maximum number of LRU pages to flush per round.</td>
</tr>
<tr>
<td>bgwriter_lru_multiplier</td>
<td>Dynamic</td>
<td>Multiple of the average buffer usage to free per round.</td>
</tr>
<tr>
<td>bytea_output</td>
<td>Dynamic</td>
<td>Sets the output format for bytes.</td>
</tr>
<tr>
<td>check_function_bodies</td>
<td>Dynamic</td>
<td>Checks function bodies during CREATE FUNCTION.</td>
</tr>
<tr>
<td>checkpoint_completion_target</td>
<td>Dynamic</td>
<td>Time spent flushing dirty buffers during checkpoint, as a fraction of the checkpoint interval.</td>
</tr>
<tr>
<td>checkpoint_segments</td>
<td>Dynamic</td>
<td>Sets the maximum distance in log segments between automatic write-ahead log (WAL) checkpoints.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>checkpoint_timeout</td>
<td>Dynamic</td>
<td>Sets the maximum time between automatic WAL checkpoints.</td>
</tr>
<tr>
<td>checkpoint_warning</td>
<td>Dynamic</td>
<td>Enables warnings if checkpoint segments are filled more frequently than this.</td>
</tr>
<tr>
<td>client_encoding</td>
<td>Dynamic</td>
<td>Sets the client's character set encoding.</td>
</tr>
<tr>
<td>client_min_messages</td>
<td>Dynamic</td>
<td>Sets the message levels that are sent to the client.</td>
</tr>
<tr>
<td>commit_delay</td>
<td>Dynamic</td>
<td>Sets the delay in microseconds between transaction commit and flushing WAL to disk.</td>
</tr>
<tr>
<td>commit_siblings</td>
<td>Dynamic</td>
<td>Sets the minimum concurrent open transactions before performing commit_delay.</td>
</tr>
<tr>
<td>constraint_exclusion</td>
<td>Dynamic</td>
<td>Enables the planner to use constraints to optimize queries.</td>
</tr>
<tr>
<td>cpu_index_tuple_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of processing each index entry during an index scan.</td>
</tr>
<tr>
<td>cpu_operator_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of processing each operator or function call.</td>
</tr>
<tr>
<td>cpu_tuple_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of processing each tuple (row).</td>
</tr>
<tr>
<td>cursor_tuple_fraction</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the fraction of a cursor's rows that will be retrieved.</td>
</tr>
<tr>
<td>datestyle</td>
<td>Dynamic</td>
<td>Sets the display format for date and time values.</td>
</tr>
<tr>
<td>deadlock_timeout</td>
<td>Dynamic</td>
<td>Sets the time to wait on a lock before checking for deadlock.</td>
</tr>
<tr>
<td>debug_pretty_print</td>
<td>Dynamic</td>
<td>Indents parse and plan tree displays.</td>
</tr>
<tr>
<td>debug_print_parse</td>
<td>Dynamic</td>
<td>Logs each query's parse tree.</td>
</tr>
<tr>
<td>debug_print_plan</td>
<td>Dynamic</td>
<td>Logs each query's execution plan.</td>
</tr>
<tr>
<td>debug_print_rewritten</td>
<td>Dynamic</td>
<td>Logs each query's rewritten parse tree.</td>
</tr>
<tr>
<td>default_statistics_target</td>
<td>Dynamic</td>
<td>Sets the default statistics target.</td>
</tr>
<tr>
<td>default_tablespace</td>
<td>Dynamic</td>
<td>Sets the default tablespace to create tables and indexes in.</td>
</tr>
<tr>
<td>default_transaction_deferrable</td>
<td>Dynamic</td>
<td>Sets the default deferrable status of new transactions.</td>
</tr>
<tr>
<td>default_transaction_isolation</td>
<td>Dynamic</td>
<td>Sets the transaction isolation level of each new transaction.</td>
</tr>
<tr>
<td>default_transaction_read_only</td>
<td>Dynamic</td>
<td>Sets the default read-only status of new transactions.</td>
</tr>
<tr>
<td>default_with_oids</td>
<td>Dynamic</td>
<td>Creates new tables with object IDs (OIDs) by default.</td>
</tr>
<tr>
<td>effective_cache_size</td>
<td>Dynamic</td>
<td>Sets the planner's assumption about the size of the disk cache.</td>
</tr>
<tr>
<td>effective_io_concurrency</td>
<td>Dynamic</td>
<td>Number of simultaneous requests that can be handled efficiently by the disk subsystem.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>enable_bitmapscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of bitmap-scan plans.</td>
</tr>
<tr>
<td>enable_hashagg</td>
<td>Dynamic</td>
<td>Enables the planner's use of hashed aggregation plans.</td>
</tr>
<tr>
<td>enable_hashjoin</td>
<td>Dynamic</td>
<td>Enables the planner's use of hash join plans.</td>
</tr>
<tr>
<td>enable_indexscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of index-scan plans.</td>
</tr>
<tr>
<td>enable_material</td>
<td>Dynamic</td>
<td>Enables the planner's use of materialization.</td>
</tr>
<tr>
<td>enable_mergejoin</td>
<td>Dynamic</td>
<td>Enables the planner's use of merge join plans.</td>
</tr>
<tr>
<td>enable_nestloop</td>
<td>Dynamic</td>
<td>Enables the planner's use of nested-loop join plans.</td>
</tr>
<tr>
<td>enable_seqscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of sequential-scan plans.</td>
</tr>
<tr>
<td>enable_sort</td>
<td>Dynamic</td>
<td>Enables the planner's use of explicit sort steps.</td>
</tr>
<tr>
<td>enable_tidscan</td>
<td>Dynamic</td>
<td>Enables the planner's use of TID scan plans.</td>
</tr>
<tr>
<td>escape_string_warning</td>
<td>Dynamic</td>
<td>Warns about backslash () escapes in ordinary string literals.</td>
</tr>
<tr>
<td>extra_float_digits</td>
<td>Dynamic</td>
<td>Sets the number of digits displayed for floating-point values.</td>
</tr>
<tr>
<td>fromCollapse_limit</td>
<td>Dynamic</td>
<td>Sets the FROM-list size beyond which subqueries are not collapsed.</td>
</tr>
<tr>
<td>fsync</td>
<td>Dynamic</td>
<td>Forces synchronization of updates to disk.</td>
</tr>
<tr>
<td>full_page_writes</td>
<td>Dynamic</td>
<td>Writes full pages to WAL when first modified after a checkpoint.</td>
</tr>
<tr>
<td>geqo</td>
<td>Dynamic</td>
<td>Enables genetic query optimization.</td>
</tr>
<tr>
<td>geqo_effort</td>
<td>Dynamic</td>
<td>GEQO: effort is used to set the default for other GEQO parameters.</td>
</tr>
<tr>
<td>geqo_generations</td>
<td>Dynamic</td>
<td>GEQO: number of iterations of the algorithm.</td>
</tr>
<tr>
<td>geqo_pool_size</td>
<td>Dynamic</td>
<td>GEQO: number of individuals in the population.</td>
</tr>
<tr>
<td>geqo_seed</td>
<td>Dynamic</td>
<td>GEQO: seed for random path selection.</td>
</tr>
<tr>
<td>geqo_selection_bias</td>
<td>Dynamic</td>
<td>GEQO: selective pressure within the population.</td>
</tr>
<tr>
<td>geqo_threshold</td>
<td>Dynamic</td>
<td>Sets the threshold of FROM items beyond which GEQO is used.</td>
</tr>
<tr>
<td>gin_fuzzy_search_limit</td>
<td>Dynamic</td>
<td>Sets the maximum allowed result for exact search by GIN.</td>
</tr>
<tr>
<td>hot_standby_feedback</td>
<td>Dynamic</td>
<td>Determines whether a hot standby sends feedback messages to the primary or upstream standby.</td>
</tr>
<tr>
<td>intervalstyle</td>
<td>Dynamic</td>
<td>Sets the display format for interval values.</td>
</tr>
<tr>
<td>joinCollapseLimit</td>
<td>Dynamic</td>
<td>Sets the FROM-list size beyond which JOIN constructs are not flattened.</td>
</tr>
<tr>
<td>lc_messages</td>
<td>Dynamic</td>
<td>Sets the language in which messages are displayed.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>lc_monetary</td>
<td>Dynamic</td>
<td>Sets the locale for formatting monetary amounts.</td>
</tr>
<tr>
<td>lc_numeric</td>
<td>Dynamic</td>
<td>Sets the locale for formatting numbers.</td>
</tr>
<tr>
<td>lc_time</td>
<td>Dynamic</td>
<td>Sets the locale for formatting date and time values.</td>
</tr>
<tr>
<td>log_autovacuum_min_duration</td>
<td>Dynamic</td>
<td>Sets the minimum running time above which autovacuum actions will be logged.</td>
</tr>
<tr>
<td>log_checkpoints</td>
<td>Dynamic</td>
<td>Logs each checkpoint.</td>
</tr>
<tr>
<td>log_connections</td>
<td>Dynamic</td>
<td>Logs each successful connection.</td>
</tr>
<tr>
<td>log_disconnections</td>
<td>Dynamic</td>
<td>Logs end of a session, including duration.</td>
</tr>
<tr>
<td>log_duration</td>
<td>Dynamic</td>
<td>Logs the duration of each completed SQL statement.</td>
</tr>
<tr>
<td>log_error_verbosity</td>
<td>Dynamic</td>
<td>Sets the verbosity of logged messages.</td>
</tr>
<tr>
<td>log_executor_stats</td>
<td>Dynamic</td>
<td>Writes executor performance statistics to the server log.</td>
</tr>
<tr>
<td>log_filename</td>
<td>Dynamic</td>
<td>Sets the file name pattern for log files.</td>
</tr>
<tr>
<td>log_hostname</td>
<td>Dynamic</td>
<td>Logs the host name in the connection logs.</td>
</tr>
<tr>
<td>log_lock_waits</td>
<td>Dynamic</td>
<td>Logs long lock waits.</td>
</tr>
<tr>
<td>log_min_duration_statement</td>
<td>Dynamic</td>
<td>Sets the minimum running time above which statements will be logged.</td>
</tr>
<tr>
<td>log_min_error_statement</td>
<td>Dynamic</td>
<td>Causes all statements generating an error at or above this level to be logged.</td>
</tr>
<tr>
<td>log_min_messages</td>
<td>Dynamic</td>
<td>Sets the message levels that are logged.</td>
</tr>
<tr>
<td>log_parser_stats</td>
<td>Dynamic</td>
<td>Writes parser performance statistics to the server log.</td>
</tr>
<tr>
<td>log_planner_stats</td>
<td>Dynamic</td>
<td>Writes planner performance statistics to the server log.</td>
</tr>
<tr>
<td>log_rotation_age</td>
<td>Dynamic</td>
<td>Automatic log file rotation will occur after N minutes.</td>
</tr>
<tr>
<td>log_rotation_size</td>
<td>Dynamic</td>
<td>Automatic log file rotation will occur after N kilobytes.</td>
</tr>
<tr>
<td>log_statement</td>
<td>Dynamic</td>
<td>Sets the type of statements logged.</td>
</tr>
<tr>
<td>log_statement_stats</td>
<td>Dynamic</td>
<td>Writes cumulative performance statistics to the server log.</td>
</tr>
<tr>
<td>log_temp_files</td>
<td>Dynamic</td>
<td>Logs the use of temporary files larger than this number of kilobytes.</td>
</tr>
<tr>
<td>maintenance_work_mem</td>
<td>Dynamic</td>
<td>Sets the maximum memory to be used for maintenance operations.</td>
</tr>
<tr>
<td>max_connections</td>
<td>Static</td>
<td>Sets the maximum number of concurrent connections.</td>
</tr>
<tr>
<td>max_files_per_process</td>
<td>Static</td>
<td>Sets the maximum number of simultaneously open files for each server process.</td>
</tr>
<tr>
<td>max_locks_per_transaction</td>
<td>Static</td>
<td>Sets the maximum number of locks per transaction.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>max_pred_locks_per_transaction</td>
<td>Static</td>
<td>Sets the maximum number of predicate locks per transaction.</td>
</tr>
<tr>
<td>max_prepared_transactions</td>
<td>Static</td>
<td>Sets the maximum number of simultaneously prepared transactions.</td>
</tr>
<tr>
<td>max_stack_depth</td>
<td>Dynamic</td>
<td>Sets the maximum stack depth, in kilobytes.</td>
</tr>
<tr>
<td>max_standby_archive_delay</td>
<td>Dynamic</td>
<td>Sets the maximum delay before canceling queries when a hot standby server is processing archived WAL data.</td>
</tr>
<tr>
<td>max_standby_streaming_delay</td>
<td>Dynamic</td>
<td>Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.</td>
</tr>
<tr>
<td>max_wal_size</td>
<td>Dynamic</td>
<td>Sets the WAL size that triggers the checkpoint. For PostgreSQL version 9.6 and earlier, max_wal_size is in units of 16 MB. For PostgreSQL version 10 and later, max_wal_size is in units of 1 MB.</td>
</tr>
<tr>
<td>min_wal_size</td>
<td>Dynamic</td>
<td>Sets the minimum size to shrink the WAL to. For PostgreSQL version 9.6 and earlier, min_wal_size is in units of 16 MB. For PostgreSQL version 10 and later, min_wal_size is in units of 1 MB.</td>
</tr>
<tr>
<td>quote_all_identifiers</td>
<td>Dynamic</td>
<td>Adds quotes (&quot;) to all identifiers when generating SQL fragments.</td>
</tr>
<tr>
<td>random_page_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of a non-sequentially fetched disk page.</td>
</tr>
<tr>
<td>rds.adaptive_autovacuum</td>
<td>Dynamic</td>
<td>Automatically tunes the autovacuum parameters whenever the transaction ID thresholds are exceeded.</td>
</tr>
<tr>
<td>rds.log_retention_period</td>
<td>Dynamic</td>
<td>Sets log retention such that Amazon RDS deletes PostgreSQL logs that are older than N minutes.</td>
</tr>
<tr>
<td>rds.restrict_password_commands</td>
<td>Static</td>
<td>Restricts who can manage passwords to users with the rds_password role. Set this parameter to 1 to enable password restriction. The default is 0.</td>
</tr>
<tr>
<td>search_path</td>
<td>Dynamic</td>
<td>Sets the schema search order for names that are not schema-qualified.</td>
</tr>
<tr>
<td>seq_page_cost</td>
<td>Dynamic</td>
<td>Sets the planner's estimate of the cost of a sequentially fetched disk page.</td>
</tr>
<tr>
<td>session_replication_role</td>
<td>Dynamic</td>
<td>Sets the sessions behavior for triggers and rewrite rules.</td>
</tr>
<tr>
<td>shared_buffers</td>
<td>Static</td>
<td>Sets the number of shared memory buffers used by the server.</td>
</tr>
<tr>
<td>ssl</td>
<td>Static</td>
<td>Enables SSL connections.</td>
</tr>
<tr>
<td>sql_inheritance</td>
<td>Dynamic</td>
<td>Causes subtables to be included by default in various commands.</td>
</tr>
<tr>
<td>ssl_renegotiation_limit</td>
<td>Dynamic</td>
<td>Sets the amount of traffic to send and receive before renegotiating the encryption keys.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Apply_Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>standard_conforming_strings</td>
<td>Dynamic</td>
<td>Causes ... strings to treat backslashes literally.</td>
</tr>
<tr>
<td>statement_timeout</td>
<td>Dynamic</td>
<td>Sets the maximum allowed duration of any statement.</td>
</tr>
<tr>
<td>synchronize_seqscans</td>
<td>Dynamic</td>
<td>Enables synchronized sequential scans.</td>
</tr>
<tr>
<td>synchronous_commit</td>
<td>Dynamic</td>
<td>Sets the current transactions synchronization level.</td>
</tr>
<tr>
<td>tcp_keepalives_count</td>
<td>Dynamic</td>
<td>Maximum number of TCP keepalive retransmits.</td>
</tr>
<tr>
<td>tcp_keepalives_idle</td>
<td>Dynamic</td>
<td>Time between issuing TCP keepalives.</td>
</tr>
<tr>
<td>tcp_keepalives_interval</td>
<td>Dynamic</td>
<td>Time between TCP keepalive retransmits.</td>
</tr>
<tr>
<td>temp_buffers</td>
<td>Dynamic</td>
<td>Sets the maximum number of temporary buffers used by each session.</td>
</tr>
<tr>
<td>temp_file_limit</td>
<td>Static</td>
<td>Sets the maximum size in KB to which the temporary files can grow.</td>
</tr>
<tr>
<td>temp_tablespaces</td>
<td>Dynamic</td>
<td>Sets the tablespaces to use for temporary tables and sort files.</td>
</tr>
<tr>
<td>timezone</td>
<td>Dynamic</td>
<td>Sets the time zone for displaying and interpreting time stamps.</td>
</tr>
<tr>
<td>track_activities</td>
<td>Dynamic</td>
<td>Collects information about running commands.</td>
</tr>
<tr>
<td>track_activity_query_size</td>
<td>Static</td>
<td>Sets the size reserved for pg_stat_activity.current_query, in bytes.</td>
</tr>
<tr>
<td>track_counts</td>
<td>Dynamic</td>
<td>Collects statistics on database activity.</td>
</tr>
<tr>
<td>track_functions</td>
<td>Dynamic</td>
<td>Collects function-level statistics on database activity.</td>
</tr>
<tr>
<td>track_io_timing</td>
<td>Dynamic</td>
<td>Collects timing statistics on database I/O activity.</td>
</tr>
<tr>
<td>transaction_deferrable</td>
<td>Dynamic</td>

### Understanding the rds_superuser role

When you create an RDS for PostgreSQL DB instance, the main user system account that you create is assigned to the rds_superuser role. The rds_superuser role is a predefined Amazon RDS role similar to the PostgreSQL superuser role (customarily named postgres in local instances), but with some restrictions. As with the PostgreSQL superuser role, the rds_superuser role has the most privileges for your DB instance. Don’t assign this role to users unless they need the most access to the DB instance.

The rds_superuser role can do the following:

- Add extensions that are available for use with Amazon RDS. For more information, see Working with PostgreSQL features supported by Amazon RDS for PostgreSQL (p. 1688) and the PostgreSQL documentation.
- Manage tablespaces, including creating and deleting them. For more information, see Tables for RDS for PostgreSQL (p. 1692) and the Tablespaces section in the PostgreSQL documentation.
Understanding the rds_superuser role

- View all users that aren't assigned the rds_superuser role using the `pg_stat_activity` command and stop their connections using the `pg_terminate_backend` and `pg_cancel_backend` commands.
- Grant and revoke the rds_replication role for all roles that aren't the rds_superuser role. For more information, see the GRANT section in the PostgreSQL documentation.

As mentioned, the rds_superuser role can't do everything that the postgres superuser can do. For example, rds_superuser can't bypass the CONNECT privilege when connecting to a database. This role must be specifically granted to any users that you create that should have rds_superuser privileges.

The following example shows how to create a user and then grant the user the rds_superuser role.

```
postgres=> CREATE ROLE bus_app_admin WITH PASSWORD 'change_me' LOGIN;
CREATE ROLE
postgres=> GRANT rds_superuser TO bus_app_admin;
GRANT ROLE
```
Using PostgreSQL extensions with Amazon RDS for PostgreSQL

You can install and configure various PostgreSQL extensions to add more functionality to your RDS for PostgreSQL DB instance. For example, to work with spatial data you can install and use the PostGIS extension. For more information, see Managing spatial data with the PostGIS extension (p. 1733). As another example, if you want to improve data entry for very large tables, you can consider partitioning your data by using the pg_partman extension. To learn more, see Managing PostgreSQL partitions with the pg_partman extension (p. 1717).

Following are some of the PostgreSQL extensions that you can install and use with your Amazon RDS for PostgreSQL DB instance.

Topics

- Using functions from the orafce extension (p. 1715)
- Managing PostgreSQL partitions with the pg_partman extension (p. 1717)
- Logging at the session and object level with the pgaudit extension (p. 1721)
- Scheduling maintenance with the PostgreSQL pg_cron extension (p. 1723)
- Reducing bloat in tables and indexes with the pg_repack extension (p. 1730)
- Upgrading and using the PLV8 extension (p. 1731)
- Managing spatial data with the PostGIS extension (p. 1733)

Using functions from the orafce extension

The orafce extension provides functions and operators that emulate a subset of functions and packages from an Oracle database. The orafce extension makes it easier for you to port an Oracle application to PostgreSQL. RDS for PostgreSQL versions 9.6.6 and higher support this extension. For more information about orafce, see orafce on GitHub.

**Note**
RDS for PostgreSQL doesn't support the utl_file package that is part of the orafce extension. This is because the utl_file schema functions provide read and write operations on operating-system text files, which requires superuser access to the underlying host. As a managed service, RDS for PostgreSQL doesn't provide host access.

To use the orafce extension

1. Connect to the DB instance with the master user name that you used to create the DB instance.

   If you want to turn on orafce for a different database in the same DB instance, use the /c dbname psql command. Using this command, you change from the primary database after initiating the connection.

2. Turn on the orafce extension with the CREATE EXTENSION statement.

   ```sql
   CREATE EXTENSION orafce;
   ```

3. Transfer ownership of the oracle schema to the rds_superuser role with the ALTER SCHEMA statement.

   ```sql
   ALTER SCHEMA oracle OWNER TO rds_superuser;
   ```

   If you want to see the list of owners for the oracle schema, use the \dn psql command.
Managing PostgreSQL partitions with the pg_partman extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day’s worth of data, and so on. The partition key controls the size of a partition.

When you use an INSERT or UPDATE SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the WHERE clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.
  For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.

- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints
  - References
  - Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

Topics

- Overview of the PostgreSQL pg_partman extension (p. 1718)
- Enabling the pg_partman extension (p. 1718)
- Configuring partitions using the create_parent function (p. 1719)
- Configuring partition maintenance using the run_maintenance_proc function (p. 1720)
Overview of the PostgreSQL pg_partman extension

You can use the PostgreSQL pg_partman extension to automate the creation and maintenance of table partitions. For more general information, see PG Partition Manager in the pg_partman documentation.

Note
The pg_partman extension is supported on RDS for PostgreSQL versions 12.5 and higher.

Instead of having to manually create each partition, you configure pg_partman with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with pg_partman by calling the create_parent function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The pg_partman extension also provides the run_maintenance_proc function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

Enabling the pg_partman extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the pg_partman extension separately for each database. To enable the pg_partman extension for a specific database, create the partition maintenance schema and then create the pg_partman extension as follows.

```
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

Note
To create the pg_partman extension, make sure that you have rds_superuser privileges.

If you receive an error such as the following, grant the rds_superuser privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant rds_superuser privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the pg_partman extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema data_mart contains a table named events with a column named created_at. The following settings are included in the events table:
• Primary keys event_id and created_at, which must have the column used to guide the partition.
• A check constraint ck_valid_operation to enforce values for an operation table column.
• Two foreign keys, where one (fk_orga_membership) points to the external table organization and the other (fk_parent_event_id) is a self-referenced foreign key.
• Two indexes, where one (idx_org_id) is for the foreign key and the other (idx_event_type) is for the event type.

The follow DDL statements create these objects, which are automatically included on each partition.

```sql
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization (
  org_id BIGSERIAL,
  org_name TEXT,
  CONSTRAINT pk_organization PRIMARY KEY (org_id)
);

CREATE TABLE data_mart.events(
  event_id        BIGSERIAL,
  operation       CHAR(1),
  value           FLOAT(24),
  parent_event_id BIGINT,
  event_type      VARCHAR(25),
  org_id          BIGSERIAL,
  created_at      timestamp,
  CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
  CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
  CONSTRAINT fk_orga_membership
    FOREIGN KEY(org_id)
    REFERENCES data_mart.organization (org_id),
  CONSTRAINT fk_parent_event_id
    FOREIGN KEY(parent_event_id, created_at)
    REFERENCES data_mart.events (event_id, created_at)
) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id     ON  data_mart.events(org_id);
CREATE INDEX idx_event_type ON  data_mart.events(event_type);
```

**Configuring partitions using the create_parent function**

After you enable the `pg_partman` extension, use the `create_parent` function to configure partitions inside the partition maintenance schema. The following example uses the events table example created in Enabling the `pg_partman` extension (p. 1718). Call the `create_parent` function as follows.

```sql
SELECT partman.create_parent( p_parent_table => 'data_mart.events',
  p_control => 'created_at',
  p_type => 'native',
  p_interval=> 'daily',
  p_premake => 30);
```

The parameters are as follows:

• p_parent_table – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
• p_control – The column on which the partitioning is to be based. The data type must be an integer or time-based.
• p_type – The type is either 'native' or 'partman'. You typically use the native type for its performance improvements and flexibility. The partman type relies on inheritance.
• **p_interval** – The time interval or integer range for each partition. Example values include daily, hourly, and so on.
• **p_premake** – The number of partitions to create in advance to support new inserts.

For a complete description of the create_parent function, see Creation Functions in the pg_partman documentation.

### Configuring partition maintenance using the run_maintenance_proc function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the run_maintenance_proc function of the pg_partman extension and the pg_cron extension, which initiates an internal scheduler. The pg_cron scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the events table example created in Enabling the pg_partman extension (p. 1718) to set partition maintenance operations to run automatically. As a prerequisite, add pg_cron to the shared_preload_libraries parameter in the DB instance's parameter group.

```sql
CREATE EXTENSION pg_cron;
UPDATE partman.part_config
SET infinite_time_partitions = true,
    retention = '3 months',
    retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add pg_cron to the shared_preload_libraries parameter value. This change requires a DB instance restart for it to take effect. For more information, see Modifying parameters in a DB parameter group (p. 282).
2. Run the command `CREATE EXTENSION pg_cron;` using an account that has the rds_superuser permissions. Doing this enables the pg_cron extension. For more information, see Scheduling maintenance with the PostgreSQL pg_cron extension (p. 1723).
3. Run the command `UPDATE partman.part_config` to adjust the pg_partman settings for the `data_mart.events` table.
4. Run the command `SET ...` to configure the `data_mart.events` table, with these clauses:
   a. `infinite_time_partitions = true`, – Configures the table to be able to automatically create new partitions without any limit.
   b. `retention = '3 months'`, – Configures the table to have a maximum retention of three months.
   c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.
5. Run the command `SELECT cron.schedule ...` to make a pg_cron function call. This call defines how often the scheduler runs the pg_partman maintenance procedure, partman.run_maintenance_proc. For this example, the procedure runs every hour.

For a complete description of the run_maintenance_proc function, see Maintenance Functions in the pg_partman documentation.
Logging at the session and object level with the pgaudit extension

You can log activity at the session level or at the object level by installing the pgaudit extension on your RDS for PostgreSQL DB instance. This extension is supported for all available RDS for PostgreSQL versions. It uses the underlying native PostgreSQL logging mechanism.

To learn more about the pgaudit extension, see pgAudit on GitHub.

With session auditing, you can log audit events from various sources and include the fully qualified command text when available. Modify the custom parameter group that is associated with your DB instance so that shared_preload_libraries contains pgaudit. Then set the pgaudit.log parameter to log any of the following types of events:

- **READ** – Logs SELECT and COPY when the source is a relation or a query.
- **WRITE** – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation.
- **FUNCTION** – Logs function calls and DO blocks.
- **ROLE** – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- **DDL** – Logs all data definition language (DDL) statements that aren’t included in the ROLE class.
- **MISC** – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set pgaudit.log to ALL. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for READ operations on a specific number of tables.

To use the pgaudit extension, add it to the shared_preload_libraries parameter on the RDS for PostgreSQL DB instance. You can’t edit values in the default DB parameter groups, so that means you need to use a custom DB parameter group for the DB instance. For more information about parameter groups, see Working with parameter groups (p. 278).

To use object auditing with the pgaudit extension

1. Create a database role called rds_pgaudit using the following command.

   ```bash
   CREATE ROLE rds_pgaudit;
   ```

2. Modify the DB custom parameter group that is associated with your DB instance as follows:
   a. Add pgaudit to the shared_preload_libraries parameter list. Using the AWS CLI, run the following.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-reboot" \
   --region aws-region
   ```
   b. Set pgaudit.role to the role rds_pgaudit. Using the AWS CLI, run the following.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   ```
3. Reboot the DB instance so that the changes to the parameter group take effect.

```bash
aws rds reboot-db-instance
   --db-instance-identifier your-RDS-db-instance
   --region aws-region
```

4. Run the following command to confirm that pgaudit has been initialized.

```sql
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

5. Run the following command to create the pgaudit extension.

```sql
CREATE EXTENSION pgaudit;
```

6. Run the following command to confirm pgaudit.role is set to rds_pgaudit.

```sql
SHOW pgaudit.role;
pгаudit.role
------------------
rds_pgaudit
```

To test the pgaudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```sql
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
id
----
(0 rows)
```

The database logs should contain an entry similar to the following.

```
2017-06-12 19:09:49 UTC:...:rds_test@postgres:[11701]:LOG: AUDIT: OBJECT,1,1,READ,SELECT,TABLE,public.t1,select * from t1;
...```

For information on viewing the logs, see Monitoring Amazon RDS log files (p. 646).
Scheduling maintenance with the PostgreSQL pg_cron extension

You can use the PostgreSQL pg_cron extension to schedule maintenance commands within a PostgreSQL database. For a complete description, see What is pg_cron? in the pg_cron documentation.

The pg_cron extension is supported on RDS for PostgreSQL engine versions 12.5 and higher.

Topics
- Enabling the pg_cron extension (p. 1723)
- Granting permissions to pg_cron (p. 1723)
- Scheduling pg_cron jobs (p. 1724)
- pg_cron reference (p. 1726)

Enabling the pg_cron extension

Enable the pg_cron extension as follows:

1. Modify the parameter group associated with your PostgreSQL DB instance and add pg_cron to the shared_preload_libraries parameter value. This change requires a PostgreSQL DB instance restart to take effect. For more information, see Modifying parameters in a DB parameter group (p. 282).

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has rds_superuser permissions. For example, if you used the default settings when you created your RDS for PostgreSQL DB instance, connect as user postgres and create the extension.

```
CREATE EXTENSION pg_cron;
```

The pg_cron scheduler is set in the default PostgreSQL database named postgres. The pg_cron objects are created in this postgres database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than postgres (p. 1726).

Granting permissions to pg_cron

As the rds_superuser role, you can create the pg_cron extension and then grant permissions to other users. For other users to be able to schedule jobs, grant them permissions to objects in the cron schema.

**Important**

We recommend that you grant access to the cron schema sparingly.

To grant others permission to the cron schema, run the following command.

```
postgres=> GRANT USAGE ON SCHEMA cron TO other-user;
```

This permission provides other-user with access to the cron schema to schedule and unschedule cron jobs. However, for the cron jobs to run successfully, the user also needs permission to access the objects in the cron jobs. If the user doesn't have permission, the job fails and errors such as the following appears in the postgresql.log. In this example, the user doesn't have permission to access the pgbench_accounts table.
Scheduling maintenance with the pg_cron extension

- **2020-12-08 16:41:00 UTC:** ERROR: permission denied for table pgbench_accounts
- **2020-12-08 16:41:00 UTC:** STATEMENT: update pgbench_accounts set abalance = abalance + 1
- **2020-12-08 16:41:00 UTC:** LOG: background worker "pg_cron" (PID 30647) exited with exit code 1

Other messages in the cron.job_run_details table appear like the following.

```
postgres=# SELECT jobid, username, status, return_message, start_time FROM cron.job_run_details WHERE status = 'failed';
jobid | username | status   | return_message                              | start_time
-------+----------+----------+----------------------------------------------+-----------------------
   143 | unprivuser | failed   | ERROR: permission denied for table pgbench_accounts | 2020-12-08 16:41:00.036268+00
   143 | unprivuser | failed   | ERROR: permission denied for table pgbench_accounts | 2020-12-08 16:40:00.050844+00
   143 | unprivuser | failed   | ERROR: permission denied for table pgbench_accounts | 2020-12-08 16:42:00.175644+00
   143 | unprivuser | failed   | ERROR: permission denied for table pgbench_accounts | 2020-12-08 16:43:00.069174+00
   143 | unprivuser | failed   | ERROR: permission denied for table pgbench_accounts | 2020-12-08 16:44:00.059466+00
(5 rows)
```

For more information, see The pg_cron tables (p. 1728).

### Scheduling pg_cron jobs

The following sections show how you can schedule various management tasks using pg_cron jobs.

**Note**

When creating pg_cron jobs, make sure that the number of max_worker_processes is always greater than the number of cron.max_running_jobs. A pg_cron job will fail if it runs out of background worker processes. The default number of pg_cron jobs is 5; for more information, see The pg_cron parameters (p. 1726).

**Topics**

- Vacuuming a table (p. 1724)
- Purging the pg_cron history table (p. 1725)
- Disabling logging of pg_cron history (p. 1725)
- Scheduling a cron job for a database other than postgres (p. 1726)

### Vacuuming a table

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

See also, Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL (p. 1694).

Following is an example of using the cron.schedule function to set up a job to use VACUUM FREEZE on a specific table every day at 22:00 (GMT).

```
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
```
After the preceding example runs, you can check the history in the `cron.job_run_details` table as follows.

```sql
postgres=> SELECT * FROM cron.job_run_details;
```

```
jobid | runid | job_pid | database | username | command | status | return_message |
start_time | end_time
-------+-------+---------+----------+----------+----------------------------------------
1 | 1 | 3395 | postgres | adminuser| vacuum freeze pgbench_accounts | succeeded | VACUUM |
2020-12-04 21:10:00.050386+00 | 2020-12-04 21:10:00.072028+00
```

(1 row)

Following is an example of viewing the history in the `cron.job_run_details` table to investigate why a job failed.

```sql
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
```

```
jobid | runid | job_pid | database | username | command | status | return_message |
start_time | end_time
-------+-------+---------+----------+----------+----------------------------------------
5 | 4 | 30339 | postgres | adminuser| vacuum freeze pgbench_account | failed | ERROR: relation "pgbench_account" does not exist | 2020-12-04 21:48:00.015145+00 | 2020-12-04 21:48:00.029567+00
```

(1 row)

For more information, see The pg_cron tables (p. 1728).

### Purging the pg_cron history table

The `cron.job_run_details` table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the `cron.schedule` (p. 1727) function to schedule a job that runs every day at midnight to purge the `cron.job_run_details` table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```sql
SELECT cron.schedule('0 0 * * *', $$DELETE FROM cron.job_run_details WHERE end_time < now() - interval '7 days$$);
```

For more information, see The pg_cron tables (p. 1728).

### Disabling logging of pg_cron history

To completely disable writing anything to the `cron.job_run_details` table, modify the parameter group associated with the PostgreSQL DB instance and set the `cron.log_run` parameter to off. If you do this, the `pg_cron` extension no longer writes to the table and produces errors only in the `postgresql.log` file. For more information, see Modifying parameters in a DB parameter group (p. 282).

Use the following command to check the value of the `cron.log_run` parameter.
Scheduling maintenance with the pg_cron extension

postgres=> SHOW cron.log_run;

For more information, see The pg_cron parameters (p. 1726).

Scheduling a cron job for a database other than postgres

The metadata for pg_cron is all held in the PostgreSQL default database named postgres. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the cron.schedule (p. 1727).

   postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum freeze test_table');

2. As a user with the rds_superuser role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

   postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;

3. Verify by querying the cron.job table.

   postgres=> SELECT * FROM cron.job;
   jobid | schedule | command | nodename | nodeport | database | username | active | jobname
   -------+-------------+----------------------------------------+-----------+----------+-----------+-----------+--------+-------------------------
   106 | 29 03 * * * | vacuum freeze test_table | localhost | 8192 | database1 | adminuser | t | database1 manual vacuum
   1 | 59 23 * * * | vacuum freeze pgbench_accounts | localhost | 8192 | postgres | adminuser | t | manual vacuum
   (2 rows)

Note

In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (postgres) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

pg_cron reference

You can use the following parameters, functions, and tables with the pg_cron extension. For more information, see What is pg_cron? in the pg_cron documentation.

Topics

- The pg_cron parameters (p. 1726)
- The cron.schedule() function (p. 1727)
- The cron.unschedule() function (p. 1728)
- The pg_cron tables (p. 1728)

The pg_cron parameters

Following is a list of parameters that control the pg_cron extension behavior.
### Parameter Table

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.database_name</td>
<td>The database in which pg_cron metadata is kept.</td>
</tr>
<tr>
<td>cron.host</td>
<td>The hostname to connect to PostgreSQL. You can't modify this value.</td>
</tr>
<tr>
<td>cron.log_run</td>
<td>Log all the jobs that run into the job_run_details table. Values are on or off. For more information, see The pg_cron tables (p. 1728).</td>
</tr>
<tr>
<td>cron.log_statement</td>
<td>Log all cron statements before running them. Values are on or off.</td>
</tr>
<tr>
<td>cron.max_running_jobs</td>
<td>The maximum number of jobs that can run concurrently.</td>
</tr>
<tr>
<td>cron.use_background_workers</td>
<td>Use background workers instead of client sessions. You can't modify this value.</td>
</tr>
</tbody>
</table>

Use the following SQL command to display these parameters and their values.

```
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%' ORDER BY name;
```

### The cron.schedule() function

This function schedules a cron job. The job is initially scheduled in the default postgres database. The function returns a bigint value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than postgres (p. 1726).

The function has two syntax formats.

**Syntax**

```
cron.schedule (job_name, schedule, command);
cron.schedule (schedule, command);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the cron job.</td>
</tr>
<tr>
<td>schedule</td>
<td>Text indicating the schedule for the cron job. The format is the standard cron format.</td>
</tr>
<tr>
<td>command</td>
<td>Text of the command to run.</td>
</tr>
</tbody>
</table>
Examples

```
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');
schedule
--------
    145
(1 row)
postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
schedule
--------
     146
(1 row)
```

The cron.unschedule() function

This function deletes a cron job. You can either pass in the job_name or the job_id. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

**Syntax**

```
cron.unschedule (job_id);
cron.unschedule (job_name);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_id</td>
<td>A job identifier that was returned from the cron.schedule function when the cron job was scheduled.</td>
</tr>
<tr>
<td>job_name</td>
<td>The name of a cron job that was scheduled with the cron.schedule function.</td>
</tr>
</tbody>
</table>

Examples

```
postgres=> SELECT cron.unschedule(108);
unschedule
---------
   t
(1 row)
postgres=> SELECT cron.unschedule('test');
unschedule
---------
   t
(1 row)
```

The pg_cron tables

The following tables are used to schedule the cron jobs and record how the jobs completed.
### Table: `cron.job`

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cron.job</code></td>
<td>Contains the metadata about each scheduled job. Most interactions with this table should be done by using the <code>cron.schedule</code> and <code>cron.unschedule</code> functions.</td>
</tr>
<tr>
<td><strong>Important</strong></td>
<td>We recommend that you don't give update or insert privileges directly to this table. Doing so would allow the user to update the <code>username</code> column to run as <code>rds-superuser</code>.</td>
</tr>
</tbody>
</table>

### Table: `cron.job_run_details`

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cron.job_run_details</code></td>
<td>Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To prevent this table from growing indefinitely, purge it on a regular basis. For an example, see Purging the <code>pg_cron</code> history table (p. 1725).</td>
</tr>
</tbody>
</table>
Reducing bloat in tables and indexes with the pg_repack extension

You can use the pg_repack extension to remove bloat from tables and indexes. This extension is supported on RDS for PostgreSQL versions 9.6.3 and higher. For more information on the pg_repack extension, see the GitHub project documentation.

To use the pg_repack extension

1. Install the pg_repack extension on your RDS for PostgreSQL DB instance by running the following command.

    ```sql
    CREATE EXTENSION pg_repack;
    ```

2. Run the following commands to grant write access to repack temporary log tables created by pg_repack.

    ```sql
    ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT INSERT ON TABLES TO PUBLIC;
    ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT USAGE, SELECT ON SEQUENCES TO PUBLIC;
    ```

3. Connect to the database using the pg_repack client utility. Use an account that has rds_superuser privileges. As an example, assume that rds_test role has rds_superuser privileges. The command syntax is shown following.

    ```bash
    pg_repack -h db-instance-name.111122233333.aws-region.rds.amazonaws.com -U rds_test -k postgres
    ```

    Connect using the -k option. The -a option is not supported.

4. The response from the pg_repack client provides information on the tables on the DB instance that are repacked.

    ```txt
    INFO: repacking table "pgbench_tellers"
    INFO: repacking table "pgbench_accounts"
    INFO: repacking table "pgbench_branches"
    ```
Upgrading and using the PLV8 extension

PLV8 is a trusted Javascript language extension for PostgreSQL. You can use it for stored procedures, triggers, and other procedural code that's callable from SQL. This language extension is supported by all current releases of PostgreSQL.

If you use PLV8 and upgrade PostgreSQL to a new PLV8 version, you immediately take advantage of the new extension. Take the following steps to synchronize your catalog metadata with the new version of PLV8. These steps are optional, but we highly recommend that you complete them to avoid metadata mismatch warnings.

The upgrade process drops all your existing PLV8 functions. Thus, we recommend that you create a snapshot of your RDS for PostgreSQL DB instance before upgrading. For more information, see Creating a DB snapshot (p. 428).

To synchronize your catalog metadata with a new version of PLV8

1. Verify that you need to update. To do this, run the following command while connected to your instance.

   ```sql
   SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
   ```

   If your results contain values for an installed version that is a lower number than the default version, continue with this procedure to update your extensions. For example, the following result set indicates that you should update.

<table>
<thead>
<tr>
<th>name</th>
<th>default_version</th>
<th>installed_version</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>plls</td>
<td>2.1.0</td>
<td>1.5.3</td>
<td>PL/LiveScript (v8) trusted procedural language</td>
</tr>
<tr>
<td>plcoffee</td>
<td>2.1.0</td>
<td>1.5.3</td>
<td>PL/CoffeeScript (v8) trusted procedural language</td>
</tr>
<tr>
<td>plv8</td>
<td>2.1.0</td>
<td>1.5.3</td>
<td>PL/JavaScript (v8) trusted procedural language</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. Create a snapshot of your RDS for PostgreSQL DB instance if you haven't done so yet. You can continue with the following steps while the snapshot is being created.

3. Get a count of the number of PLV8 functions in your DB instance so you can validate that they are all in place after the upgrade. For example, the following SQL query returns the number of functions written in plv8, plcoffee, and plls.

   ```sql
   SELECT proname, nspname, lanname
   FROM pg_proc p, pg_language l, pg_namespace n
   WHERE p.prolang = l.oid
   AND n.oid = p.pronamespace
   AND lanname IN ('plv8','plcoffee','plls');
   ```

4. Use pg_dump to create a schema-only dump file. For example, create a file on your client machine in the /tmp directory.

   ```sh
   ./pg_dump -Fc --schema-only -U master postgres >/tmp/test.dmp
   ```

   This example uses the following options:

   - `-Fc` – Custom format
- `--schema-only` – Dump only the commands necessary to create schema (functions in this case)
- `-U` – The RDS master user name
- `database` – The database name for our DB instance

For more information on pg_dump, see `pg_dump` in the PostgreSQL documentation.

5. Extract the "CREATE FUNCTION" DDL statement that is present in the dump file. The following example uses the `grep` command to extract the DDL statement that creates the functions and save them to a file. You use this in subsequent steps to recreate the functions.

```
./pg_restore -l /tmp/test.dmp | grep FUNCTION > /tmp/function_list/
```

For more information on pg_restore, see `pg_restore` in the PostgreSQL documentation.

6. Drop the functions and extensions. The following example drops any PLV8 based objects. The cascade option ensures that any dependent are dropped.

```
DROP EXTENSION plv8 CASCADE;
```

If your PostgreSQL instance contains objects based on plcoffee or plls, repeat this step for those extensions.

7. Create the extensions. The following example creates the plv8, plcoffee, and plls extensions.

```
CREATE EXTENSION plv8;
CREATE EXTENSION plcoffee;
CREATE EXTENSION plls;
```

8. Create the functions using the dump file and "driver" file.

The following example recreates the functions that you extracted previously.

```
./pg_restore -U master -d postgres -Fc -L /tmp/function_list /tmp/test.dmp
```

9. Verify that all your functions have been recreated by using the following query.

```
SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
```

The PLV8 version 2 adds the following extra row to your result set:

```
<table>
<thead>
<tr>
<th>proname</th>
<th>nsname</th>
<th>lanname</th>
</tr>
</thead>
<tbody>
<tr>
<td>plv8_version</td>
<td>pg_catalog</td>
<td>plv8</td>
</tr>
</tbody>
</table>
```
Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see PostGIS.net.

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.

Before you can use the PostGIS extension, you need to perform some setup. The following list shows what you need to do. Each step is described in greater detail later in this section.

**Topics**
- Step 1: Connect to the DB instance using the user name used to create the DB instance (p. 1733)
- Step 2: Load the PostGIS extensions (p. 1733)
- Step 3: Transfer ownership of the extensions to the rds_superuser role (p. 1734)
- Step 4: Transfer ownership of the objects to the rds_superuser role (p. 1734)
- Step 5: Test the extensions (p. 1735)
- Step 6: Update the PostGIS extension (p. 1735)
- PostGIS extension versions (p. 1736)

**Step 1: Connect to the DB instance using the user name used to create the DB instance**

First, you connect to the DB instance using the user name that was used to create the DB instance. That name is automatically assigned the rds_superuser role. You need the rds_superuser role to do the remaining steps.

The following example uses SELECT to show you the current user. In this case, the current user should be the user name you chose when creating the DB instance.

```
SELECT CURRENT_USER;
```

```sql
  current_user
  -------------
  myawsuser
  (1 row)
```

**Step 2: Load the PostGIS extensions**

Use CREATE EXTENSION statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;
CREATE EXTENSION fuzzystrmatch;
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION postgis_topology;
```

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.
SELECT n.nspname AS "Name",
    pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;

List of schemas

<table>
<thead>
<tr>
<th>Name</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>myawsuser</td>
</tr>
<tr>
<td>tiger</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>tiger_data</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>topology</td>
<td>rdsadmin</td>
</tr>
</tbody>
</table>

(4 rows)

If you use the psql command line, you can get the same information by running the \dn metacommand.

**Note**

Extra extensions aren't required for some use cases.

### Step 3: Transfer ownership of the extensions to the rds_superuser role

Use the ALTER SCHEMA statements to transfer ownership of the schemas to the rds_superuser role.

```
ALTER SCHEMA tiger OWNER TO rds_superuser;
ALTER SCHEMA tiger_data OWNER TO rds_superuser;
ALTER SCHEMA topology OWNER TO rds_superuser;
```

If you want to confirm the ownership change, you can run the following SQL query. Or you can use the \dn metacommand from the psql command line.

```
SELECT n.nspname AS "Name",
    pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;

List of schemas

<table>
<thead>
<tr>
<th>Name</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>myawsuser</td>
</tr>
<tr>
<td>tiger</td>
<td>rds_superuser</td>
</tr>
<tr>
<td>tiger_data</td>
<td>rds_superuser</td>
</tr>
<tr>
<td>topology</td>
<td>rds_superuser</td>
</tr>
</tbody>
</table>

(4 rows)
```

### Step 4: Transfer ownership of the objects to the rds_superuser role

Use the following function to transfer ownership of the PostGIS objects to the rds_superuser role.

Run the following statement from the psql prompt to create the function.

```
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $$
BEGIN EXECUTE $1;
RETURN $1; END; $$;
```
Next, run the following query to run the `exec` function that in turn runs the statements and alters the permissions.

```sql
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname) || ' OWNER TO rds_superuser;')
FROM (SELECT nsname, relname FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
    WHERE nsname in ('tiger','topology') AND relkind IN ('r','S','v') ORDER BY relkind = 'S') s;
```

### Step 5: Test the extensions

Add `tiger` to your search path using the following command.

```
SET search_path=public,tiger;
```

Test `tiger` by using the following `SELECT` statement.

```sql
SELECT na.address, na.streetname, na.streettypeabbrev, na.zip FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
```

<table>
<thead>
<tr>
<th>address</th>
<th>streetname</th>
<th>streettypeabbrev</th>
<th>zip</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Devonshire</td>
<td>Pl</td>
<td>02109</td>
</tr>
</tbody>
</table>

Test `topology` by using the following `SELECT` statement.

```sql
SELECT topology.createtopology('my_new_topo',26986,0.5);
```

<table>
<thead>
<tr>
<th>createtopology</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

### Step 6: Update the PostGIS extension

Different versions of PostgreSQL support different versions of the PostGIS extension. You can check to see if an upgrade is available by running the following command. This function is available with PostGIS 2.5.0 and higher versions.

```sql
SELECT PostGIS_Extensions_Upgrade();
```

Depending on the version that you're upgrading from, this function might need to run a second time. The result of the first run of the function determines if an additional upgrade function is needed.

If your application doesn't support the latest PostGIS version, you can still create an older version of PostGIS that is available in your major version as follows.

```sql
CREATE EXTENSION postgis VERSION "2.5.5"
```

If you want to upgrade to a specific PostGIS VERSION from an older version, you can also use the following command.

```sql
ALTER EXTENSION postgis UPDATE TO "2.5.5"
```
PostGIS extension versions

You can list the versions that are available in your release by using the following command.

```
SELECT * from pg_available_extension_versions where name='postgis';
```

You can also find version information in the following sections in the *Amazon RDS for PostgreSQL Release Notes*:

- PostgreSQL version 13 extensions supported on Amazon RDS
- PostgreSQL version 12 extensions supported on Amazon RDS
- PostgreSQL version 11.x extensions supported on Amazon RDS
- PostgreSQL version 10.x extensions supported on Amazon RDS
- PostgreSQL version 9.6.x extensions supported on Amazon RDS
Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the `oracle_fdw` extension allows your RDS for PostgreSQL DB cluster to work with Oracle databases. As another example, by using the PostgreSQL native `postgres_fdw` extension you can access data stored in PostgreSQL DB instances external to your RDS for PostgreSQL DB instance.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

Topics

- Using the `log_fdw` extension to access the DB log using SQL (p. 1737)
- Using the `postgres_fdw` extension to access external data (p. 1738)
- Working with MySQL databases by using the `mysql_fdw` extension (p. 1739)
- Working with Oracle databases by using the `oracle_fdw` extension (p. 1742)
- Working with SQL Server databases by using the `tds_fdw` extension (p. 1745)

Using the `log_fdw` extension to access the DB log using SQL

RDS for PostgreSQL supports the `log_fdw` extension, which you can use to access your database engine log using a SQL interface. You can view the default `stderr` log files that are generated by Amazon RDS. You can also view comma-separated values (CSV) logs and build foreign tables with the data neatly split into several columns. To do so, you first set the `log_destination` parameter to `csvlog` on your RDS for PostgreSQL DB instance. This setting means that you need to be using a custom DB parameter group for the instance. To learn how, see Working with parameters on your RDS for PostgreSQL DB instance (p. 1704).

The `log_fdw` extension provides two functions that make it easy to create foreign tables for database logs:

- `list_postgres_log_files` – Lists the files in the database log directory and the file size in bytes.
- `create_foreign_table_for_log_file` (table_name text, server_name text, log_file_name text) – Builds a foreign table for the specified file in the current database.

All functions created by `log_fdw` are owned by `rds_superuser`. Members of the `rds_superuser` role can grant access to these functions to other database users.

The following example shows how to use the `log_fdw` extension with an RDS for PostgreSQL DB instance with the `log_destination` parameter set to `csvlog`.

To use the `log_fdw` extension

1. Get the `log_fdw` extension.

   ```sql
   postgres=> CREATE EXTENSION log_fdw;
   ```

2. Create the log server as a foreign data wrapper.

   ```sql
   postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;
   ```
CREATE SERVER

3. Select all from a list of log files.

postgres=> SELECT * from list_postgres_log_files() ORDER BY 1;

A sample response is as follows.

<table>
<thead>
<tr>
<th>file_name</th>
<th>file_size_bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgresql.log.2016-08-09-22.csv</td>
<td>1111</td>
</tr>
<tr>
<td>postgresql.log.2016-08-09-23.csv</td>
<td>1172</td>
</tr>
<tr>
<td>postgresql.log.2016-08-10-00.csv</td>
<td>1744</td>
</tr>
<tr>
<td>postgresql.log.2016-08-10-01.csv</td>
<td>1102</td>
</tr>
</tbody>
</table>
(4 rows)

4. Create a table with a single 'log_entry' column for the selected file.

postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log', 'log_server', 'postgresql.log.2016-08-09-22.csv');

The response provides no detail other than that the table now exists.

(1 row)

5. Select a sample of the log file. The following code retrieves the log time and error message description.

postgres=> SELECT log_time, message from my_postgres_error_log ORDER BY 1;

A sample response is as follows.

<table>
<thead>
<tr>
<th>log_time</th>
<th>message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tue Aug 09 15:45:18.172 2016 PDT</td>
<td>ending log output to stderr</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.175 2016 PDT</td>
<td>database system was interrupted; last known up at 2016-08-09 22:43:34 UTC</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>checkpoint record is at 0/90002E0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.225 2016 PDT</td>
<td>redo record is at 0/90002A8; shutdown FALSE</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>next transaction ID: 0/1879; next OID: 24578</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>next MultiXactId: 1; next MultiXactOffset: 0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2016 PDT</td>
<td>oldest unfrozen transaction ID: 1822, in database 1</td>
</tr>
</tbody>
</table>
(7 rows)

Using the postgres_fdw extension to access external data

You can access data in a table on a remote database server with the postgres_fdw extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.

To use postgres_fdw to access a remote database server

1. Install the postgres_fdw extension.
CREATE EXTENSION postgres_fdw;

2. Create a foreign data server using CREATE SERVER.

```sql
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');
```

3. Create a user mapping to identify the role to be used on the remote server.

```sql
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

4. Create a table that maps to the table on the remote server.

```sql
CREATE FOREIGN TABLE foreign_table (
  id integer NOT NULL,
  data text
) SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

## Working with MySQL databases by using the mysql_fdw extension

To access a MySQL-compatible database from your RDS for PostgreSQL DB instance, you can install and use the `mysql_fdw` extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from RDS for PostgreSQL to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see Using encryption in transit with the extension (p. 1741).

The `mysql_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

### Topics
- Setting up your RDS for PostgreSQL DB to use the `mysql_fdw` extension (p. 1739)
- Example: Working with an RDS for MySQL database from RDS for PostgreSQL (p. 1740)
- Using encryption in transit with the extension (p. 1741)

### Setting up your RDS for PostgreSQL DB to use the `mysql_fdw` extension

Setting up the `mysql_fdw` extension on your RDS for PostgreSQL DB instance involves loading the extension in your DB instance and then creating the connection point to the MySQL DB instance. For that task, you need to have the following details about the MySQL DB instance:

- Hostname or endpoint. For an RDS for MySQL DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for MySQL is 3306.
- Name of the database. The DB identifier.
You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the RDS for PostgreSQL DB instance and the RDS for MySQL DB instance need access to port 3306. If access isn't configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the rds_superuser account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

**To use mysql_fdw to access a MySQL database server**

1. Connect to your PostgreSQL DB instance using an account that has the rds_superuser role. If you accepted the defaults when you created your RDS for PostgreSQL DB instance, the user name is postgres, and you can connect using the psql command line tool as follows:

```
psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

2. Install the mysql_fdw extension as follows:

```
postgres=> CREATE EXTENSION mysql_fdw;
```

After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server that provides the connection to a MySQL database.

**To create the foreign server**

Perform these tasks on the RDS for PostgreSQL DB instance. The steps assume that you're connected as a user with rds_superuser privileges, such as postgres.

1. Create a foreign server in the RDS for PostgreSQL DB instance:

```
postgres=> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'dbname.11112223333.aws-region.rds.amazonaws.com', port '3306');
```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the rds_superuser role.

```
postgres=> GRANT USAGE ON FOREIGN SERVER mysql-db to user1;
```

PostgreSQL users create and manage their own connections to the MySQL database through the foreign server.

**Example: Working with an RDS for MySQL database from RDS for PostgreSQL**

Suppose that you have a simple table on an RDS for MySQL DB instance. Your RDS for PostgreSQL users want to query (SELECT), INSERT, UPDATE, and DELETE items on that table. Assume that the mysql_fdw extension was created on your RDS for PostgreSQL DB instance, as detailed in the preceding procedure.
After you connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges, you can proceed with the following steps.

1. On the RDS for PostgreSQL DB instance, create a foreign server:
   
   ```sql
   test=> CREATE SERVER mysqldb FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'your-DB.aws-region.rds.amazonaws.com', port '3306');
   CREATE SERVER
   ```

2. Grant usage to a user who doesn't have `rds_superuser` permissions, for example, `user1`:
   
   ```sql
   test=> GRANT USAGE ON FOREIGN SERVER mysqldb TO user1;
   GRANT
   ```

3. Connect as `user1`, and then create a mapping to the MySQL user:
   
   ```sql
   test=> CREATE USER MAPPING FOR user1 SERVER mysqldb OPTIONS (username 'myuser', password 'mypassword');
   CREATE USER MAPPING
   ```

4. Create a foreign table linked to the MySQL table:
   
   ```sql
   test=> CREATE FOREIGN TABLE mytab (a int, b text) SERVER mysqldb OPTIONS (dbname 'test', table_name '');
   CREATE FOREIGN TABLE
   ```

5. Run a simple query against the foreign table:
   
   ```sql
   test=> SELECT * FROM mytab;
   a | b
   ---+-------
   1 | apple
   (1 row)
   ```

6. You can add, change, and remove data from the MySQL table. For example:
   
   ```sql
   test=> INSERT INTO mytab values (2, 'mango');
   INSERT 0 1
   Run the SELECT query again to see the results:
   ```
   
   ```sql
   test=> SELECT * FROM mytab ORDER BY 1;
   a | b
   ---+-------
   1 | apple
   2 | mango
   (2 rows)
   ```

**Using encryption in transit with the extension**

The connection to MySQL from RDS for PostgreSQL uses encryption in transit (TLS/SSL) by default. However, the connection falls back to non-encrypted when the client and server configuration differ. You can enforce encryption for all outgoing connections by specifying the `REQUIRE SSL` option on the RDS for MySQL user accounts. This same approach also works for MariaDB and Aurora MySQL user accounts.

For MySQL user accounts configured to `REQUIRE SSL`, the connection attempt fails if a secure connection can't be established.
To enforce encryption for existing MySQL database user accounts, you can use the `ALTER USER` command. The syntax varies, depending on the MySQL version, as shown in the following table. For more information, see `ALTER USER` in MySQL Reference Manual.

<table>
<thead>
<tr>
<th>MySQL 5.7, MySQL 8</th>
<th>MySQL 5.6</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ALTER USER 'user'@'%' REQUIRE SSL;</code></td>
<td><code>GRANT USAGE ON *.* to 'user'@'%' REQUIRE SSL;</code></td>
</tr>
</tbody>
</table>

For more information about the `mysql_fdw` extension, see the `mysql_fdw` documentation.

### Working with Oracle databases by using the `oracle_fdw` extension

To access an Oracle database from your RDS for PostgreSQL DB instance you can install and use the `oracle_fdw` extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the `oracle_fdw` documentation.

The `oracle_fdw` extension is supported on Amazon RDS for PostgreSQL versions 12.7, 13.3, and higher.

#### Topics

- Turning on the `oracle_fdw` extension (p. 1742)
- Example: Using a foreign server linked to an Amazon RDS for Oracle database (p. 1742)
- Working with encryption in transit (p. 1743)
- `pg_user_mapping` and `pg_user_mappings` permissions (p. 1743)

### Turning on the `oracle_fdw` extension

To use the `oracle_fdw` extension, perform the following procedure.

#### To turn on the `oracle_fdw` extension

- Run the following command using an account that has `rds_superuser` permissions.

  ```sql
  CREATE EXTENSION oracle_fdw;
  ```

### Example: Using a foreign server linked to an Amazon RDS for Oracle database

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.

#### To create a foreign server linked to an RDS for Oracle database

1. Note the following on the RDS for Oracle DB instance:
   - Endpoint
   - Port
   - Database name
2. Create a foreign server.

```
CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS ('dbserver '//endpoint:port/DB_name');
```

3. Grant usage to a user who doesn't have rds_superuser privileges, for example user1.

```
GRANT USAGE ON FOREIGN SERVER oradb TO user1;
```

4. Connect as user1, and create a mapping to an Oracle user.

```
CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS ('oracleuser', 'mypassword');
```

5. Create a foreign table linked to an Oracle table.

```
CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS ('MYTABLE');
```

6. Query the foreign table.

```
SELECT * FROM mytab;
a ---
1 (1 row)
```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```

**Working with encryption in transit**

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see About the Values for Negotiating Encryption and Integrity in the Oracle documentation. The client used for oracle_fdw on Amazon RDS is configured with ACCEPTED, meaning that the encryption depends on the Oracle database server configuration.

If your database is on RDS for Oracle, see Oracle native network encryption to configure the encryption.

**pg_user_mapping and pg_user_mappings permissions**

In the following output, you can find roles and permissions mapped to three different example users. Users rdssu1 and rdssu2 are members of the rds_superuser role, and user1 isn't. The example shows how you can use the psql metacommand \\du to list existing roles.

```
\du
```

<table>
<thead>
<tr>
<th>Role name</th>
<th>Attributes</th>
<th>List of roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdssu1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rdssu2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>user1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1743
All users, including users that have rds_superuser privileges, are allowed to view their own user mappings (umoptions) in the pg_user_mappings table. As shown in the following example, when rdssu1 tries to obtain all user mappings, an error is raised even though rdssu1 rds_superuser privileges:

```sql
SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

```sql
SET SESSION AUTHORIZATION rdssu1;
SELECT * FROM pg_user_mappings;
```

| umid  | srvid | srvname | umuser | usename    | umoptions                  |
|-------+-------+---------+--------+------------+----------------------------------|
| 16414 | 16411 | oradb   |  16412 | user1      | {user=oracleuser,password=mypwd}|
| 16423 | 16411 | oradb   |  16421 | rdssu1     | {user=oracleuser,password=mypwd}|
| 16424 | 16411 | oradb   |  16422 | rdssu2     |                                 |

(3 rows)

```sql
SET SESSION AUTHORIZATION rdssu2;
SELECT * FROM pg_user_mappings;
```

| umid  | srvid | srvname | umuser | usename    | umoptions                  |
|-------+-------+---------+--------+------------+----------------------------------|
| 16414 | 16411 | oradb   |  16412 | user1      | {user=oracleuser,password=mypwd}|
| 16423 | 16411 | oradb   |  16421 | rdssu1     |                                 |
| 16424 | 16411 | oradb   |  16422 | rdssu2     | {user=oracleuser,password=mypwd}|

(3 rows)

```sql
SET SESSION AUTHORIZATION user1;
SELECT * FROM pg_user_mappings;
```

| umid  | srvid | srvname | umuser | usename    | umoptions                  |
|-------+-------+---------+--------+------------+----------------------------------|
| 16414 | 16411 | oradb   |  16412 | user1      | {user=oracleuser,password=mypwd}|
| 16423 | 16411 | oradb   |  16421 | rdssu1     |                                 |
| 16424 | 16411 | oradb   |  16422 | rdssu2     |                                 |

(3 rows)

Because of implementation differences between information_schema.pg_user_mappings and pg_catalog.pg_user_mappings, a manually created rds_superuser requires additional permissions to view passwords in pg_catalog.pg_user_mappings.

No additional permissions are required for an rds_superuser to view passwords in information_schema.pg_user_mappings.

Users who don't have the rds_superuser role can view passwords in pg_user_mappings only under the following conditions:

- The current user is the user being mapped and owns the server or holds the USAGE privilege on it.
- The current user is the server owner and the mapping is for PUBLIC.
Working with SQL Server databases by using the tds_fdw extension

You can use the PostgreSQL tds_fdw extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your RDS for PostgreSQL DB instance to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see tds-fdw/tds_fdw documentation on GitHub.

The tds_fdw extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases.

Setting up your RDS for PostgreSQL DB to use the tds_fdw extension

In the following procedures, you can find an example of setting up and using the tds_fdw with an RDS for PostgreSQL DB instance. Before you can connect to a SQL Server database using tds_fdw, you need to get the following details for the instance:

- Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for Microsoft SQL Server is 1433.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the RDS for PostgreSQL DB instance and the RDS for SQL Server DB instance need access to port 1433. If access isn't configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect: Adaptive Server is unavailable or does not exist (mssql2019.aws-region.rds.amazonaws.com), OS #: 0, OS Msg: Success, Level: 9
```

To use tds_fdw to connect to a SQL Server database

1. Connect to your PostgreSQL DB instance using an account that has the rds_superuser role:

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=test --password
   ```

2. Install the tds_fdw extension:

   ```
   test=> CREATE EXTENSION tds_fdw;
   CREATE EXTENSION
   ```

After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server.

To create the foreign server

Perform these tasks on the RDS for PostgreSQL DB instance using an account that has rds_superuser privileges.

1. Create a foreign server in the RDS for PostgreSQL DB instance:
2. Grant permissions to a user who doesn't have `rds_superuser` role privileges, for example, `user1`:

```sql
test=> GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
```

3. Connect as `user1` and create a mapping to a SQL Server user:

```sql
test=> CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username 'sqlserveruser', password 'password');
```

4. Create a foreign table linked to a SQL Server table:

```sql
test=> CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table 'MYTABLE');
```

5. Query the foreign table:

```sql
test=> SELECT * FROM mytab;
a
---
1
(1 row)
```

**Using encryption in transit for the connection**

The connection from RDS for PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the `rds.force_ssl` parameter. To learn how, see [Forcing connections to your DB instance to use SSL](#). For more information about SSL/TLS configuration for RDS for SQL Server, see [Using SSL with a Microsoft SQL Server DB instance](#).
Security in Amazon RDS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon RDS, see AWS services in scope by compliance program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon RDS. The following topics show you how to configure Amazon RDS to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon RDS resources.

You can manage access to your Amazon RDS resources and your databases on a DB instance. The method you use to manage access depends on what type of task the user needs to perform with Amazon RDS:

- Run your DB instance in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB instance in a VPC, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon RDS resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB instances, tag resources, or modify security groups.

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB instance. When you first create a DB instance, its firewall prevents any database access except through rules specified by an associated security group.

- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB instances running the MySQL, MariaDB, PostgreSQL, Oracle, or Microsoft SQL Server database engines. For more information on using SSL/TLS with a DB instance, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

- Use Amazon RDS encryption to secure your DB instances and snapshots at rest. Amazon RDS encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB instance. For more information, see Encrypting Amazon RDS resources (p. 1750).

- Use network encryption and transparent data encryption with Oracle DB instances; for more information, see Oracle native network encryption (p. 1503) and Oracle Transparent Data Encryption (p. 1542)

- Use the security features of your DB engine to control who can log in to the databases on a DB instance. These features work just as if the database was on your local network.

**Note**

You only have to configure security for your use cases. You don’t have to configure security access for processes that Amazon RDS manages. These include creating backups, replicating data between a primary DB instance and a read replica, and other processes.
Database authentication with Amazon RDS

Amazon RDS supports several ways to authenticate database users.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

Password authentication

With *password authentication*, your DB instance performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER name IDENTIFIED BY password`, while in PostgreSQL, the statement is `CREATE USER name WITH PASSWORD password`.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because
clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon RDS, see Creating a basic secret and Rotating secrets for supported Amazon RDS databases in the AWS Secrets Manager User Guide. For information about programmatically retrieving your secrets in your custom applications, see Retrieving the secret value in the AWS Secrets Manager User Guide.

IAM database authentication

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MySQL and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786).

Kerberos authentication

Amazon RDS supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon RDS support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB instances.

You can enable your database users to authenticate against DB instances in two ways. They can use credentials stored either in AWS Directory Service for Microsoft Active Directory or in your on-premises Active Directory.

Microsoft SQL Server, MySQL, and PostgreSQL DB instances support one- and two-way forest trust relationships. Oracle DB instances support one- and two-way external and forest trust relationships. For more information, see When to create a trust relationship in the AWS Directory Service Administration Guide.

For information about Kerberos authentication with a specific DB engine, see the following:

- Using Windows Authentication with an Amazon RDS for SQL Server DB instance (p. 1004)
- Using Kerberos authentication for MySQL (p. 1250)
- Configuring Kerberos authentication for Amazon RDS for Oracle (p. 1325)
- Using Kerberos authentication with Amazon RDS for PostgreSQL (p. 1611)

Note
Currently, Kerberos authentication isn't supported for MariaDB DB instances.

Data protection in Amazon RDS

The AWS shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the
AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing personal data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form fields such as a Name field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Topics
- Protecting data using encryption (p. 1750)
- Internetwork traffic privacy (p. 1765)

Protecting data using encryption

You can enable encryption for database resources. You can also encrypt connections to DB instances.

Topics
- Encrypting Amazon RDS resources (p. 1750)
- AWS KMS key management (p. 1754)
- Using SSL/TLS to encrypt a connection to a DB instance (p. 1755)
- Rotating your SSL/TLS certificate (p. 1757)

Encrypting Amazon RDS resources

Amazon RDS can encrypt your Amazon RDS DB instances. Data that is encrypted at rest includes the underlying storage for DB instances, its automated backups, read replicas, and snapshots.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

Note
For encrypted and unencrypted DB instances, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.
Topics
- Overview of encrypting Amazon RDS resources (p. 1751)
- Encrypting a DB instance (p. 1751)
- Determining whether encryption is turned on for a DB instance (p. 1752)
- Availability of Amazon RDS encryption (p. 1753)
- Limitations of Amazon RDS encrypted DB instances (p. 1753)

Overview of encrypting Amazon RDS resources

Amazon RDS encrypted DB instances provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon RDS encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

Amazon RDS also supports encrypting an Oracle or SQL Server DB instance with Transparent Data Encryption (TDE). TDE can be used with encryption at rest, although using TDE and encryption at rest simultaneously might slightly affect the performance of your database. You must manage different keys for each encryption method. For more information on TDE, see Oracle Transparent Data Encryption (p. 1542) or Support for Transparent Data Encryption in SQL Server (p. 1049).

For an Amazon RDS encrypted DB instance, all logs, backups, and snapshots are encrypted. Amazon RDS uses an AWS KMS key to encrypt these resources. For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide. If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

A read replica of an Amazon RDS encrypted instance must be encrypted using the same KMS key as the primary DB instance when both are in the same AWS Region. If the primary DB instance and read replica are in different AWS Regions, you encrypt the read replica using the KMS key for that AWS Region.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon RDS resources, you use the AWS Key Management Service (AWS KMS). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see AWS Service Integration.

Encrypting a DB instance

To encrypt a new DB instance, choose Enable encryption on the Amazon RDS console. For information on creating a DB instance, see Creating an Amazon RDS DB instance (p. 175).

If you use the create-db-instance AWS CLI command to create an encrypted DB instance, set the --storage-encrypted parameter. If you use the CreateDBInstance API operation, set the StorageEncrypted parameter to true.

When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don't specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

Once you have created an encrypted DB instance, you can't change the KMS key used by that DB instance. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB instance.
If you use the AWS CLI `create-db-instance` command to create an encrypted DB instance with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

**Important**
Amazon RDS can lose access to the KMS key for a DB instance. For example, RDS loses access when the KMS key is disabled, or when RDS access to a KMS key is revoked. In these cases, the encrypted DB instance goes into `inaccessible-encryption-credentials-recoverable` state. The DB instance remains in this state for seven days. When you start the DB instance during that time, it checks if the KMS key is active and recovers the DB instance if it is. Restart the DB instance using the AWS CLI command `start-db-instance`. Currently, you can't start a DB instance in this state using the AWS Management Console.

If the DB instance isn't recovered, then it goes into the terminal `inaccessible-encryption-credentials` state. In this case, you can only restore the DB instance from a backup. We strongly recommend that you always turn on backups for encrypted DB instances to guard against the loss of encrypted data in your databases.

**Determining whether encryption is turned on for a DB instance**

You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB instance.

**Console**

**To determine whether encryption at rest is turned on for a DB instance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to check to view its details.
4. Choose the **Configuration** tab, and check the **Encryption** value under **Storage**.

It shows either **Enabled** or **Not enabled**.
AWS CLI

To determine whether encryption at rest is turned on for a DB instance by using the AWS CLI, call the `describe-db-instances` command with the following option:

- `--db-instance-identifier` – The name of the DB instance.

The following example uses a query to return either `TRUE` or `FALSE` regarding encryption at rest for the `mydb` DB instance.

Example

```
aws rds describe-db-instances --db-instance-identifier mydb --query "[{StorageEncrypted:StorageEncrypted}]" --output text
```

RDS API

To determine whether encryption at rest is turned on for a DB instance by using the Amazon RDS API, call the `DescribeDBInstances` operation with the following parameter:

- `DBInstanceIdentifier` – The name of the DB instance.

Availability of Amazon RDS encryption

Amazon RDS encryption is currently available for all database engines and storage types.

Amazon RDS encryption is available for most DB instance classes. The following table lists DB instance classes that `do not support` Amazon RDS encryption:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Instance class</th>
</tr>
</thead>
<tbody>
<tr>
<td>General purpose (M1)</td>
<td><code>db.m1.small</code></td>
</tr>
<tr>
<td></td>
<td><code>db.m1.medium</code></td>
</tr>
<tr>
<td></td>
<td><code>db.m1.large</code></td>
</tr>
<tr>
<td></td>
<td><code>db.m1.xlarge</code></td>
</tr>
<tr>
<td>Memory optimized (M2)</td>
<td><code>db.m2.xlarge</code></td>
</tr>
<tr>
<td></td>
<td><code>db.m2.2xlarge</code></td>
</tr>
<tr>
<td></td>
<td><code>db.m2.4xlarge</code></td>
</tr>
<tr>
<td>Burstable (T2)</td>
<td><code>db.t2.micro</code></td>
</tr>
</tbody>
</table>

Note

Encryption at rest is not available for DB instances running SQL Server Express Edition.

Limitations of Amazon RDS encrypted DB instances

The following limitations exist for Amazon RDS encrypted DB instances:

- You can only encrypt an Amazon RDS DB instance when you create it, not after the DB instance is created.
However, because you can encrypt a copy of an unencrypted snapshot, you can effectively add encryption to an unencrypted DB instance. That is, you can create a snapshot of your DB instance, and then create an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot, and thus you have an encrypted copy of your original DB instance. For more information, see Copying a snapshot (p. 438).

- You can't disable encryption on an encrypted DB instance.
- You can't create an encrypted snapshot of an unencrypted DB instance.
- A snapshot of an encrypted DB instance must be encrypted using the same KMS key as the DB instance.
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
- Encrypted read replicas must be encrypted with the same KMS key as the source DB instance when both are in the same AWS Region.
- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.

- You can't unencrypt an encrypted DB instance. However, you can export data from an encrypted DB instance and import the data into an unencrypted DB instance.

**AWS KMS key management**

Amazon RDS automatically integrates with AWS Key Management Service (AWS KMS) for key management. Amazon RDS uses envelope encryption. For more information about envelope encryption, see Envelope encryption in the AWS Key Management Service Developer Guide.

An AWS KMS key is a logical representation of a key. The KMS key includes metadata, such as the key ID, creation date, description, and key state. The KMS key also contains the key material used to encrypt and decrypt data. For more information about KMS keys, see AWS KMS keys in the AWS Key Management Service Developer Guide.

You can manage KMS keys used for Amazon RDS encrypted DB instances using the AWS Key Management Service (AWS KMS) in the AWS KMS console, the AWS CLI, or the AWS KMS API. If you want full control over a KMS key, then you must create a customer managed key. For more information about customer managed keys, see Customer managed keys in the AWS Key Management Service Developer Guide.

AWS managed keys are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. You can't delete, edit, or rotate AWS managed keys. For more information about AWS managed keys, see AWS managed keys in the AWS Key Management Service Developer Guide.

You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.

You can view audit logs of every action taken with an AWS managed or customer managed key by using AWS CloudTrail.

**Important**

If you disable or revoke permissions to a KMS key used by an RDS database, RDS puts your database into a terminal state when access to the KMS key is required. This change could be
immediate, or deferred, depending on the use case that required access to the KMS key. In this state, the DB instance is no longer available, and the current state of the database can't be recovered. To restore the DB instance, you must re-enable access to the KMS key for RDS, and then restore the DB instance from the latest available backup.

**Authorizing use of a customer managed key**

When RDS uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the RDS resource.

To use the customer managed key for an RDS resource on your behalf, a user must have permissions to call the following operations on the customer managed key:

- `kms:GenerateDataKey`
- `kms:Decrypt`

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

You can make the IAM policy stricter in various ways. For example, to allow the customer managed key to be used only for requests that originate in RDS, you can use the `kms:ViaService condition key` with the `rds.<region>.amazonaws.com` value.

You can also use the keys or values in the encryption context as a condition for using the customer managed key for cryptographic operations.

For more information, see [Allowing users in other accounts to use a KMS key](https://aws.amazon.com/key-manager/) in the *AWS Key Management Service Developer Guide*.

**Using SSL/TLS to encrypt a connection to a DB instance**

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB instance running MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL.

SSL/TLS connections provide one layer of security by encrypting data that moves between your client and a DB instance. Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon RDS DB instance. It does so by checking the server certificate that is automatically installed on all DB instances that you provision.

Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your DB instance, use the link following that corresponds to your DB engine:

- [Using SSL with a MariaDB DB instance](p. 847)
- [Using SSL with a Microsoft SQL Server DB instance](p. 996)
- [Using SSL with a MySQL DB instance](p. 1140)
- [Encrypting client connections with SSL](p. 1322)
- [Using SSL with a PostgreSQL DB instance](p. 1605)

**Note**

All certificates are only available for download using SSL/TLS connections.

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at [https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b](https://truststore.pki.rds.amazonaws.com/global/global-bundle.p7b).
Note
Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using
RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use
RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see Using
TLS/SSL with RDS Proxy (p. 218).

Certificate bundles for AWS Regions
To get a certificate bundle that contains both the intermediate and root certificates for an AWS Region,
download from the link for the AWS Region in the following table.

<table>
<thead>
<tr>
<th>AWS Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1-bundle.pem</td>
<td>us-east-1-bundle.p7b</td>
</tr>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2-bundle.pem</td>
<td>us-east-2-bundle.p7b</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1-bundle.pem</td>
<td>us-west-1-bundle.p7b</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2-bundle.pem</td>
<td>us-west-2-bundle.p7b</td>
</tr>
<tr>
<td>Africa (Cape Town)</td>
<td>af-south-1-bundle.pem</td>
<td>af-south-1-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Hong Kong)</td>
<td>ap-east-1-bundle.pem</td>
<td>ap-east-1-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Jakarta)</td>
<td>ap-southeast-3-bundle.pem</td>
<td>ap-southeast-3-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Mumbai)</td>
<td>ap-south-1-bundle.pem</td>
<td>ap-south-1-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Osaka)</td>
<td>ap-northeast-3-bundle.pem</td>
<td>ap-northeast-3-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Tokyo)</td>
<td>ap-northeast-1-bundle.pem</td>
<td>ap-northeast-1-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Seoul)</td>
<td>ap-northeast-2-bundle.pem</td>
<td>ap-northeast-2-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Singapore)</td>
<td>ap-southeast-1-bundle.pem</td>
<td>ap-southeast-1-bundle.p7b</td>
</tr>
<tr>
<td>Asia Pacific (Sydney)</td>
<td>ap-southeast-2-bundle.pem</td>
<td>ap-southeast-2-bundle.p7b</td>
</tr>
<tr>
<td>Canada (Central)</td>
<td>ca-central-1-bundle.pem</td>
<td>ca-central-1-bundle.p7b</td>
</tr>
<tr>
<td>Europe (Frankfurt)</td>
<td>eu-central-1-bundle.pem</td>
<td>eu-central-1-bundle.p7b</td>
</tr>
<tr>
<td>Europe (Ireland)</td>
<td>eu-west-1-bundle.pem</td>
<td>eu-west-1-bundle.p7b</td>
</tr>
<tr>
<td>Europe (London)</td>
<td>eu-west-2-bundle.pem</td>
<td>eu-west-2-bundle.p7b</td>
</tr>
<tr>
<td>Europe (Milan)</td>
<td>eu-south-1-bundle.pem</td>
<td>eu-south-1-bundle.p7b</td>
</tr>
<tr>
<td>Europe (Paris)</td>
<td>eu-west-3-bundle.pem</td>
<td>eu-west-3-bundle.p7b</td>
</tr>
<tr>
<td>Europe (Stockholm)</td>
<td>eu-north-1-bundle.pem</td>
<td>eu-north-1-bundle.p7b</td>
</tr>
<tr>
<td>Middle East (Bahrain)</td>
<td>me-south-1-bundle.pem</td>
<td>me-south-1-bundle.p7b</td>
</tr>
<tr>
<td>South America (São Paulo)</td>
<td>sa-east-1-bundle.pem</td>
<td>sa-east-1-bundle.p7b</td>
</tr>
</tbody>
</table>
AWS GovCloud (US) certificates

If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle. This bundle contains both the intermediate and root certificates at https://truststore.pki.us-gov-west-1.rds.amazonaws.com/global/global-bundle.p7b.

To get a certificate bundle that contains both the intermediate and root certificates for an AWS GovCloud (US) Region, download from the link for the AWS GovCloud (US) Region in the following table.

<table>
<thead>
<tr>
<th>AWS GovCloud (US) Region</th>
<th>Certificate bundle (PEM)</th>
<th>Certificate bundle (PKCS7)</th>
</tr>
</thead>
</table>

Rotating your SSL/TLS certificate

As of March 5, 2020, Amazon RDS CA-2015 certificates have expired. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances, you require Amazon RDS CA-2019 certificates, which are enabled by default for new DB instances. If you currently do not use SSL/TLS with certificate verification, you might still have expired CA-2015 certificates and must update them to CA-2019 certificates if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Follow these instructions to complete your updates. Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

Note
Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you are using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information about using TLS/SSL with RDS Proxy, see Using TLS/SSL with RDS Proxy (p. 218).

Note
If you are using a Go version 1.15 application with a DB instance that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Run the modify-db-instance command shown in the AWS CLI section using rds-ca-2019 as the CA certificate identifier. In this case, it isn't possible to update the certificate using the AWS Management Console. If you created your DB instance or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

Topics
- Updating your CA certificate by modifying your DB instance (p. 1757)
- Updating your CA certificate by applying DB instance maintenance (p. 1760)
- Sample script for importing certificates into your trust store (p. 1764)

Updating your CA certificate by modifying your DB instance

Complete the following steps to update your CA certificate.
To update your CA certificate by modifying your DB instance

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

2. Update your applications to use the new SSL/TLS certificate.

   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

- Updating applications to connect to MariaDB DB instances using new SSL/TLS certificates (p. 858)
- Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates (p. 954)
- Updating applications to connect to MySQL DB instances using new SSL/TLS certificates (p. 1154)
- Updating applications to use new SSL/TLS certificates (p. 1322)
- Updating applications to use new SSL/TLS certificates (p. 1608)

For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store (p. 1764).

Note

The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB instance, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from rds-ca-2015 to rds-ca-2019.

   Important

   By default, this operation restarts your DB instance. If you don't want to restart your DB instance during this operation, you can use the modify-db-instance CLI command and specify the --no-certificate-rotation-restart option. This option will not rotate the certificate until the next time the database restarts, either for planned or unplanned maintenance. This option is only recommended if you don't use SSL/TLS.

   If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying Apply immediately in the console or by specifying the --apply-immediately option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.

You can use the AWS Management Console or the AWS CLI to change the CA certificate from rds-ca-2015 to rds-ca-2019 for a DB instance.

Console

To change the CA from rds-ca-2015 to rds-ca-2019 for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. In the navigation pane, choose Databases, and then choose the DB instance that you want to modify.

3. Choose Modify.
The **Modify DB Instance** page appears.

4. In the **Connectivity** section, choose `rds-ca-2019`.

5. Choose **Continue** and check the summary of modifications.

6. To apply the changes immediately, choose **Apply immediately**.

   **Important**
   Choosing this option restarts your database immediately.

7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

   **Important**
   When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

   Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

**AWS CLI**

To use the AWS CLI to change the CA from `rds-ca-2015` to `rds-ca-2019` for a DB instance, call the `modify-db-instance` command. Specify the DB instance identifier and the `--ca-certificate-identifier` option.

**Important**
When you schedule this operation, make sure that you have updated your client-side trust store beforehand.
Example

The following code modifies mydbinstance by setting the CA certificate to rds-ca-2019. The changes are applied during the next maintenance window by using --no-apply-immediately. Use --apply-immediately to apply the changes immediately.

**Important**

By default, this operation reboots your DB instance. If you don't want to reboot your DB instance during this operation, you can use the modify-db-instance CLI command and specify the --no-certificate-rotation-restart option.

This option will not rotate the certificate until the next time the database restarts, either for planned or unplanned maintenance. This option is only recommended if you do not use SSL/TLS.

Use --apply-immediately to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --ca-certificate-identifier rds-ca-2019 \
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --ca-certificate-identifier rds-ca-2019 ^
  --no-apply-immediately
```

**Updating your CA certificate by applying DB instance maintenance**

Complete the following steps to update your CA certificate by applying DB instance maintenance.

**To update your CA certificate by applying DB instance maintenance**

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

2. Update your database applications to use the new SSL/TLS certificate.

   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

   For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

   - Updating applications to connect to MariaDB DB instances using new SSL/TLS certificates (p. 858)
   - Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates (p. 954)
   - Updating applications to connect to MySQL DB instances using new SSL/TLS certificates (p. 1154)
   - Updating applications to use new SSL/TLS certificates (p. 1322)
   - Updating applications to use new SSL/TLS certificates (p. 1608)

   For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store (p. 1764).
Note
The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period.

3. Apply DB instance maintenance to change the CA from rds-ca-2015 to rds-ca-2019.

Important
You can choose to apply the change immediately. By default, this operation is scheduled to run during your next maintenance window.

You can use the AWS Management Console to apply DB instance maintenance to change the CA certificate from rds-ca-2015 to rds-ca-2019 for multiple DB instances.

Updating your CA certificate by applying maintenance to multiple DB instances

Use the AWS Management Console to change the CA certificate for multiple DB instances.

To change the CA from rds-ca-2015 to rds-ca-2019 for multiple DB instances

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
   In the navigation pane, there is a Certificate update option that shows the total number of affected DB instances.
Choose **Certificate update** in the navigation pane.

The **Update your Amazon RDS SSL/TLS certificates** page appears.
Note
This page only shows the DB instances for the current AWS Region. If you have DB instances in more than one AWS Region, check this page in each AWS Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing Update at the next maintenance window. Apply the rotation immediately by choosing Update now.

Important
When your CA certificate is rotated, the operation restarts your DB instance. If you experience connectivity issues after certificate expiry, use the Update now option.

4. If you choose Update at the next maintenance window or Update now, you are prompted to confirm the CA certificate rotation.

Important
Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. To determine whether your applications use SSL/TLS and the server certificate to connect, see Step 2: Update Your Database Applications to Use the New SSL/TLS Certificate (p. 1760). After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose Confirm.

5. Repeat steps 3 and 4 for each DB instance that you want to update.
Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see JDK Installation Guide.

Topics
- Sample script for importing certificates on Linux (p. 1764)
- Sample script for importing certificates on macOS (p. 1764)

Sample script for importing certificates on Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```bash
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/ {split_after=1}{print > "rds-ca-" n ".pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do
    alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
    echo "Importing $alias"
    keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -keystore ${truststore} -noprompt
    rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias | cut -d " " -f3- | while read alias
do
    expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)
/) { print "$1\n"; }'`
    echo " Certificate ${alias} expires in '"$expiry'"
done
```

Sample script for importing certificates on macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```bash
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
```

1764
mkdir -p "$mydir"

truststore=$mydir/rds-truststore.jks
storepassword=changeit

global-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-

for CERT in rds-ca-*; do
    alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
    echo "Importing $alias"
    keytool -import -file $CERT -alias "$alias" -storepass $storepassword -keystore
    ${truststore} -noprompt
    rm $CERT
done

done

global-bundle.pem

for CERT in rds-ca-*; do
    alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
    echo "Importing $alias"
    keytool -import -file $CERT -alias "$alias" -storepass $storepassword -keystore
    ${truststore} -noprompt
    rm $CERT
done

echo "Trust store content is: "

echo "Certificate ${alias} expires in '$expiry'"

done

Internetwork traffic privacy

Connections are protected both between Amazon RDS and on-premises applications and between
Amazon RDS and other AWS resources within the same AWS Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

You get access to Amazon RDS through the network by using AWS-published API operations. Clients
must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2. Clients must also support
cipher suites with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic
Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these
modes. Additionally, you must sign requests using an access key identifier and a secret access key that
are associated with an IAM principal. Or you can use the AWS security token service (STS) to generate
temporary security credentials to sign requests.
Identity and access management in Amazon RDS

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

Topics
- Audience (p. 1766)
- Authenticating with identities (p. 1766)
- Managing access using policies (p. 1768)
- How Amazon RDS works with IAM (p. 1769)
- Amazon RDS identity-based policy examples (p. 1772)
- Amazon RDS updates to AWS managed policies (p. 1783)
- Preventing cross-service confused deputy problems (p. 1784)
- IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786)
- Troubleshooting Amazon RDS identity and access (p. 1812)

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon RDS.

Service user – If you use the Amazon RDS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon RDS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon RDS, see Troubleshooting Amazon RDS identity and access (p. 1812).

Service administrator – If you're in charge of Amazon RDS resources at your company, you probably have full access to Amazon RDS. It's your job to determine which Amazon RDS features and resources your employees should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon RDS, see How Amazon RDS works with IAM (p. 1769).

IAM administrator – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to Amazon RDS. To view example Amazon RDS identity-based policies that you can use in IAM, see Amazon RDS identity-based policy examples (p. 1772).

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see The IAM console and sign-in page in the IAM User Guide.

You must be authenticated (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company's single sign-on authentication, or even sign in using Google or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.

To sign in directly to the AWS Management Console, use your password with your root user email or your IAM user name. You can access AWS programmatically using your root user or IAM user access keys. AWS
provides SDK and command line tools to cryptographically sign your request using your credentials. If you don't use AWS tools, you must sign the request yourself. Do this using Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. An IAM user can have long-term credentials such as a user name and password or a set of access keys. To learn how to generate access keys, see Managing access keys for IAM users in the IAM User Guide. When you generate access keys for an IAM user, make sure you view and securely save the key pair. You cannot recover the secret access key in the future. Instead, you must generate a new access key pair.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

You can authenticate to your DB instance using IAM database authentication.

IAM database authentication works with the following DB engines:

- Amazon RDS for MySQL
- Amazon RDS for PostgreSQL

For more information about authenticating to your DB instance using IAM, see IAM database authentication for MariaDB, MySQL, and PostgreSQL (p. 1786).

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:
Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when an entity (root user, IAM user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

An IAM administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (user or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the iam:GetRole action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, role, or group. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that
you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

The following AWS managed policies, which you can attach to users in your account, are specific to Amazon RDS:

- **AmazonRDSReadOnlyAccess** – Grants read-only access to all Amazon RDS resources for the AWS account specified.
- **AmazonRDSFullAccess** – Grants full access to all Amazon RDS resources for the AWS account specified.

**Other policy types**

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.

**Multiple policy types**

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

For more information about identity and access management for Amazon RDS, continue to the following pages:

- How Amazon RDS works with IAM (p. 1769)
- Troubleshooting Amazon RDS identity and access (p. 1812)

**How Amazon RDS works with IAM**

Before you use IAM to manage access to Amazon RDS, you should understand what IAM features are available to use with Amazon RDS. To get a high-level view of how Amazon RDS and other AWS services work with IAM, see AWS services that work with IAM in the IAM User Guide.
Amazon RDS identity-based policies

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. Amazon RDS supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON policy elements reference in the IAM User Guide.

Actions

The Action element of an IAM identity-based policy describes the specific action or actions that will be allowed or denied by the policy. Policy actions usually have the same name as the associated AWS API operation. The action is used in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon RDS use the following prefix before the action: rds:. For example, to grant someone permission to describe DB instances with the Amazon RDS DescribeDBInstances API operation, you include the rds:DescribeDBInstances action in their policy. Policy statements must include either an Action or NotAction element. Amazon RDS defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": [
    "rds:action1",
    "rds:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```
"Action": "rds:Describe*"
```

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

Resources

The Resource element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. You specify a resource using an ARN or using the wildcard (*) to indicate that the statement applies to all resources.

The DB instance resource has the following ARN:

```
arn:${Partition}:rds:${Region}:${Account}:${ResourceType}/${Resource}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and AWS service namespaces.

For example, to specify the dbtest DB instance in your statement, use the following ARN:

To specify all DB instances that belong to a specific account, use the wildcard (*):

"Resource": "arn:aws:rds:us-east-1:123456789012:db:*"

Some RDS API operations, such as those for creating resources, cannot be performed on a specific resource. In those cases, you must use the wildcard (*).

"Resource": "*"

Many Amazon RDS API operations involve multiple resources. For example, CreateDBInstance creates a DB instance. You can specify that an IAM user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

"Resource": ["resource1", "resource2"

To see a list of Amazon RDS resource types and their ARNs, see Resources Defined by Amazon RDS in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

**Condition keys**

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can build conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: Variables and tags in the IAM User Guide.

Amazon RDS defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

All RDS API operations support the aws:RequestedRegion condition key.

To see a list of Amazon RDS condition keys, see Condition Keys for Amazon RDS in the Service Authorization Reference. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon RDS.

**Examples**

To view examples of Amazon RDS identity-based policies, see Amazon RDS identity-based policy examples (p. 1772).

**Amazon RDS resource-based policies**

Amazon RDS does not support resource-based policies.
Authorization based on Amazon RDS tags

You can attach tags to Amazon RDS resources or pass tags in a request to Amazon RDS. To control access based on tags, you provide tag information in the condition element of a policy using the aws:ResourceTag/key-name, aws:RequestTag/key-name, or aws:TagKeys condition keys. For more information, see Controlling access to AWS resources using tags in the IAM User Guide. For more information about tagging Amazon RDS resources, see Specifying conditions: Using custom tags (p. 1779).

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Grant permission for actions on a resource with a specific tag with two different values (p. 1776).

Amazon RDS IAM roles

An IAM role is an entity within your AWS account that has specific permissions.

Using temporary credentials with Amazon RDS

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

Amazon RDS supports using temporary credentials.

Service-linked roles

Service-linked roles allow AWS services to access resources in other services to complete an action on your behalf. Service-linked roles appear in the Roles list in the IAM Management Console and are owned by the service. An IAM administrator can view but not edit the permissions for service-linked roles.

Amazon RDS supports service-linked roles. For details about creating or managing Amazon RDS service-linked roles, see Using service-linked roles for Amazon RDS (p. 1837).

Service roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in the Roles list in the IAM Management Console and are owned by your account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

Amazon RDS supports service roles.

Amazon RDS identity-based policy examples

By default, IAM users and roles don’t have permission to create or modify Amazon RDS resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the IAM User Guide.

Topics

- Policy best practices (p. 1773)
- Using the Amazon RDS console (p. 1773)
Identity-based policy examples

- Allow users to view their own permissions (p. 1774)
- Allow a user to create DB instances in an AWS account (p. 1774)
- Permissions required to use the console (p. 1775)
- Allow a user to perform any describe action on any RDS resource (p. 1776)
- Allow a user to create a DB instance that uses the specified DB parameter group and subnet group (p. 1776)
- Grant permission for actions on a resource with a specific tag with two different values (p. 1776)
- Prevent a user from deleting a DB instance (p. 1777)
- Deny all access to a resource (p. 1777)
- Example policies: Using condition keys (p. 1777)
- Specifying conditions: Using custom tags (p. 1779)

Policy best practices

Identity-based policies are very powerful. They determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get Started Using AWS Managed Policies** – To start using Amazon RDS quickly, use AWS managed policies to give your employees the permissions they need. These policies are already available in your account and are maintained and updated by AWS. For more information, see Get started using permissions with AWS managed policies in the IAM User Guide.

- **Grant Least Privilege** – When you create custom policies, grant only the permissions required to perform a task. Start with a minimum set of permissions and grant additional permissions as necessary. Doing so is more secure than starting with permissions that are too lenient and then trying to tighten them later. For more information, see Grant least privilege in the IAM User Guide.

- **Enable MFA for Sensitive Operations** – For extra security, require IAM users to use multi-factor authentication (MFA) to access sensitive resources or API operations. For more information, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

- **Use Policy Conditions for Extra Security** – To the extent that it's practical, define the conditions under which your identity-based policies allow access to a resource. For example, you can write conditions to specify a range of allowable IP addresses that a request must come from. You can also write conditions to allow requests only within a specified date or time range, or to require the use of SSL or MFA. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

Using the Amazon RDS console

To access the Amazon RDS console, you must have a minimum set of permissions. These permissions must enable you to list and view details about the Amazon RDS resources in your AWS account. You can create an identity-based policy that is more restrictive than the minimum required permissions. However, if you do, the console doesn't function as intended for entities (IAM users or roles) with that policy.

To ensure that those entities can still use the Amazon RDS console, also attach the following AWS managed policy to the entities. For more information, see Adding permissions to a user in the IAM User Guide.

AmazonRDSReadOnlyAccess

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.
Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": [
                "arn:aws:iam::*:user/${aws:username}"
            ]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:GetUser"
            ],
            "Resource": "*"
        }
    ]
}
```

Allow a user to create DB instances in an AWS account

The following is an example policy that allows the user with the ID 123456789012 to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with test. The new DB instance must also use the MySQL database engine and the db.t2.micro DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with default, and it must use the default subnet group.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCreateDBInstanceOnly",
            "Effect": "Allow",
            "Action": [
                "rds:CreateDBInstance"
            ],
            "Resource": [
                "arn:aws:rds::*:123456789012:db:test*",
                "arn:aws:rds::*:123456789012:og:default*",
                "arn:aws:rds::*:123456789012:pg:default*"
            ]
        }
    ]
}
```
The policy includes a single statement that specifies the following permissions for the IAM user:

- The policy allows the IAM user to create a DB instance using the CreateDBInstance API operation (this also applies to the create-db-instance AWS CLI command and the AWS Management Console).
- The Resource element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (rds), the AWS Region (* indicates any region in this example), the user account number (123456789012 is the user ID in this example), and the type of resource. For more information about creating ARNs, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385).

The Resource element in the example specifies the following policy constraints on resources for the user:

- The DB instance identifier for the new DB instance must begin with test (for example, testCustomerData1, test-region2-data).
- The option group for the new DB instance must begin with default.
- The DB parameter group for the new DB instance must begin with default.
- The subnet group for the new DB instance must be the default subnet group.
- The Condition element specifies that the DB engine must be MySQL and the DB instance class must be db.t2.micro. The Condition element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the Condition element. For more information about specifying conditions, see Condition keys (p. 1771). This example specifies the rds:DatabaseEngine and rds:DatabaseClass conditions. For information about the valid condition values for rds:DatabaseEngine, see the list under the Engine parameter in CreateDBInstance. For information about the valid condition values for rds:DatabaseClass, see Supported DB engines for DB instance classes (p. 11).

The policy doesn't specify the Principal element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon RDS resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the AmazonRDSReadOnlyAccess managed policy to the user, as described in Managing access using policies (p. 1768).
You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon RDS resources for the root AWS account:

AmazonRDSFullAccess

**Allow a user to perform any describe action on any RDS resource**

The following permissions policy grants permissions to a user to run all of the actions that begin with Describe. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the Resource element indicates that the actions are allowed for all Amazon RDS resources owned by the account.

```
{  
  "Version": "2012-10-17",
  "Statement": [  
    {  
      "Sid": "AllowRDSDescribe",
      "Effect": "Allow",
      "Action": "rds:Describe*",
      "Resource": "*"
    }
  ]
}
```

**Allow a user to create a DB instance that uses the specified DB parameter group and subnet group**

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the mydbpg DB parameter group and the mydbsubnetgroup DB subnet group.

```
{  
  "Version": "2012-10-17",
  "Statement": [  
    {  
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": [  
        "arn:aws:rds:*:*:pg:mydbpg",
        "arn:aws:rds:*:*:subgrp:mydbsubnetgroup"
      ]
    }
  ]
}
```

**Grant permission for actions on a resource with a specific tag with two different values**

You can use conditions in your identity-based policy to control access to Amazon RDS resources based on tags. The following policy allows permission to perform the ModifyDBInstance and CreateDBSnapshot APIs on DB instances with either the stage tag set to development or test.
Identity-based policy examples

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowDevTestCreate",
      "Effect": "Allow",
      "Action": [
        "rds:ModifyDBInstance",
        "rds:CreateDBSnapshot"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "rds:db-tag/stage": [
            "development",
            "test"
          ]
        }
      }
    }
  ]
}
```

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyDelete1",
      "Effect": "Deny",
      "Action": "rds:DeleteDBInstance",
    }
  ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "rds:*",
    }
  ]
}
```

Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon RDS IAM permissions policies.
Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The Condition element indicates the requirement that the database engine is MySQL.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowMySQLCreate",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": "+",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseEngine": "mysql"
        },
        "Bool": {
          "rds:MultiAz": false
        }
      }
    }
  ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes db.r3.8xlarge and db.m4.10xlarge, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyLargeCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseClass": [
            "db.r3.8xlarge",
            "db.m4.10xlarge"
          ]
        }
      }
    },
    {
      "Sid": "DenyPIOPSCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
```
Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key `stage` to be added to a resource with the values `test`, `qa`, and `production`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "*",
      "Condition": {
        "streq": {
          "rds:req-tag/stage": [
            "test",
            "qa",
            "production"
          ]
        }
      }
    }
  ]
}
```

Specifying conditions: Using custom tags

Amazon RDS supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

**Note**

Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a `Condition` element.

<table>
<thead>
<tr>
<th>RDS tag identifier</th>

</tbody>
</table>

The syntax for a custom tag condition is as follows:

"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name": ["value"]} }

For example, the following Condition element applies to DB instances with a tag named environment and a tag value of production.

"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]} }

For information about creating tags, see Tagging Amazon RDS resources (p. 375).

**Important**

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the AddTagsToResource and RemoveTagsFromResource actions. For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```json
```

To see a list of Amazon RDS actions, see Actions Defined by Amazon RDS in the Service Authorization Reference.

**Example policies: Using custom tags**

Following are examples of how you can use custom tags in Amazon RDS IAM permissions policies. For more information about adding tags to an Amazon RDS resource, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385).

**Note**

All examples use the us-west-2 region and contain fictitious account IDs.
Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the `ModifyDBInstance` and `CreateDBSnapshot` APIs on DB instances with either the `stage` tag set to `development` or `test`.

```json
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"AllowDevTestCreate",
      "Effect":"Allow",
      "Action":[
        "rds:ModifyDBInstance",
        "rds:CreateDBSnapshot"
      ],
      "Resource": "*",
      "Condition":{
        "StringEquals":{
          "rds:db-tag/stage": ["development", "test"]
        }
      }
    }
  ]
}
```

Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use `Deny` are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

```json
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"DenyProductionCreate",
      "Effect":"Deny",
      "Action":"rds:CreateDBInstance",
      "Resource": "*",
      "Condition":{
        "StringEquals":{
          "rds:pg-tag/usage": "prod"
        }
      }
    }
  ]
}
```
Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to AddTagsToResource or RemoveTagsFromResource) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called stage equal to devo or that has no tag called stage.

The Resource line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon RDS resources, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385).

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid":"AllowFullDevAccessNoTags",
      "Effect":"Allow",
      "NotAction": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "arn:aws:rds:*:123456789012:db:${aws:username}*",
      "Condition": {
        "StringEqualsIfExists": {
          "rds:db-tag/stage":"devo"
        }
      }
    }
  ]
}
```
# Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS Document history page.

Preventing cross-service confused deputy problems

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem in the IAM User Guide.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see Working with Amazon Resource Names (ARNs) in Amazon RDS (p. 385).

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. An example is `arn:aws:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Sid": "ConfusedDeputyPreventionExamplePolicy",
        "Effect": "Allow",
        "Principal": {
            "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
            },
            "StringEquals": {
                "aws:SourceAccount": "123456789012"
            }
        }
    }
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:
• Manually creating an IAM role for native backup and restore (p. 964)
• Setting up Windows Authentication for SQL Server DB instances (p. 1005)
• Prerequisites for integrating RDS for SQL Server with S3 (p. 1014)
• Manually creating an IAM role for SQL Server Audit (p. 1056)
• Configuring IAM permissions for Amazon RDS for Oracle integration with Amazon S3 (p. 1452)
• Setting up access to an Amazon S3 bucket (p. 1650) (PostgreSQL import)
• Setting up access to an Amazon S3 bucket (p. 1669) (PostgreSQL export)
IAM database authentication for MariaDB, MySQL, and PostgreSQL

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MariaDB, MySQL and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

An authentication token is a unique string of characters that Amazon RDS generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon RDS, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB instance.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

Topics

- Availability for IAM database authentication (p. 1786)
- Limitations for IAM database authentication (p. 1786)
- MariaDB and MySQL recommendations for IAM database authentication (p. 1787)
- Enabling and disabling IAM database authentication (p. 1787)
- Creating and using an IAM policy for IAM database access (p. 1789)
- Creating a database account using IAM authentication (p. 1792)
- Connecting to your DB instance using IAM authentication (p. 1793)

Availability for IAM database authentication

IAM database authentication is available for the following database engines:

- MariaDB 10.6, all minor versions
- MySQL 8.0, minor version 8.0.16 or higher
- MySQL 5.7, minor version 5.7.16 or higher
- MySQL 5.6, minor version 5.6.34 or higher
- PostgreSQL 14, 13, 12, and 11, all minor versions
- PostgreSQL 10, minor version 10.6 or higher
- PostgreSQL 9.6, minor version 9.6.11 or higher
- PostgreSQL 9.5, minor version 9.5.15 or higher

Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:
• The maximum number of connections per second for your DB instance might be limited depending on its DB instance class and your workload.
• Currently, IAM database authentication doesn't support all global condition context keys.

For more information about global condition context keys, see AWS global condition context keys in the IAM User Guide.
• Currently, IAM database authentication isn't supported for CNAMEs.
• For PostgreSQL, if the IAM role (rds_iam) is added to the master user, IAM authentication takes precedence over Password authentication so the master user has to log in as an IAM user.

MariaDB and MySQL recommendations for IAM database authentication

We recommend the following when using the MariaDB or MySQL DB engine:
• Use IAM database authentication as a mechanism for temporary, personal access to databases.
• Use IAM database authentication only for workloads that can be easily retried.
• Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon RDS don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB instance. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling. The extra overhead can cause even existing connections to drop. For information about the maximum total connections for MariaDB and MySQL, see Maximum MySQL and MariaDB connections (p. 1886).

Note
These recommendations don't apply to Amazon RDS for PostgreSQL DB instances.

Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB instances. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:
• To create a new DB instance with IAM database authentication enabled, see Creating an Amazon RDS DB instance (p. 175).
• To modify a DB instance to enable IAM database authentication, see Modifying an Amazon RDS DB instance (p. 309).
• To restore a DB instance from a snapshot with IAM database authentication enabled, see Restoring from a DB snapshot (p. 432).
• To restore a DB instance to a point in time with IAM database authentication enabled, see Restoring a DB instance to a specified time (p. 480).

IAM authentication for PostgreSQL DB instances requires that the SSL value be 1. You can't enable IAM authentication for a PostgreSQL DB instance if the SSL value is 0. You can't change the SSL value to 0 if IAM authentication is enabled for a PostgreSQL DB instance.
Console

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

**To enable or disable IAM database authentication for an existing DB instance**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.

   **Note**
   Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in **Availability for IAM database authentication (p. 1786)**.

4. Choose **Modify**.
5. In the **Database authentication** section, choose **Password and IAM database authentication** to enable IAM database authentication.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
8. Choose **Modify DB instance**.

**AWS CLI**

To create a new DB instance with IAM authentication by using the AWS CLI, use the `create-db-instance` command. Specify the `--enable-iam-database-authentication` option, as shown in the following example.

```
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --db-instance-class db.m3.medium \
  --engine MySQL \
  --allocated-storage 20 \
  --master-username masterawsuser \
  --master-user-password masteruserpassword \
  --enable-iam-database-authentication
```

To update an existing DB instance to have or not have IAM authentication, use the AWS CLI command `modify-db-instance`. Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

**Note**
Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in **Availability for IAM database authentication (p. 1786)**.

By default, Amazon RDS performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

The following example shows how to immediately enable IAM authentication for an existing DB instance.

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --apply-immediately \
  --enable-iam-database-authentication
```
If you are restoring a DB instance, use one of the following AWS CLI commands:

- `restore-db-instance-to-point-in-time`
- `restore-db-instance-from-db-snapshot`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

**RDS API**

To create a new DB instance with IAM authentication by using the API, use the API operation `CreateDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB instance to have IAM authentication, use the API operation `ModifyDBInstance`. Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

**Note**

Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in Availability for IAM database authentication (p. 1786).

If you are restoring a DB instance, use one of the following API operations:

- `RestoreDBInstanceFromDBSnapshot`
- `RestoreDBInstanceToPointInTime`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

**Creating and using an IAM policy for IAM database access**

To allow an IAM user or role to connect to your DB instance, you must create an IAM policy. After that, you attach the policy to an IAM user or role.

**Note**

To learn more about IAM policies, see Identity and access management in Amazon RDS (p. 1766).

The following example policy allows an IAM user to connect to a DB instance using IAM database authentication.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
            ]
        }
    ]
}
```
Important
An IAM administrator user can access DB instances without explicit permissions in an IAM policy. The example in Create an IAM user (p. 93) creates an IAM administrator user. If you want to restrict administrator access to DB instances, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

Note
Don't confuse the rds-db: prefix with other RDS API operation prefixes that begin with rds:. You use the rds-db: prefix and the rds-db:connect action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- **Effect** – Specify Allow to grant access to the DB instance. If you don't explicitly allow access, then access is denied by default.
- **Action** – Specify rds-db:connect to allow connections to the DB instance.
- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB instance. The ARN format is as follows.

```
arn:aws:rds-db:region:account-id:dbuser:DbiResourceId/db-user-name
```

In this format, replace the following:

- **region** is the AWS Region for the DB instance. In the example policy, the AWS Region is us-east-2.
- **account-id** is the AWS account number for the DB instance. In the example policy, the account number is 1234567890.
- **DbiResourceId** is the identifier for the DB instance. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is db-ABCDEFGHIJKL01234.

To find a DB instance resource ID in the AWS Management Console for Amazon RDS, choose the DB instance to see its details. Then choose the Configuration tab. The Resource ID is shown in the Configuration section.

Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB instance in the current AWS Region, as shown following.

```
aws rds describe-db-instances --query "DBInstances[*].
[DBInstanceIdentifier,DbiResourceId]"
```

Note
If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as prx-ABCDEFGHijkl01234. For information about using IAM database authentication with RDS Proxy, see Connecting to a proxy using IAM authentication (p. 230).

- **db-user-name** is the name of the database account to associate with IAM authentication. In the example policy, the database account is db_user.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB instance.
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "rds-db:connect"
    ],
    "Resource": [
    ]
  }
]}

The following policy uses the "+*" character to match all DB instances and database accounts for a particular AWS account and AWS Region.

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
      ]
    }
  ]
}

The following policy matches all of the DB instances for a particular AWS account and AWS Region. However, the policy only grants access to DB instances that have a jane_doe database account.

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"
      ]
    }
  ]
}

The IAM user or role has access to only those databases that the database user does. For example, suppose that your DB instance has a database named dev, and another database named test. If the database user jane_doe has access only to dev, any IAM users or roles that access that DB instance with the jane_doe user also have access only to dev. This access restriction is also true for other database objects, such as tables, views, and so on.
An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions. For examples of policies, see Amazon RDS identity-based policy examples (p. 1772).

**Attaching an IAM policy to an IAM user or role**

After you create an IAM policy to allow database authentication, you need to attach the policy to an IAM user or role. For a tutorial on this topic, see Create and attach your first customer managed policy in the IAM User Guide.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have an IAM user with an attached policy that can make use of the `rds-db:connect` action.

**Note**

You can map multiple IAM users or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

```
arn:aws:rds-db:us-east-2:123456789012:dbuser:db-12ABC34DEFG5HIJ6KLMNOP78QR/jane_doe
```

If you attach the policy to IAM users Jane, Bob, and Diego, then each of those users can connect to the specified DB instance using the `jane_doe` database account.

**Creating a database account using IAM authentication**

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove an IAM user that is mapped to a database account, you should also remove the database account with the `DROP USER` statement.

**Note**

The user name used for IAM authentication must match the case of the user name in the database.

**Topics**

- Using IAM authentication with MariaDB or MySQL (p. 1792)
- Using IAM authentication with PostgreSQL (p. 1793)

**Using IAM authentication with MariaDB or MySQL**

With MariaDB or MySQL, authentication is handled by `AWSAuthenticationPlugin`—an AWS-provided plugin that works seamlessly with IAM to authenticate your IAM users. Connect to the DB instance and issue the `CREATE USER` statement, as shown in the following example.

```
CREATE USER jane_doe IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The `IDENTIFIED WITH` clause allows MariaDB or MySQL to use the `AWSAuthenticationPlugin` to authenticate the database account (`jane_doe`). The `AS 'RDS'` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 1789).

**Note**

If you see the following message, it means that the AWS-provided plugin is not available for the current DB instance.
ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded
To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB instance. For more information, see Availability for IAM database authentication (p. 1786) and Enabling and disabling IAM database authentication (p. 1787).

After you create an account using AWSAuthenticationPlugin, you manage it in the same way as other database accounts. For example, you can modify account privileges with GRANT and REVOKE statements, or modify various account attributes with the ALTER USER statement.

Using IAM authentication with PostgreSQL

To use IAM authentication with PostgreSQL, connect to the DB instance, create database users, and then grant them the rds_iam role as shown in the following example.

```
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access (p. 1789).

Connecting to your DB instance using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB instance. An authentication token is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see Signature Version 4 signing process in the AWS General Reference.) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon RDS from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Amazon RDS DB instance. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL
- Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1787)
- Creating and using an IAM policy for IAM database access (p. 1789)
- Creating a database account using IAM authentication (p. 1792)

Topics
Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client (p. 1794)

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client (p. 1796)

Connecting to your DB instance using IAM authentication and the AWS SDK for .NET (p. 1797)

Connecting to your DB instance using IAM authentication and the AWS SDK for Go (p. 1799)

Connecting to your DB instance using IAM authentication and the AWS SDK for Java (p. 1803)

Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3) (p. 1811)

Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Amazon RDS DB instance with the AWS CLI and mysql command line tool as described following.

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1787)
- Creating and using an IAM policy for IAM database access (p. 1789)
- Creating a database account using IAM authentication (p. 1792)

Note
For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics

- Generating an IAM authentication token (p. 1794)
- Connecting to a DB instance (p. 1795)

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```
aws rds generate-db-auth-token \
  --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
  --port 3306 \
  --region us-west-2 \
  --username jane_doe
```

In the example, the parameters are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```
Connecting to a DB instance

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- `--host` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--ssl-ca` – The full path to the SSL certificate file that contains the public key

For more information about SSL/TLS support for MariaDB, see Using SSL with a MariaDB DB instance (p. 847).

For more information about SSL/TLS support for MySQL, see Using SSL with a MySQL DB instance (p. 1140).

To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

- `--enable-cleartext-plugin` – A value that specifies that AWSAuthenticationPlugin must be used for this connection

  If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn't required.

- `--user` – The database account that you want to access
- `--password` – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
TOKEN=$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-west-2 --username jane_doe )

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using AWSAuthenticationPlugin, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable_name</td>
<td>Value</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------</td>
</tr>
<tr>
<td>Ssl_cipher</td>
<td>AES256-SHA</td>
</tr>
</tbody>
</table>
Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Amazon RDS for PostgreSQL DB instance with the AWS CLI and psql command line tool as described following.

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1787)
- Creating and using an IAM policy for IAM database access (p. 1789)
- Creating a database account using IAM authentication (p. 1792)

Note
For information about connecting to your database using pgAdmin with IAM authentication, see the blog post Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL.

Topics
- Generating an IAM authentication token (p. 1796)
- Connecting to an Amazon RDS PostgreSQL instance (p. 1797)

Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```bash
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
rdspostgres.123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```
Connecting to an Amazon RDS PostgreSQL instance

The general format for using psql to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full
sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName password=authToken"
```

The parameters are as follows:

- **host** – The host name of the DB instance that you want to access
- **port** – The port number used for connecting to your DB instance
- **sslmode** – The SSL mode to use
  
  When you use `sslmode=verify-full`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.
- **sslrootcert** – The full path to the SSL certificate file that contains the public key
  
  For more information, see Using SSL with a PostgreSQL DB instance (p. 1605).
  
  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).
- **dbname** – The database that you want to access
- **user** – The database account that you want to access
- **password** – A signed IAM authentication token

The following example shows using psql to connect. In the example, psql uses the environment variable `RDSHOST` for the host and the environment variable `PGPASSWORD` for the generated token. Also, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --region us-west-2 --username jane_doe )"
psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

Connecting to your DB instance using IAM authentication and the AWS SDK for .NET

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for .NET as described following.

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1787)
- Creating and using an IAM policy for IAM database access (p. 1789)
- Creating a database account using IAM authentication (p. 1792)

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the AWS SDK for .NET, found on the AWS site. The AWSSDK.CORE and the AWSSDK.RDS packages are required. To connect to a DB instance, use the .NET database connector for the DB engine, such as MySqlConnector for MariaDB or MySQL, or Npgsql for PostgreSQL.

This code connects to a MariaDB or MySQL DB instance.
Modify the values of the following variables as needed:

- **server** – The endpoint of the DB instance that you want to access
- **user** – The database account that you want to access
- **database** – The database that you want to access
- **port** – The port number used for connecting to your DB instance
- **SslMode** – The SSL mode to use

When you use `SslMode=Required`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- **SslCa** – The full path to the SSL certificate for Amazon RDS

To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

```csharp
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd = Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1, "mysqldb.123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
            // for debug only
            Console.Write("{0}\n", pwd);  // this verifies the token is generated

            MySqlConnection conn = new MySqlConnection("server=mysqldb.123456789012.us-east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password=pwd;SslMode=Required;SslCa=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
            MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

            // Execute a query
            MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

            // Read all rows and output the first column in each row
            while (mysqlDataRdr.Read())
            {
                Console.WriteLine(mysqlDataRdr[0]);
            }
            mysqlDataRdr.Close();
            // Close connection
            conn.Close();
        }
    }
}
```

This code connects to a PostgreSQL DB instance.

Modify the values of the following variables as needed:

- **Server** – The endpoint of the DB instance that you want to access
- **User ID** – The database account that you want to access
IAM database authentication

- **Database** – The database that you want to access
- **Port** – The port number used for connecting to your DB instance
- **SSL Mode** – The SSL mode to use

    When you use SSL Mode=Required, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- **Root Certificate** – The full path to the SSL certificate for Amazon RDS

    To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

```csharp
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd = RDSAuthTokenGenerator.GenerateAuthToken("postgresmydb.123456789012.us-east-1.rds.amazonaws.com", 5432, "jane_doe"); // for debug only Console.Write("{0}\n", pwd);  //this verifies the token is generated

            NpgsqlConnection conn = new NpgsqlConnection("Server=postgresmydb.123456789012.us-east-1.rds.amazonaws.com;User Id=jane_doe;Password=pwd;Database=mydb;SSL Mode=Require;Root Certificate=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
            NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM pg_user", conn);

            // Execute a query
            NpgsqlDataReader dr = cmd.ExecuteReader();

            // Read all rows and output the first column in each row
            while (dr.Read())
            {
                Console.Write("{0}\n", dr[0]);
            }

            // Close connection
            conn.Close();
        }
    }
}
```

Connecting to your DB instance using IAM authentication and the AWS SDK for Go

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Go as described following.

The following are prerequisites for connecting to your DB instance using IAM authentication:

- **Enabling and disabling IAM database authentication** (p. 1787)
- **Creating and using an IAM policy for IAM database access** (p. 1789)
- **Creating a database account using IAM authentication** (p. 1792)
To run these code examples, you need the AWS SDK for Go, found on the AWS site.

Modify the values of the following variables as needed:

- **dbName** – The database that you want to access
- **dbUser** – The database account that you want to access
- **dbHost** – The endpoint of the DB instance that you want to access
- **dbPort** – The port number used for connecting to your DB instance
- **region** – The AWS Region where the DB instance is running

In addition, make sure the imported libraries in the sample code exist on your system.

**Important**
The examples in this section use the following code to provide credentials that access a database from a local environment:

```go
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```go
sess := session.Must(session.NewSession())
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:

`"github.com/aws/aws-sdk-go/aws/session"`

**Topics**

- Connecting using IAM authentication and the AWS SDK for Go V2 (p. 1800)
- Connecting using IAM authentication and the AWS SDK for Go V1. (p. 1802)

**Connecting using IAM authentication and the AWS SDK for Go V2**

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V2.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```go
package main

import (
    "context"
    "database/sql"
    "fmt"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    _ "github.com/lib/pq"
)

func main() {
    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysqlb.123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 3306
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        // Handle error
    }
```
This code connects to a PostgreSQL DB instance.

```go
package main

import (  
    "context"  
    "database/sql"  
    "fmt"  
    "github.com/aws/aws-sdk-go-v2/config"  
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"  
    _ "github.com/lib/pq"
)

func main() {  
    var dbName string = "DatabaseName"  
    var dbUser string = "DatabaseUser"  
    var dbHost string = "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"  
    var dbPort int = 5432  
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)  
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())  
    if err != nil {  
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(  
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)  
    if err != nil {  
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",  
        dbHost, dbPort, dbUser, authenticationToken, dbName,
    )

    db, err := sql.Open("postgres", dsn)  
    if err != nil {  
        panic(err)
    }

    err = db.Ping()  
    if err != nil {  
        panic(err)
    }
}
```
Connecting using IAM authentication and the AWS SDK for Go V1.

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V1.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```go
package main

import {
    "database/sql"
    "fmt"
    "log"

    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    "github.com/go-sql-driver/mysql"
}

func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "mysqldb.123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 3306
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"

    creds := credentials.NewEnvCredentials()
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
    if err != nil {
        panic(err)
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true", dbUser, authToken, dbEndpoint, dbName,
    region)

    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

This code connects to a PostgreSQL DB instance.

```go
package main

import {
    "database/sql"
    "fmt"
    "log"

    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    "github.com/go-sql-driver/mysql"
}

func main() {
    dbName := "app"
    dbUser := "jane_doe"
    dbHost := "mysqldb.123456789012.us-east-1.rds.amazonaws.com"
    dbPort := 3306
    dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
    region := "us-east-1"

    creds := credentials.NewEnvCredentials()
    authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
    if err != nil {
        panic(err)
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true", dbUser, authToken, dbEndpoint, dbName,
    region)

    db, err := sql.Open("mysql", dsn)
    if err != nil {
        panic(err)
    }

    err = db.Ping()
    if err != nil {
        panic(err)
    }
}
```

1802
Connecting to your DB instance using IAM authentication and the AWS SDK for Java

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Java as described following.

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1787)
- Creating and using an IAM policy for IAM database access (p. 1789)
- Creating a database account using IAM authentication (p. 1792)
- Set up the AWS SDK for Java

Topics

- Generating an IAM authentication token (p. 1803)
- Manually constructing an IAM authentication token (p. 1804)
- Connecting to a DB instance (p. 1807)

Generating an IAM authentication token

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the RdsIamAuthTokenGenerator class. Using this class requires that you provide AWS
credentials. To do this, you create an instance of the DefaultAWSCredentialsProviderChain class. DefaultAWSCredentialsProviderChain uses the first AWS access key and secret key that it finds in the default credential provider chain. For more information about AWS access keys, see Managing access keys for IAM users.

After you create an instance of RdsIamAuthTokenGenerator, you can call the getAuthToken method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```java
package com.amazonaws.codesamples;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {
    public static void main(String[] args) {
        String region = "us-west-2";
        String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        System.out.println(generateAuthToken(region, hostname, port, username));
    }

    static String generateAuthToken(String region, String hostName, String port, String username) {
        RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
                .credentials(new DefaultAWSCredentialsProviderChain())
                .region(region)
                .build();

        String authToken = generator.getAuthToken(
                GetIamAuthTokenRequest.builder()
                        .hostname(hostName)
                        .port(Integer.parseInt(port))
                        .userName(username)
                        .build());

        return authToken;
    }
}
```

**Manually constructing an IAM authentication token**

In Java, the easiest way to generate an authentication token is to use RdsIamAuthTokenGenerator. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see Signature version 4 signing process in the AWS General Reference.

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```java
package com.amazonaws.codesamples;
import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;
```
public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
    public static String canonicalURIParameter = "/";
    public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();
    public static String payload = StringUtils.EMPTY;
    public static String signedHeader = "host";
    public static String algorithm = "AWS4-HMAC-SHA256";
    public static String serviceName = "rds-db";
    public static String requestWithoutSignature;

    public static void main(String[] args) throws Exception {
        String region = "us-west-2";
        String instanceName = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        Date now = new Date();
        String date = new SimpleDateFormat("yyyyMMdd").format(now);
        String dateTimeStamp = new SimpleDateFormat("yyyyMMdd'T'HHmmss'Z'").format(now);
        DefaultAWSCredentialsProviderChain creds = new DefaultAWSCredentialsProviderChain();
        String awsAccessKey = creds.getCredentials().getAWSAccessKeyId();
        String awsSecretKey = creds.getCredentials().getAWSSecretKey();
        String expiryMinutes = "900";

        System.out.println("Step 1: Create a canonical request:");  
        String canonicalString = createCanonicalString(username, awsAccessKey, date, dateTimeStamp, region, expiryMinutes, instanceName, port);  
        System.out.println(canonicalString);

        System.out.println("Step 2: Create a string to sign:");
        String stringToSign = createStringToSign(dateTimeStamp, canonicalString, awsAccessKey, date, region);
        System.out.println(stringToSign);

        System.out.println("Step 3: Calculate the signature:");
        String signature = BinaryUtils.toHex(calculateSignature(stringToSign, newSigningKey(awsSecretKey, date, region, serviceName)));
        System.out.println(signature);

        System.out.println("Step 4: Add the signing info to the request");
        System.out.println(appendSignature(signature));
        System.out.println();
    }
}

//Step 1: Create a canonical request date should be in format YYYYMMDD and dateTime should be in format YYYYMMDDTHHMMSSZ
public static String createCanonicalString(String user, String accessKey, String date,
String dateTime, String region, String expiryPeriod, String hostName, String port) throws
Exception {
    canonicalQueryParameters.put("Action", action);
    canonicalQueryParameters.put("DBUser", user);
    canonicalQueryParameters.put("X-Amz-Algorithm", "AWS4-HMAC-SHA256");
    canonicalQueryParameters.put("X-Amz-Credential", accessKey + "/" + date + "/" + region + "/" + serviceId + "/aws4_request");
    canonicalQueryParameters.put("X-Amz-Date", dateTime);
    canonicalQueryParameters.put("X-Amz-Expires", expiryPeriod);
    canonicalQueryParameters.put("X-Amz-SignedHeaders", signedHeader);
    String canonicalQueryString = ";
    while(!canonicalQueryParameters.isEmpty()) {
        String currentQueryParameter = canonicalQueryParameters.firstKey();
        String currentQueryParameterValue =
        canonicalQueryParameters.remove(currentQueryParameter);
        canonicalQueryString = canonicalQueryString + currentQueryParameter + ";" + currentQueryParameterValue;
        if (!currentQueryParameter.equals("X-Amz-SignedHeaders")) {
            canonicalQueryString += ";
        }
    }
    String canonicalHeaders = "host:" + hostName + ";" + port + "\n";
    requestWithoutSignature = hostName + ";" + port + ";" + canonicalQueryString;

    String hashedPayload = BinaryUtils.toHex(hash(payload));
    return httpMethod + ";" + canonicalURIParameter + ";" + canonicalQueryString + ";" + canonicalHeaders + ";" + signedHeader + ";" + hashedPayload;
}

//Step 2: Create a string to sign using sig v4
public static String createStringToSign(String dateTime, String canonicalRequest,
String accessKey, String date, String region) throws Exception {
    String credentialScope = date + ";" + region + ";" + serviceId + ";/aws4_request";
    return algorithm + ";" + dateTime + ";" + credentialScope + ";" + BinaryUtils.toHex(hash(canonicalRequest));
}

//Step 3: Calculate signature
/**
 * Step 3 of the &AWS; Signature version 4 calculation. It involves deriving
 * the signing key and computing the signature. Refer to
 * http://docs.aws.amazon
 * .com/general/latest/gr/sigv4-calculate-signature.html
 */
public static byte[] calculateSignature(String stringToSign,
    byte[] signingKey) {
    return sign(stringToSign.getBytes(Charset.forName("UTF-8")), signingKey,
        SigningAlgorithm.HmacSHA256);

    } catch (Exception e) {
        throw new SdkClientException(
            "Unable to compute hash while signing request: 
            + e.getMessage(), e);
    }
}

Connecting to a DB instance

The following code example shows how to generate an authentication token, and then use it to connect to an instance running MariaDB or MySQL.

To run this code example, you need the AWS SDK for Java, found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with mysql-connector-java-5.1.33-bin.jar.
- An intermediate certificate for Amazon RDS that is specific to an AWS Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - RDS_INSTANCE_HOSTNAME – The host name of the DB instance that you want to access.
  - RDS_INSTANCE_PORT – The port number used for connecting to your PostgreSQL DB instance.
  - REGION_NAME – The AWS Region where the DB instance is running.
  - DB_USER – The database account that you want to access.
  - SSL_CERTIFICATE – An SSL certificate for Amazon RDS that is specific to an AWS Region.
To download a certificate for your AWS Region, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755). Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the default credential provider chain.

```java
package com.amazonaws.samples;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.AWSStaticCredentialsProvider;
import java.io.File;
import java.io.FileOutputStream;
import java.io.InputStream;
import java.security.KeyStore;
import java.security.cert.CertificateFactory;
import java.security.cert.X509Certificate;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;
import java.util.Properties;
import java.net.URL;

Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Python (Boto3) as described following.

The following are prerequisites for connecting to your DB instance using IAM authentication:

- Enabling and disabling IAM database authentication (p. 1787)
- Creating and using an IAM policy for IAM database access (p. 1789)
- Creating a database account using IAM authentication (p. 1792)

In addition, make sure the imported libraries in the sample code exist on your system.

The code examples use profiles for shared credentials. For information about the specifying credentials, see Credentials in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the AWS SDK for Python (Boto3), found on the AWS site.

Modify the values of the following variables as needed:

- ENDPOINT – The endpoint of the DB instance that you want to access
- PORT – The port number used for connecting to your DB instance
- USER – The database account that you want to access.
- REGION – The AWS Region where the DB instance is running
- DBNAME – The database that you want to access
- SSLCERIFICATE – The full path to the SSL certificate for Amazon RDS

To download a certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

For ssl_ca, specify an SSL certificate. To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1755).

This code connects to a MariaDB or MySQL DB instance.

Before running this code, install Connector/Python by following the instructions in Connector/Python Installation in the MySQL documentation.

```python
import mysql.connector
import sys
import boto3
import os

ENDPOINT="mysql-db.123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ["LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN"] = '1'

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
```
This code connects to a PostgreSQL DB instance.

Before running this code, install psycopg2 by following the instructions in Psycopg documentation.

Troubleshooting Amazon RDS identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon RDS and IAM.

Topics

- I'm not authorized to perform an action in Amazon RDS (p. 1813)
- I'm not authorized to perform iam:PassRole (p. 1813)
- I want to view my access keys (p. 1813)
- I'm an administrator and want to allow others to access Amazon RDS (p. 1814)
• I want to allow people outside of my AWS account to access my Amazon RDS resources (p. 1814)

I'm not authorized to perform an action in Amazon RDS

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a widget but does not have rds:GetWidget permissions.

User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: rds:GetWidget on resource: my-example-widget

In this case, Mateo asks his administrator to update his policies to allow him to access the my-example-widget resource using the rds:GetWidget action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password. Ask that person to update your policies to allow you to pass a role to Amazon RDS.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in Amazon RDS. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole

In this case, Mary asks her administrator to update her policies to allow her to perform the iam:PassRole action.

I want to view my access keys

After you create your IAM user access keys, you can view your access key ID at any time. However, you can't view your secret access key again. If you lose your secret key, you must create a new access key pair.

Access keys consist of two parts: an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

**Important**

Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the *IAM User Guide*. 

1813
I'm an administrator and want to allow others to access Amazon RDS

To enable others to access Amazon RDS, you must create an IAM entity (user or role) for the person or application that needs access. They use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in Amazon RDS.

To get started right away, see Creating your first IAM delegated user and group in the IAM User Guide.

I want to allow people outside of my AWS account to access my Amazon RDS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon RDS supports these features, see How Amazon RDS works with IAM (p. 1769).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

Logging and monitoring in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon RDS resources and responding to potential incidents:

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS. CloudTrail captures all API calls for Amazon RDS as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon RDS, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Monitoring Amazon RDS API calls in AWS CloudTrail (p. 686).
Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 582).

Amazon RDS Performance Insights

Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see Monitoring DB load with Performance Insights on Amazon RDS (p. 521).

Database Logs

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see Monitoring Amazon RDS log files (p. 646).

Amazon RDS Recommendations

Amazon RDS provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data. For more information, see Viewing Amazon RDS recommendations (p. 500).

Amazon RDS Event Notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see Using Amazon RDS event notification (p. 623).

AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon RDS-related checks:

- Amazon RDS Idle DB Instances
- Amazon RDS Security Group Access Risk
- Amazon RDS Backups
- Amazon RDS Multi-AZ

For more information on these checks, see Trusted Advisor best practices (checks).

For more information about monitoring Amazon RDS, see Monitoring metrics in an Amazon RDS instance (p. 491).
Compliance validation for Amazon RDS

Third-party auditors assess the security and compliance of Amazon RDS as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.

Your compliance responsibility when using Amazon RDS is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and compliance quick start guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA security and compliance whitepaper** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS compliance resources** – This collection of workbooks and guides that might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
Resilience in Amazon RDS

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.

In addition to the AWS global infrastructure, Amazon RDS offers features to help support your data resiliency and backup needs.

Backup and restore

Amazon RDS creates and saves automated backups of your DB instance. Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases.

Amazon RDS creates automated backups of your DB instance during the backup window of your DB instance. Amazon RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period. You can also back up your DB instance manually, by manually creating a DB snapshot.

You can create a DB instance by restoring from this DB snapshot as a disaster recovery solution if the source DB instance fails.

For more information, see Backing up and restoring an Amazon RDS DB instance (p. 406).

Replication

Amazon RDS uses the MariaDB, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. Updates made to the source DB instance are asynchronously copied to the read replica. You can reduce the load on your source DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads. You can promote a read replica to a standalone instance as a disaster recovery solution if the source DB instance fails. For some DB engines, Amazon RDS also supports other replication options.

For more information, see Working with read replicas (p. 354).

Failover

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments. Amazon RDS uses several different technologies to provide failover support. Multi-AZ deployments for Oracle, PostgreSQL, MySQL, and MariaDB DB instances use Amazon's failover technology. SQL Server DB instances use SQL Server Database Mirroring (DBM).

For more information, see Multi-AZ deployments for high availability (p. 65).
Infrastructure security in Amazon RDS

As a managed service, Amazon RDS is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of security processes whitepaper.

You use AWS published API calls to access Amazon RDS through the network. Clients must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

In addition, Amazon RDS offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off to a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group.

For more information, see Controlling access with security groups (p. 1822).

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the Public accessibility parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the Public accessibility parameter.

For more information, see Hiding a DB instance in a VPC from the internet (p. 1851).

Note
If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 1765).
You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an interface VPC endpoint. Interface endpoints are powered by AWS PrivateLink.

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances. Your instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see Elastic network interfaces in the Amazon EC2 User Guide.

For more information about VPC endpoints, see Interface VPC endpoints (AWS PrivateLink) in the Amazon VPC User Guide. For more information about RDS API operations, see Amazon RDS API Reference.

Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review Interface endpoint properties and limitations in the Amazon VPC User Guide.

All RDS API operations relevant to managing Amazon RDS resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Availability

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the Amazon VPC User Guide.

Create a VPC endpoint for Amazon RDS API using the service name com.amazonaws.region.rds.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example rds.us-east-1.amazonaws.com. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using rds-api.cn-north-1.amazonaws.com.cn and rds-api.cn-northwest-1.amazonaws.com.cn, respectively.

For more information, see Accessing a service through an interface endpoint in the Amazon VPC User Guide.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```json
{
    "Statement": [
        {
            "Principal": "*",
            "Action": ["rds:*"],
            "Resource": ["*"]
        }
    ]
}
```
Security best practices for Amazon RDS

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon RDS resources. Such resources include DB instances, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB instances.

- Create an individual IAM user for each person who manages Amazon RDS resources, including yourself. Don’t use AWS root credentials to manage Amazon RDS resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon RDS. For more information, see Rotating your AWS Secrets Manager secrets in the AWS Secrets Manager User Guide. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see Retrieving the secret value in the AWS Secrets Manager User Guide.

For more information about Amazon RDS security, see Security in Amazon RDS (p. 1747). For more information about IAM, see AWS Identity and Access Management. For information on IAM best practices, see IAM best practices.
Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

Controlling access with security groups

Security groups control the access that traffic has in and out of a DB instance. Three types of security groups are used with Amazon RDS: VPC security groups, DB security groups, and EC2-Classic security groups. In simple terms, these work as follows:

- A VPC security group controls access to DB instances and EC2 instances inside a VPC.
- A DB security group controls access to EC2-Classic DB instances that are not in a VPC.
- An EC2-Classic security group controls access to an EC2 instance. For more information about EC2-Classic security groups, see EC2-Classic in the Amazon EC2 documentation.

By default, network access is disabled for a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. Once ingress rules are configured, the same rules apply to all DB instances that are associated with that security group. You can specify up to 20 rules in a security group.

VPC security groups

Each VPC security group rule enables a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic, though the outbound traffic rules typically do not apply to DB instances. Outbound traffic rules only apply if the DB instance acts as a client. For example, outbound traffic rules apply to an Oracle DB instance with outbound database links. You must use the Amazon EC2 API or the Security Group option on the VPC Console to create VPC security groups.

When you create rules for your VPC security group that allow access to the instances in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to enable SSH access to instances in the VPC, then you create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for RDS for MySQL DB instances in your VPC.

For more information on VPC security groups, see Security groups in the Amazon Virtual Private Cloud User Guide.

Note
If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 1765).

DB security groups

DB security groups are used with DB instances that are not in a VPC and on the EC2-Classic platform. Each DB security group rule enables a specific source to access a DB instance that is associated with that
DB security group. The source can be a range of addresses (for example, 203.0.113.0/24), or an EC2-Classic security group. When you specify an EC2-Classic security group as the source, you allow incoming traffic from all EC2 instances that use that EC2-Classic security group. DB security group rules apply to inbound traffic only; outbound traffic is not currently permitted for DB instances.

You don't need to specify a destination port number when you create DB security group rules. The port number defined for the DB instance is used as the destination port number for all rules defined for the DB security group. DB security groups can be created using the Amazon RDS API operations or the Amazon RDS page of the AWS Management Console.

For more information about working with DB security groups, see Working with DB security groups (EC2-Classic platform) (p. 1827).

### DB security groups vs. VPC security groups

The following table shows the key differences between DB security groups and VPC security groups.

<table>
<thead>
<tr>
<th>DB security group</th>
<th>VPC security group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Controls access to DB instances outside a VPC.</td>
<td>Controls access to DB instances in VPC.</td>
</tr>
<tr>
<td>Uses Amazon RDS API operations or the Amazon RDS page of the AWS Management Console to create and manage group and rules.</td>
<td>Uses Amazon EC2 API operations or the Amazon VPC page of the AWS Management Console to create and manage group and rules.</td>
</tr>
<tr>
<td>When you add a rule to a group, you don't need to specify port number or protocol.</td>
<td>When you add a rule to a group, specify the protocol as TCP. In addition, specify the same port number that you used to create the DB instances (or options) that you plan to add as members to the group.</td>
</tr>
<tr>
<td>Groups allow access from EC2-Classic security groups in your AWS account or other accounts.</td>
<td>Groups allow access from other VPC security groups in your VPC only.</td>
</tr>
</tbody>
</table>

### Security group scenario

A common use of a DB instance in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, sg-0123ec2example) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.
2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (sg-0123ec2example) that you created in the previous step.
3. Create a second VPC security group (for example, sg-6789rdsexample) and create a new rule by specifying the VPC security group that you created in step 1 (sg-0123ec2example) as the source.
4. Create a new DB instance and add the DB instance to the VPC security group (sg-6789rdsexample) that you created in the previous step. When you create the DB instance, use the same port number as the one specified for the VPC security group (sg-6789rdsexample) rule that you created in step 3.

The following diagram shows this scenario.
Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see Provide access to your DB instance in your VPC by creating a security group (p. 96) and Security groups in the Amazon Virtual Private Cloud User Guide.

Associating a security group with a DB instance

You can associate a security group with a DB instance by using Modify on the RDS console, the ModifyDBInstance Amazon RDS API, or the modify-db-instance AWS CLI command.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309). For security group considerations when you restore a DB instance from a DB snapshot, see Security group considerations (p. 432).

Deleting DB VPC security groups

DB VPC security groups are an RDS mechanism to synchronize security information with a VPC security group. However, this synchronization is no longer required, because RDS has been updated to use VPC security group information directly.

**Note**
DB VPC security groups are deprecated, and they are different from DB security groups, VPC security groups, and EC2-Classic security groups.

We strongly recommend that you delete any DB VPC security groups that you currently use. If you don't delete your DB VPC security groups, you might encounter unintended behaviors with your DB instances,
which can be as severe as losing access to a DB instance. The unintended behaviors might result from taking an action such as an update to a DB instance, a parameter group, or similar. Such updates cause RDS to resynchronize the DB VPC security group with the VPC security group. This resynchronization can result in your security information being overwritten with incorrect and outdated security information. This in turn can have a severe impact on your ability to access to your DB instances.

How can I determine if I have a DB VPC security group?

Because DB VPC security groups have been deprecated, they don't appear in the RDS console. However, you can call the describe-db-security-groups AWS CLI command or the DescribeDBSecurityGroups API operation to determine if you have any DB VPC security groups.

In this case, you can call the describe-db-security-groups AWS CLI command with JSON specified as the output format. If you do, you can identify DB VPC security groups by the VPC identifier on the second line of the output for the security group as shown in the following example.

```
{
   "DBSecurityGroups": [
   {
      "VpcId": "vpc-abcd1234",
      "DBSecurityGroupDescription": "default:vpc-abcd1234",
      "IPRanges": [
         {
            "Status": "authorized",
            "CIDRIP": "xxx.xxx.xxx.xxx/n"
         },
         {
            "Status": "authorized",
            "CIDRIP": "xxx.xxx.xxx.xxx/n"
         }
      ],
      "OwnerId": "123456789012",
      "EC2SecurityGroups": [],
      "DBSecurityGroupName": "default:vpc-abcd1234"
   }
   ]
}
```

If you run the DescribeDBSecurityGroups API operation, then you can identify DB VPC security groups using the <VpcId> response element as shown in the following example.

```
<DBSecurityGroup>
<EC2SecurityGroups/>
<DBSecurityGroupDescription>default:vpc-abcd1234</DBSecurityGroupDescription>
<IPRanges>
   <IPRange>
      <CIDRIP>xxx.xxx.xxx.xxx/n</CIDRIP>
      <Status>authorized</Status>
   </IPRange>
   <IPRange>
      <CIDRIP>xxx.xxx.xxx.xxx/n</CIDRIP>
      <Status>authorized</Status>
   </IPRange>
</IPRanges>
<VpcId>vpc-abcd1234</VpcId>
<OwnerId>123456789012</OwnerId>
<DBSecurityGroupName>default:vpc-abcd1234</DBSecurityGroupName>
</DBSecurityGroup>
```
How do I delete a DB VPC security group?

Because DB VPC security groups don't appear in the RDS console, you must call the delete-db-security-group AWS CLI command or the DeleteDBSecurityGroup API operation to delete a DB VPC security group.

After you delete a DB VPC security group, your DB instances in your VPC continue to be secured by the VPC security group for that VPC. The DB VPC security group that was deleted was merely a copy of the VPC security group information.

Review your AWS CloudFormation templates

Older versions of AWS CloudFormation templates can contain instructions to create a DB VPC security group. Because DB VPC security groups are not yet fully deprecated, they can still be created. Make sure that any AWS CloudFormation templates that you use to provision a DB instance with security settings don't also create a DB VPC security group. Don't use AWS CloudFormation templates that create an RDS DBSecurityGroup with an EC2VpcId as shown in the following example.

```json
{
  "DbSecurityByEC2SecurityGroup" : {
    "Type" : "AWS::RDS::DBSecurityGroup",
    "Properties" : {
      "GroupDescription" : "Ingress for security group",
      "EC2VpcId" : "MyVPC",
      "DBSecurityGroupIngress" : [ {
        "EC2SecurityGroupId" : "sg-b0ff1111",
        "EC2SecurityGroupOwnerId" : "111122223333"
      }, {
        "EC2SecurityGroupId" : "sg-ffd722222",
        "EC2SecurityGroupOwnerId" : "111122223333"
      } ]
    }
  }
}
```

Instead, add security information for your DB instances in a VPC using VPC security groups, as shown in the following example.

```json
{
  "DBInstance" : {
    "Type" : "AWS::RDS::DBInstance",
    "Properties" : {
      "DBName" : { "Ref" : "DBName" },
      "Engine" : "MySQL",
      "MultiAZ" : { "Ref" : "MultiAZDatabase" },
      "MasterUsername" : { "Ref" : "<master_username>" },
      "DBInstanceClass" : { "Ref" : "DBClass" },
      "AllocatedStorage" : { "Ref" : "DBAllocatedStorage" },
      "MasterUserPassword" : { "Ref" : "<master_password>" },
      "VPCSecurityGroups" : [ { "Fn::GetAtt" : [ "VPCSecurityGroup", "GroupId" ] } ]
    }
  }
}
```
Working with DB security groups (EC2-Classic platform)

By default, network access is turned off to a DB instance. You can specify rules in a security group that allows access from an IP address range, port, or security group. Once ingress rules are configured, the same rules apply to all DB instances that are associated with that security group. You can specify up to 20 rules in a security group.

Amazon RDS supports two different kinds of security groups. The one you use depends on which Amazon RDS platform you are on:

- **VPC security groups** – for the EC2-VPC platform.
- **DB security groups** – for the EC2-Classic platform.

You are most likely on the EC2-VPC platform (and must use VPC security groups) if any of the following are true:

- If you are a new Amazon RDS customer.
- If you have never created a DB instance before.
- If you are creating a DB instance in an AWS Region you have not used before.

Otherwise, if you are on the EC2-Classic platform, you use DB security groups to manage access to your Amazon RDS DB instances. For more information about the differences between DB security groups and VPC security groups, see Controlling access with security groups (p. 1822).

**Note**
To determine which platform you are on, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869).
If you are on the EC2-VPC platform, you must use VPC security groups instead of DB security groups. For more information about using a VPC, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

**Topics**

- Creating a DB security group (p. 1827)
- Listing available DB security groups (p. 1829)
- Viewing a DB security group (p. 1829)
- Associating a DB security group with a DB instance (p. 1830)
- Authorizing network access to a DB security group from an IP range (p. 1831)
- Authorizing network access to a DB instance from an Amazon EC2 instance (p. 1832)
- Revoking network access to a DB instance from an IP range (p. 1834)

**Creating a DB security group**

To create a DB security group, you need to provide a name and a description.

**Console**

**To create a DB security group**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the navigation pane, choose Security Groups.
Note
If you are on the EC2-VPC platform, the Security Groups option does not appear in the navigation pane. In this case, you must use VPC security groups instead of DB security groups. For more information about using a VPC, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

4. Type the name and description of the new DB security group in the Name and Description text boxes. The security group name can't contain spaces and can't start with a number.
5. Choose Yes, Create.

The DB security group is created.

A newly created DB security group doesn't provide access to a DB instance by default. You must specify a range of IP addresses or an EC2-Classic security group that can have access to the DB instance. To specify IP addresses or an EC2-Classic security group for a DB security group, see Authorizing network access to a DB security group from an IP range (p. 1831).

AWS CLI
To create a DB security group, use the AWS CLI command create-db-security-group.

Example
For Linux, macOS, or Unix:

```bash
aws rds create-db-security-group
   --db-security-group-name mydbsecuritygroup
   --db-security-group-description "My new security group"
```

For Windows:

```bash
aws rds create-db-security-group
   --db-security-group-name mydbsecuritygroup
   --db-security-group-description "My new security group"
```

A newly created DB security group doesn't provide access to a DB instance by default. You must specify a range of IP addresses or an EC2-Classic security group that can have access to the DB instance. To specify IP addresses or an EC2-Classic security group for a DB security group, see Authorizing network access to a DB security group from an IP range (p. 1831).

API
To create a DB security group, call the Amazon RDS function CreateDBSecurityGroup with the following parameters:

- DBSecurityGroupName = mydbsecuritygroup
- Description = "My new security group"

Example

```sql
https://rds.amazonaws.com/?Action=CreateDBSecurityGroup
   &DBSecurityGroupName=mydbsecuritygroup
   &Description=My%20new%20db%20security%20group
   &Version=2012-01-15
   &SignatureVersion=2
```

1828
A newly created DB security group doesn't provide access to a DB instance by default. You must specify a range of IP addresses or an EC2-Classic security group that can have access to the DB instance. To specify IP addresses or an EC2-Classic security group for a DB security group, see Authorizing network access to a DB security group from an IP range (p. 1831).

**Listing available DB security groups**

You can list which DB security groups have been created for your AWS account.

**Console**

**To list all available DB security groups for an AWS account**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the navigation pane, choose **Security Groups**.

   The available DB security groups appear in the **DB Security Groups** list.

   **Note**
   If you are on the EC2-VPC platform, the **Security Groups** option does not appear in the navigation pane. In this case, you must use VPC security groups instead of DB security groups. For more information about using a VPC, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

**AWS CLI**

To list all available DB security groups for an AWS account, Use the AWS CLI command `describe-db-security-groups` with no parameters.

**Example**

```
aws rds describe-db-security-groups
```

**API**

To list all available DB security groups for an AWS account, call `DescribeDBSecurityGroups` with no parameters.

**Example**

```
https://rds.amazonaws.com/
?Action=DescribeDBSecurityGroups
&MaxRecords=100
&Version=2009-10-16
&SignatureVersion=2
&SignatureMethod=HmacSHA256
&AWSAccessKeyId=<Access Key ID>
&Signature=<Signature>
```

**Viewing a DB security group**

You can view detailed information about your DB security group to see what IP ranges have been authorized.
**Console**

**To view properties of a specific DB security group**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the navigation pane, choose **Security Groups**.
   
   **Note**
   
   If you are on the EC2-VPC platform, the **Security Groups** option does not appear in the navigation pane. In this case, you must use VPC security groups instead of DB security groups. For more information about using a VPC, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

3. Select the details icon for the DB security group you want to view. The detailed information for the DB security group is displayed.

**AWS CLI**

To view the properties of a specific DB security group use the AWS CLI `describe-db-security-groups`. Specify the DB security group you want to view.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds describe-db-security-groups \
  --db-security-group-name mydbsecuritygroup
```

For Windows:

```bash
aws rds describe-db-security-groups ^
  --db-security-group-name mydbsecuritygroup
```

**API**

To view properties of a specific DB security group, call `DescribeDBSecurityGroups` with the following parameters:

- `DBSecurityGroupName=mydbsecuritygroup`

**Example**

```xml
https://rds.amazonaws.com/?
  ?Action=DescribeDBSecurityGroups
  &DBSecurityGroupName=mydbsecuritygroup
  &Version=2009-10-16
  &SignatureVersion=2
  &SignatureMethod=HmacSHA256
  &Timestamp=2009-10-16T22%3A23%3A07.107Z
  &AWSAccessKeyId=<Access Key ID>
  &Signature=<Signature>
```

**Associating a DB security group with a DB instance**

You can associate a DB security group with a DB instance using the RDS console’s **Modify** option, the `ModifyDBInstance` Amazon RDS API, or the AWS CLI `modify-db-instance` command.
For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

Authorizing network access to a DB security group from an IP range

By default, network access is turned off to a DB instance. If you want to access a DB instance that is not in a VPC, you must set access rules for a DB security group to allow access from specific EC2-Classic security groups or CIDR IP ranges. You then must associate that DB instance with that DB security group. This process is called ingress. Once ingress is configured for a DB security group, the same ingress rules apply to all DB instances associated with that DB security group.

Warning
Talk with your network administrator if you are intending to access a DB instance behind a firewall to determine the IP addresses you should use.

In following example, you configure a DB security group with an ingress rule for a CIDR IP range.

Console

To configure a DB security group with an ingress rule for a CIDR IP range

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the navigation pane, choose Security Groups.

   Note
   If you are on the EC2-VPC platform, the Security Groups option does not appear in the navigation pane. In this case, you must use VPC security groups instead of DB security groups. For more information about using a VPC, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).

3. Select the details icon for the DB security group you want to authorize.
4. In the details page for your security group, select CIDR/IP from the Connection Type drop-down list, type the CIDR range for the ingress rule you want to add to this DB security group into the CIDR text box, and choose Authorize.

   Tip
   The AWS Management Console displays a CIDR IP based on your connection below the CIDR text field. If you are not accessing the DB instance from behind a firewall, you can use this CIDR IP.

5. The status of the ingress rule is authorizing until the new ingress rule has been applied to all DB instances that are associated with the DB security group that you modified. After the ingress rule has been successfully applied, the status changes to authorized.

AWS CLI

To configure a DB security group with an ingress rule for a CIDR IP range, use the AWS CLI command authorize-db-security-group-ingress.

Example

For Linux, macOS, or Unix:

```
aws rds authorize-db-security-group-ingress \
  --db-security-group-name mydbsecuritygroup \
  --cidrip 192.168.1.10/27
```

For Windows:
To configure a DB security group with an ingress rule for a CIDR IP range, call the Amazon RDS API `AuthorizeDBSecurityGroupIngress` with the following parameters:

- **DBSecurityGroupName** = *mydbsecuritygroup*
- **CIDRIP** = *192.168.1.10/27*

**Example**

```plaintext
https://rds.amazonaws.com/?Action=AuthorizeDBSecurityGroupIngress
&CIDRIP=192.168.1.10%2F27
&DBSecurityGroupName=mydbsecuritygroup
&Version=2009-10-16
&Action=AuthorizeDBSecurityGroupIngress
&SignatureVersion=2
&SignatureMethod=HmacSHA256
&Timestamp=2009-10-22T17%3A10%3A50.274Z
&AWSAccessKeyId=<Access Key ID>
&Signature=<Signature>
```

**Authorizing network access to a DB instance from an Amazon EC2 instance**

If you want to access your DB instance from an Amazon EC2 instance, you must first determine if your EC2 instance and DB instance are in a VPC. If you are using a default VPC, you can assign the same EC2 or VPC security group that you used for your EC2 instance when you create or modify the DB instance that the EC2 instance accesses.

If your DB instance and EC2 instance are not in a VPC, you must configure the DB instance's security group with an ingress rule that allows traffic from the Amazon EC2 instance. You do this by adding the EC2-Classic security group for the EC2 instance to the DB security group for the DB instance. In this example, you add an ingress rule to a DB security group for an EC2-Classic security group.

**Important**

- Adding an ingress rule to a DB security group for an EC2-Classic security group only grants access to your DB instances from Amazon EC2 instances associated with that EC2-Classic security group.
- You can't authorize an EC2-Classic security group that is in a different AWS Region than your DB instance. You can authorize an IP range, or specify an EC2-Classic security group in the same AWS Region that refers to IP address in another AWS Region. If you specify an IP range, we recommend that you use the private IP address of your Amazon EC2 instance, which provides a more direct network route from your Amazon EC2 instance to your Amazon RDS DB instance, and doesn't incur network charges for data sent outside of the Amazon network.
Console

To add an EC2-Classic security group to a DB security group

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the navigation pane, choose Security Groups.

   Note
   If you are on the EC2-VPC platform, the Security Groups option does not appear in the
   navigation pane. In this case, you must use VPC security groups instead of DB security
   groups. For more information about using a VPC, see Amazon Virtual Private Cloud VPCs
   and Amazon RDS (p. 1849).
3. Select the details icon for the DB security group you want to grant access.
4. In the details page for your security group, choose EC2 Security Group for Connection Type, and
   then select the EC2-Classic security group you want to use. Then choose Authorize.
5. The status of the ingress rule is authorizing until the new ingress rule has been applied to all DB
   instances that are associated with the DB security group that you modified. After the ingress rule has
   been successfully applied, the status changes to authorized.

AWS CLI

To grant access to an EC2-Classic security group, use the AWS CLI command authorize-db-
security-group-ingress.

Example

For Linux, macOS, or Unix:

```bash
aws rds authorize-db-security-group-ingress \
   --db-security-group-name default \
   --ec2-security-group-name myec2group \
   --ec2-security-group-owner-id 987654321021
```

For Windows:

```bash
aws rds authorize-db-security-group-ingress ^
   --db-security-group-name default ^
   --ec2-security-group-name myec2group ^
   --ec2-security-group-owner-id 987654321021
```

The command should produce output similar to the following:

<table>
<thead>
<tr>
<th>SECGROUP</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECGROUP</td>
<td>default</td>
<td>default</td>
</tr>
<tr>
<td>EC2-SECGROUP</td>
<td>myec2group</td>
<td>987654321021</td>
</tr>
</tbody>
</table>

API

To authorize network access to an EC2-Classic security group, call that Amazon RDS
API function, https://docs.aws.amazon.com/AmazonRDS/latest/APIReference/
API_AuthorizeDBSecurityGroupIngress.htmlAuthorDBSecurityGroupIngress with the following
parameters:

- EC2SecurityGroupName = myec2group
- EC2SecurityGroupOwnerId = 987654321021
Revoking network access to a DB instance from an IP range

You can easily revoke network access from a CIDR IP range to DB instances belonging to a DB security group by revoking the associated CIDR IP ingress rule.

In this example, you revoke an ingress rule for a CIDR IP range on a DB security group.

**Console**

**To revoke an ingress rule for a CIDR IP range on a DB security group**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the navigation pane, choose **Security Groups**.
   
   **Note**
   
   If you are on the EC2-VPC platform, the **Security Groups** option does not appear in the navigation pane. In this case, you must use VPC security groups instead of DB security groups. For more information about using a VPC, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1849).
3. Select the details icon for the DB security group that has the ingress rule you want to revoke.
4. In the details page for your security group, choose **Remove** next to the ingress rule you want to revoke.
5. The status of the ingress rule is **revoking** until the ingress rule has been removed from all DB instances that are associated with the DB security group that you modified. After the ingress rule has been successfully removed, the ingress rule is removed from the DB security group.

**AWS CLI**

To revoke an ingress rule for a CIDR IP range on a DB security group, use the AWS CLI command `revoke-db-security-group-ingress`.

**Example**

For Linux, macOS, or Unix:

```bash
aws rds revoke-db-security-group-ingress
   --db-security-group-name mydbsecuritygroup
   --cidrip 192.168.1.1/27
```

For Windows:

```bash
aws rds revoke-db-security-group-ingress
   --db-security-group-name mydbsecuritygroup
```

---

**Example**

https://rds.amazonaws.com/

```bash
?Action=AuthorizeDBSecurityGroupIngress
&EC2SecurityGroupOwnerId=987654321021
&EC2SecurityGroupName=myec2group
&Version=2009-10-16
&SignatureVersion=2
&SignatureMethod=HmacSHA256
&Timestamp=2009-10-22T17%3A10%3A50.274Z
&AWSAccessKeyId=<Access Key ID>
&Signature=<Signature>
```
Master user account privileges

When you create a new DB instance, the default master user that you use gets certain privileges for that DB instance. The following table shows the privileges and database roles the master user gets for each of the database engines.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>System privilege</th>
<th>Database role</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL and MariaDB</td>
<td>SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES, INDEX, ALTER, SHOW DATABASES, CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION CLIENT, CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER ON <em>,.</em> WITH GRANT OPTION, REPLICATION SLAVE (only for RDS for MySQL versions 5.6, 5.7 and 8.0, RDS for MariaDB)</td>
<td>—</td>
</tr>
</tbody>
</table>

**Important**
We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

**Note**
If you accidentally delete the permissions for the master user, you can restore them by modifying the DB instance and setting a new master user password. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).
<table>
<thead>
<tr>
<th>Database engine</th>
<th>System privilege</th>
<th>Database role</th>
</tr>
</thead>
<tbody>
<tr>
<td>PostgreSQL</td>
<td>CREATE ROLE, CREATE DB, PASSWORD VALID UNTIL INFINITY, CREATE EXTENSION, ALTER EXTENSION, DROP EXTENSION, CREATE TABLESPACE, ALTER &lt; OBJECT&gt; OWNER, CHECKPOINT, PG_CANCEL_BACKEND(), PG_TERMINATE_BACKEND(), SELECT PG_STAT_REPLICATION, EXECUTE PG_STAT_STATEMENTS_RESET(), OWN POSTGRES_FDW_HANDLER(), OWN POSTGRES_FDW_VALIDATOR(), OWN POSTGRES_FDW, EXECUTE PG_BUFFERCACHE_PAGES(), SELECT PG_BUFFERCACHE</td>
<td>RDS_SUPERUSER For more information about RDS_SUPERUSER, see Understanding the rds_superuser role (p. 1713).</td>
</tr>
<tr>
<td>Oracle</td>
<td>ALTER DATABASE LINK, ALTER PUBLIC DATABASE LINK, DROP ANY DIRECTORY, EXEMPT ACCESS POLICY, EXEMPT IDENTITY POLICY, GRANT ANY OBJECT PRIVILEGE, RESTRICTED SESSION, EXEMPT REDACTION POLICY</td>
<td>AQ_ADMINISTRATOR_ROLE, AQ_USER_ROLE, CONNECT, CTXAPP, DBA, EXECUTE_CATALOG_ROLE, RECOVERY_CATALOG_OWNER, RESOURCE, SELECT_CATALOG_ROLE</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td>ADMINISTER BULK OPERATIONS, ALTER ANY CONNECTION, ALTER ANY CREDENTIAL, ALTER ANY EVENT SESSION, ALTER ANY LINKED SERVER, ALTER ANY LOGIN, ALTER ANY SERVER AUDIT, ALTER ANY SERVER ROLE, ALTER SERVER STATE, ALTER TRACE, CONNECT SQL, CREATE ANY DATABASE, VIEW ANY DATABASE, VIEW ANY DEFINITION, VIEW SERVER STATE, ALTER ON ROLE SQLAgentOperatorRole, SQLAgentUserRole</td>
<td>DB_OWNER (database-level role), PROCESSADMIN (server-level role), SETUPADMIN (server-level role), SQLAgentUserRole (database-level role)</td>
</tr>
</tbody>
</table>
Using service-linked roles for Amazon RDS

Amazon RDS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon RDS. Service-linked roles are predefined by Amazon RDS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon RDS easier because you don’t have to manually add the necessary permissions. Amazon RDS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon RDS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon RDS resources because you can’t inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon RDS

Amazon RDS uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call AWS services on behalf of your DB instances.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- rds.amazonaws.com

This service-linked role has a permissions policy attached to it called AmazonRDSServiceRolePolicy that grants it permissions to operate in your account. The role permissions policy allows Amazon RDS to complete the following actions on the specified resources:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:CrossRegionCommunication"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AllocateAddress",
        "ec2: AssociateAddress",
        "ec2: AuthorizeSecurityGroupIngress",
        "ec2: CreateCoipPoolPermission",
        "ec2: CreateLocalGatewayRouteTablePermission",
        "ec2: CreateNetworkInterface",
        "ec2: CreateSecurityGroup",
        "ec2: DeleteCoipPoolPermission",
        "ec2: DeleteLocalGatewayRouteTablePermission",
        "ec2: DeleteNetworkInterface",
        "ec2: DeleteSecurityGroup",
        "ec2: DescribeAddresses",
        "ec2: DescribeAvailabityZones",
        "ec2: DescribeCoipPools"
      ],
      "Resource": "*"
    }
  ]
}
```
"ec2:DescribeInternetGateways",
"ec2:DescribeLocalGatewayRouteTablePermissions",
"ec2:DescribeLocalGatewayRouteTables",
"ec2:DescribeLocalGatewayRouteTableVpcAssociations",
"ec2:DescribeLocalGateways",
"ec2:DescribeSecurityGroups",
"ec2:DescribeSubnets",
"ec2:DescribeVpcAttribute",
"ec2:DescribeVpcs",
"ec2:DisassociateAddress",
"ec2:ModifyNetworkInterfaceAttribute",
"ec2:ModifyVpcEndpoint",
"ec2:ReleaseAddress",
"ec2:RevokeSecurityGroupIngress",
"ec2:CreateVpcEndpoint",
"ec2:DescribeVpcEndpoints",
"ec2:DeleteVpcEndpoints",
"ec2:AssignPrivateIpAddresses",
"ec2:UnassignPrivateIpAddresses"
],
"Resource": "*",
},
{
"Effect": "Allow",
"Action": [
"sns:Publish"
],
"Resource": "*"
},
{
"Effect": "Allow",
"Action": [
"logs:CreateLogGroup"
],
"Resource": [
"arn:aws:logs:*:*:log-group:/aws/rds/*",
"arn:aws:logs:*:*:log-group:/aws/docdb/*",
"arn:aws:logs:*:*:log-group:/aws/neptune/*"
]
},
{
"Effect": "Allow",
"Action": [
"logs:CreateLogStream",
"logs:PutLogEvents",
"logs:DescribeLogStreams"
],
"Resource": [
"arn:aws:logs:*:*:log-group:/aws/rds/*:log-stream:*",
"arn:aws:logs:*:*:log-group:/aws/docdb/*:log-stream:*",
"arn:aws:logs:*:*:log-group:/aws/neptune/*:log-stream:*"
]
},
{
"Effect": "Allow",
"Action": [
"kinesis:CreateStream",
"kinesis:PutRecord",
"kinesis:PutRecords",
"kinesis:DescribeStream",
"kinesis:SplitShard",
"kinesis:MergeShards",
"kinesis:DeleteStream",
"kinesis:UpdateShardCount"
],
"Resource": [

1838

"arn:aws:kinesis::*:stream/aws-rds-das-*"
},
{
"Effect": "Allow",
"Action": [
"cloudwatch:PutMetricData"
],
"Resource": "*",
"Condition": {
"StringEquals": {
"cloudwatch:namespace": [
"AWS/DocDB",
"AWS/Neptune",
"AWS/RDS"
]
}
}
]

Note
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:
Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.
Make sure you have the following permissions enabled:

{  
"Action": "iam:CreateServiceLinkedRole",
"Effect": "Allow",
"Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/AWSServiceRoleForRDS",
"Condition": {
"StringLike": {
"iam:AWSServiceName":"rds.amazonaws.com"
}
}
}

For more information, see Service-linked role permissions in the IAM User Guide.

Creating a service-linked role for Amazon RDS

You don't need to manually create a service-linked role. When you create a DB instance, Amazon RDS creates the service-linked role for you.

Important
If you were using the Amazon RDS service before December 1, 2017, when it began supporting service-linked roles, then Amazon RDS created the AWSServiceRoleForRDS role in your account.
To learn more, see A new role appeared in my AWS account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB instance, Amazon RDS creates the service-linked role for you again.

Editing a service-linked role for Amazon RDS

Amazon RDS does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference
the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon RDS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB instances before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the Summary page for the chosen role, choose the Access Advisor tab.
4. On the Access Advisor tab, review recent activity for the service-linked role.

   Note
   If you are unsure whether Amazon RDS is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete all of your DB instances.

Deleting all of your instances

Use one of these procedures to delete each of your instances.

To delete an instance (console)

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the instance that you want to delete.
4. For Actions, choose Delete.
5. If you are prompted for Create final Snapshot?, choose Yes or No.
6. If you chose Yes in the previous step, for Final snapshot name enter the name of your final snapshot.
7. Choose Delete.

To delete an instance (CLI)

See delete-db-instance in the AWS CLI Command Reference.

To delete an instance (API)

See DeleteDBInstance in the Amazon RDS API Reference.
You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Service-linked role permissions for Amazon RDS Custom

Amazon RDS Custom uses the service-linked role named AWSServiceRoleForRDSCustom to allow RDS Custom to call AWS services on behalf of your DB instances.

The AWSServiceRoleForRDSCustom service-linked role trusts the following services to assume the role:

- custom.rds.amazonaws.com

This service-linked role has a permissions policy attached to it called AmazonRDSCustomServiceRolePolicy that grants it permissions to operate in your account. The role permissions policy allows RDS Custom to complete the following actions on the specified resources:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "ecc1",
         "Effect": "Allow",
         "Action": [
            "ec2:DescribeInstances",
            "ec2:DescribeInstanceAttribute",
            "ec2:DescribeRegions",
            "ec2:DescribeSnapshots",
            "ec2:DescribeNetworkInterfaces",
            "ec2:DescribeVolumes",
            "ec2:DescribeInstanceStatus",
            "ec2:DescribeIamInstanceProfileAssociations",
            "ec2:DescribeImages",
            "ec2:DescribeVpcs",
            "ec2:RegisterImage",
            "ec2:DeregisterImage",
            "ec2:DescribeTags",
            "ec2:DescribeSecurityGroups",
            "ec2:DescribeVolumesModifications",
            "ec2:DescribeSubnets",
            "ec2:DescribeVpcAttribute"
         ],
         "Resource": ["*"]
      },
      {
         "Sid": "ecc2",
         "Effect": "Allow",
         "Action": [

Creating, editing, or deleting the service-linked role for RDS Custom works the same as for Amazon RDS. For more information, see Service-linked role permissions for Amazon RDS (p. 1837).

**Note**
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:
Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.
Make sure you have the following permissions enabled:

```json
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/AmazonRDSCustomServiceRolePolicy",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName":"custom.rds.amazonaws.com"
    }
  }
}
```

For more information, see Service-linked role permissions in the IAM User Guide.
Amazon Virtual Private Cloud VPCs and Amazon RDS

There are two Amazon Elastic Compute Cloud (EC2) platforms that host Amazon RDS DB instances, EC2-VPC and EC2-Classic. Amazon Virtual Private Cloud (Amazon VPC) enables you to launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC).

When you use an Amazon VPC, you have control over your virtual networking environment: you can choose your own IP address range, create subnets, and configure routing and access control lists. The basic functionality of Amazon RDS is the same whether your DB instance is running in an Amazon VPC or not: Amazon RDS manages backups, software patching, automatic failure detection, and recovery. There is no additional cost to run your DB instance in an Amazon VPC.

Accounts that support only the EC2-VPC platform have a default VPC. All new DB instances are created in the default VPC unless you specify otherwise. If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, you are most likely on the EC2-VPC platform and have a default VPC.

Some legacy DB instances on the EC2-Classic platform are not in a VPC. The legacy EC2-Classic platform does not have a default VPC, but as is true for either platform, you can create your own VPC and specify that a DB instance be located in that VPC.

- Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863)
- Working with a DB instance that is not in a VPC (p. 1869)

This documentation only discusses VPC functionality relevant to Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide. For information about using a network address translation (NAT) gateway, see NAT gateways in the Amazon Virtual Private Cloud User Guide.

Working with a DB instance in a VPC

Unless you are working with a legacy DB instance, your DB instance is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC lets you launch AWS resources, such as an Amazon RDS DB instance or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon RDS DB instances in a VPC and outside of a VPC, see Scenarios for accessing a DB instance in a VPC (p. 1857).

For a tutorial that shows you how to create a VPC that you can use with a common Amazon RDS scenario, see Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863).

To learn how to work with DB instances inside a VPC, see the following:

Topics
Working with a DB instance in a VPC

Here are some tips on working with a DB instance in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB instance. A subnet is a segment of a VPC’s IP address range that you can specify and that lets you group instances based on your security and operational needs.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone should the need arise. You need to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

Note
The DB subnet group for a Local Zone can have only one subnet.

- If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes DNS hostnames and DNS resolution.

- Your VPC must have a DB subnet group that you create (for more information, see the next section). You create a DB subnet group by specifying the subnets you created. Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet.

- Your VPC must have a VPC security group that allows access to the DB instance.

- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon RDS to use during maintenance activities, including failover and compute scaling.

- A VPC can have an instance tenancy attribute of either default or dedicated. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB instance in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB instance must be one of the approved Amazon EC2 dedicated instance types. For example, the m3.medium EC2 dedicated instance corresponds to the db.m3.medium DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

For more information about the instance types that can be in a dedicated instance, see Amazon EC2 dedicated instances on the EC2 pricing page.

Note
When you set the instance tenancy attribute to dedicated for an Amazon RDS DB instance, it doesn’t guarantee that the DB instance will run on a dedicated host.

- When an option group is assigned to a DB instance, it is linked to the supported platform the DB instance is on, either VPC or EC2-Classic (non-VPC). Furthermore, if a DB instance is in a VPC, the option group associated with the DB instance is linked to that VPC. This linkage means that you cannot use the option group assigned to a DB instance if you attempt to restore the DB instance into a different VPC or onto a different platform.

- If you restore a DB instance into a different VPC or onto a different platform, you must either assign the default option group to the DB instance, assign an option group that is linked to that VPC or platform, or create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC.
Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A DB subnet group is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when creating DB instances using the CLI or API; if you use the console, you can just choose the VPC and subnets you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB instance in a VPC, you must choose a DB subnet group. From the DB subnet group, Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet. If the primary DB instance of a Multi-AZ deployment fails, Amazon RDS can promote the corresponding standby and subsequently create a new standby using an IP address of the subnet in one of the other Availability Zones.

The subnets in a DB subnet group are either public or private. They can't be a mix of both public and private subnets. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables.

**Note**
The DB subnet group for a Local Zone can have only one subnet.

When Amazon RDS creates a DB instance in a VPC, it assigns a network interface to your DB instance by using an IP address from your DB subnet group. However, we strongly recommend that you use the DNS name to connect to your DB instance because the underlying IP address changes during failover.

**Note**
For each DB instance that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon RDS for recovery actions.

Hiding a DB instance in a VPC from the internet

One common Amazon RDS scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB instance with a database that is not publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet, and the DB instances are deployed in the private subnet. In such a deployment, only the web servers have access to the DB instances. For an illustration of this scenario, see A DB instance in a VPC accessed by an EC2 instance in the same VPC (p. 1857).

When you launch a DB instance inside a VPC, the DB instance has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the `Public access` option to designate whether the DB instance also has a public IP address in addition to the private IP address. If the DB instance is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the DB instance's VPC, and to the public IP address from outside of the DB instance's VPC. Access to the DB instance is ultimately controlled by the security group it uses, and that public access is not permitted if the security group assigned to the DB instance doesn't permit it.

You can modify a DB instance to turn on or off public accessibility by modifying the `Public access` option. For more information, see the modifying section for your DB engine.

The following illustration shows the `Public access` option in the `Additional connectivity configuration` section. To set the option, open the `Additional connectivity configuration` section in the `Connectivity` section.
Creating a DB instance in a VPC

The following procedures help you create a DB instance in a VPC. If your account has a default VPC, you can begin with step 3 because the VPC and DB subnet group have already been created for you. If your AWS account doesn't have a default VPC, or if you want to create an additional VPC, you can create a new VPC.

If you don't know if you have a default VPC, see Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869).

**Note**
If you want your DB instance in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes *DNS hostnames* and *DNS resolution.* For
Follow these steps to create a DB instance in a VPC:

- **Step 1: Create a VPC (p. 1853)**
- **Step 2: Add subnets to the VPC (p. 1853)**
- **Step 3: Create a DB subnet group (p. 1853)**
- **Step 4: Create a VPC security group (p. 1856)**
- **Step 5: Create a DB instance in the VPC (p. 1856)**

### Step 1: Create a VPC

If your AWS account does not have a default VPC or if you want to create an additional VPC, follow the instructions for creating a new VPC. See Create a VPC with private and public subnets (p. 1863), or see Step 1: Create a VPC in the Amazon VPC documentation.

### Step 2: Add subnets to the VPC

Once you have created a VPC, you need to create subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For instructions on how to create subnets in a VPC, see Create a VPC with private and public subnets (p. 1863).

### Step 3: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when you create DB instances using the CLI or API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region.

As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region. For Multi-AZ deployments, defining a subnet for all Availability Zones in an AWS Region enables Amazon RDS to create a new standby replica in another Availability Zone if necessary. You can follow this best practice even for Single-AZ deployments, because you might convert them to Multi-AZ deployments in the future.

For a DB instance to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see Internet gateways in the Amazon VPC documentation.

**Note**

The DB subnet group for a Local Zone can have only one subnet.

When you create a DB instance in a VPC, make sure to choose a DB subnet group. Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. Amazon RDS creates and associates an Elastic Network Interface to your DB instance with that IP address. The DB instance uses the Availability Zone that contains the subnet. For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone should the need arise. You need to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.
To create a DB subnet group
1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Subnet groups.
3. Choose Create DB Subnet Group.
4. For Name, type the name of your DB subnet group.
5. For Description, type a description for your DB subnet group.
6. For VPC, choose the VPC that you created.
7. In the Add subnets section, choose the Availability Zones that include the subnets from Availability Zones, and then choose the subnets from Subnets.
Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

**Subnet group details**

**Name**
You won’t be able to modify the name after your subnet group has been created.

mydbsubnetgroup

Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

**Description**

My DB Subnet Group

**VPC**
Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won’t be able to choose a different VPC identifier after your subnet group has been created.

tutorial-vpc (vpc-06bf3b3b3b3b3b3b3)

**Add subnets**

**Availability Zones**
Choose the Availability Zones that include the subnets you want to add.

Choose an availability zone

us-east-1a ✗   us-east-1c ✗

**Subnets**
Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

Select subnets

subnet-079bd4b8953aee1dd (10.0.0.0/24) ✗
subnet-057e85b72c46fdd9a (10.0.1.0/24) ✗

**Subnets selected (2)**

<table>
<thead>
<tr>
<th>Availability zone</th>
<th>Subnet ID</th>
<th>CIDR block</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east-1a</td>
<td>subnet-079bd4b8953aee1dd</td>
<td>10.0.0.0/24</td>
</tr>
<tr>
<td>us-east-1c</td>
<td>subnet-057e85b72c46fdd9a</td>
<td>10.0.1.0/24</td>
</tr>
</tbody>
</table>
Note
If you have enabled a Local Zone, you can choose an Availability Zone group on the Create DB subnet group page. In this case, choose the Availability Zone group, Availability Zones, and Subnets.

8. Choose Create.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

Step 4: Create a VPC security group

Before you create your DB instance, you must create a VPC security group to associate with your DB instance. For instructions on how to create a security group for your DB instance, see Create a VPC security group for a private DB instance (p. 1866), or see Security groups for your VPC in the Amazon VPC documentation.

Step 5: Create a DB instance in the VPC

In this step, you create a DB instance and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

Note
If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes DNS hostnames and DNS resolution. For information on updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

For details on how to create a DB instance, see Creating an Amazon RDS DB instance (p. 175).

When prompted in the Connectivity section, enter the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

Updating the VPC for a DB instance

You can use the AWS Management Console to move your DB instance to a different VPC.

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309). In the Connectivity section of the modify page, shown following, enter the new subnet group for Subnet group. The new subnet group must be a subnet group in a new VPC.

Connectivity

<table>
<thead>
<tr>
<th>Subnet group</th>
</tr>
</thead>
<tbody>
<tr>
<td>default-vpc-665e7a1f</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Security group</th>
</tr>
</thead>
<tbody>
<tr>
<td>List of DB security groups to associate with this DB instance.</td>
</tr>
</tbody>
</table>

You can't change the VPC for a DB instance if the following conditions apply:
• The DB instance is in multiple Availability Zones. You can convert the DB instance to a single Availability Zone, move it to a new VPC, and then convert it back to a Multi-AZ DB instance. For more information, see Multi-AZ deployments for high availability (p. 65).

• The DB instance has one or more read replicas. You can remove the read replicas, move the DB instance to a new VPC, and then add the read replicas again. For more information, see Working with read replicas (p. 354).

• The DB instance is a read replica. You can promote the read replica, and then move the standalone DB instance to a new VPC. For more information, see Promoting a read replica to be a standalone DB instance (p. 361).

• The subnet group in the target VPC doesn’t have subnets in the DB instance’s the Availability Zone. You can add subnets in the DB instance’s Availability Zone to the DB subnet group, and then move the DB instance to the new VPC. For more information, see Working with DB subnet groups (p. 1851).

Scenarios for accessing a DB instance in a VPC

Amazon RDS supports the following scenarios for accessing a DB instance in a VPC:

• An EC2 instance in the same VPC (p. 1857)
• An EC2 instance in a different VPC (p. 1859)
• A client application through the internet (p. 1860)
• A private network (p. 1860)
• An EC2 instance not in a VPC (p. 1861)

A DB instance in a VPC accessed by an EC2 instance in the same VPC

A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC. This is the user scenario created if you use AWS Elastic Beanstalk to create an EC2 instance and a DB instance in the same VPC.

The following diagram shows this scenario.
The simplest way to manage access between EC2 instances and DB instances in the same VPC is to do the following:

- Create a VPC security group for your DB instances to be in. This security group can be used to restrict access to the DB instances. For example, you can create a custom rule for this security group that allows TCP access using the port you assigned to the DB instance when you created it and an IP address you use to access the DB instance for development or other purposes.

- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.

- Create custom rules in the security group for your DB instances that allow connections from the security group you created for your EC2 instances. This would allow any member of the security group to access the DB instances.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863).

**To create a rule in a VPC security group that allows connections from another security group, do the following:**

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose Security Groups.
3. Choose or create a security group for which you want to allow access to members of another security group. In the scenario preceding, this is the security group that you use for your DB instances. Choose the Inbound rules tab, and then choose Edit inbound rules.
5. From **Type**, choose the entry that corresponds to the port you used when you created your DB instance, such as **MYSQL/Aurora**.

6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.

7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in the **Source** box.

8. Choose **Save rules** when you are done.

The following screen shows an inbound rule with a security group for its source.

![Screenshot of inbound rule](image)

**A DB instance in a VPC accessed by an EC2 instance in a different VPC**

When your DB instance is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB instance.

The following diagram shows this scenario.

![Diagram of VPC peering](image)

A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Instances in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see **VPC peering** in the *Amazon Virtual Private Cloud User Guide*. 1859
A DB instance in a VPC accessed by a client application through the internet

To access a DB instance in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon RDS DB instance that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB instance.
- An internet gateway which connects the VPC to the internet and to other AWS products.
- A security group associated with the DB instance. The security group's inbound rules allow your client application to access to your DB instance.

For information about creating a DB instance in a VPC, see Creating a DB instance in a VPC (p. 1852).

A DB instance in a VPC accessed by a private network

If your DB instance isn't publicly accessible, you have the following options for accessing it from a private network:

- An AWS Site-to-Site VPN connection. For more information, see What is AWS Site-to-Site VPN?
- An AWS Direct Connect connection. For more information, see What is AWS Direct Connect?

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.
Scenarios for accessing a DB instance in a VPC

For more information, see Internetwork traffic privacy (p. 1765).

A DB instance in a VPC accessed by an EC2 instance not in a VPC

You can communicate between an Amazon RDS DB instance that is in a VPC and an EC2 instance that is not in an Amazon VPC by using ClassicLink. When you use ClassicLink, an application on the EC2 instance can connect to the DB instance by using the endpoint for the DB instance. ClassicLink is available at no charge.

Important
If your EC2 instance was created after 2013, it is probably in a VPC.

The following diagram shows this scenario.

Using ClassicLink, you can connect an EC2 instance to a logically isolated database where you define the IP address range and control the access control lists (ACLs) to manage network traffic. You don't have to use public IP addresses or tunneling to communicate with the DB instance in the VPC. This arrangement provides you with higher throughput and lower latency connectivity for inter-instance communications.

To enable ClassicLink between a DB instance in a VPC and an EC2 instance not in a VPC

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc.
2. In the navigation pane, choose Your VPCs.
3. Choose the VPC used by the DB instance.
4. In Actions, choose Enable ClassicLink. In the confirmation dialog box, choose Yes, Enable.
5. On the EC2 console, choose the EC2 instance you want to connect to the DB instance in the VPC.
6. In Actions, choose ClassicLink, and then choose Link to VPC.
7. On the Link to VPC page, choose the security group you want to use, and then choose Link to VPC.

Note
The ClassicLink features are only visible in the consoles for accounts and regions that support EC2-Classic. For more information, see ClassicLink in the Amazon EC2 User Guide for Linux Instances.
Tutorial: Create an Amazon VPC for use with a DB instance

A common scenario includes a DB instance in an Amazon VPC, that shares data with a web server that is running in the same VPC. In this tutorial you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB instance in a VPC (p. 1857).

Because your DB instance only needs to be available to your web server, and not to the public Internet, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public Internet. The DB instance is hosted in a private subnet. The web server is able to connect to the DB instance because it is hosted within the same VPC, but the DB instance is not available to the public Internet, providing greater security.

This tutorial describes configuring a VPC for Amazon RDS DB instances. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Note
For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon RDS DB instance (p. 141).

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.
To create a VPC and subnets

1. If you don't have an Elastic IP address to associate with a network address translation (NAT) gateway, allocate one now. A NAT gateway is required for this tutorial. If you have an available Elastic IP address, move on to the next step.
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the top-right corner of the AWS Management Console, choose the Region to allocate your Elastic IP address in. The Region of your Elastic IP address should be the same as the Region where you want to create your VPC. This example uses the US West (Oregon) Region.
   c. In the navigation pane, choose Elastic IPs.
   d. Choose Allocate Elastic IP address.
   e. If the console shows the Network Border Group field, keep the default value for it.
   f. For Public IPv4 address pool, choose Amazon's pool of IPv4 addresses.
   g. Choose Allocate.
      
      Note the allocation ID of the new Elastic IP address because you'll need this information when you create your VPC.

   For more information about Elastic IP addresses, see Elastic IP addresses in the Amazon EC2 User Guide. For more information about NAT gateways, see NAT gateways in the Amazon VPC User Guide.

2. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
3. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
4. In the upper-left corner, choose VPC Dashboard. To begin creating a VPC, choose Launch VPC Wizard.
5. On the Step 1: Select a VPC Configuration page, choose VPC with Public and Private Subnets, and then choose Select.
6. On the Step 2: VPC with Public and Private Subnets page, set these values:
   - IPv4 CIDR block: 10.0.0.0/16
   - IPv6 CIDR block: No IPv6 CIDR Block
   - VPC name: tutorial-vpc
   - Public subnet's IPv4 CIDR: 10.0.0.0/24
   - Availability Zone: us-west-2a
   - Public subnet name: Tutorial public
   - Private subnet's IPv4 CIDR: 10.0.1.0/24
   - Availability Zone: us-west-2b
   - Private subnet name: Tutorial private 1
   - Elastic IP Allocation ID: An Elastic IP address to associate with the NAT gateway
   - Service endpoints: Skip this field.
   - Enable DNS hostnames: Yes
   - Hardware tenancy: Default
7. Choose Create VPC.

Create additional subnets

You must have either two private subnets or two public subnets available to create a DB subnet group for a DB instance to use in a VPC. Because the DB instance for this tutorial is private, add a second private subnet to the VPC.
To create an additional subnet

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. To add the second private subnet to your VPC, choose **VPC Dashboard**, choose **Subnets**, and then choose **Create subnet**.
3. On the **Create subnet** page, set these values:
   - **VPC ID**: Choose the VPC that you created in the previous step, for example: vpc-identifier (tutorial-vpc)
   - **Subnet name**: Tutorial private 2
   - **Availability Zone**: us-west-2c
     *Note*
     Choose an Availability Zone that is different from the one that you chose for the first private subnet.
   - **IPv4 CIDR block**: 10.0.2.0/24
4. Choose **Create subnet**.
5. To ensure that the second private subnet that you created uses the same route table as the first private subnet, complete the following steps:
   a. Choose **VPC Dashboard**, choose **Subnets**, and then choose the first private subnet that you created for the VPC, Tutorial private 1.
   b. Below the list of subnets, choose the **Route table** tab, and note the value for **Route Table**—for example: rtb-98b613fd.
   c. In the list of subnets, deselect the first private subnet.
   d. In the list of subnets, choose the second private subnet **Tutorial private 2**, and choose the **Route table** tab.
   e. If the current route table is not the same as the route table for the first private subnet, choose **Edit route table association**. For **Route table ID**, choose the route table that you noted earlier—for example: rtb-98b613fd. Next, to save your selection, choose **Save**.

Create a VPC security group for a public web server

Next you create a security group for public access. To connect to public instances in your VPC, you add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name**: tutorial-securitygroup
   - **Description**: Tutorial Security Group
   - **VPC**: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to instances in your VPC. To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is 203.0.113.25/32.

   If you are connecting through an Internet service provider (ISP) or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.
Warning
If you use 0.0.0.0/0, you enable all IP addresses to access your public instances. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you'll authorize only a specific IP address or range of addresses to access your instances.

b. In the Inbound rules section, choose Add rule.
c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your EC2 instance. If you do this, you can connect to your EC2 instance to install the web server and other utilities, and to upload content for your web server.

• Type: SSH
• Source: The IP address or range from Step a, for example: 203.0.113.25/32.
d. Choose Add rule.
e. Set the following values for your new inbound rule to allow HTTP access to your web server.

• Type: HTTP
• Source: 0.0.0.0/0

5. To create the security group, choose Create security group.

Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private instances in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose VPC Dashboard, choose Security Groups, and then choose Create security group.
3. On the Create security group page, set these values:

• Security group name: tutorial-db-securitygroup
• Description: Tutorial DB Instance Security Group
• VPC: Choose the VPC that you created earlier, for example: vpc-identifier (tutorial-vpc)
4. Add inbound rules to the security group.

a. In the Inbound rules section, choose Add rule.
b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your EC2 instance. If you do this, you can connect from your web server to your DB instance to store and retrieve data from your web application to your database.

• Type: MySQL/Aurora
• Source: The identifier of the tutorial-securitygroup security group that you created previously in this tutorial, for example: sg-9edd5cfb.
5. To create the security group, choose Create security group.

Create a DB subnet group

A DB subnet group is a collection of subnets that you create in a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when creating DB instances.
To create a DB subnet group

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   
   **Note**  
   Make sure you connect to the Amazon RDS console, not to the Amazon VPC console.

2. In the navigation pane, choose **Subnet groups**.

3. Choose **Create DB Subnet Group**.

4. On the **Create DB subnet group** page, set these values in **Subnet group details**:
   - **Name**: tutorial-db-subnet-group
   - **Description**: Tutorial DB Subnet Group
   - **VPC**: tutorial-vpc (vpc-identifier)

5. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.
   
   For this tutorial, choose **us-west-2b** and **us-west-2c** for the **Availability Zones**. Next, for **Subnets**, choose the subnets for IPv4 CIDR block 10.0.1.0/24 and 10.0.2.0/24.
   
   **Note**  
   If you have enabled a Local Zone, you can choose an Availability Zone group on the **Create DB subnet group** page. In this case, choose the **Availability Zone group**, **Availability Zones**, and **Subnets**.

6. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can click the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

   **Note**  
   If you created this VPC to complete Tutorial: Create a web server and an Amazon RDS DB instance (p. 141), create the DB instance by following the instructions in Create a DB instance (p. 142).

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

**Note**  
If you added resources in the Amazon VPC you created for this tutorial, such as Amazon EC2 instances or Amazon RDS DB instances, you might need to delete these resources before you can delete the VPC. For more information, see Delete your VPC in the Amazon VPC User Guide.

To delete a VPC and related resources

1. Delete the DB subnet group.
   
   a. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group you want to delete, such as tutorial-db-subnet-group.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.

2. Note the VPC ID.
   
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose **VPC Dashboard**, and then choose **VPCs**.
   c. In the list, identify the VPC you created, such as tutorial-vpc.
d. Note the VPC ID of the VPC you created. You will need the VPC ID in subsequent steps.

3. Delete the security groups.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose Security Groups.
   c. Select the security group for the Amazon RDS DB instance, such as tutorial-db-securitygroup.
   d. From Actions, choose Delete security groups, and then choose Delete on the confirmation page.
   e. On the Security Groups page, select the security group for the Amazon EC2 instance, such as tutorial-securitygroup.
   f. From Actions, choose Delete security groups, and then choose Delete on the confirmation page.

4. Delete the NAT gateway.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose NAT Gateways.
   c. Select the NAT gateway of the VPC you created. Use the VPC ID to identify the correct NAT gateway.
   d. From Actions, choose Delete NAT gateway.
   e. On the confirmation page, enter delete, and then choose Delete.

5. Delete the VPC.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose VPC Dashboard, and then choose VPCs.
   c. Select the VPC you want to delete, such as tutorial-vpc.
   d. From Actions, choose Delete VPC.
      The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.
   e. On the confirmation page, enter delete, and then choose Delete.

   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. Choose EC2 Dashboard, and then choose Elastic IPs.
   c. Select the Elastic IP address you want to release.
   d. From Actions, choose Release Elastic IP addresses.
   e. On the confirmation page, choose Release.
Working with a DB instance that is not in a VPC

The legacy *EC2-Classic* platform is the original platform used by Amazon RDS. If you are on the *EC2-Classic* platform, your DB instances are not in an Amazon VPC.

**Important**
If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, in almost all cases you are on the *EC2-Classic* platform and have a default VPC. Also, if your DB instance was created after 2013, it is probably in a VPC. For information about working with DB instances in a VPC, see *Working with a DB instance in a VPC (p. 1849)*.

**Topics**
- Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1869)
- Scenarios for accessing a DB instance not in a VPC (p. 1871)
- Moving a DB instance not in a VPC into a VPC (p. 1873)

**Determining whether you are using the EC2-VPC or EC2-Classic platform**

Your AWS account and the AWS Region you choose determines which of the two RDS platforms your DB instance is created on: *EC2-VPC or EC2-Classic*. The type of platform determines if you have a default VPC, and which type of security group you use to provide access to your DB instance.

The legacy *EC2-Classic* platform is the original platform used by Amazon RDS. If you are on this platform and want to use a VPC, you must create the VPC using the Amazon VPC console or Amazon VPC API. Accounts that only support the *EC2-VPC* platform have a default VPC where all DB instances are created, and you must use either an EC2 or VPC security group to provide access to the DB instance.

**Important**
If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, in almost all cases you are on the *EC2-VPC* platform and have a default VPC. Also, if your DB instance was created after 2013, it is probably in a VPC. For information about working with DB instances in a VPC, see *Working with a DB instance in a VPC (p. 1849)*.

You can tell which platform your AWS account in a given AWS Region is using by looking at the dashboard on the RDS console or EC2 console. If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, you might be redirected to the first-run console page and not see the home page following.

**EC2-VPC platform in the console**

If **Supported platforms** indicates only *VPC*, as shown following in the RDS console, your AWS account in the current AWS Region uses the *EC2-VPC* platform, and uses a default VPC.
Similarly, if **Supported platforms** indicates only VPC, as shown following in the EC2 console, your AWS account in the current AWS Region uses the **EC2-VPC** platform, and uses a default VPC.

In both the RDS and EC2 console, the name of the default VPC is shown below the supported platform. To provide access to a DB instance created on the **EC2-VPC** platform, you must create a VPC security group. For information about creating a VPC security group, see Tutorial: Create an Amazon VPC for use with a DB instance (p. 1863).

**EC2-Classic platform in the console**

In both the RDS and EC2 console, if **Supported platforms** indicates both EC2 and VPC, your AWS account in the current AWS Region uses the **EC2-Classic** platform, and you do not have a default VPC. To provide access to a DB instance created on the **EC2-Classic** platform, you must create a DB security group. For information about creating a DB security group, see Creating a DB security group (p. 1827).

**Note**

- You can create a VPC on the **EC2-Classic** platform, but one is not created for you by default as it is on accounts that support the **EC2-VPC** platform.
• If you want to move an existing DB instance into a VPC, you can use the AWS Management Console to do it easily. For more information, see Moving a DB instance not in a VPC into a VPC (p. 1873).

Scenarios for accessing a DB instance not in a VPC

Amazon RDS supports the following scenarios for accessing a DB instance that is not in a VPC:

• An EC2 instance in a VPC (p. 1857)
• A client application through the internet (p. 1872)
• An EC2 instance not in a VPC (p. 1872)

Important
If your DB instance was created after 2013, it is probably in a VPC. For information about accessing a DB instance in a VPC, see Scenarios for accessing a DB instance in a VPC (p. 1857).

A DB instance not in a VPC accessed by an EC2 instance in a VPC

In the case where you have an EC2 instance in a VPC and an RDS DB instance not in a VPC, you can connect them over the public internet.

The following diagram shows this scenario.

Note
ClassicLink, as described in A DB instance in a VPC accessed by an EC2 instance not in a VPC (p. 1861), is not available for this scenario.

To connect your DB instance and your EC2 instance over the public internet, do the following:

• Ensure that the EC2 instance is in a public subnet in the VPC.
• Ensure that the RDS DB instance was marked as publicly accessible.
• A note about network ACLs here. A network ACL is like a firewall for your entire subnet. Therefore, all instances in that subnet are subject to network ACL rules. By default, network ACLs allow all traffic and you generally don’t need to worry about them, unless you particularly want to add rules as an extra
layer of security. A security group, on the other hand, is associated with individual instances, and you do need to worry about security group rules.

- Add the necessary ingress rules to the DB security group for the RDS DB instance.

  An ingress rule specifies a network port and a CIDR/IP range. For example, you can add an ingress rule that allows port 3306 to connect to a MySQL RDS DB instance, and a CIDR/IP range of 203.0.113.25/32. For more information, see Authorizing network access to a DB security group from an IP range (p. 1831).

**Note**

If you are interested in moving an existing DB instance into a VPC, you can use the AWS Management Console to do it easily. For more information, see Moving a DB instance not in a VPC into a VPC (p. 1873).

**A DB instance not in a VPC accessed by a client application through the internet**

New Amazon RDS customers can only create a DB instance in a VPC. However, you might need to connect to an existing Amazon RDS DB instance that is not in a VPC from a client application through the internet.

The following diagram shows this scenario.

![Diagram showing a DB instance not in a VPC accessed by a client application through the internet](image.png)

In this scenario, you must ensure that the DB security group for the RDS DB instance includes the necessary ingress rules for your client application to connect. An ingress rule specifies a network port and a CIDR/IP range. For example, you can add an ingress rule that allows port 3306 to connect to a MySQL RDS DB instance, and a CIDR/IP range of 203.0.113.25/32. For more information, see Authorizing network access to a DB security group from an IP range (p. 1831).

**Warning**

If you intend to access a DB instance behind a firewall, talk with your network administrator to determine the IP addresses you should use.

**Note**

If you are interested in moving an existing DB instance into a VPC, you can use the AWS Management Console to do it easily. For more information, see Moving a DB instance not in a VPC into a VPC (p. 1873).

**A DB instance not in a VPC accessed by an EC2 instance not in a VPC**

When neither your DB instance nor an application on an EC2 instance are in a VPC, you can access the DB instance by using its endpoint and port.

The following diagram shows this scenario.
You must create a security group for the DB instance that permits access from the port you specified when creating the DB instance. For example, you could use a connection string similar to this connection string used with `sqlplus` to access an Oracle DB instance:

```
PROMPT>sqlplus 'mydbusr@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<endpoint>)(PORT=<port number>))(CONNECT_DATA=(SID=<database name>)))'
```

For more information, see the following documentation.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Relevant documentation</th>

<tr>
<td>MariaDB</td>
<td>Connecting to a DB instance running the MariaDB database engine (p. 851)</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td>Connecting to a DB instance running the Microsoft SQL Server database engine (p. 947)</td>
</tr>
<tr>
<td>MySQL</td>
<td>Connecting to a DB instance running the MySQL database engine (p. 1146)</td>
</tr>
<tr>
<td>Oracle</td>
<td>Connecting to your Oracle DB instance (p. 1312)</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>Connecting to a DB instance running the PostgreSQL database engine (p. 1599)</td>
</tr>
</tbody>
</table>

**Note**

If you are interested in moving an existing DB instance into a VPC, you can use the AWS Management Console to do it easily. For more information, see Moving a DB instance not in a VPC into a VPC (p. 1873).

### Moving a DB instance not in a VPC into a VPC

Some legacy DB instances on the EC2-Classic platform are not in a VPC. If your DB instance is not in a VPC, you can use the AWS Management Console to easily move your DB instance into a VPC. Before you can move a DB instance not in a VPC, into a VPC, you must create the VPC.

**Important**

If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, in almost all cases you are on the EC2-VPC platform and have a default VPC. For information about working with DB instances in a VPC, see Working with a DB instance in a VPC (p. 1849)

Follow these steps to create a VPC for your DB instance.

- **Step 1:** Create a VPC (p. 1853)
- **Step 2:** Add subnets to the VPC (p. 1853)
Each DB subnet group must include at least the Availability Zones in which the DB instance is located.

After you create the VPC, follow these steps to move your DB instance into the VPC.

- **Updating the VPC for a DB instance (p. 1856)**

We highly recommend that you create a backup of your DB instance immediately before the migration. Doing so ensures that you can restore the data if the migration fails. For more information, see Backing up and restoring an Amazon RDS DB instance (p. 406).

The following are some limitations to moving your DB instance into the VPC.

- **Previous generation DB instance classes** – Previous generation DB instance classes might not be supported on the VPC platform. When moving a DB instance to a VPC, choose a db.m3 or db.r3 DB instance class. After you move the DB instance to a VPC, you can scale the DB instance to use a later DB instance class. For a full list of VPC supported instance classes, see Amazon RDS instance types.

- **Multi-AZ** – Moving a Multi-AZ DB instance not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first modify the DB instance so that it is a single-AZ deployment. Change the Multi-AZ deployment setting to **No**. After you move the DB instance to a VPC, modify it again to make it a Multi-AZ deployment. For more information, see Modifying an Amazon RDS DB instance (p. 309).

- **Read replicas** – Moving a DB instance with read replicas not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first delete all of its read replicas. After you move the DB instance to a VPC, recreate the read replicas. For more information, see Working with read replicas (p. 354).

- **Option groups** – If you move your DB instance to a VPC, and the DB instance is using a custom option group, change the option group that is associated with your DB instance. Option groups are platform-specific, and moving to a VPC is a change in platform. To use a custom option group in this case, assign the default VPC option group to the DB instance, assign an option group that is used by other DB instances in the VPC you are moving to, or create a new option group and assign it to the DB instance. For more information, see Working with option groups (p. 262).

**Alternatives for moving a DB instance not in a VPC into a VPC with minimal downtime**

Using the following alternatives, you can move a DB instance not in a VPC into a VPC with minimal downtime. These alternatives cause minimum disruption to the source DB instance and allow it to serve user traffic during the migration. However, the time required to migrate to a VPC will vary based on the database size and the live workload characteristics.

- **AWS Database Migration Service (AWS DMS)** – AWS DMS enables the live migration of data while keeping the source DB instance fully operational, but it replicates only a limited set of DDL statements. AWS DMS doesn't propagate items such as indexes, users, privileges, stored procedures, and other database changes not directly related to table data. In addition, AWS DMS doesn't automatically use RDS snapshots for the initial DB instance creation, which can increase migration time. For more information, see AWS Database Migration Service.

- **DB snapshot restore or point-in-time recovery** – You can move a DB instance to a VPC by restoring a snapshot of the DB instance or by restoring a DB instance to a point in time. For more information, see Restoring from a DB snapshot (p. 432) and Restoring a DB instance to a specified time (p. 480).
Quotas and constraints for Amazon RDS

Following, you can find a description of the resource quotas and naming constraints for Amazon RDS.

Topics
- Quotas in Amazon RDS (p. 1875)
- Naming constraints in Amazon RDS (p. 1877)
- Maximum number of database connections (p. 1877)
- File size limits in Amazon RDS (p. 1879)

Quotas in Amazon RDS

Each AWS account has quotas, for each AWS Region, on the number of Amazon RDS resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorizations per DB security group</td>
<td>Each supported Region: 20</td>
<td>No</td>
</tr>
<tr>
<td>DB cluster parameter groups</td>
<td>Each supported Region: 50</td>
<td>No</td>
</tr>
<tr>
<td>DB clusters</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
</tr>
<tr>
<td>DB instances</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
</tr>
<tr>
<td>DB subnet groups</td>
<td>Each supported Region: 50</td>
<td>Yes</td>
</tr>
<tr>
<td>Data API HTTP request body size</td>
<td>Each supported Region: 4 Megabytes</td>
<td>No</td>
</tr>
<tr>
<td>Data API maximum concurrent cluster-secret pairs</td>
<td>Each supported Region: 30</td>
<td>No</td>
</tr>
<tr>
<td>Data API maximum concurrent requests</td>
<td>Each supported Region: 500</td>
<td>No</td>
</tr>
<tr>
<td>Data API maximum result set size</td>
<td>Each supported Region: 1 Megabytes</td>
<td>No</td>
</tr>
<tr>
<td>Data API requests per second</td>
<td>Each supported Region: 1,000 per second</td>
<td>No</td>
</tr>
<tr>
<td>Event subscriptions</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
</tr>
<tr>
<td>IAM roles per DB cluster</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
</tr>
<tr>
<td>IAM roles per DB instance</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Adjustable</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>----------------------------------------------</td>
<td>------------</td>
</tr>
<tr>
<td>Manual DB cluster snapshots</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
</tr>
<tr>
<td>Manual DB instance snapshots</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
</tr>
<tr>
<td>Option groups</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
</tr>
<tr>
<td>Parameter groups</td>
<td>Each supported Region: 50</td>
<td>Yes</td>
</tr>
<tr>
<td>Proxies</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
</tr>
<tr>
<td>Read replicas per master</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
</tr>
<tr>
<td>Reserved DB instances</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
</tr>
<tr>
<td>Rules per security group</td>
<td>Each supported Region: 20</td>
<td>No</td>
</tr>
<tr>
<td>Security groups</td>
<td>Each supported Region: 25</td>
<td>Yes</td>
</tr>
<tr>
<td>Security groups (VPC)</td>
<td>Each supported Region: 5</td>
<td>No</td>
</tr>
<tr>
<td>Subnets per DB subnet group</td>
<td>Each supported Region: 20</td>
<td>No</td>
</tr>
<tr>
<td>Tags per resource</td>
<td>Each supported Region: 50</td>
<td>No</td>
</tr>
<tr>
<td>Total storage for all DB instances</td>
<td>Each supported Region: 100,000 Gigabytes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Note**
By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota. The following limitations apply to the Amazon RDS DB instances:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

If your application requires more DB instances, you can request additional DB instances by opening the Service Quotas console. In the navigation pane, choose AWS services. Choose Amazon Relational Database Service (Amazon RDS), choose a quota, and follow the directions to request a quota increase. For more information, see Requesting a quota increase in the Service Quotas User Guide.

Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the manual snapshot quota. For information about AWS Backup, see the AWS Backup Developer Guide.

If you use any of the Amazon RDS APIs and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error similar to the following: ClientError: An error occurred (ThrottlingException) when calling the API_name operation: Rate exceeded. Reduce the number of calls per second. The quota is meant to cover most use cases. If higher limits are needed, request a quota increase by contacting AWS Support. Open the AWS Support Center page, sign in if necessary, and choose Create case. Choose Service limit increase. Complete and submit the form.

**Note**
This quota can't be changed in the Amazon RDS Service Quotas console.
Naming constraints in Amazon RDS

The following table describes naming constraints in Amazon RDS.

<table>
<thead>
<tr>
<th>Resource or item</th>
<th>Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB instance identifier</td>
<td>Identifiers have these naming constraints:</td>
</tr>
<tr>
<td></td>
<td>• Must contain 1–63 alphanumeric characters or hyphens.</td>
</tr>

</tr>
</tbody>
</table>

Maximum number of database connections

The maximum number of simultaneous database connections varies by the DB engine type and the memory allocation for the DB instance class. The maximum number of connections is set in the parameter group associated with the DB instance, except for Microsoft SQL Server, where it is set in the server properties for the DB instance in SQL Server Management Studio (SSMS).
### DBInstanceClassMemory

DBInstanceClassMemory is in bytes. For details about how this value is calculated, see Specifying DB parameters (p. 298). In particular, due to memory reserved for the operating system and the RDS management processes, this memory size is smaller than the value in gibibytes (GiB) shown in the table of Hardware specifications for DB instance classes (p. 44).

**Note**

For Oracle, you set the maximum number of user processes and user and system sessions.

### Maximum database connections

<table>
<thead>
<tr>

<td>concurrent connections</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In an instance where the total RAM is 16 GiB, or 17,179,869,184 bytes, the variable DBInstanceClassMemory will automatically subtract the amounts reserved to the operating system and the RDS processes that manage the instance. The remainder of the subtraction is then divided by 12,582,880, which will result in the maximum connections number being around 1300, depending on instance type, instance size and DB engine.

Database connections consume memory. Setting one of these parameters too high can cause a low memory condition that might cause a DB instance to be placed in the incompatible-parameters status. For more information, see Diagnosing and resolving incompatible parameters status for a memory limit (p. 1886).

**Note**

You might see fewer than the maximum number of DB connections. This is to avoid potential out-of-memory issues.
File size limits in Amazon RDS

File size limits apply to certain Amazon RDS DB instances. For more information, see the following engine-specific limits:

- MariaDB file size limits in Amazon RDS (p. 844)
- MySQL file size limits in Amazon RDS (p. 1262)
- Oracle file size limits in Amazon RDS (p. 1310)
Troubleshooting for Amazon RDS

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Aurora.

Topics
- Can’t connect to Amazon RDS DB instance (p. 1880)
- Amazon RDS security issues (p. 1882)
- Resetting the DB instance owner password (p. 1882)
- Amazon RDS DB instance outage or reboot (p. 1883)
- Amazon RDS DB parameter changes not taking effect (p. 1883)
- Amazon RDS DB instance running out of storage (p. 1884)
- Amazon RDS insufficient DB instance capacity (p. 1885)
- MySQL and MariaDB issues (p. 1885)
- Can’t set backup retention period to 0 (p. 1892)

For information about debugging problems using the Amazon RDS API, see Troubleshooting applications on Amazon RDS (p. 1894).

Can’t connect to Amazon RDS DB instance

When you can’t connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

  By default, DB instances don’t allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

  **Note**
  When adding a new inbound rule, you can choose My IP for Source to allow access to the DB instance from the IP address detected in your browser.

  For more information about setting up security groups, see Provide access to your DB instance in your VPC by creating a security group (p. 96).

  **Note**
  Client connections from IP addresses within the range 169.254.0.0/16 aren’t permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

  To make the instance publicly accessible, modify it and choose Yes under Public accessibility. For more information, see Hiding a DB instance in a VPC from the internet (p. 1851).

- **Port** – The port that you specified when you created the DB instance can’t be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the
specified port to be used for inbound and outbound communication, check with your network administrator.

- **Availability** – For a newly created DB instance, the DB instance has a status of creating until the DB instance is ready to use. When the state changes to available, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.
- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

### To configure an internet gateway for a subnet

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases, and then choose the name of the DB instance.
3. In the Connectivity & security tab, write down the values of the VPC ID under VPC and the subnet ID under Subnets.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose Internet Gateways. Verify that there is an internet gateway attached to your VPC. Otherwise, choose Create Internet Gateway to create an internet gateway. Select the internet gateway, and then choose Attach to VPC and follow the directions to attach it to your VPC.
6. In the navigation pane, choose Subnets, and then select your subnet.
7. On the Route Table tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target.
   a. Choose the ID of the route table (rtb-xxxxxxxx) to navigate to the route table.
   b. On the Routes tab, choose Edit routes. Choose Add route, use 0.0.0.0/0 as the destination and the internet gateway as the target.
   c. Choose Save routes.

For more information, see Working with a DB instance in a VPC (p. 1849).

For engine-specific connection issues, see the following topics:

- Troubleshooting connections to your SQL Server DB instance (p. 952)
- Troubleshooting connections to your Oracle DB instance (p. 1317)
- Troubleshooting connections to your RDS for PostgreSQL instance (p. 1603)
- Maximum MySQL and MariaDB connections (p. 1886)

### Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following (replace DB-instance-endpoint with the endpoint and port with the port of your DB instance).

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299
```
Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

C:\>telnet sg-postgresql1.c6c8m7fake0.us-west-2.rds.amazonaws.com 819
Connecting To sg-postgresql1.c6c8m7fake0.us-west-2.rds.amazonaws.com...Could not open connection to the host, on port 819: Connect failed

If Telnet actions return success, your security group is properly configured.

**Note**
Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

**Troubleshooting connection authentication**

If you can connect to your DB instance but you get authentication errors, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

**Amazon RDS security issues**

To avoid security issues, never use your master AWS user name and password for a user account. Best practice is to use your master AWS account to create AWS Identity and Access Management (IAM) users and assign those to DB user accounts. You can also use your master account to create other user accounts, if necessary.

For more information on creating IAM users, see Create an IAM user (p. 93).

**Error message "failed to retrieve account attributes, certain console functions may be impaired."**

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your IAM administrator needs to provide the necessary roles to your account. For more information, see the IAM documentation.

**Resetting the DB instance owner password**

If you get locked out of your DB instance, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see Master user account privileges (p. 1835).
You can change the DB instance password by using the Amazon RDS console, the AWS CLI command `modify-db-instance`, or by using the `ModifyDBInstance` API operation. For more information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you either manually reboot your DB instance or change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0 and set `Apply Immediately` to `true`.
- You change the DB instance class, and `Apply Immediately` is set to `true`.
- You change the storage type from Magnetic (Standard) to General Purpose (SSD) or Provisioned IOPS (SSD), or from Provisioned IOPS (SSD) or General Purpose (SSD) to Magnetic (Standard).

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and `Apply Immediately` is set to `false`.
- You change the DB instance class, and `Apply Immediately` is set to `false`.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

To see a table that shows DB instance actions and the effect that setting the `Apply Immediately` value has, see Modifying an Amazon RDS DB instance (p. 309).

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console or explicitly calling the `RebootDBInstance` API operation (without failover, if the DB instance is in a Multi-AZ deployment). The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this might be calling `ModifyDBInstance` to
change the DB instance class. For more information, see Modifying parameters in a DB parameter group (p. 282).

Amazon RDS DB instance running out of storage

If your DB instance runs out of storage space, it might no longer be available. We highly recommend that you constantly monitor the FreeStorageSpace metric published in CloudWatch to make sure that your DB instance has enough free storage space.

If your database instance runs out of storage, its status changes to storage-full. For example, a call to the DescribeDBInstances API operation for a DB instance that has used up its storage outputs the following.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa storage-full  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306 us-east-1b  3 SECGROUP  default  active PARAMGRP  default.mysql8.0  in-sync
```

To recover from this scenario, add more storage space to your instance using the ModifyDBInstance API operation or the following AWS CLI command.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --allocated-storage 60 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --allocated-storage 60 ^
  --apply-immediately
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa storage-full  mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306 us-east-1b  3  60 SECGROUP  default  active PARAMGRP  default.mysql8.0  in-sync
```

Now, when you describe your DB instance, you see that your DB instance has modifying status, which indicates the storage is being scaled.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE  mydbinstance  2009-12-22T23:06:11.915Z  db.m5.large  mysql8.0  50  sa modifying mydbinstance.clla4j4jgyph.us-east-1.rds.amazonaws.com  3306 us-east-1b  3  60 SECGROUP  default  active
```

1884
After storage scaling is complete, your DB instance status changes to available.

You can receive notifications when your storage space is exhausted using the DescribeEvents operation. For example, in this scenario, if you make a DescribeEvents call after these operations you see the following output.

Amazon RDS insufficient DB instance capacity

The InsufficientDBInstanceCapacity error can be returned when you try to create, start or modify a DB instance, or when you try to restore a DB instance from a DB snapshot. When this error is returned, the following are common causes:

- The specific DB instance class isn't available in the requested Availability Zone. You can try one of the following to solve the problem:
  - Retry the request with a different DB instance class.
  - Retry the request with a different Availability Zone.
  - Retry the request without specifying an explicit Availability Zone.

For information about troubleshooting instance capacity issues for Amazon EC2, see Insufficient instance capacity in the Amazon Elastic Compute Cloud User Guide.

- The DB instance is on the EC2-Classic platform and therefore isn't in a VPC. Some DB instance classes require a VPC. For example, if you're on the EC2-Classic platform and try to increase capacity by switching to a DB instance class that requires a VPC, this error results. For information about Amazon EC2 instance types that are only available in a VPC, see Instance types available in EC2-Classic in the Amazon Elastic Compute Cloud User Guide. To correct the problem, you can move the DB instance into a VPC. For more information, see Moving a DB instance not in a VPC into a VPC (p. 1873).

For information about modifying a DB instance, see Modifying an Amazon RDS DB instance (p. 309).

MySQL and MariaDB issues

You can diagnose and correct issues with MySQL and MariaDB DB instances.
Maximum MySQL and MariaDB connections

The maximum number of connections allowed to an RDS for MySQL or RDS for MariaDB DB instance is based on the amount of memory available for its DB instance class. A DB instance class with more memory available results in a larger number of connections available. For more information on DB instance classes, see DB instance classes (p. 9).

The connection limit for a DB instance is set by default to the maximum for the DB instance class. You can limit the number of concurrent connections to any value up to the maximum number of connections allowed. Use the `max_connections` parameter in the parameter group for the DB instance. For more information, see Maximum number of database connections (p. 1877) and Working with parameter groups (p. 278).

You can retrieve the maximum number of connections allowed for a MySQL or MariaDB DB instance by running the following query.

```
SELECT @@max_connections;
```

You can retrieve the number of active connections to a MySQL or MariaDB DB instance by running the following query.

```
SHOW STATUS WHERE `variable_name` = 'Threads_connected';
```

Diagnosing and resolving incompatible parameters status for a memory limit

A MariaDB or MySQL DB instance can be placed in `incompatible-parameters` status for a memory limit when both of the following conditions are met:

- The DB instance is either restarted at least three time in one hour or at least five times in one day, or an attempt to restart the DB instance fails.
- The potential memory usage of the DB instance exceeds 1.2 times the memory allocated to its DB instance class.

When a DB instance is restarted for the third time in one hour or for the fifth time in one day, Amazon RDS for MySQL performs a check for memory usage. The check makes the a calculation of the potential memory usage of the DB instance. The value returned by the calculation is the sum of the following values:

- **Value 1** – The sum of the following parameters:
Diagnosing and resolving lag between read replicas

After you create a MySQL or MariaDB read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric.

The ReplicaLag metric reports the value of the Seconds_Behind_Master field of the MariaDB or MySQL SHOW REPLICA STATUS command. For more information, see SHOW REPLICA STATUS.

To resolve the problem, complete the following steps:

1. Adjust the memory parameters in the DB parameter group associated with the DB instance so that the potential memory usage is lower than 1.2 times the memory allocated to its DB instance class.

   For information about setting parameters, see Modifying parameters in a DB parameter group (p. 282).

2. Restart the DB instance.

   For information about setting parameters, see Starting an Amazon RDS DB instance that was previously stopped (p. 308).
When the ReplicaLag metric reaches 0, the replica has caught up to the source DB instance. If the ReplicaLag metric returns -1, replication might not be active. To troubleshoot a replication error, see Diagnosing and resolving a MySQL or MariaDB read replication failure (p. 1889). A ReplicaLag value of -1 can also mean that the Seconds_Behind_Master value can't be determined or is NULL.

**Note**
Previous versions of MariaDB and MySQL used **SHOW SLAVE STATUS** instead of **SHOW REPLICA STATUS**. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use **SHOW SLAVE STATUS**.

The ReplicaLag metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the ReplicaLag metric again.

The MySQL and MariaDB read replication technology is asynchronous. Thus, you can expect occasional increases for the BinLogDiskUsage metric on the source DB instance and for the ReplicaLag metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see Replication implementation details in the MySQL documentation. For more information about read replicas and MariaDB, see Replication overview in the MariaDB documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type` parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see Query cache configuration.
- Warm the buffer pool on the read replica for InnoDB for MySQL or MariaDB. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```
PROMPT> mysqldump
   \-h <endpoint> \
   --port=<port> \
   -u=<username> \
   -p <password>
   database_name table1 table2 > /dev/null
```

For Windows:

```
PROMPT> mysqldump ^
   -h <endpoint> ^
   --port=<port> ^
   -u=<username> ^
```

1888
Diagnosing and resolving a MySQL or MariaDB read replication failure

Amazon RDS monitors the replication status of your read replicas and updates the Replication State field of the read replica instance to Error if replication stops for any reason. You can review the details of the associated error thrown by the MySQL or MariaDB engines by viewing the Replication Error field. Events that indicate the status of the read replica are also generated, including RDS-EVENT-0045 (p. 630), RDS-EVENT-0046 (p. 630), and RDS-EVENT-0047 (p. 628). For more information about events and subscribing to events, see Using Amazon RDS event notification (p. 623). If a MySQL error message is returned, check the error in the MySQL error message documentation. If a MariaDB error message is returned, check the error in the MariaDB error message documentation.

Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

  The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. If the `max_allowed_packet` value for the source DB instance is larger than the `max_allowed_packet` value for the read replica, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to 0 to create the indexes. If you're writing to tables on the read replica, it can break replication.

- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

  You can convert a MyISAM table to InnoDB with the following command:

  \[\text{alter table `<schema>.<table_name>` engine=innodb;}\]

- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in Skipping the current replication error (p. 1245). Your MySQL or MariaDB DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see `mysql.rds_skip_repl_error` (p. 1281).

- If you encounter a binary log (binlog) position issue, you can change the replica replay position with the `mysql_rds_next_master_log` command. Your MySQL or MariaDB DB instance must be running a version that supports the `mysql_rds_next_master_log` command to change the replica replay position. For version information, see `mysql.rds_next_master_log` (p. 1281).

- If you encounter a temporary performance issue due to high DML load, you can set the `innodb_flush_log_at_trx_commit` parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).
• You can delete the read replica and create an instance using the same DB instance identifier. If you do this, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the Replication State changes to replicating. For more information, see Troubleshooting a MySQL read replica problem (p. 1216).

Creating triggers with binary logging enabled requires SUPER privilege

When trying to create triggers in an RDS for MySQL or RDS for MariaDB DB instance, you might receive the following error.

“You do not have the SUPER privilege and binary logging is enabled”

To use triggers when binary logging is enabled requires the SUPER privilege, which is restricted for RDS for MySQL and RDS for MariaDB DB instances. You can create triggers when binary logging is enabled without the SUPER privilege by setting the log_bin_trust_function_creators parameter to true. To set the log_bin_trust_function_creators to true, create a new DB parameter group or modify an existing DB parameter group.

To create a new DB parameter group that allows you to create triggers in your RDS for MySQL or RDS for MariaDB DB instance with binary logging enabled, use the following CLI commands. To modify an existing parameter group, start with step 2.

To create a new parameter group to allow triggers with binary logging enabled using the CLI

1. Create a new parameter group.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-parameter-group \
   --db-parameter-group-name allow-triggers \
   --db-parameter-group-family mysql8.0 \
   --description "parameter group allowing triggers"
   ```

   For Windows:

   ```bash
   aws rds create-db-parameter-group ^
   --db-parameter-group-name allow-triggers ^
   --db-parameter-group-family mysql8.0 ^
   --description "parameter group allowing triggers"
   ```

2. Modify the DB parameter group to allow triggers.

   For Linux, macOS, or Unix:

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name allow-triggers \
   --parameters "ParameterName=log_bin_trust_function_creators, ParameterValue=true, ApplyMethod=pending-reboot"
   ```

   For Windows:

   ```bash
   aws rds modify-db-parameter-group ^
   ```
Diagnosing and resolving point-in-time restore failures

Restoring a DB Instance That Includes Temporary Tables

When attempting a point-in-time restore (PITR) of your MySQL or MariaDB DB instance, you might encounter the following error.

```
Database instance could not be restored because there has been incompatible database activity for restore functionality. Common examples of incompatible activity include using temporary tables, in-memory tables, or using MyISAM tables. In this case, use of Temporary table was detected.
```

PITR relies on both backup snapshots and binary logs (binlogs) from MySQL or MariaDB to restore your DB instance to a particular time. Temporary table information can be unreliable in binlogs and can cause a PITR failure. If you use temporary tables in your MySQL or MariaDB DB instance, you can minimize the possibility of a PITR failure by performing more frequent backups. A PITR failure is most probable in the time between a temporary table's creation and the next backup snapshot.

Restoring a DB Instance That Includes In-Memory Tables

You might encounter a problem when restoring a database that has in-memory tables. In-memory tables are purged during a restart. As a result, your in-memory tables might be empty after a reboot. We recommend that when you use in-memory tables, you architect your solution to handle empty tables in the event of a restart. If you're using in-memory tables with replicated DB instances, you might need to recreate the read replicas after a restart. This might be necessary if a read replica reboots and can't restore data from an empty in-memory table.

For more information about backups and PITR, see Working with backups (p. 407) and Restoring a DB instance to a specified time (p. 480).
Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration` procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, up to 720 (30 days). The following example sets the retention period for binlog files to 48 hours.

```sql
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

Read replica create fails or replication breaks with fatal error 1236

After changing default parameter values for a MySQL or MariaDB DB instance, you might encounter one of the following problems:

- You can't create a read replica for the DB instance.
- Replication fails with `fatal error 1236`.

Some default parameter values for MySQL and MariaDB DB instances help to make sure that the database is ACID compliant and read replicas are crash-safe. They do this by making sure that each commit is fully synchronized by writing the transaction to the binary log before it's committed. Changing these parameters from their default values to improve performance can cause replication to fail when a transaction hasn't been written to the binary log.

To resolve this issue, set the following parameter values:

- `sync_binlog = 1`
- `innodb_support_xa = 1`
- `innodb_flush_log_at_trx_commit = 1`

Can't set backup retention period to 0

There are several reasons why you might need to set the backup retention period to 0. For example, you can disable automatic backups immediately by setting the retention period to 0.

In some cases, you might set the value to 0 and receive a message saying that the retention period must be between 1 and 35. In these cases, check to make sure that you haven't set up a read replica for the instance. Read replicas require backups for managing read replica logs, and therefore you can't set a retention period of 0.
Amazon RDS application programming interface (API) reference

In addition to the AWS Management Console, and the AWS Command Line Interface (AWS CLI), Amazon Relational Database Service (Amazon RDS) also provides an application programming interface (API). You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon RDS.

Topics
- Using the Query API (p. 1893)
- Troubleshooting applications on Amazon RDS (p. 1894)

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the Amazon EC2 API Reference.

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named Action.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the param. n notation. Values of n are integers starting from 1.

For information about Amazon RDS regions and endpoints, go to Amazon Relational Database Service (RDS) in the Regions and Endpoints section of the Amazon Web Services General Reference.

Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.
Troubleshooting applications on Amazon RDS

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

Topics

- Retrieving errors (p. 1894)
- Troubleshooting tips (p. 1894)

For information about troubleshooting for Amazon RDS DB instances, see Troubleshooting for Amazon RDS (p. 1880).

Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an Error node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an Error node, as well as an easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```perl
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find("//Error") ) {
  print "There was an error processing your request:\n", " Error code: ",
    $xp->findvalue("//Error[1]/Code"), "\n", " ",
    $xp->findvalue("//Error[1]/Message"), "\n\n";
}
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API.

- Verify that Amazon RDS is operating normally in the AWS Region you are targeting by visiting http://status.aws.amazon.com.
- Check the structure of your request
  
  Each Amazon RDS operation has a reference page in the Amazon RDS API Reference. Double-check that you are using parameters correctly. In order to give you ideas regarding what might be wrong, look at the sample requests or user scenarios to see if those examples are doing similar operations.
- Check the forum
  
  Amazon RDS has a development community forum where you can search for solutions to problems others have experienced along the way. To view the forum, go to AWS Discussion Forums.
## Document history

**Current API version:** 2014-10-31

The following table describes important changes in each release of the Amazon RDS User Guide after May 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

**Note**
You can filter new Amazon RDS features on the What's New with Database? page. For Products, choose Amazon RDS. Then search using keywords such as RDS Proxy or Oracle 2022.

<tr>
<td>Automatic rollback on failed Amazon RDS for MySQL upgrade (p. 1895)</td>
<td>If a DB instance upgrade from MySQL version 5.7 to MySQL version 8.0 fails, Amazon RDS rolls back the changes performed for the upgrade automatically. After the rollback, the MySQL DB instance is running MySQL version 5.7. For more information, see Rollback after failure to upgrade from MySQL 5.7 to 8.0.</td>
<td>March 18, 2021</td>
</tr>
<tr>
<td>Amazon RDS supports cross-Region read replicas in opt-in Regions (p. 1895)</td>
<td>You can now replicate DB instances to opt-in Regions. For more information, see Creating a read replica in a different AWS Region.</td>
<td>March 18, 2021</td>
</tr>
<tr>
<td>Amazon RDS plans to deprecate Oracle Database 18c (p. 1895)</td>
<td>Oracle Database 18c (18.0.0.0) is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 18c after the end-of-support date. On July 1, 2021, Amazon RDS plans to begin automatically upgrading Oracle Database 18c instances to Oracle Database 19c. Before the automatic upgrades begin, we highly recommend that you manually upgrade your existing Oracle Database 18c instances to Oracle Database 19c. For more information, see Preparing for the automatic upgrade of Oracle Database 18c.</td>
<td>March 11, 2021</td>
</tr>
<tr>
<td>Amazon RDS has ended support for Oracle Database 11g (p. 1895)</td>
<td>You can only create DB instances for Oracle Database 12c Release 1 (12.1.0.2) and later. If you have Oracle Database 11g snapshots, upgrade them to a later release. For more information, see Upgrading an Oracle DB snapshot.</td>
<td>March 11, 2021</td>
</tr>
<tr>
<td>Amazon RDS supports continuous backups of DB instances in AWS Backup (p. 1895)</td>
<td>You can now create automated backups in AWS Backup and restore DB instances from these backups to a specified time. For more information, see Using AWS Backup to manage automated backups.</td>

<tr>
<td><strong>Amazon RDS supports Oracle Management Agent (OMA) version 13.4 (p. 1895)</strong></td>
<td>You can use Oracle Management Agent (OMA) version 13.4 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 4 Update 9. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitoring information. If you run OMS 13.4, you can manage databases by installing OMA 13.4. For more information, see Oracle Management Agent for Enterprise Manager Cloud Control.</td>
<td>March 10, 2021</td>
</tr>
<tr>
<td><strong>RDS Proxy endpoint enhancements (p. 1895)</strong></td>
<td>You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see &quot;Managing Connections with Amazon RDS Proxy&quot; in the Amazon RDS User Guide or the Aurora user guide.</td>
<td>March 8, 2021</td>
</tr>
<tr>
<td><strong>Amazon RDS extends supports for cross-Region automated backups (p. 1895)</strong></td>
<td>You can now configure Amazon RDS database instances running PostgreSQL to replicate DB snapshots and transaction logs to a different AWS Region. For more information, see Replicating automated backups to another AWS Region.</td>
<td>March 8, 2021</td>
</tr>
<tr>
<td><strong>Replication filters for Amazon RDS for MariaDB and MySQL supported in the China (Beijing) Region and China (Ningxia) Region (p. 1895)</strong></td>
<td>Replication filtering is now supported in the China (Beijing) Region and China (Ningxia) Region. For more information, see Configuring replication filters with MariaDB and Configuring replication filters with MySQL.</td>

<tr>
<td>Amazon RDS supports cross-Region DB snapshot copy in opt-in Regions (p. 1895)</td>
<td>You can now copy DB snapshots to and from opt-in AWS Regions. For more information, see Copying snapshots across AWS Regions.</td>
<td>March 4, 2021</td>
</tr>
<tr>
<td>Amazon RDS for Oracle introduces advisor-related procedures (p. 1895)</td>
<td>The <code>rdsadmin_util</code> package includes the procedures <code>advisor_task_set_parameter</code>, <code>advisor_task_drop</code>, and <code>dbms_stats_init</code>. You can use these procedures to modify, stop, and re-enable advisor tasks such as <code>AUTO_STATS_ADVISOR_TASK</code>. For more information, see Setting parameters for advisor tasks.</td>
<td>February 23, 2021</td>
</tr>
<tr>
<td>Amazon RDS provides failover reasons for Multi-AZ DB instances (p. 1895)</td>
<td>You can now see more detailed explanations when a Multi-AZ DB instance fails over to a standby replica. For more information, see Failover process for Amazon RDS.</td>
<td>February 18, 2021</td>
</tr>
<tr>
<td>Amazon RDS extends support for exporting snapshots to Amazon S3 (p. 1895)</td>
<td>You can now export DB snapshot data to Amazon S3 in China. For more information, see Exporting DB snapshot data to Amazon S3.</td>
<td>February 17, 2021</td>
</tr>
<tr>
<td>Replication filters for Amazon RDS for MariaDB and MySQL (p. 1895)</td>
<td>You can configure replication filters for MySQL and MariaDB instances. Replication filters specify which databases and tables are replicated in a read replica. You can create lists of databases and tables to include or exclude for each read replica. For more information, see Configuring replication filters with MariaDB and Configuring replication filters with MySQL.</td>
<td>February 12, 2021</td>
</tr>
<tr>
<td>RDS for Oracle supports APEX 20.2v1 (p. 1895)</td>

<tr>
<td>Amazon RDS for SQL Server supports local instance storage for the tempdb database (p. 1895)</td>
<td>You can now launch Amazon RDS for SQL Server on Amazon EC2 db.r5d and db.m5d instance types with the tempdb database configured to use an instance store. By placing tempdb data files and log files locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see Instance store support for the tempdb database on Amazon RDS for SQL Server.</td>
<td>January 27, 2021</td>
</tr>
<tr>
<td>Amazon RDS for PostgreSQL supports pg_partman and pg_cron (p. 1895)</td>
<td>Amazon RDS for PostgreSQL now supports the pg_partman and pg_cron extensions. For more information on the pg_partman extension, see Managing PostgreSQL partitions with the pg_partman extension. For more information on the pg_cron extension, see Scheduling maintenance with the PostgreSQL pg_cron extension.</td>
<td>January 12, 2021</td>
</tr>
<tr>
<td>Amazon RDS supports publishing the Oracle Management Agent log to Amazon CloudWatch Logs (p. 1895)</td>
<td>The Oracle Management Agent log consists of emctl.log, emdctlj.log, gcagent.log, gcagent_errors.log, emagent.nohup, and secure.log. Amazon RDS publishes each of these logs as a separate CloudWatch log stream. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs.</td>
<td>December 28, 2020</td>
</tr>
<tr>
<td>Amazon RDS on AWS Outposts supports additional database versions (p. 1895)</td>
<td>RDS on Outposts now supports additional MySQL and PostgreSQL versions. For more information, see Amazon RDS on AWS Outposts support for Amazon RDS features.</td>

<tr>
<td><strong>Amazon RDS on AWS Outposts supports CoIPs (p. 1895)</strong></td>
<td>RDS on Outposts now supports customer-owned IP addresses (CoIPs). CoIPs provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information, see Customer-owned IP addresses for RDS on Outposts.</td>
<td>December 22, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for Oracle plans upgrade of 11g BYOL instances to 19c (p. 1895)</strong></td>
<td>On January 4, 2021, we plan to begin automatically upgrading all editions of Oracle Database 11g instances on the Bring Your Own License (BYOL) model to Oracle Database 19c. All Oracle Database 11g instances, including reserved instances, will move to the latest available Release Update (RU). For more information, see Preparing for the automatic upgrade of Oracle Database 11g BYOL.</td>
<td>December 11, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS supports replicating automated backups to another AWS Region (p. 1895)</strong></td>
<td>You can now configure your Amazon RDS database instances to replicate snapshots and transaction logs to a destination AWS Region of your choice. For more information, see Replicating automated backups to another AWS Region.</td>
<td>December 4, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for Oracle and Microsoft SQL Server support a new DB instance class (p. 1895)</strong></td>
<td>You can now use the db.r5b instance class to create Amazon RDS DB instances running Oracle or SQL Server. For more information, see Supported DB engines for DB instance classes.</td>
<td>December 4, 2020</td>
</tr>
<tr>
<td><strong>Support for MariaDB 10.2.32 (p. 1895)</strong></td>
<td>You can now create Amazon RDS DB instances running MariaDB version 10.2.32. For more information, see MariaDB on Amazon RDS versions.</td>
<td>November 25, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for SQL Server supports the Microsoft Business Intelligence Suite on SQL Server 2019 (p. 1895)</strong></td>
<td>You can now run SQL Server Analysis Services, SQL Server Integration Services, and SQL Server Reporting Services on DB instances using the latest major version. For more information, see Options for the Microsoft SQL Server database engine.</td>
<td>November 24, 2020</td>
</tr>
<tr>
<td>Amazon RDS for PostgreSQL version 13 in the database preview environment (p. 1895)</td>
<td>Amazon RDS for PostgreSQL now supports PostgreSQL version 13 in the database preview environment. For more information, see PostgreSQL 13 versions.</td>
<td>November 24, 2020</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Amazon RDS Performance Insights introduces new dimensions (p. 1895)</td>
<td>You can group database load according to the dimension groups for database (PostgreSQL, MySQL, and MariaDB), application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name (PostgreSQL, MySQL, and MariaDB), db.application.name (PostgreSQL), and db.session_type.name (PostgreSQL). For more information, see Top load table.</td>
<td>November 24, 2020</td>
</tr>
<tr>
<td>Amazon RDS for MariaDB supports a new major version (p. 1895)</td>
<td>You can now create Amazon RDS DB instances running MariaDB version 10.5. For more information, see MariaDB on Amazon RDS versions.</td>
<td>November 23, 2020</td>
</tr>
<tr>
<td>Support for MySQL 5.6.49 (p. 1895)</td>
<td>You can now create Amazon RDS DB instances running MySQL version 5.6.49. For more information, see MySQL on Amazon RDS versions.</td>
<td>November 20, 2020</td>
</tr>
<tr>
<td>Support for MySQL 5.5.62 (p. 1895)</td>
<td>You can now create Amazon RDS DB instances running MySQL version 5.5.62. For more information, see MySQL on Amazon RDS versions.</td>
<td>November 20, 2020</td>
</tr>
<tr>
<td>Performance Insights supports analyzing statistics for running PostgreSQL queries (p. 1895)</td>
<td>You can now analyze statistics for running queries with Performance Insights for PostgreSQL DB instances. For more information, see Statistics for PostgreSQL.</td>
<td>November 18, 2020</td>
</tr>
<tr>
<td>Amazon RDS extends support for storage autoscaling (p. 1895)</td>
<td>You can now enable storage autoscaling when creating a read replica, restoring a DB instance to a specified time, or restoring a MySQL DB instance from an Amazon S3 backup. For more information, see Managing capacity automatically with Amazon RDS storage autoscaling.</td>
<td>November 18, 2020</td>
</tr>

<tr>
<td>Amazon RDS for SQL Server supports Database Mail</td>
<td>With Database Mail you can send email messages from your Amazon RDS for SQL Server database instance. After specifying the email recipients, you can add files or query results to the message you send. For more information, see Using Database Mail on Amazon RDS for SQL Server.</td>
<td>November 4, 2020</td>
</tr>
<tr>
<td>Support for MySQL 8.0.21</td>
<td>You can now create Amazon RDS DB instances running MySQL version 8.0.21. For more information, see MySQL on Amazon RDS versions.</td>
<td>October 22, 2020</td>
</tr>
<tr>
<td>Amazon RDS extends support for exporting snapshots to Amazon S3</td>
<td>You can now export DB snapshot data to Amazon S3 in all commercial AWS Regions. For more information, see Exporting DB snapshot data to Amazon S3.</td>
<td>October 22, 2020</td>
</tr>
<tr>
<td>Amazon RDS for PostgreSQL supports read replica upgrades</td>
<td>With Amazon RDS for PostgreSQL, when you do a major version upgrade of the primary DB instance, read replicas are also automatically upgraded. For more information, see Upgrading the PostgreSQL DB engine.</td>
<td>October 15, 2020</td>
</tr>
<tr>
<td>Amazon RDS for MariaDB, MySQL and PostgreSQL support the Graviton2 DB instance classes</td>
<td>You can now use the Graviton2 DB instance classes db.m6g.x and db.r6g.x to create Amazon RDS DB instances running MariaDB, MySQL or PostgreSQL. For more information, see Supported DB Engines for All Available DB Instance Classes.</td>
<td>October 15, 2020</td>
</tr>
<tr>
<td>Amazon RDS for SQL Server supports upgrades to SQL Server 2019</td>
<td>You can upgrade your SQL Server DB instances to SQL Server 2019. For more information, see Upgrading the Microsoft SQL Server DB Engine.</td>
<td>October 6, 2020</td>
</tr>
<tr>
<td>Amazon RDS for Oracle supports specifying the national character set</td>
<td>The national character set, also called the NCHAR character set, is used in the NCHAR, NVARCHAR2, and NCLOB data types. When you create a database, you can specify either AL16UTF16 (default) or UTF8 as the NCHAR character set. For more information, see Oracle character sets supported in Amazon RDS.</td>
<td>October 2, 2020</td>

<tr>
<td><strong>Support for MySQL 5.7.31 (p. 1895)</strong></td>
<td>You can now create Amazon RDS DB instances running MySQL version 5.7.31. For more information, see MySQL on Amazon RDS versions.</td>
<td>October 1, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for PostgreSQL supports exporting data to Amazon S3 (p. 1895)</strong></td>
<td>You can query data from a PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. For more information, see Exporting data from an RDS for PostgreSQL DB instance to Amazon S3.</td>
<td>September 24, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for MySQL 8.0 supports Percona XtraBackup (p. 1895)</strong></td>
<td>You can now use Percona XtraBackup to restore a backup into an Amazon RDS for MySQL 8.0 DB instance. For more information, see Restoring a backup into a MySQL DB instance.</td>
<td>September 17, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for SQL Server supports native backup and restore on DB instances with read replicas (p. 1895)</strong></td>
<td>You can restore a SQL Server native backup onto a DB instance that has read replicas configured. For more information, see Importing and exporting SQL Server databases.</td>
<td>September 16, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for SQL Server supports additional time zones (p. 1895)</strong></td>
<td>You can match your DB instance time zone with your chosen time zone. For more information, see Local time zone for Microsoft SQL Server DB instances.</td>
<td>September 11, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for PostgreSQL version 13 beta 3 in the database preview environment (p. 1895)</strong></td>
<td>Amazon RDS for PostgreSQL now supports PostgreSQL Version 13 Beta 3 in the Database Preview Environment. For more information, see PostgreSQL 13 versions.</td>
<td>September 9, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for SQL Server supports trace flag 692 (p. 1895)</strong></td>
<td>You can now use trace flag 692 as a startup parameter using DB parameter groups. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes. For more information, see Disabling fast inserts during bulk loading.</td>
<td>August 27, 2020</td>
</tr>
<tr>
<td><strong>Amazon RDS for SQL Server supports Microsoft SQL Server 2019 (p. 1895)</strong></td>
<td>You can now create RDS DB instances that use SQL Server 2019. For more information, see Microsoft SQL Server versions on Amazon RDS.</td>
<td>August 26, 2020</td>
</tr>
<tr>
<td>RDS for Oracle supports mounted replica database (p. 1895)</td>
<td>When creating or modifying an Oracle replica, you can place it in mounted mode. Because the replica database doesn't accept user connections, it can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them. The primary use for mounted replicas is cross-Region disaster recovery. For more information, see Overview of Oracle replicas.</td>

</table>
Amazon RDS for Microsoft SQL Server supports SQL Server Analysis Services (SSAS) (p. 1895)

SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You can enable SSAS on existing or new DB instances. It's installed on the same DB instance as your database engine. For more information, see Support for SQL Server Analysis Services in SQL Server.

April 17, 2020

Amazon RDS proxy for PostgreSQL (p. 1895)

Amazon RDS Proxy is now available for PostgreSQL. You can use RDS Proxy to reduce the overhead of connection management on your DB instance and also the chance of "too many connections" errors. The RDS Proxy is currently in public preview for PostgreSQL. For more information, see Managing connections with Amazon RDS proxy (preview).

April 8, 2020

Amazon RDS for Oracle supports Oracle APEX version 19.2.v1 (p. 1895)

Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 19.2.v1. For more information, see Oracle application Express.

April 8, 2020

Amazon RDS for MariaDB supports a new major version (p. 1895)

You can now create Amazon RDS DB instances running MariaDB version 10.4. For more information, see MariaDB on Amazon RDS versions.

April 6, 2020

Amazon RDS Performance Insights is available for Amazon RDS for MariaDB 10.4 (p. 1895)

Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB version 10.4. For more information, see Using Amazon RDS performance insights.

April 6, 2020

Amazon RDS for PostgreSQL versions 9.3.x are deprecated (p. 1895)

Amazon RDS for PostgreSQL no longer supports versions 9.3.x. For supported versions, see Supported PostgreSQL database versions.

April 3, 2020

Amazon RDS for Microsoft SQL Server supports read replicas (p. 1895)

You can now create read replicas for SQL Server DB instances. For more information, see Working with read replicas.

<td>August 6, 2018</td>
</tr>
<tr>
<td>Amazon RDS Performance Insights is available for Aurora MySQL (p. 1895)</td>
<td>Amazon RDS Performance Insights is now available for Aurora MySQL. For more information, see Using Amazon RDS Performance Insights.</td>
<td>August 6, 2018</td>
</tr>
<tr>
<td>Amazon RDS Performance Insights integration with Amazon CloudWatch (p. 1895)</td>
<td>Amazon RDS Performance Insights automatically publishes metrics to Amazon CloudWatch. For more information, see Performance Insights metrics published to CloudWatch.</td>
<td>August 6, 2018</td>
</tr>
<tr>
<td>Amazon RDS recommendations (p. 1895)</td>
<td>Amazon RDS now provides automated recommendations for database resources. For more information, see Using Amazon RDS recommendations.</td>
<td>July 25, 2018</td>
</tr>
<tr>
<td>Incremental snapshot copies across AWS Regions (p. 1895)</td>
<td>Amazon RDS supports incremental snapshot copies across AWS Regions for both unencrypted and encrypted instances. For more information, see Copying snapshots across AWS Regions.</td>
<td>July 24, 2018</td>
</tr>
<tr>
<td>Amazon RDS Performance Insights is available for Amazon RDS for PostgreSQL (p. 1895)</td>
<td>Amazon RDS Performance Insights is now available for Amazon RDS for PostgreSQL. For more information, see Using Amazon RDS Performance Insights.</td>
<td>July 18, 2018</td>
</tr>
<tr>
<td>Amazon RDS for Oracle supports Oracle APEX version 5.1.4.v1 (p. 1895)</td>
<td>Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 5.1.4.v1. For more information, see Oracle application Express.</td>
<td>July 10, 2018</td>
</tr>
<tr>
<td>Amazon RDS for Oracle supports publishing logs to Amazon CloudWatch Logs (p. 1895)</td>
<td>Amazon RDS for Oracle now supports publishing alert, audit, trace, and listener log data to a log group in CloudWatch Logs. For more information, see Publishing Oracle logs to Amazon CloudWatch Logs.</td>
<td>July 9, 2018</td>
</tr>
</tbody>
</table>
MariaDB 10.2.15, 10.1.34, and 10.0.35 (p. 1895)

You can now create Amazon RDS DB instances running MariaDB versions 10.2.15, 10.1.34, and 10.0.35. For more information, see MariaDB on Amazon RDS versions.

July 5, 2018

Aurora PostgreSQL 1.2 is available and compatible with PostgreSQL 9.6.8 (p. 1895)

Aurora PostgreSQL 1.2 is now available and is compatible with PostgreSQL 9.6.8. For more information, see Version 1.2.

June 27, 2018

Read replicas for Amazon RDS PostgreSQL support Multi-AZ deployments (p. 1895)

RDS read replicas in Amazon RDS PostgreSQL now support multiple Availability Zones. For more information, see Working with PostgreSQL read replicas.

June 25, 2018

Performance Insights available for Aurora PostgreSQL (p. 1895)

Performance Insights is generally available for Aurora PostgreSQL, with support for extended retention of performance data. For more information, see Using Amazon RDS performance insights.

June 21, 2018

Aurora PostgreSQL available in western US (northern California) region (p. 1895)

Aurora PostgreSQL is now available in the western United States (Northern California) region. For more information, see Availability for Amazon Aurora PostgreSQL.

June 11, 2018

Amazon RDS for Oracle now supports CPU configuration (p. 1895)

Amazon RDS for Oracle supports configuring the number of CPU cores and the number of threads for each core for the processor of a DB instance class. For more information, see Configuring the processor of the DB instance class.

June 5, 2018

Earlier updates

The following table describes the important changes in each release of the Amazon RDS User Guide before June 2018.

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon RDS for PostgreSQL now supports PostgreSQL Version 11 Beta 1 in the</td>
<td>PostgreSQL version 11 Beta 1 contains several improvements that are described in PostgreSQL 11 beta 1 released!</td>
<td>May 31, 2018</td>
</tr>
<tr>
<td></td>
<td>For information on the Database Preview Environment, see Working with the database preview environment (p. 1593).</td>
<td></td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Database Preview Environment</td>
<td>Amazon RDS for Oracle now supports Transport Layer Security (TLS) versions 1.0 and 1.2. For more information, see TLS versions for the Oracle SSL option (p. 1514).</td>
<td>May 30, 2018</td>
</tr>
<tr>
<td>Aurora MySQL supports publishing logs to Amazon CloudWatch Logs</td>
<td>Aurora MySQL now supports publishing general, slow, audit, and error log data to a log group in CloudWatch Logs. For more information, see Publishing Aurora MySQL to CloudWatch Logs.</td>
<td>May 23, 2018</td>
</tr>
<tr>
<td>Database Preview Environment for Amazon RDS PostgreSQL</td>
<td>You can now launch a new instance of Amazon RDS PostgreSQL in a preview mode. For more information about the Database Preview Environment see, Working with the database preview environment (p. 1593).</td>
<td>May 22, 2018</td>
</tr>
<tr>
<td>Amazon RDS for Oracle DB instances support new DB instance classes</td>
<td>Oracle DB instances now support the db.x1e and db.x1 DB instance classes. For more information, see DB instance classes (p. 9) and RDS for Oracle instance classes (p. 1302).</td>
<td>May 22, 2018</td>
</tr>
<tr>
<td>Amazon RDS PostgreSQL now supports postgres_fdw on a read replica.</td>
<td>You can now use postgres_fdw to connect to a remote server from a read replica. For more information see, Using the postgres_fdw extension to access external data (p. 1738).</td>
<td>May 17, 2018</td>
</tr>
<tr>
<td>Amazon RDS for Oracle now supports setting sqlnet.ora parameters</td>
<td>You can now set sqlnet.ora parameters with Amazon RDS for Oracle. For more information, see Modifying connection properties using sqlnet.ora parameters (p. 1318).</td>
<td>May 10, 2018</td>
</tr>
<tr>
<td>Aurora PostgreSQL available in Asia Pacific (Seoul) region.</td>
<td>Aurora PostgreSQL is now available in the Asia Pacific (Seoul) region. For more information, see Availability for Amazon Aurora PostgreSQL.</td>
<td>May 9, 2018</td>
</tr>
<tr>
<td>Aurora MySQL supports backtracking</td>
<td>Aurora MySQL now supports &quot;rewinding&quot; a DB cluster to a specific time, without restoring data from a backup. For more information, see Backtracking an Aurora DB cluster.</td>
<td>May 9, 2018</td>
</tr>
<tr>
<td>Aurora MySQL supports encrypted migration and replication from external MySQL</td>
<td>Aurora MySQL now supports encrypted migration and replication from an external MySQL database. For more information, see Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster and Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster.</td>
<td>April 25, 2018</td>
</tr>
<tr>
<td>Aurora PostgreSQL-Compatible Edition support for the Copy-on-Write protocol.</td>
<td>You can now clone databases in an Aurora PostgreSQL database cluster. For more information see, Cloning databases in an Aurora DB cluster.</td>
<td>April 10, 2018</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>MariaDB 10.2.12, 10.1.31, and 10.0.34</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.2.12, 10.1.31, and 10.0.34. For more information, see MariaDB on Amazon RDS versions (p. 838).</td>
<td>March 21, 2018</td>
</tr>
<tr>
<td>Aurora PostgreSQL Support for new regions</td>
<td>Aurora PostgreSQL is now available in the EU (London) and Asia Pacific (Singapore) regions. For more information, see Availability for Amazon Aurora PostgreSQL.</td>
<td>March 13, 2018</td>
</tr>
<tr>
<td>MySQL 5.7.21, 5.6.39, and 5.5.59</td>
<td>You can now create Amazon RDS DB instances running MySQL versions 5.7.21, 5.6.39, and 5.5.59. For more information, see MySQL on Amazon RDS versions (p. 1133).</td>
<td>March 9, 2018</td>
</tr>
<tr>
<td>Amazon RDS for Oracle now supports Oracle REST Data Services</td>
<td>Amazon RDS for Oracle supports Oracle REST Data Services as part of the APEX option. For more information, see Oracle Application Express (APEX) (p. 1465).</td>
<td>March 9, 2018</td>
</tr>
<tr>
<td>Amazon Aurora MySQL-Compatible Edition available in new AWS Region</td>
<td>Aurora MySQL is now available in the Asia Pacific (Singapore) region. For the complete list of AWS Regions for Aurora MySQL, see Availability for Amazon Aurora MySQL.</td>
<td>March 6, 2018</td>
</tr>
<tr>
<td>Amazon RDS DB instances running Microsoft SQL Server support change data capture (CDC)</td>
<td>DB instances running Amazon RDS for Microsoft SQL Server now support change data capture (CDC). For more information, see Change data capture support for Microsoft SQL Server DB instances (p. 933).</td>
<td>February 6, 2018</td>
</tr>
<tr>
<td>Aurora MySQL supports a new major version</td>
<td>You can now create Aurora MySQL DB clusters running MySQL version 5.7. For more information, see Amazon Aurora MySQL database engine updates 2018-02-06.</td>
<td>February 6, 2018</td>
</tr>
<tr>
<td>Publish MySQL and MariaDB logs to Amazon CloudWatch Logs</td>
<td>You can now publish MySQL and MariaDB log data to CloudWatch Logs. For more information, see Publishing MySQL logs to Amazon CloudWatch Logs (p. 666) and Publishing MariaDB logs to Amazon CloudWatch Logs (p. 653).</td>
<td>January 17, 2018</td>
</tr>
<tr>
<td>Multi-AZ support for read replicas</td>
<td>You can now create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance. For more information, see Working with read replicas (p. 354).</td>
<td>January 11, 2018</td>
</tr>
<tr>
<td>Amazon RDS for MariaDB supports a new major version</td>
<td>You can now create Amazon RDS DB instances running MariaDB version 10.2. For more information, see MariaDB 10.2 support on Amazon RDS (p. 842).</td>
<td>January 3, 2018</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Amazon Aurora PostgreSQL- Compatible Edition available in new AWS Region</td>
<td>Aurora PostgreSQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora PostgreSQL, see Availability for Amazon Aurora PostgreSQL.</td>
<td>December 22, 2017</td>
</tr>
<tr>
<td>Aurora PostgreSQL supports new instance types</td>
<td>Aurora PostgreSQL now supports new instance types. For the complete list of instance types, see Choosing the DB instance class.</td>
<td>December 20, 2017</td>
</tr>
<tr>
<td>Amazon Aurora MySQL-Compatible Edition available in new AWS Region</td>
<td>Aurora MySQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora MySQL, see Availability for Amazon Aurora MySQL.</td>
<td>December 18, 2017</td>
</tr>
<tr>
<td>Aurora MySQL supports hash joins</td>
<td>This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information, see Working with hash joins in Aurora MySQL.</td>
<td>December 11, 2017</td>
</tr>
<tr>
<td>Aurora MySQL supports native functions to invoke AWS Lambda functions</td>
<td>You can call the native functions <code>lambda_sync</code> and <code>lambda_async</code> when you use Aurora MySQL. For more information, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster.</td>
<td>December 11, 2017</td>
</tr>
<tr>
<td>Added Aurora PostgreSQL HIPAA eligibility</td>
<td>Aurora PostgreSQL now supports building HIPAA compliant applications. For more information, see Working with Amazon Aurora PostgreSQL.</td>
<td>December 6, 2017</td>
</tr>
<tr>
<td>Additional AWS Regions available for Amazon Aurora with PostgreSQL compatibility</td>
<td>Amazon Aurora with PostgreSQL compatibility is now available in four new AWS Regions. For more information, see Availability for Amazon Aurora PostgreSQL.</td>
<td>November 22, 2017</td>
</tr>
<tr>
<td>Modify storage for Amazon RDS DB instances running Microsoft SQL Server</td>
<td>You can now modify the storage of your Amazon RDS DB instances running SQL Server. For more information, see Modifying an Amazon RDS DB instance (p. 309).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports 16 TiB storage for Linux-based engines</td>
<td>You can now create MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances with up to 16 TiB of storage. For more information, see Amazon RDS DB instance storage (p. 53).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports fast scale up of storage</td>
<td>You can now add storage to MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances in a few minutes. For more information, see Amazon RDS DB instance storage (p. 53).</td>
<td>November 21, 2017</td>
</tr>
<tr>
<td>Amazon RDS supports MariaDB versions 10.1.26 and 10.0.32</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.1.26 and 10.0.32. For more information, see MariaDB on Amazon RDS versions (p. 838).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Amazon RDS for Microsoft SQL Server now supports new DB instance classes</td>
<td>You can now create Amazon RDS DB instances running SQL Server that use the db.r4 and db.m4.16xlarge DB instance classes. For more information, see [DB instance class support for Microsoft SQL Server](p. 925).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>Amazon RDS for MySQL and MariaDB now supports new DB instance classes</td>
<td>You can now create Amazon RDS DB instances running MySQL and MariaDB that use the db.r4, db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge DB instance classes. For more information, see [DB instance classes](p. 9).</td>
<td>November 20, 2017</td>
</tr>
<tr>
<td>SQL Server 2017</td>
<td>You can now create Amazon RDS DB instances running Microsoft SQL Server 2017. You can also create DB instances running SQL Server 2016 SP1 CU5. For more information, see [Microsoft SQL Server on Amazon RDS](p. 921).</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Restore MySQL backups from Amazon S3</td>
<td>You can now create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see [Restoring a backup into a MySQL DB instance](p. 1178).</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Auto Scaling with Aurora Replicas</td>
<td>Amazon Aurora MySQL now supports Aurora Auto Scaling. Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas based on increases or decreases in connectivity or workload. For more information, see [Using Amazon Aurora Auto Scaling with Aurora replicas](p. 1178).</td>
<td>November 17, 2017</td>
</tr>
<tr>
<td>Oracle default edition support</td>
<td>Amazon RDS for Oracle DB instances now supports setting the default edition for the DB instance. For more information, see [Setting the default edition for a DB instance](p. 1375).</td>
<td>November 3, 2017</td>
</tr>
<tr>
<td>Oracle DB instance file validation</td>
<td>Amazon RDS for Oracle DB instances now supports validating DB instance files with the Oracle Recovery Manager (RMAN) logical validation utility. For more information, see [Validating DB instance files](p. 1393).</td>
<td>November 3, 2017</td>
</tr>
<tr>
<td>Management Agent for OEM 13c</td>
<td>Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c. For more information, see [Oracle Management Agent for Enterprise Manager Cloud Control](p. 1484).</td>
<td>November 1, 2017</td>
</tr>
<tr>
<td>Storage reconfiguration for Microsoft SQL Server snapshots</td>
<td>You can now reconfigure the storage when you restore a snapshot to an Amazon RDS DB instance running Microsoft SQL Server. For more information, see [Restoring from a DB snapshot](p. 432).</td>
<td>October 26, 2017</td>
</tr>
<tr>
<td>Asynchronous key prefetch for Aurora MySQL-Compatible Edition</td>
<td>Asynchronous key prefetch (AKP) improves the performance of noncached index joins, by prefetching keys in memory ahead of when they are needed. For more information, see [Working with asynchronous key prefetch in Amazon Aurora](p. 1178).</td>
<td>October 26, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>MySQL 5.7.19, 5.6.37, and 5.5.57</td>
<td>You can now create Amazon RDS DB instances running MySQL versions 5.7.19, 5.6.37, and 5.5.57. For more information, see MySQL on Amazon RDS versions (p. 1133).</td>
<td>October 25, 2017</td>
</tr>
<tr>
<td>General availability of Amazon Aurora with PostgreSQL compatibility</td>
<td>Amazon Aurora with PostgreSQL compatibility makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. For more information, see Working with Amazon Aurora PostgreSQL.</td>
<td>October 24, 2017</td>
</tr>
<tr>
<td>Amazon RDS for Oracle DB instances support new DB instance classes</td>
<td>Amazon RDS for Oracle DB instances now support memory optimized next generation (db.r4) instance classes. Amazon RDS for Oracle DB instances also now support the following new current generation instance classes: db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge. For more information, see DB instance classes (p. 9) and RDS for Oracle instance classes (p. 1302).</td>
<td>October 23, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Your new and existing Reserved Instances can now cover multiple sizes in the same DB instance class. Size-flexible reserved instances are available for DB instances with the same AWS Region, database engine, and instance family, and across AZ configuration. Size-flexible reserved instances are available for the following database engines: Amazon Aurora, MariaDB, MySQL, Oracle (Bring Your Own License), PostgreSQL. For more information, see Size-flexible reserved DB instances (p. 85).</td>
<td>October 11, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Oracle SQLT option to tune a SQL statement for optimal performance. For more information, see Oracle SQLT (p. 1524).</td>
<td>September 22, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>If you have existing manual DB snapshots of your Amazon RDS for Oracle DB instances, you can now upgrade them to a later version of the Oracle database engine. For more information, see Upgrading an Oracle DB snapshot (p. 1556).</td>
<td>September 20, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Spatial to store, retrieve, update, and query spatial data in your Amazon RDS DB instances running Oracle. For more information, see Oracle Spatial (p. 1521).</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Locator to support internet and wireless service-based applications and partner-based GIS solutions with your Amazon RDS DB instances running Oracle. For more information, see Oracle Locator (p. 1497).</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data in your Amazon RDS DB instances running Oracle. For more information, see Oracle Multimedia (p. 1500).</td>
<td>September 15, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now export audit logs from your Amazon Aurora MySQL DB clusters to Amazon CloudWatch Logs. For more information, see  Publishing Aurora MySQL logs to Amazon CloudWatch Logs.</td>
<td>September 14, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports multiple versions of Oracle Application Express (APEX) for your DB instances running Oracle. For more information, see Oracle Application Express (APEX) (p. 1465).</td>
<td>September 13, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Amazon Aurora to migrate an unencrypted or encrypted DB snapshot or MySQL DB instance to an encrypted Aurora MySQL DB cluster. For more information, see Migrating an RDS for MySQL snapshot to Aurora and Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica.</td>
<td>September 5, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. For more information, see Compliance program support for Microsoft SQL Server DB instances (p. 927).</td>
<td>August 31, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. For more information, see MariaDB on Amazon RDS (p. 836).</td>
<td>August 31, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create Amazon RDS DB instances running Microsoft SQL Server with allocated storage up to 16 TiB, and Provisioned IOPS to storage ranges of 1:1–50:1. For more information, see Amazon RDS DB instance storage (p. 53).</td>
<td>August 22, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Multi-AZ deployments for DB instances running Microsoft SQL Server in the EU (Frankfurt) region. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 990).</td>
<td>August 3, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create Amazon RDS DB instances running MariaDB versions 10.1.23 and 10.0.31. For more information, see MariaDB on Amazon RDS versions (p. 838).</td>
<td>July 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server Enterprise Edition with the License Included model in all AWS Regions. For more information, see Licensing Microsoft SQL Server on Amazon RDS (p. 946).</td>
<td>July 13, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS for Oracle now supports Linux kernel huge pages for increased database scalability. The use of huge pages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. You can use huge pages with your Amazon RDS DB instances running all editions of Oracle versions 12.1.0.2 and 11.2.0.4. For more information, see Enabling HugePages for an Oracle DB instance (p. 1424).</td>
<td>July 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support encryption at rest (EAR) for db.t2.small and db.t2.medium DB instance classes for all non-Aurora DB engines. For more information, see Availability of Amazon RDS encryption (p. 1753).</td>
<td>June 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Europe (Frankfurt) region. For more information, see Availability for Amazon Aurora MySQL.</td>
<td>June 16, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now specify an option group when you copy a DB snapshot across AWS regions. For more information, see Option group considerations (p. 443).</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy DB snapshots created from specialized DB instances across AWS regions. You can copy snapshots from DB instances that use Oracle TDE, Microsoft SQL Server TDE, and Microsoft SQL Server Multi-AZ with Mirroring. For more information, see Copying a DB snapshot (p. 444).</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora now allows you to quickly and cost-effectively copy all of your databases in an Amazon Aurora DB cluster. For more information, see Cloning databases in an Aurora DB cluster.</td>
<td>June 12, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server 2016 SP1 CU2. For more information, see Microsoft SQL Server on Amazon RDS (p. 921).</td>
<td>June 7, 2017</td>
</tr>
<tr>
<td>Preview</td>
<td>Public preview of Amazon Aurora with PostgreSQL Compatibility. For more information, see Working with Amazon Aurora PostgreSQL.</td>
<td>April 19, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora now allows you to run an ALTER TABLE tbl_name ADD COLUMN col_name column_definition operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. For more information, see Altering tables in Amazon Aurora using fast DDL.</td>
<td>April 5, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>We have added a new monitoring command, SHOW VOLUME STATUS, to display the number of nodes and disks in a volume. For more information, see Displaying volume status for an Aurora DB cluster.</td>
<td>April 5, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use your own custom logic in your custom password verification functions for Oracle on Amazon RDS. For more information, see Creating custom functions to verify passwords (p. 1359).</td>
<td>March 21, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now access your online and archived redo log files on your Oracle DB instances on Amazon RDS. For more information, see Accessing online and archived redo logs (p. 1388).</td>
<td>March 21, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy both encrypted and unencrypted DB cluster snapshots between accounts in the same region. For more information, see Copying a DB cluster snapshot across accounts.</td>
<td>March 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now share encrypted DB cluster snapshots between accounts in the same region. For more information, see Sharing a DB cluster snapshot.</td>
<td>March 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now replicate encrypted Amazon Aurora MySQL DB clusters to create cross-region Aurora Replicas. For more information, see Replicating Aurora MySQL DB clusters across AWS Regions.</td>
<td>March 7, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now require that all connections to your DB instance running Microsoft SQL Server use Secure Sockets Layer (SSL). For more information, see Using SSL with a Microsoft SQL Server DB instance (p. 996).</td>
<td>February 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now set your local time zone to one of 15 additional time zones. For more information, see Supported time zones (p. 938).</td>
<td>February 27, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Amazon RDS procedure msdb.dbo.rds_shrink_tempdbfile to shrink the tempdb database on your DB instances running Microsoft SQL Server. For more information, see Shrinking the tempdb database (p. 1114).</td>
<td>February 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now compress your backup file when you export your Enterprise and Standard Edition Microsoft SQL Server database from an Amazon RDS DB instance to Amazon S3. For more information, see Compressing backup files (p. 976).</td>
<td>February 17, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports custom DNS servers to resolve DNS names used in outbound network access on your DB instances running Oracle. For more information, see Setting up a custom DNS server (p. 1363).</td>
<td>January 26, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports creating an encrypted read replica in another region. For more information, see Creating a read replica in a different AWS Region (p. 366) and CreateDBInstanceReadReplica.</td>
<td>January 23, 2017</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports upgrading a MySQL DB snapshot from MySQL 5.1 to MySQL 5.5. For more information, see Upgrading a MySQL DB snapshot (p. 1170) and ModifyDBSnapshot.</td>
<td>January 20, 2017</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports copying an encrypted DB snapshot to another region for the MariaDB, MySQL, Oracle, PostgreSQL, and Microsoft SQL Server database engines. For more information, see Copying a DB snapshot (p. 444) and CopyDBSnapshot.</td>
<td>December 20, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora MySQL now supports spatial indexing. Spatial indexing improves query performance on large datasets for queries that use spatial data. For more information, see Amazon Aurora MySQL and spatial data.</td>
<td>December 14, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports outbound network access on your DB instances running Oracle. You can use utl_http, utl_tcp, and utl_smtp to connect from your DB instance to the network. For more information, see Configuring UTL_HTTP access using certificates and an Oracle wallet (p. 1336).</td>
<td>December 5, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS has retired support for MySQL version 5.1. However, you can restore existing MySQL 5.1 snapshots to a MySQL 5.5 instance. For more information, see Supported storage engines for RDS for MySQL (p. 1137).</td>
<td>November 15, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports Microsoft SQL Server 2016 RTM CU2. For more information, see Microsoft SQL Server on Amazon RDS (p. 921).</td>
<td>November 4, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports major version upgrades for DB instances running Oracle. You can now upgrade your Oracle DB instances from 11g to 12c. For more information, see Upgrading the Oracle DB engine (p. 1548).</td>
<td>November 2, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now create DB instances running Microsoft SQL Server 2014 Enterprise Edition. Amazon RDS now supports SQL Server 2014 SP2 for all editions and all regions. For more information, see Microsoft SQL Server on Amazon RDS (p. 921).</td>
<td>October 25, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora MySQL now integrates with other AWS services: You can load text or XML data into a table from an Amazon S3 bucket, or invoke an AWS Lambda function from database code. For more information, see Integrating Aurora MySQL with other AWS services.</td>
<td>October 18, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now access the tempdb database on your Amazon RDS DB instances running Microsoft SQL Server. You can access the tempdb database by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information, see Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS (p. 1114).</td>
<td>September 29, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the UTL_MAIL package with your Amazon RDS DB instances running Oracle. For more information, see Oracle UTL_MAIL (p. 1544).</td>
<td>September 20, 2016</td>
</tr>
<tr>
<td>New features</td>
<td>You can now set the time zone of your new Microsoft SQL Server DB instances to a local time zone, to match the time zone of your applications. For more information, see Local time zone for Microsoft SQL Server DB instances (p. 937).</td>
<td>September 19, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the Oracle Label Security option to control access to individual table rows in your Amazon RDS DB instances running Oracle Database 12c. With Oracle Label Security, you can enforce regulatory compliance with a policy-based administration model, and ensure that an access to sensitive data is restricted to only users with the appropriate clearance level. For more information, see Oracle Label Security (p. 1494).</td>
<td>September 8, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now connect to an Amazon Aurora DB cluster using the reader endpoint, which load-balances connections across the Aurora Replicas that are available in the DB cluster. As clients request new connections to the reader endpoint, Aurora distributes the connection requests among the Aurora Replicas in the DB cluster. This functionality can help balance your read workload across multiple Aurora Replicas in your DB cluster. For more information, see Amazon Aurora endpoints.</td>
<td>September 8, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now support the Oracle Enterprise Manager Cloud Control on your Amazon RDS DB instances running Oracle. You can enable the Management Agent on your DB instances, and share data with your Oracle Management Service (OMS). For more information, see Oracle Management Agent for Enterprise Manager Cloud Control (p. 1484).</td>
<td>September 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>This release adds support to get an ARN for a resource. For more information, see Getting an existing ARN (p. 389).</td>
<td>August 23, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now assign up to 50 tags for each Amazon RDS resource, for managing your resources and tracking costs. For more information, see Tagging Amazon RDS resources (p. 375).</td>
<td>August 19, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports the License Included model for Oracle Standard Edition Two. For more information, see [Creating an Amazon RDS DB instance](p. 175).</td>
<td>August 5, 2016</td>
</tr>
<tr>
<td></td>
<td>You can now change the license model of your Amazon RDS DB instances running Microsoft SQL Server and Oracle. For more information, see [Licensing Microsoft SQL Server on Amazon RDS](p. 946) and [Oracle licensing options](p. 1299).</td>
<td></td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the AWS Management Console to easily move your DB instance to a different VPC, or to a different subnet group in the same VPC. For more information, see [Updating the VPC for a DB instance](p. 1856).</td>
<td>August 4, 2016</td>
</tr>
<tr>
<td></td>
<td>If your DB instance is not in a VPC, you can now use the AWS Management Console to easily move your DB instance into a VPC. For more information, see [Moving a DB instance not in a VPC into a VPC](p. 1873).</td>
<td></td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon RDS now supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). You can now easily migrate SQL Server databases to Amazon RDS, and import and export databases in a single, easily-portable file, using Amazon S3 for storage, and AWS KMS for encryption. For more information, see [Importing and exporting SQL Server databases](p. 962).</td>
<td>July 27, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now copy the source files from a MySQL database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora DB cluster from those files. This option can be considerably faster than migrating data using mysqldump. For more information, see [Migrating data from an external MySQL database to an Aurora MySQL DB cluster](p. 1602).</td>
<td>July 20, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now restore an unencrypted Amazon Aurora DB cluster snapshot to create an encrypted Amazon Aurora DB cluster by including an AWS Key Management Service (AWS KMS) encryption key during the restore operation. For more information, see [Encrypting Amazon RDS resources](p. 654).</td>
<td>June 30, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can use the Oracle Repository Creation Utility (RCU) to create a repository on Amazon RDS for Oracle. For more information, see [Using the Oracle Repository Creation Utility on Amazon RDS for Oracle](p. 1578).</td>
<td>June 17, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Adds support for PostgreSQL cross-region read replicas. For more information, see [Creating a read replica in a different AWS Region](p. 366).</td>
<td>June 16, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>

<tr>
<td>New feature</td>
<td>You can now use the AWS Management Console to easily add Multi-AZ with Mirroring to a Microsoft SQL Server DB instance. For more information, see Adding Multi-AZ to a Microsoft SQL Server DB instance (p. 991).</td>
<td>June 9, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use Multi-AZ Deployments Using SQL Server Mirroring in the following additional regions: Asia Pacific (Sydney), Asia Pacific (Tokyo), and South America (São Paulo). For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 990).</td>
<td>June 9, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support MariaDB version 10.1. For more information, see MariaDB on Amazon RDS (p. 836).</td>
<td>June 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora cross-region DB clusters that are read replicas. For more information, see Replicating Aurora MySQL DB clusters across AWS Regions.</td>
<td>June 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available for Oracle DB instances. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 582) and Modifying an Amazon RDS DB instance (p. 309).</td>
<td>May 27, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support manual snapshot sharing for Amazon Aurora DB cluster snapshots. For more information, see Sharing a DB cluster snapshot.</td>
<td>May 18, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>You can now use the MariaDB Audit Plugin to log database activity on MariaDB and MySQL database instances. For more information, see Options for MariaDB database engine (p. 906) and Options for MySQL DB instances (p. 1234).</td>
<td>April 27, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>In-place, major version upgrades are now available for upgrading from MySQL version 5.6 to version 5.7. For more information, see Upgrading the MySQL DB engine (p. 1159).</td>
<td>April 26, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Enhanced Monitoring is now available for Microsoft SQL Server DB instances. For more information, see Monitoring OS metrics with Enhanced Monitoring (p. 582).</td>
<td>April 22, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to provide an Amazon Aurora Clusters view in the Amazon RDS console. For more information, see Viewing an Aurora DB cluster.</td>
<td>April 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see Multi-AZ deployments for Amazon RDS for Microsoft SQL Server (p. 990).</td>
<td>March 31, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see Availability for Amazon Aurora MySQL.</td>
<td>March 31, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>

<tr>
<td>New feature</td>
<td>Updated to support encryption when migrating to an Aurora DB cluster. For more information, see Migrating data to an Aurora DB cluster.</td>
<td>March 2, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support local time zone for Aurora DB clusters. For more information, see Local time zone for Aurora DB clusters.</td>
<td>March 1, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to add support for MySQL version 5.7 for current generation Amazon RDS DB instance classes.</td>
<td>February 22, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support db.r3 and db.t2 DB instance classes in the AWS GovCloud (US-West) region.</td>
<td>February 11, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support encrypting copies of DB snapshots and sharing encrypted DB snapshots. For more information, see Copying a snapshot (p. 438) and Sharing a DB snapshot (p. 452).</td>
<td>February 11, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Asia Pacific (Sydney) region. For more information, see Availability for Amazon Aurora MySQL.</td>
<td>February 11, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SSL for Oracle DB Instances. For more information, see Encrypting client connections with SSL (p. 1322).</td>
<td>February 9, 2016</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support local time zone for MySQL and MariaDB DB instances. For more information, see Local time zone for MySQL DB instances (p. 1142) and Local time zone for MariaDB DB instances (p. 849).</td>
<td>December 21, 2015</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Enhanced Monitoring of OS metrics for MySQL and MariaDB instances and Aurora DB clusters. For more information, see Viewing metrics in the Amazon RDS console (p. 505).</td>
<td>December 18, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support db.t2, db.r3, and db.m4 DB instance classes for MySQL version 5.5. For more information, see DB instance classes (p. 9).</td>
<td>December 4, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support modifying the database port for an existing DB instance.</td>
<td>December 3, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support major version upgrades of the database engine for PostgreSQL instances. For more information, see Upgrading the PostgreSQL DB engine for Amazon RDS (p. 1626).</td>
<td>November 19, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support modifying the public accessibility of an existing DB instance. Updated to support db.m4 standard DB instance classes.</td>
<td>November 11, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support manual DB snapshot sharing. For more information, see Sharing a DB snapshot (p. 452).</td>
<td>October 28, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Microsoft SQL Server 2014 for the Web, Express, and Standard editions.</td>
<td>October 26, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the MySQL-based MariaDB database engine. For more information, see MariaDB on Amazon RDS (p. 836).</td>
<td>October 7, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Amazon Aurora in the Asia Pacific (Tokyo) region. For more information, see Availability for Amazon Aurora MySQL.</td>
<td>October 7, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support db.t2 burst-capable DB instance classes for all DB engines and the addition of the db.t2.large DB instance class. For more information, see DB instance classes (p. 9).</td>
<td>September 25, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Oracle DB instances on R3 and T2 DB instance classes. For more information, see DB instance classes (p. 9).</td>
<td>August 5, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Microsoft SQL Server Enterprise Edition is now available with the License Included service model. For more information, see Licensing Microsoft SQL Server on Amazon RDS (p. 946).</td>
<td>July 29, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Amazon Aurora has officially released. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. For detailed information, see What is Amazon Aurora?.</td>
<td>July 27, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support copying tags to DB snapshots.</td>
<td>July 20, 2015</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support increases in storage size for all DB engines and an increase in Provisioned IOPS for SQL Server.</td>
<td>June 18, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated options for reserved DB instances.</td>
<td>June 15, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support using Amazon CloudHSM with Oracle DB instances using TDE.</td>
<td>January 8, 2015</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to include the new Amazon DB engine: Aurora. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. Amazon Aurora is currently in preview release and is subject to change. For detailed information, see What is Amazon Aurora?.</td>
<td>November 12, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support PostgreSQL read replicas.</td>
<td>November 10, 2014</td>
</tr>
<tr>
<td>New API and features</td>
<td>Updated to support the GP2 storage type and new API version 2014-09-01. Updated to support the ability to copy an existing option or parameter group to create a new option or parameter group.</td>
<td>October 7, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support InnoDB Cache Warming for DB instances running MySQL version 5.6.19 and later.</td>
<td>September 3, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SSL certificate verification when connecting to MySQL version 5.6, SQL Server, and PostgreSQL database engines.</td>
<td>August 5, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the db.t2 burstable DB instance classes.</td>
<td>August 4, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the db.r3 memory optimized DB instance classes for use with the MySQL (version 5.6), SQL Server, and PostgreSQL database engines.</td>
<td>May 28, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server Multi-AZ deployments using SQL Server Mirroring.</td>
<td>May 19, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support upgrades from MySQL version 5.5 to version 5.6.</td>
<td>April 23, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Oracle GoldenGate.</td>
<td>April 3, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the M3 DB instance classes.</td>
<td>February 20, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the Oracle Timezone option.</td>
<td>January 13, 2014</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support replication between MySQL DB instances in different regions.</td>
<td>November 26, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support the PostgreSQL DB engine.</td>
<td>November 14, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server transparent data encryption (TDE).</td>
<td>November 7, 2013</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>New API and new feature</td>
<td>Updated to support cross region DB snapshot copies; new API version, 2013-09-09.</td>
<td>October 31, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support Oracle Statspack.</td>
<td>September 26, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support using replication to import or export data between instances of MySQL running in Amazon RDS and instances of MySQL running on-premises or on Amazon EC2.</td>
<td>September 5, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support the db.cr1.8xlarge DB instance class for MySQL 5.6.</td>
<td>September 4, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support replication of read replicas.</td>
<td>August 28, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support parallel read replica creation.</td>
<td>July 22, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support fine-grained permissions and tagging for all Amazon RDS resources.</td>
<td>July 8, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support MySQL 5.6 for new instances, including support for the MySQL 5.6 memcached interface and binary log access.</td>
<td>July 1, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support major version upgrades from MySQL 5.1 to MySQL 5.5.</td>
<td>June 20, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated DB parameter groups to allow expressions for parameter values.</td>
<td>June 20, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support Oracle Advanced Security features for native network encryption and Oracle Transparent Data Encryption.</td>
<td>April 18, 2013</td>
</tr>
<tr>
<td>New features</td>
<td>Updated to support major version upgrades for SQL Server and additional functionality for Provisioned IOPS.</td>
<td>March 13, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support VPC By Default for RDS.</td>
<td>March 11, 2013</td>
</tr>
<tr>
<td>New API and feature</td>
<td>Updated to support log access; new API version 2013-02-12</td>
<td>March 4, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support RDS event notification subscriptions.</td>
<td>February 4, 2013</td>
</tr>
<tr>
<td>New API and feature</td>
<td>Updated to support DB instance renaming and the migration of DB security group members in a VPC to a VPC security group.</td>
<td>January 14, 2013</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for AWS GovCloud (US-West) support.</td>
<td>December 17, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support \texttt{m1.medium} and \texttt{m1.xlarge} DB Instance classes.</td>
<td>November 6, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support read replica promotion.</td>
<td>October 11, 2012</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date changed</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SSL in Microsoft SQL Server DB Instances.</td>
<td>October 10, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support Oracle micro DB Instances.</td>
<td>September 27, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated to support SQL Server 2012.</td>
<td>September 26, 2012</td>
</tr>
<tr>
<td>New API and feature</td>
<td>Updated to support provisioned IOPS. API version 2012-09-17.</td>
<td>September 25, 2012</td>
</tr>
<tr>
<td>New features</td>
<td>Updated for SQL Server support for DB Instances in VPC and Oracle support for Data Pump.</td>
<td>September 13, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for support for SQL Server Agent.</td>
<td>August 22, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for support for tagging of DB Instances.</td>
<td>August 21, 2012</td>
</tr>
<tr>
<td>New features</td>
<td>Updated for support for Oracle APEX and XML DB, Oracle time zones, and Oracle DB Instances in a VPC.</td>
<td>August 16, 2012</td>
</tr>
<tr>
<td>New features</td>
<td>Updated for support for SQL Server Database Engine Tuning Advisor and Oracle DB Instances in VPC.</td>
<td>July 18, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for support for option groups and first option, Oracle Enterprise Manager Database Control.</td>
<td>May 29, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for support for read replicas in Amazon Virtual Private Cloud.</td>
<td>May 17, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for Microsoft SQL Server support.</td>
<td>May 8, 2012</td>
</tr>
<tr>
<td>New features</td>
<td>Updated for support for forced failover, Multi-AZ deployment of Oracle DB Instances, and nondefault character sets for Oracle DB Instances.</td>
<td>May 2, 2012</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for Amazon Virtual Private Cloud (VPC) Support.</td>
<td>February 13, 2012</td>
</tr>
<tr>
<td>Updated content</td>
<td>Updated for new Reserved Instance types.</td>
<td>December 19, 2011</td>
</tr>
<tr>
<td>New feature</td>
<td>Updated for Oracle engine support.</td>
<td>May 23, 2011</td>
</tr>
<tr>
<td>Updated content</td>
<td>Console updates.</td>
<td>May 13, 2011</td>
</tr>
<tr>
<td>Updated content</td>
<td>Edited content for shortened backup and maintenance windows.</td>
<td>February 28, 2011</td>
</tr>
<tr>
<td>New feature</td>
<td>Added support for MySQL 5.5.</td>
<td>January 31, 2011</td>
</tr>
<tr>
<td>New feature</td>
<td>Added support for read replicas.</td>
<td>October 4, 2010</td>
</tr>
<tr>
<td>New feature</td>
<td>Added support for AWS Identity and Access Management (IAM).</td>
<td>September 2, 2010</td>
</tr>
<tr>
<td>New feature</td>
<td>Added Reserved DB Instances.</td>
<td>August 16, 2010</td>
</tr>
<tr>
<td>New Feature</td>
<td>Amazon RDS now supports SSL connections to your DB Instances.</td>
<td>June 28, 2010</td>
</tr>
